For infants with severe NOWS, use of a medication in addition to nonpharmacologic measures is necessary to improve clinical signs of withdrawal and minimize complications from withdrawal (eg, severe weight loss). Ideally, pharmacotherapy minimizes clinical signs of withdrawal, and then the infant is weaned off the medication using a standardized protocol to minimize total medication exposure.[72] Pharmacologic therapy should be considered for severe opioid withdrawal despite nonpharmacologic interventions. Vomiting and loose stools are associated with dehydration and poor weight gain and are relative indications for treatment. Naloxone should never be administered to an infant with NOWS because it will exacerbate the underlying withdrawal syndrome.

The literature supports the use of an opioid for opioid withdrawal as a first-line agent.[73] In the United States, the most common first-line therapy for NOWS is morphine.[61] In several recently published studies, it was found that longer-acting opioids may reduce length of stay when compared with morphine. Kraft et al[74] found that when compared with morphine, buprenorphine used for NOWS resulted in a shorter median duration of treatment (15 vs 18 days; $P < .001$) and length of hospital stay (21 vs 33 days; $P < .001$). Similarly, Davis et al[75] found that when compared with morphine, methadone resulted in a shorter duration of treatment (11.5 vs 15 days; $P = .009$) and length of stay (16 vs 20 days; $P = .005$). Importantly, both clinical trials occurred in the context of rigorous study protocols and included only women in treatment of OUD to test the efficacy of these medications; therefore, one limitation of these clinical trials may be generalizability to other populations (ie, infants of mothers not in treatment of OUD).

There is evidence to support the use of secondary medications for NOWS, either when initiating pharmacotherapy[76] or, more commonly, as an additional medication when clinical signs continue to escalate despite

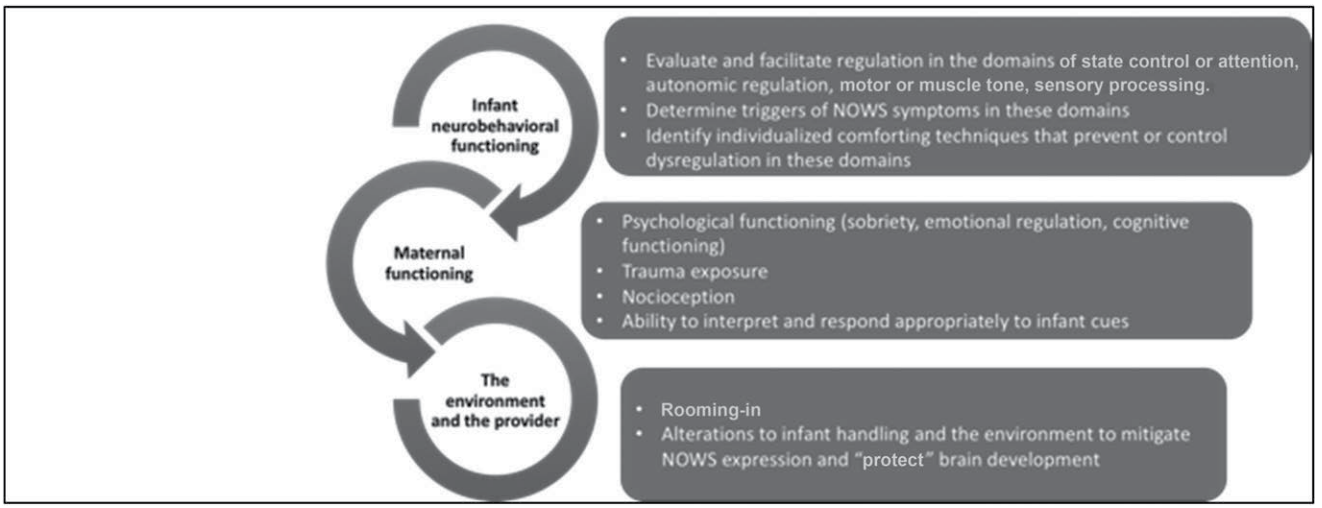

FIGURE 2
Nonpharmacologic approaches to NOWS. Adapted from Velez M, Jansson LM. The opioid dependent mother and newborn dyad: non-pharmacologic care. *J Addict Med.* 2008;2(3):113–120.

pharmacotherapy with an opioid. The most common medications used after initiation of an opioid for NOWS are clonidine and phenobarbital. The majority of practitioners use phenobarbital as a second drug if the opioid does not adequately control withdrawal signs.[77,78] In recent years, clonidine has increased in the United States as a therapy for NOWS.[61] Clonidine is an α-2-adrenergic receptor agonist that has been used in combination with an opioid or other drug in older children and adults to reduce withdrawal symptoms.[79,80] There is not sufficient evidence to suggest greater efficacy of clonidine over phenobarbital; however, phenobarbital has been shown to have neurotoxicity in animal studies,[81,82] and its use has been associated with adverse developmental outcomes.[83] Therefore, clinicians should consider use of clonidine as a second-line agent over phenobarbital, and additional study is needed to test the effects of both agents on infants' long-term development.

Clinicians should be mindful that some drug preparations may include a high alcohol content (eg, buprenorphine), and choosing preparations of low alcohol content is preferred. In addition, consistent with previous AAP statements, camphorated tincture of opium (paregoric) and/or deodorized tincture of opioid (laudanum) should not be used for NOWS.

PREPARING FOR DISCHARGE

It is important to plan effectively for a safe transition from the hospital to home after birth for the mother-infant dyad. Families of infants with opioid exposure are disproportionately impoverished,[28] may face multiple economic and social challenges,[12,25,84] and are frequently involved in the child welfare system. Adequate preparation for hospital discharge cannot be the pediatrician's responsibility alone; it requires hospital supports (eg, social work) to appropriately assess and assist families in this critical transition.

The immediate postnatal period is a time of high risk for mothers with OUD, especially if they lose access to medications for OUD. Recent data suggest that loss of access to medications for OUD after delivery is associated with overdose death.[85] In addition, a key support to give mothers the best chance of remission of OUD and improved dyadic relational health is partnering with mental health clinicians to provide comprehensive treatment. For example, maternal screening for treatable problems, such as traumatic stress and depression, could be addressed by referral to evidence-based, dyadic-focused interventions, such as child-parent psychotherapy.[86]

Infants with opioid exposure are also at risk for adverse outcomes, including hospital readmission.[87,88] Women may have to manage their own medical follow-up needs (eg, obstetrics, addiction medicine), their infant's medical follow-up needs (eg, general pediatrician, pediatric infectious disease, lactation support), and additional services (eg, the Special Supplemental Nutrition Program for Women, Infants, and Children, early intervention, child welfare). The task of coordinating these multiple stakeholders, combined with the risk of adverse postdischarge outcomes (such as readmission),[88] makes formalizing the discharge process for infants with opioid exposure critical. Use of simplified electronic or print checklists can be helpful in improving discharge processes (Table 4).[89] When possible, postdischarge care for the mother-infant dyad should be coordinated and comprehensive. Lastly, hospitals should ensure adequate handoffs and information transfer to postdischarge care providers, including, pediatricians, early intervention providers, and home-nurse visitation programs.

Discharge Education

In addition to routine newborn education, emphasis should be placed on the needs of the opioid-exposed dyad. Ideally, the infant caregiver has been engaged in care during the pregnancy and is familiar with common clinical signs and scoring processes. The caregiver should know when and how to seek help if signs of infant withdrawal become unmanageable or if additional challenges present (eg, maternal depression, relapse). Infants with substance exposure are at an increased risk of sleep-related deaths[90]; therefore, additional emphasis on safe sleep and safe sleep environments is recommended. Similar to all infant discharges, parents of infants with opioid exposure should be provided education on how to deal with challenging infant behaviors (eg, subacute withdrawal signs) that may increase the risk of nonaccidental trauma.

Medical Follow-up

Infants should be observed for 24 to 48 hours after finishing any medication taper. Ideally, an infant with opioid exposure would be seen by his or her pediatrician within 48 hours of discharge from the hospital to monitor for adequate weight gain and to monitor for any continued signs of withdrawal. The frequency of pediatrician visits may need to be higher than that for uncomplicated term infants. Although there are no data to inform the most optimal pediatrician visit schedule for infants with opioid exposure, the infant should be seen within 48 hours of discharge, with a 1-week follow-up. Additional visits should be tailored to the needs of the dyad. Ideally, breastfed infants should also have outpatient lactation support

TABLE 4 Discharge Checklist for Infants With Opioid Exposure

Completed (Check Yes)
Task
No significant clinical signs of withdrawal for 24–48 h
Parent education about NOWS and routine newborn care, emphasizing safe sleep
Pediatrician or primary care provider follow-up visit scheduled within 48 h of discharge
Early intervention services referral
Home-nurse visitation referral
Hepatitis C testing follow-up, including referral to pediatric infectious disease when appropriate
Plan of safe care, coordinating with child welfare as appropriate
Developmental-behavioral pediatrician referral as appropriate

and be assessed in the first 48 hours of life.

Outpatient Pharmacotherapy

With increasing focus on reducing length of hospital stay for infants with NOWS, many institutions began discharging infants from the hospital on medications. Among infants treated in the nearly 200 centers participating in the Vermont Oxford Network collaboration focused on improving care for NOWS, >25% were discharged from the hospital on medications at the end of the 2-year collaborative.[60] Consistently, the literature suggests that discharging infants from the hospital on pharmacotherapy reduces length of hospital stay[91–94]; however, comparative outcomes, in particular duration of total treatment and development outcomes, are scant. In a recent study, of nearly 1000 infants with NOWS enrolled in the Tennessee Medicaid program, infants discharged from the hospital on medications had a shorter median length of hospital stay (11 vs 23 days; $P < .001$) but longer median lengths of treatment (60 vs 19 days; $P < .001$).[87] Given the lack of long-term follow-up data, clinicians should avoid outpatient tapers when possible. If outpatient tapers are used, a structured weaning plan with comprehensive follow-up should be implemented to minimize total medication time.

Hepatitis C

HCV screening among pregnant women is not universal in the United States, potentially missing a window of opportunity to identify HCV in the mother-infant dyad. Even without universal screening, data suggest that as the opioid crisis grew, rates of HCV infection among pregnant women increased.[95] From 2009 to 2014, the rate of HCV infection among US pregnant women doubled to 3.4 per 1000 live births and as high as 1 in 50 births in West Virginia.[96] Given this rising risk to maternal and infant health, hospitals should consider universally screening pregnant women for HCV and creating processes to connect the dyad to treatment postnatally.

Because vertical transmission occurs in 6% of infants exposed to HCV (11% if HIV coinfection), infants must be tested after discharge to determine if they seroconvert. Maternal antibodies can persist for 18 months; thus, antibody testing must occur after 18 months; however, RNA polymerase chain reaction testing may occur earlier. Data suggest, however, that only a minority of exposed infants are tested.[97,98] Because infants with opioid exposure are at risk for HCV exposure, it is imperative that (1) all infants with opioid exposure are evaluated for HCV exposure and (2) all infants with HCV exposure are adequately managed to determine if they acquire the virus. All infants HCV exposure should be evaluated and should be tested for seroconversion by using RNA polymerase chain reaction or antibody testing.

Postdischarge Services

Infants with opioid exposure, regardless of the need for pharmacotherapy for NOWS, are at increased risk for developmental alterations.[99] In addition to developmental, behavioral, and mental health[100] screenings by the primary care pediatrician, all infants with substance exposure should be referred to early intervention services, and developmental screenings in a NICU developmental assessment clinic or equivalent should be considered. Early intervention services are available in all areas of the United States as part C of the Individuals with Disabilities Education Act. Strong consideration should also be given to referral to home-nurse visitation programs (eg, the Maternal, Infant, and Early Childhood Home Visiting Program) as a resource to families.

Early Head Start programs are similar to Head Start but are targeted to pregnant women and infants until age 3 years. These programs support parental and infant development and can further enable family success, promoting housing and financial stability. Pediatricians should consider referrals to Early Head Start programs for opioid-exposed infants. Early Head Start programs can be identified by using the Center Locator (https://eclkc.ohs.acf.hhs.gov/center-locator).

In addition, the AAP has several resources to aid pediatricians in connecting children to developmental resources that are free and available online, including the National Center on Early Childhood Health and Wellness (https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/NCECHW/Pages/National-Center-on-Early-Childhood-Health-and-Wellness.aspx) and publications such as *Caring for Our Children* (https://nrckids.org/CFOC/). Similar resources, such as HealthySteps (https://www.healthysteps.org/),

may also serve pediatricians in developing models of care to meet the needs of infants with opioid exposure.

The Child Welfare System and Plans of Safe Care

The opioid crisis resulted in greater demands on the US child welfare system.[12,13] Although evidence suggests that keeping the family intact improves outcomes for parents and infants, child safety must still be paramount.[12] A report to child protective services should be considered when the mother has not received or been adherent to treatment of OUD, when there is concern or evidence of polysubstance use during pregnancy, or when there is a concern for infant safety. In cases in which a child cannot be safely cared for by his or her parents, appropriately trained kinship or foster care placement may be necessary. Referral to child protective services is not a substitute for referral to treatment of the pregnant or parenting woman.

Recently, there have been numerous changes to the child welfare system to provide parental supports and connection to treatment. In 2016, the Comprehensive Addiction and Recovery Act amended the Child Abuse Prevention and Treatment Act to ensure that "plans of safe care" are created for infants "being affected by substance abuse or withdrawal symptoms, or a fetal alcohol spectrum disorder." Importantly, these plans should address the "health and substance use disorder treatment needs of the infant and affected family or caregiver."[101] Ideally, plans of safe care are well coordinated within state child welfare agencies, and planning begins before birth. States may interpret and implement legislation related to plans of safe care differently; therefore, it is important for pediatricians to be aware of their local requirements. The creation of plans of safe care are actively being developed, and there is evidence that many states are struggling with implementation.[13] Pediatricians should consider involvement in the development of plans of safe care in their communities. Because of their expansive nature of supporting the mother-infant dyad, some states have elected to call their plans of safe care "plans of supportive care." Such partnerships between pediatricians and child welfare professionals can help fill education gaps, foster positive partnerships, and promote understanding, with the ultimate goal of improving outcomes for the mother-infant dyad.[102]

Public Health Considerations

NOWS reflects the downstream implications of a complex public health crisis. To prevent NOWS, pregnant women, women and men of reproductive age, and the communities they live in need effective access to prevention, treatment, and services (eg, access to comprehensive treatment of substance use disorder, access to highly effective contraception) (Fig 3).[103,104] As public health and surveillance efforts continue to evolve, involvement of pediatricians at the local, state, and national level will continue to be important to ensure that the unique needs of children are addressed.

A federal prevention strategy outlined in the 2015 Protecting our Infants Act[105] provides several mandates for the US Department of Health and Human Services (HHS) to address problems related to prenatal opioid exposure. The strategy requires HHS agencies to plan, review, and coordinate activities related to prenatal opioid exposure and NOWS to (1) develop recommendations for prevention; (2) treat OUD in pregnant women and infants with NOWS; (3) identify pregnant women and infants in need of services to treat OUD in pregnancy and NOWS, including any long-term consequences; and (4) develop a coordinated strategy to address gaps in research. In fall 2018, the HHS held a summit to improve coordination of national surveillance, research, and prevention efforts.[106]

Currently, there is considerable variation in reporting of NOWS by state or jurisdiction. Improvement in reporting of NOWS to public health officials can help to identify communities in critical need of intervention. Currently, only a handful of states have mandatory reporting of NOWS,[107] and states vary in case definitions for state reporting. In a study of 6 states with case reporting for NOWS during 2013–2017, considerable variability was found in how states defined and used surveillance.[107] Nevertheless, for states and other jurisdictions to improve reporting, a consistent definition is needed. In an attempt to provide a more universal definition for public health surveillance, the Council on State and Territorial Epidemiologists, in collaboration with the Centers for Disease Control and Prevention, met with state health officials to improve reporting in all states on the basis of maternal opioid use reported in prenatal and delivery records as well as newborn hospitalization records.[108] With more consistent reporting, states may be able to better and more rapidly identify needs among and between localities.

State and regional collaborations are developing strategies to improve access to maternal medications for OUD, improve the quality of care for newborn infants with NOWS, and reduce hospital length of stay and associated costs. Ohio's Perinatal Quality Collaborative initiated a statewide approach to the care of infants with NOWS that included standardized assessment and treatment, including both pharmacologic and nonpharmacologic interventions.

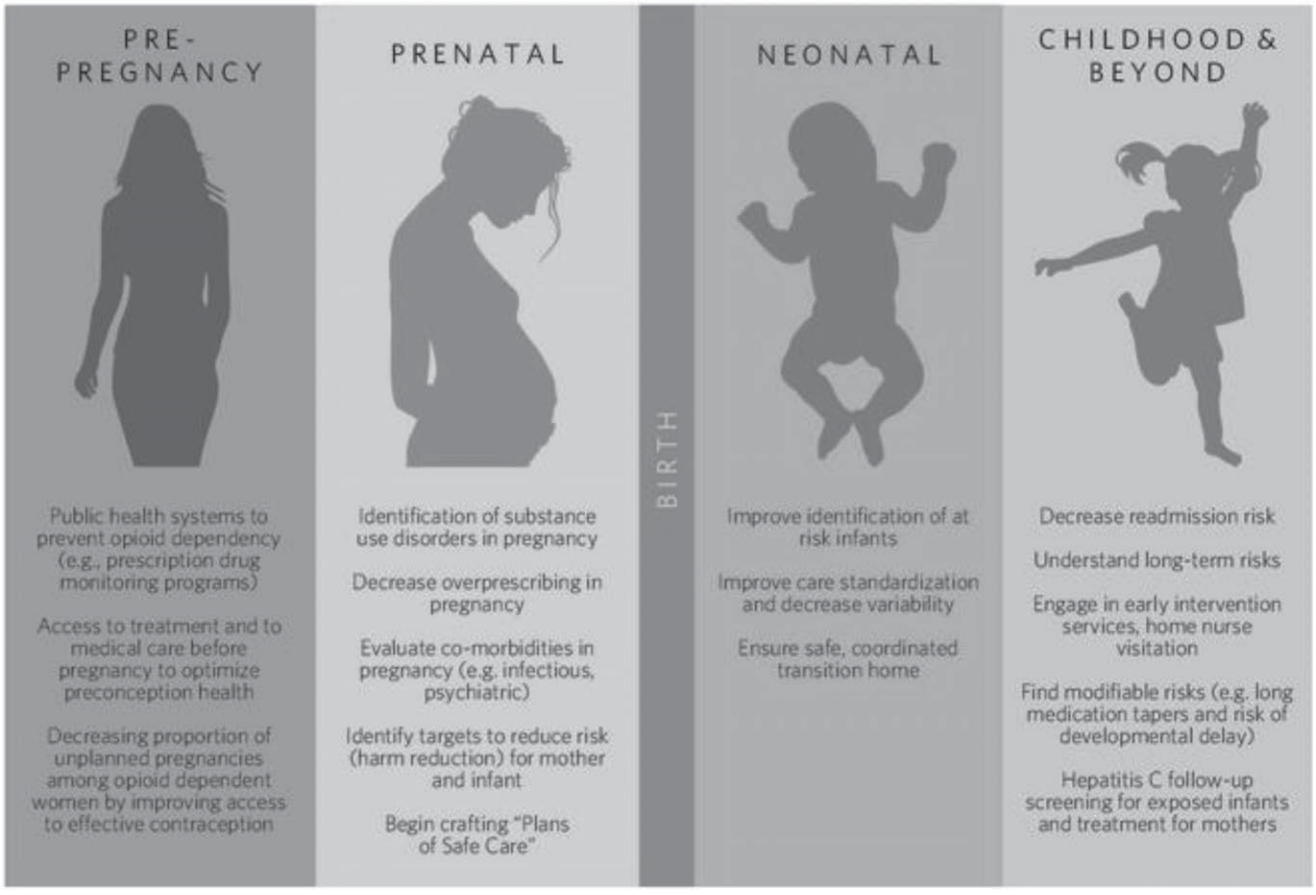

FIGURE 3
Public health approaches to opioid use in pregnancy and in infants with opioid exposure. (Reprinted with permission from Patrick SW. Improving public health systems for substance-affected pregnancies. *Am J Public Health.* 2019;109(1):22–23.)

Among 52 of the state's 54 neonatal care facilities, standardized pharmacologic treatment and increased use of nonpharmacologic treatment reduced both the length of treatment and the length of hospital stay from 13.4 to 12 days and from 18.3 to 17 days, respectively.[109] Among a multistate, multicenter quality improvement collaborative, participating hospitals were able to reduce the median length of pharmacologic treatment from 16 to 15 days and the infant length of hospital stay from 21 to 19 days through a standardized scoring process for NOWS. Albeit noteworthy, these reductions in length of stay and costs are modest. Additional quality improvement approaches and measures are needed to improve care to the mother-infant dyad.

CONCLUSIONS

The opioid crisis has had a profound effect on pregnant women and their infants. Despite improvements in the identification, assessment, and treatment of NOWS, substantial knowledge gaps remain. Pediatricians are well positioned to improve outcomes for the mother-infant dyad through evidence-based practice and connection of families to public resources.

RECOMMENDATIONS

NOWS is a major consequence of the opioid crisis, with dramatic increases over the last decade. Pediatric care clinicians can help reduce newborn morbidity, hospitalization, and costs and help improve maternal screening, referral, and follow-up for the mother-infant dyad. We present the following recommendations for care.

Access to Treatment

1. All pregnant women should have access to medications for OUD because they have been shown to reduce risk of overdose death and improve pregnancy outcomes.
2. Pediatricians should partner with state and local child welfare agencies to advocate for funding to improve access to quality treatment of OUD.

Antenatal Counseling and Screening

1. Pregnant women with OUD should receive antenatal counseling to provide education on the clinical signs of withdrawal and enhance maternal understanding of postnatal treatment (eg,

nonpharmacologic treatment, including breastfeeding and pharmacotherapy). When possible, maternal antenatal counseling should be provided by a pediatric provider.

2. Multiple modalities of testing should be considered for the infant, including, infant urine, meconium, and umbilical cord tissue testing.
3. For women in treatment of OUD who receive frequent toxicology testing, infant meconium and/or umbilical cord tissue testing may not be necessary.
4. For many substances, urine toxicology only captures a short window of substance use for some systems.
5. Pediatricians should assess additional social risks, including, but not limited to, food and housing insecurity, and connect to community resources.

Observation

1. All infants with chronic opioid exposure should be observed for at least 72 hours to monitor for the development of withdrawal. Although there is increasing evidence that multiple factors may increase an opioid-exposed infant's risk of withdrawal (eg, gestational age, specific genotypes, tobacco use, benzodiazepine, and gabapentin), there remains insufficient evidence of how to use these exposures to tailor an infant's postnatal observation period. Institutions may use the following approach for observation of infants with opioid exposure:
2. immediate-release opioids: 3 days;
3. buprenorphine and sustained-release opioids: 4 to 7 days; and
4. methadone: 5 to 7 days.

Diagnosis

1. For all infants at risk for NOWS, a standardized assessment approach by using a commonly used tool (eg, modified Finnegan score) should be employed to measure the presence and severity of withdrawal symptoms as well as the response to treatment (Fig 1).
2. Comorbidities should also be considered, including infectious and neurologic conditions. If no clear in utero exposure is identified through maternal history, screening, or testing, NOWS is a diagnosis that should be used only if other potential causes of an infant's symptoms have been evaluated fully and no other cause has been identified.

Treatment

1. Hospitals should prioritize keeping the mother-infant dyad intact throughout observation and treatment of an infant with opioid exposure. Rooming-in is the preferred model of care.
2. Hospitals should have a written protocol for the nonpharmacologic and pharmacologic treatment of an infant with opioid exposure.
3. Admission to a NICU only for opioid exposure or NOWS is not required.
4. All hospitals should have a written protocol for initiating nonpharmacologic and pharmacologic treatment of an infant with opioid exposure.
5. Nonpharmacologic interventions should be used for all infants with opioid exposure and should be considered the foundation of care.
6. Nonpharmacologic treatment should be tailored to the clinical signs of the infant.
7. All hospitals should have a protocol for breastfeeding an infant with substance exposure.
8. For infants of mothers in treatment of OUD with buprenorphine or methadone who have not had relapse for $\geq$90 days, breastfeeding should be supported if there are no other contraindications.
9. For infants of women with active substance use or with relapses within the last 30 days, breastfeeding should be discouraged.
10. For infants of women in treatment between 30 and 90 days without relapse, breastfeeding should be considered.
11. HIV is a contraindication to breastfeeding in high-income countries, such as the United States. HCV-positive mothers with cracked or bleeding nipples should consider abstaining from breastfeeding.
12. Lactation support should be provided in the inpatient setting and after discharge.
13. Pharmacologic therapy should be considered for severe opioid withdrawal (eg, MOTHER score $>8 \times 2$ or $>12 \times 1$) in addition to nonpharmacologic interventions. Vomiting and loose stools are associated with dehydration and poor weight gain and are relative indications for treatment.
14. Opioids should be used as a first-line therapy for severe NOWS.
15. Infants who require pharmacologic treatment should be monitored (eg, pulse oximetry).
16. Recent data suggest that opioids with a longer half-life, such as buprenorphine and methadone, may reduce length of treatment. However, caution should be considered if the preparation has a high alcohol content.
17. Paregoric and deodorized tincture of opium should not be used.
18. If a second agent is needed for severe opioid withdrawal, the use of clonidine should be considered over phenobarbital.

19. Naloxone should never be used in the treatment of an infant with chronic opioid exposure because it may precipitate rapid withdrawal and seizure.

Discharge

1. Discharge of infants from the hospital on pharmacotherapy should be avoided and should only occur if there is a structured, close outpatient follow-up plan for the mother-infant dyad.
2. A discharge checklist should be completed (Table 3):
3. no significant clinical signs of withdrawal for 24 to 48 hours after treatment;
4. parent education about NOWS and routine newborn care, emphasizing safe sleep;
5. pediatrician or primary care provider follow-up visit with 48 hours of discharge;
6. early intervention services referral;
7. consideration of home-nurse visitation and Early Head Start;
8. hepatitis C and HIV testing referral, including referral to pediatric infectious disease when appropriate;
9. plan of safe care, coordinating with child welfare;
10. developmental-behavioral pediatrician referral, as appropriate; and
11. consideration of behavioral and/or mental health system referrals to address dyadic relational health.

Nickel Allergic Contact Dermatitis: Identification, Treatment, and Prevention

- *Policy Statement*

POLICY STATEMENT Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN®

Nickel Allergic Contact Dermatitis: Identification, Treatment, and Prevention

Nanette B. Silverberg, MD, FAAP, FAAD,[a] Janice L. Pelletier, MD, FAAP,[b,c] Sharon E. Jacob, MD, FAAP, FAAD,[d,e] Lynda C. Schneider, MD, FAAP,[f] SECTION ON DERMATOLOGY, SECTION ON ALLERGY AND IMMUNOLOGY

Nickel is a ubiquitous metal added to jewelry and metallic substances for its hardening properties and because it is inexpensive. Estimates suggest that at least 1.1 million children in the United States are sensitized to nickel. Nickel allergic contact dermatitis (Ni-ACD) is the most common cutaneous delayed-type hypersensitivity reaction worldwide. The incidence among children tested has almost quadrupled over the past 3 decades. The associated morbidities include itch, discomfort, school absence, and reduced quality of life. In adulthood, individuals with Ni-ACD may have severe disabling hand eczema. The increasing rate of Ni-ACD in children has been postulated to result from early and frequent exposure to metals with high amounts of nickel release (eg, as occurs with ear piercing or with products used daily in childhood such as toys, belt buckles, and electronics).

To reduce exposure to metal sources with high nickel release by prolonged and direct contact with human skin, Denmark and the European Union legislated a directive several decades ago with the goal of reducing high nickel release and the incidence of Ni-ACD. Since then, there has been a global reduction in incidence of Ni-ACD in population-based studies of adults and studies of children and young adults being tested for allergic contact dermatitis. These data point to nickel exposure as a trigger for elicitation of Ni-ACD and, further, provide evidence that legislation can have a favorable effect on the economic and medical health of a population.

This policy statement reviews the epidemiology, history, and appearances of Ni-ACD. Examples of sources of high nickel release are discussed to highlight how difficult it is to avoid this metal in modern daily lives. Treatments are outlined, and avoidance strategies are presented. Long-term epidemiological interventions are addressed. Advocacy for smarter nickel use is reviewed. The American Academy of Pediatrics supports US legislation that advances safety standards (as modeled by the European Union) that protect children from early and prolonged skin exposure to high–nickel-releasing items. Our final aim for this article is to aid the pediatric community in developing nickel-avoidance strategies on both individual and global levels.

abstract

INTRODUCTION

Nickel Is a Common Cutaneous Allergen

Recent estimates suggest that 1.1 million children in the United States are potentially sensitized to nickel[1]; however, this may be a gross underestimate given that nickel allergic contact dermatitis (Ni-ACD) is found in approximately one-quarter of children who undergo patch testing. Nickel is present in metallic items that are common in children's environments, including earrings, watches, toys, and fasteners on clothing and belts. Chronic exposure to nickel increases risk for Ni-ACD. Nickel has become the most common metallic cause of allergic dermatitis and was named the "Contact Allergen of the Year" in 2008 by the American Contact Dermatitis Society. Determining the presence of Ni-ACD in those with allergic dermatitis can be difficult and elusive, with patch testing being a crucial tool used to help differentiate Ni-ACD from other forms of dermatitis.[2] The risk of Ni-ACD increases when ears are pierced.[3]

Nickel Exposures Are Common

Nickel is a ubiquitous metal, being the fifth most common element in the world. Worldwide use of nickel in the production of hardened metal items has been increasing since World War II.[4] The process by which nickel use shifted from coins and military purposes to daily use products, such as clothes and electronics, was strongly influenced by metal use in the post–World War II era. Among adults who were screened in Massachusetts General Hospital from 1996 to 2006, Ni-ACD was found in 22.1% of those 20 to 40 years of age but in only 10.1% of those older than 60 years, suggesting that Ni-ACD is a problem of younger individuals (those raised or those who had their ears pierced after World War II).[5] Today, nickel has continued to be a leading production metal in home and personal goods. Over time, Ni-ACD evolved from an occupational eczema of electroplaters to a common form of allergic contact dermatitis (ACD) among both adults and children, currently affecting as many as 20% of Americans. Historically, Ni-ACD has been linked to a wide range of exposures, including suspenders in the 1950s–1960s; zippers, buttons, and rivets in the 1970s; and ear piercing in the 1980s.[4] Environmental nickel present in oxides and sulfides is not as allergenic as the free nickel present in metal fittings found in industry.[4,6]

Nickel Allergy Has Significant Symptomatology

Virtually any site of the body can be affected by Ni-ACD, but some of the more commonly affected areas are the eyelids (transfer from hands), face, neck, wrists, fingers and hands, periumbilical area, and thighs.[7] Symptoms and signs of Ni-ACD range from mild dermatitis with pruritus, to deep erythema with oozing and papulation, to a systemic reaction with generalized idiopathic hypersensitivity.[6,7] Although Ni-ACD is a delayed-type hypersensitivity, symptoms can occur within the first 30 minutes of exposure through a complex cascade of inflammatory mediators generated after sensitization.[8]

KEY POINTS IN THE EVOLUTION OF NICKEL ALLERGY AS A SERIOUS ALLERGEN

Introduction of Nickel Into the Manufacturing of Metals

Nickel was first identified as an element in 1751 by a Swiss chemist named Axel Cronstedt. In the 1800s, nickel was introduced into the manufacturing of metal alloys with copper and zinc. As an alloy, its high value is related to many inherent qualities: high strength, lengthy life, anticorrosion, heat resistance, low cost, and minimal maintenance. In the mid-1800s, coins in the United States were alloyed with copper. In the late 1800s, steel production accelerated because of the strength of steel products. During the 20th century, nickel gained a solid place in industry as part of manufactured stainless steel alloy (along with chromate and iron). Today, two-thirds of nickel production in the world is devoted to the manufacture of stainless steel, 20% is for other specialized steel alloys (for military and aerospace), 9% is for plating, and the remainder is for various uses, including batteries, coins, and electronics.[9,10]

Early Reporting of Nickel Allergy

Weston et al[11] first reported Ni-ACD in young pediatric patients in 1984. Until that point, it was unclear whether cutaneous immune function in infants was mature enough to mount such responses. After the report of this phenomenon by Weston et al,[11] more attention to allergic reactions in infants and young children made it clear that contact allergy to nickel can begin in infancy, with some authors indicating increasing incidence after the age of 5 years.[12–16] Nickel's place as a cause of contact dermatitis in pediatrics was solidified by these early reports.

Ni-ACD can cause systemic hypersensitivity in children, and this was elucidated in 2 articles in 2002. Silverberg et al[16] reported a group of 30 children with clinical features of Ni-ACD manifested by persistent umbilical or wrist dermatitis. In that cohort, all children had positive results on patch testing for nickel; furthermore, 50% had an idiopathic hypersensitivity reaction, a hypersensitivity response characterized by the presence of inflammatory papules on the extensor surfaces of the extremities in sites not exposed to nickel.[17] A similar article from Sharma et al[17] reviewed 38 children with periumbilical papules consistent with Ni-ACD, all of whom demonstrated an idiopathic reaction.[18] Systemic contact

dermatitis has been defined as "a generalized ACD rash from systemic administration of a drug, chemical, or food to which the patient previously experienced ACD." There is no known general population-based prevalence of systemic nickel hypersensitivity, neither for kids nor for adults. Strongly positive (≥3 papular) nickel patch test results in these patients suggest that severe reactions correlate with systemic disease.[17]

Pathophysiology and Genetics of Nickel Allergic Sensitization

Nickel-contact allergy is a delayed-type (type IV) cutaneous hypersensitivity reaction that develops through a biphasic process: an induction phase is followed by an elicitation phase. In the induction phase, there are repeat exposures to free nickel that are beyond a minimal threshold. During this initial phase, an antigen is presented by the skin's dendritic cells to T cells (T helper 1 and T helper 17 cells), which causes the skin to develop a set of memory T cells that specifically recognize nickel. During the elicitation phase, there is amplification of the allergy through subsequent repetitive exposures that result in the manifestations of ACD.[4,6,18]

Ni-ACD is influenced by a combination of genetic and environmental factors, the latter being more important, according to leading experts.[4] Filaggrin mutations are associated with increased Ni-ACD risk. Another genetic determinant that may increase risk for Ni-ACD is HLA antigen expression.[19,20] Staphylococcal biofilms may promote the development of Ni-ACD in the setting of atopic dermatitis.[21]

Menné and Holm[22] showed a twin concordance rate of 29% in patients with Ni-ACD, confirmed from a population-based survey. Half of the pediatric patients with severe Ni-ACD with additional idiopathic reactions had a parent with Ni-ACD in the Silverberg et al[16] cohort, a statistic that is higher than that in the general population.

Product Properties That Contribute to Allergenicity

The amount of nickel released to the skin from contact with a metal object (not the presence of nickel) determines the potential for causing Ni-ACD. The development of Ni-ACD from contact with a nickel-containing object is promoted in a 3-step process: "1) the nickel in the material must be corroded, 2) the resulting nickel compounds must be solubilized, and 3) the nickel ions must be absorbed by the skin to cause a reaction."[23,24] Other contributory factors include the use of products under occlusion (eg, piercing holes) or prolonged contact with the skin such that sweat may erode or release nickel (eg, underside of the thighs against a chair).

Rising Prevalence of Nickel Allergy

The prevalence of nickel allergy in North America has increased significantly since the 1980s in both adults and children. Data on prevalence in the United States are derived from patch testing, that is, epicutaneous allergy testing, which reveals contact sensitization but not relevance of the allergy, outcomes, and/or associated disabilities. The North American Contact Dermatitis Group (NACDG) reported that nickel sensitization rates increased steadily between 1970 and 2002 in a mixed group of adults and children from 11% to 16.9%.[25] Pediatric-specific data from Peltonen[26] revealed a prevalence of Ni-ACD of 2.5% in 1981, and the NACDG series from 2001 to 2004 demonstrated 28.3% of children with positive patch test results were nickel allergic, showing an increase even more substantial in childhood than in adulthood.[27] One series revealed that although not all children with Ni-ACD have disabling symptoms, for those who undergo a patch test series, Ni-ACD represents a common relevant allergen, being detected in as many as 36.8% of children and adolescents tested and having an 80.4% relevance (ie, being identified as contributing to dermatitis activity).[28]

Population-based screening on individuals (including adults) referred for patch testing have highlighted the pervasive issue of Ni-ACD in the United States. In 1978, a population-based study of 1158 people identified 9% of individuals with Ni-ACD,[1] and approximately 50% of those who were nickel allergic had never sought medical care.[26] In a recent meta-analysis of 5 ACD studies representing 1507 pediatric subjects, 22.9% had Ni-ACD.[29] The current estimate of Ni-ACD in children with suspected ACD who are patch tested is 28.3% according to the NACDG.[27]

Data from Denmark are the most revealing when evaluating European Union (EU) nickel directives because Denmark introduced the directives in 1990, 14 years before widespread EU adoption. The Nickel Directive states that "consumer items intended to be in direct and prolonged contact with the skin were not allowed to release more than 0.5 mcg nickel/cm^2/week." This legislation was intended to reduce Ni-ACD but not eliminate disease. The venture has been successful in reducing Ni-ACD in young women with ear piercings who are patch tested. One particular outcome has been reduced severity of reaction on epicutaneous patch testing to nickel, which suggests less severity of disease. On the other hand, because the sale of nickel-laden agents is not criminalized, sales of items with nickel release persist in Europe, especially in outdoor flea markets.[3,30]

Before EU legislation, the percentage of female first-year college students in Finland in 1995 with Ni-ACD was 39%, suggesting that the rate may continue to increase further in the United States if no population-based

restrictions are enacted.[29,31,32] Population-based data on true nickel allergy in adolescents derived from survey data in Sweden reported in 2008, 7 years after EU legislation was put into action, revealed that 14.8% of 6095 adolescents polled believed they had Ni-ACD, with confirmation in 9.9%, revealing how EU nickel directives may be benefiting adolescents.[33] Data from a Danish pediatric contact dermatology database reveal ongoing reduction in nickel sensitization, with ACD rates of 9.7% in those tested (252 of 2587) from 2003 to 2011 and 7% (107 of 1540) from 2012 to 2016 (adjusted odds ratio, 0.69; 95% confidence interval, 0.55–0.88). Predominance of girls in the Ni-ACD group persisted in this study, as with previous studies.[33,34]

Piercings and Jewelry Are Leading Sources of Nickel Sensitization

Piercings, costume jewelry, watches, belt buckles, and clothing fasteners (grommets, buttons, studs, and toggles) are leading sources of epicutaneous nickel sensitization in countries without legislation controlling nickel release.[6] The same 1995 Finnish study of first-year college students revealed that piercings in female students were associated with a rate of 42% nickel allergy, compared withs 14% for female students without piercings.[31] A study of 960 girls 8 to 15 years of age in Sweden (published in 1985) with piercings revealed that 13% were nickel allergic, compared with 1% of girls without piercings.[23] In patch testing of school-aged girls for Ni-ACD from 1999 to 2000, older girls who had piercings before Danish regulations were implemented were 4 to 5 times as likely as those who had piercings after regulations to be allergic to nickel (17.1% vs 3.9%, respectively). A Norwegian pediatric contact allergy study of 7- to 12-year-old schoolchildren, published in 1994, identified a rate of 30.8% nickel allergy in children with piercings, compared with 16.3% in children without piercings.[35,36] Nickel allergy in girls with pierced ears has dramatically decreased in Denmark over the last 3 decades since strict nickel-release legislation was enacted.[14] Although piercings have been linked to nickel sensitization, occurrence of Ni-ACD is also common in children without piercings; therefore, reduction of nickel release is needed across all costume jewelry types.[6] A recent review of NACDG data revealed that of 1894 pediatric patients who were patch tested, 23.7% had nickel contact dermatitis and 36.4% had a pattern of skin disease consistent with all types of jewelry as the source of the nickel.[37]

The High Cost of Nickel Allergy in the United States

The 2004 estimates in the United States suggest that contact dermatitis, which includes nickel sensitization, accounted for $1.918 billion in health care costs (including direct medical costs and lost productivity costs) and affected 72.29 million people. Given that nickel-contact sensitization is noted in approximately one-quarter of patients, it is likely that nickel allergy contributes heavily to this burden.[24] Recent data from the American Academy of Dermatology reveal that contact allergy costs more than $1.5 billion in 2013.[38] Given that nickel allergy is the number one allergen nationwide in all age groups, nickel allergy is costly.

Other Sources of Nickel-Contact Sensitization

Contact with commonplace nickel alloy metallic products, such as toys, can lead to nickel release that deposits on a child's skin.[39,40] In a recent radiograph fluorescence spectroscopy study of US jewelry, 79 of 96 samples released nickel.[41] In a case series of children and adolescents from Brazil, the source of nickel exposure in the setting of Ni-ACD included jewelry piercings; metal clothing appliques on garments, accessories, and shoes; nail clippers; razor blades; and cosmetics.[1] Newer nickel sources reported to cause dermatitis include devices such as metallic cell phone cases (a persistent plaque on the hollow of the cheek), laptop cases and handheld device cases (fingertip, hand, lap, and periocular dermatitis), makeup applicators and ferrules (site of application), eye makeup, dog tag necklaces, and lip balm containers (lip and perioral).[42–48] Table 1 contains a brief compendium of items of daily use linked to nickel exposure and allergy.[4,6] Many of these newer nickel sources are more difficult to diagnose because the site of allergy can be areas not in direct contact, for example, the eyes.[43] The timing and type of nickel exposures throughout life are important. Ni-ACD was shown to be much less common when ear piercing occurred after placement of metal dental braces, compared with when piercing occurred before exposure to braces. So, less nickel sensitization may occur if placement of braces occurs first and piercing later.[44] This phenomenon may be analogous to the enteral tolerance that develops to lessen peanut allergy and may be akin to reasoning forwarded by the Learning Early About Peanut Allergy study.[49]

THE CLINICAL APPEARANCE OF NICKEL CONTACT DERMATITIS IS PROTEAN

Ni-ACD commonly is diagnosed on the basis of the appearance of itchy, persistent, erythematous, and/or lichenified papules and plaques that appear to conform to the area matching the exposure pattern of the metal object with the skin, for example, a circular erythematous plaque on the extensor wrist at the site of exposure to the backside of the wristwatch. Ni-ACD can also be caused by a child playing with a nickel-releasing object and then transferring the nickel to other sites.[1,45,46] Ni-ACD has also been described with nail polish from

Nickel allergy and our children's health: a review of indexed cases and a view of future prevention. *Pediatr Dermatol.* 2015;32(6): 779–78 and Tuchman M, Silverberg JI, Jacob SE, Silverberg N. Nickel contact dermatitis in children. *Clin Dermatol.* 2015;33(3):320–326.

[a] The most commonly identified nickel-allergy sources in clinical practice.

a bottle with nickel metal balls included.[47] This itchy rash is often diffuse and can occur on other less common areas, such as the scalp and eyelids.

Other jewelry-related patterns of appearance include a plaque over the upper back at the site of a necklace clasp pressed against the skin, periumbilical plaques at the site of belt buckle or button fly skin contact, midback plaques where bra hooks press against the skin, and earring plaques and/or nodules at the site of piercing because of exposure to high–nickel-releasing earring posts.[16,17,48] Dental amalgams are rarely high nickel releasing, but they still can cause oral lesions such as persistent oral lichenoid reactions near the amalgam, anesthetic sensation, and/or systemic lesions.[52]

When the source of nickel shifts against the skin, (eg, chair nail heads, belt buckles, and coins in the pocket), the contact dermatitis may be more papular and/or diffuse, making the source less obvious. Furthermore, patients with atopic dermatitis may have background disease activity that prevents the margins of the Ni-ACD from being clearly distinguished.[4,16,17,53] In adults, nickel has been identified as a contact allergen that can worsen palmoplantar or scalp psoriasis.[54]

Idiopathic reactions, or diffuse hypersensitivity reactions, to nickel can occur. These may be associated with dietary or complementary supplements as the source of nickel ingestion,[55] creating generalized pruritus and exacerbating pruritus at the site of cutaneous nickel exposure, or they may come from a generalized idiopathic hypersensitivity reaction triggered by ongoing cutaneous exposures (a type of systemic contact dermatitis), the latter of which is manifested by extensor papules and lichenoid (flat-topped) papules and plaques over extensor surfaces. Idiopathic reactions (also called dermatophytid) are similar to those seen in some patients with tinea capitis when starting oral griseofulvin therapy.[4,6]

Dental amalgams, caps, and braces that contain or release nickel in higher concentration are associated with perioral Ni-ACD as well as Ni-ACD in eccentric sites such as ears, the waist, and wrists. Ni-ACD may precede or be caused by dental devices containing nickel. Furthermore, such Ni-ACD can be associated with lip swelling and a burning oral sensation.[52,56–58]

Although most allergic reactions to nickel are of a type IV delayed-type hypersensitivity, rare reports have appeared in the literature of individuals with systemic nickel hypersensitivity of a type I or immediate-type hypersensitivity. Other types of allergic reactions to nickel may occur after oral nickel exposure, causing symptoms as minor as flares of earlier nickel-allergic eczema sites, to a generalized maculopapular or vasculitislike rash, to more severe symptoms, including urticaria, headache malaise, diarrhea, fever, and arthralgia.[59,60] Skin prick testing has been performed in rare cases but remains controversial.[52,59,60] It is still most likely, even in such settings, that the reaction to nickel is a delayed-type hypersensitivity because rapid

reactions as fast as 10 to 30 minutes can be described in Ni-ACD delayed type.[61] The data on these cases are extremely limited, and no recommendation can be made until additional broad-based population data become available for testing.

OVERLAP WITH ATOPIC DERMATITIS

The NACDG demonstrated that 34% of children with a positive contact allergy result on testing had concurrent atopic dermatitis.[62] In children with atopic dermatitis, Ni-ACD can trigger severe exacerbations of pruritus.[6] In the setting of atopic dermatitis, Ni-ACD overlap is associated with more extensive atopic dermatitis and greater difficulty in diagnosing Ni-ACD.[7] Because the background population data on nickel allergy does not differ in prevalence, Ni-ACD can only be viewed as an aggravating or obscuring factor and not necessarily as a cause of disease.

MANAGEMENT OF NI-ACD

The broad goals of medical therapy in Ni-ACD are as follows:

1. identification and avoidance of nickel;
2. treatment of skin inflammation; and
3. restoration of the skin barrier and skin protection.

Identification and Avoidance of Nickel

Identifying sources of nickel requires investigation of personal adornments, hobbies (eg, instruments played), and jobs (eg, leisure-time activities and review of everyday device usage). Patients should be asked about garments or uniforms worn at work or school. Avoidance of nickel can be enhanced through testing objects for nickel content (see Avoidance of Nickel Exposure in Childhood section). Using Table 1 as a guide, pediatricians can ask patients targeted questions to determine nickel sources hidden in daily activities.

TABLE 2 Handout for Patients

Nickel is a metal that is added to many metal objects to harden them. Nickel can be found in almost all costume jewelry (including earrings, necklaces, watch backs, rings, and bracelets), some belt buckles, and such jewelry as ball and chain necklaces, dog tags, metal tabs, grommets, and button flies.

When you sweat, the nickel is released from the metal, even if it is only a small amount or percentage of the metal. Stainless steel is a stronger white metal and does not release nickel as easily.

If you are allergic to nickel, your rash will keep returning until you avoid nickel completely. There are many steps required to avoid nickel completely. It is not easy, but it is necessary to make you feel better.

1. Remove all nonessential metal from your clothing; replace button flies with plastic buttons and wear a belt that ties or has a plastic buckle.
2. For metal that you cannot remove, such as grommets on the side pockets of your jeans or the back of your watch, coat with 2 coats of clear nail polish every week or after washings.
3. Avoid sitting in shorts on metal chairs or plastic chairs with metal tabs.
4. Do not cook acidic foods in stainless steel cookware. Avoid stainless steel cookware if you can.
5. Tucking in your shirt does not prevent you from reacting to the nickel in your belt buckle or button fly.
6. Avoid ear piercing, especially if dental work, such as braces, is expected.
7. Sources of nickel in jewelry include costume jewelry, including earring posts that are not stainless steel, white gold, and all low-karat gold jewelry. Sterling silver and high-karat yellow gold jewelry are expected to have a low content of nickel but are not generally nickel free.
8. Tests to look for nickel released from household metals can be found at the following Web sites: https://nonickel.com/collections/nickel-test-kit-for-jewelry-and-meteorites and https://www.delasco.com/spot-test-for-nickel/. More information can be found at https://athenaallergy.com/pages/how-to-test-for-nickel-using-nickel-alert-dimethylglyoxime-test.

One of the hallmarks of good clinical care in ACD is education on how to avoid allergen-laden goods. Such is the case in Ni-ACD. Patients with Ni-ACD can be counseled to recognize objects that may be high-release nickel, to test such objects, and to protect the skin from prolonged and direct contact with the objects. Table 2 is a handout that can be used to help educate parents and children and adolescents about nickel avoidance. In general, piercing with nickel-free earrings can minimize risk of Ni-ACD, as can use of low-release nickel, but the latter still results in some release of nickel. Sterling silver (which is 92.5% pure silver), 18-karat yellow gold (which is 75% gold) or more-pure gold, platinum, titanium, and plastic earrings are alternatives that have low or no nickel content. Silver that is not sterling, such as nickel silver, 800 silver (80% silver), and German silver (which contains no silver at all; an alloy of nickel and zinc), are not ideal for the patient with Ni-ACD.

Treatment of Skin Inflammation

Inflammatory symptoms, including eczematous changes and pruritus, are the main symptoms of Ni-ACD–induced inflammation. There is no US Food and Drug Administration–approved therapy for Ni-ACD; however, Ni-ACD is a steroid-responsive dermatosis, and therefore topical corticosteroids may be helpful in conjunction with prevention of retriggering of dermatitis through avoidance of suspected sources of nickel exposure and with therapeutics to aid in pruritus or itch reduction. Although no specific regimen of topical corticosteroids has been endorsed by any organization for Ni-ACD, the American Academy of Pediatrics recommends choosing the corticosteroid class on the basis of the site of application and severity. Like in atopic dermatitis, off-label use of topical calcineurin inhibitors (eg, pimecrolimus and tacrolimus) can be effective in steroid-resistant Ni-ACD cases.[63,64] These topical therapies are used in combination with nickel avoidance, which is the cornerstone of treatment of Ni-ACD. Prevention is

paramount because there is no cure for Ni-ACD and because the disease is lifelong.[65] In recalcitrant cases or in the setting of severe Ni-ACD and severe pruritus or for those with widespread lesions, oral steroids for several days and then tapered, together with antihistamines for pruritus, can aid in symptomatic resolution.[66]

Restoration of the Skin Barrier and Skin Protection

Emollients can be used to enhance the skin barrier in children with atopic dermatitis and may benefit children with Ni-ACD and concurrent dermatitis symptoms. Skin protection can be achieved through thick physical blockage of nickel-containing metal objects, for example, cell phone cases, backing button flies in denim, or replacing metal buttons with plastic buttons. Thin fabrics and strategies such as tucking in one's shirt may not be fully protective.[4,53]

Confirmation of Suspected Ni-ACD

When a typical pattern of Ni-ACD appears on the wrist or periumbilical region, no confirmatory testing is needed.[16,17,67] In some cases in which suspicion is harder to confirm, patch testing, otherwise known as epicutaneous skin testing, is a form of testing in which a dilute version of the allergen is placed in a hypoallergenic well (sometimes called a Finn chamber) and applied to the back. Contact time with the skin of the upper back or inner upper arms is up to 48 hours. After this period, the patches are removed, and the test results are read. The patches are read again at a delayed point between 72 and 120 hours after placement. Interpretation of results is based on the appearance of redness and/or papules and/or a plaque in the shape of the chamber. Papular ($\geq$3 severity) reactions at the site of testing are common in nickel allergy in children, and they can be associated with idiopathic systemic hypersensitivity. If the testing result is negative but clinical history supports Ni-ACD, a late reading should be considered 7 to 10 days after the patch test application. There is a US Food and Drug Administration–approved series of 36 patches (T.R.U.E. Test; SmartPractice, Phoenix, AZ) that contains nickel at 200 $\mu g/cm^2$ nickel sulfate, which corresponds to 160 μg of nickel per patch. In pediatrics, standardized comprehensive patch testing is often custom tailored by history, and testing is performed with nickel sulfate hexahydrate 2.5% in petrolatum, as would be found in the American Contact Dermatitis Society Core series.[4,53] Broad-metal contact allergy screening should be performed when multiple metals are suspected as the potential source of contact dermatitis. This screening can be accomplished by using an epicutaneous metal contact allergy panel containing nickel, gold, titanium, copper, cobalt, zinc, and more than a dozen other metals.

Although children with obvious nickel allergy usually do not need confirmatory patch testing for nickel, they may need testing for other metal allergens when metal appliances for dental work or implants are needed.[68,69] In particular, the Nuss procedure, which is a placement of metal rods for the repair of pectus excavatum, has been associated with complications in patients with metal allergy, especially to nickel. Consequences include extensive granulation tissue formation, localized edema, dermatitis, lymphadenopathy, pleural effusion, and inflammation and/or infection, which may require removal of stainless steel rods in some cases.[70,71] Because of the potential consequences of undiagnosed Ni-ACD in such patients, surgeons performing the procedure often refer patients for patch testing to nickel and other metals before the procedure.[72] Stainless steel discs provided by the manufacturer are suboptimal to screen for metal allergy and Ni-ACD in this setting; it is more prudent to proceed with patch testing by using the extended metal series.[73] Titanium bars can be used safely in patients with Ni-ACD if they are identified before surgery as having no previously reported allergic events.[70]

PREVENTION OF NI-ACD

Avoidance of Nickel Exposure in Childhood

Ni-ACD is a threat to pediatric public health that persists as a problematic skin disease into adulthood. Ni-ACD is the most common cutaneous allergy and involves lifelong hazards that can affect people's lives both personally and professionally.[74] Common cutaneous nickel-containing items include earring posts, belt buckles, jewelry, zippers, snaps, clasps, grommets, electronics, coins, keys, paper clips, chairs, braces, and implants.[2,24,45,75–77] To reduce the risk and severity of Ni-ACD, avoidance of skin contact with nickel is critical. According to European reports, earrings appear to be the most common source of elicitation of Ni-ACD, providing credence to take preventive and economic measures. The United States should heed the European lead to reduce nickel release from common contacts in children to serve and protect population health. Using the handout in Table 2, parents can identify sources of high-release nickel in their children's lives. The purchase of items with no nickel or with a low release of nickel can be guided by the use of the dimethylglyoxime test, which indicates a pink or red color on exposure to a nickel-releasing metallic item. Currently, because of the lack of labeling of low–nickel-release or nickel-free metal items, parents can screen metal objects for nickel release using such test kits, which can be purchased on medical Web sites (eg, https://www.delasco.com/spot-test-for-nickel/ and

https://athenaallergy.com/pages/how-to-test-for-nickel-using-nickel-alert-dimethylglyoxime-test).[78] However, it would be more ideal if labeling of low–nickel-release or nickel-free items was available for parents.

Reduction in Dietary Nickel Exposure

Withdrawal diets in children cannot be recommended because of inadequate pediatric data and risk of malnutrition with a limited diet.[50,79,80] Data on the use of low-nickel diets in children are lacking.[51,81,82]

Advocacy

Ni-ACD represents a significant and preventable pediatric public health burden. Regulation of nickel release in materials that comes in contact with skin can decrease both the high pediatric prevalence and treatment costs of the disease. There is a call in the United States for such regulation[2] given the high number of children affected by this disease. The American Academy of Dermatology has recently accepted a proposal in support of reduced nickel release in manufacturing.[82] Adoption of legislation similar to that in the EU by the US Congress would represent a promise for prevention by starting to reduce the nickel-related health burden.

A REVIEW OF EU POLICY

Nickel is ubiquitous, and people are exposed to it primarily via metal objects throughout their lifetimes. Preventive models of safer exposures, or those less likely to trigger Ni-ACD, have been demonstrated by other countries to be medically and economically beneficial. The EU Nickel Directive of 1994 (approved June 30, 1994, and in full effect June 2001) regulated the method for measuring nickel release onto human skin and established regulations for nickel allowed to be released onto exposed skin over time, including for watches, buttons, zippers, and now mobile phone cases.[83] The EU directive was born from the original work in Denmark, where the Nickel Directive was designed to limit the maximum release of nickel in contact with human skin to an amount less than 0.2 $\mu g/cm^2$ per week for posts inserted into pierced skin and not more than 0.5 $\mu g/cm^2$ per week for products with prolonged and direct skin contact.[83,84] The European standard EN 1811:2011+A1:2015 is a standardized testing system that is approved by the EU to measure the potential amount of nickel release under the conditions of direct and prolonged contact with the skin. Articles, such as those used for earrings in children, should not release nickel more than 0.2 $\mu g/cm^2$ per week (by EN 1811 testing) to prevent children from becoming allergic to nickel or having a dermatitis reaction if they are already allergic to nickel. This nickel-release rate is for the parts of earrings that are in contact with the skin and within the pierced part of the ear.[4,83] Germany and Sweden joined in the legislation and eventually Korea and China did as well.[83]

Because the rate of release of nickel (and not nickel content itself) is important and relevant in determining whether there is a risk for Ni-ACD, articles may contain nickel but not cause a dermatitis reaction. For example, surgical stainless steel (grade 316L), which contains 10% to 15% nickel and does not release nickel more than 0.2 $\mu g/cm^2$ per week (by using EN 1811 testing), is therefore regarded as appropriate for use in articles in direct and prolonged contact with the skin. The American Section of the International Association for Testing Materials Standard Consumer Safety Specification for Adult Jewelry (designation: F2999-13) lists surgical stainless steel (typically containing 10%–15% nickel) as one of the "approved materials for adult body-piercing jewelry."[4,84,85]

The effect of the Danish decree was a drastic decrease in pediatric nickel sensitization from 24.8% to 9.2%.[85] Reduction in Ni-ACD after Denmark's Nickel Directive resulted in cost savings that grew to more than $2 billion (US dollars) over the 2 decades after implementation.[4] The EU followed the commanding lead of the Danish dermatologists who worked with the Danish ministry to advance this innovative health directive. In 2006, the Nickel Directive was incorporated into the EU regulation of toxins, which is called Registration, Evaluation, Authorization, and Restriction of Chemicals (REACH).[84] After this regulation, there was a significant reduction of Ni-ACD in patients younger than 30 years studied in European countries.[83] National databases involving 180 390 patients with suspected ACD reveal an approximately 10% reduction in Ni-ACD in young women, specifically from the following 4 countries, in the years 1985–2010: Denmark, Germany, Italy, and the United Kingdom (2004–2010 only).

REACH is a complex bill that outlines industry obligations regarding 30 000 chemicals. REACH is far more "reaching" than is the US counterpart, the Toxic Substances Control Act (TSCA) of 1975,[86] which regulates chemicals but does not differentiate toxic from nontoxic chemicals. The TSCA was supplanted by the Chemical Safety for the 21st Century Act, introduced in the Senate in 2015 and passed in the House of Representatives in May 2016. Although the TSCA required the Environmental Protection Agency (EPA) to consider least burdensome chemical regulations for industry, the Chemical Safety for the 21st Century Act tasks the EPA to focus on unreasonable risk to human health and the environment; however, unfortunately, this may not apply to

jewelry and cosmetics.[86–88] Although the EPA acknowledges the hazards of nickel as a cause of ACD, no current ruling restricts nickel exposures in childhood; however, this regulatory foundation has room to act to reduce risk for Ni-ACD in children.[86–89] The United States stands to improve collective health status and lower related medical costs if it were to follow Denmark's lead and the EU model in protecting the public from the hazards of high nickel exposure.

Stakeholders may note that the nonprofit organization Nickel Producers Environmental Research Association does support the elimination of high-release nickel alloys and plating used in products with dermal contact such as jewelry and electronics.[7,90] US legislators should advance evidenced-based policies to adopt a twofold guideline: (1) adoption of the EU guidelines on nickel release in manufacturing and (2) adoption of a policy to avoid usage of nickel in plating in household electronic devices. If the United States can incorporate safety directives and sound recommendations regarding nickel production and usage, as has been done in the EU, then the population can achieve significant reductions in Ni-ACD in the next 2 to 3 decades.

RECOMMENDATIONS

The following are recommended to reduce the US pediatric burden of Ni-ACD:

1. To minimize nickel-induced ACD in children, use of nickel in the manufacture of items that have direct or prolonged contact with the skin (eg, jewelry, electronic devices, toys, etc) should be limited. Regulations similar to the EU Nickel Directive that limit the weekly allowable release of nickel to less than 0.5 $\mu g/cm^2$/week should be adopted.
2. Additional safety and toxicity studies are needed to better understand the complex relationship between nickel exposure and population health.
3. Companies and industries using metal in products should voluntarily create labeling for low–nickel-release products and Web-based resources to identify those items in the United States that follow EU legislation guidelines, allowing individuals who are nickel allergic to shop more wisely. Ideally, the development of trustable resources for those with Ni-ACD can be met through physician and industry partnership to develop educational resources about nickel allergy that can be easily understood and accessed by children, parents, and teachers.
4. Physicians and other health care providers can support the reduction of Ni-ACD by encouraging parents to request that posts for piercings in their children's ears be made of surgical-grade steel with low nickel release, per EU standards. It is recommended that all individuals who perform piercing services mention Ni-ACD as a potential complication of piercing.
5. Nickel allergy can be genetic; therefore, physicians and other providers should consider educating at-risk groups to avoid nickel-based body piercings. There is further genetic reason to believe that children from families with a history of Ni-ACD would benefit from reduced exposure in childhood through the universal use of low–nickel-releasing jewelry.
6. It is likely that most children would benefit from lower exposure to such contact, even in the absence of family history of Ni-ACD, because such family history is only present in approximately half of cases of documented disease.
7. If orthodontic metal braces are anticipated, families should consider delaying ear piercing until after dental work is completed.
8. Until such legislation can be passed, voluntary manufacturer reduction of nickel-releasing metal in children's clothing and close contacts, including grommets, button flies, belt buckles, school chairs, and tables, aimed for use by children would reduce Ni-ACD disease burden. Reporting of voluntary reduction on labels and on public Web sites would help parents of children and adolescents with Ni-ACD identify hypoallergenic metal objects, further enhancing reduction of disease symptomatology and burden.

CONCLUSIONS

Ni-ACD is a common chronic dermatitis with detrimental effects on children now and as they progress into adulthood. The burden of symptoms and cost is high. The United States can act on EU data revealing that legislation to limit exposures in childhood, especially with earrings, can impact the prevalence and potentially the severity of disease. Until and even if legislation is available, pediatricians can help patients by identifying the allergy early and intervening with a plan of prevention and care of disease.

Optimizing Resources in Children's Surgical Care: An Update on the American College of Surgeons' Verification Program

Kasper S. Wang, MD, FAAP,[a] James Cummings, MD, FAAP,[b] Ann Stark, MD, FAAP,[c] Constance Houck, MD, MPH, FAAP,[d] Keith Oldham, MD, FAAP,[e] Catherine Grant, BSN, RN,[f] Mary Fallat, MD, FAAP,[g] SECTION ON SURGERY, COMMITTEE ON FETUS AND NEWBORN, SECTION ON ANESTHESIOLOGY AND PAIN MEDICINE

abstract

Surgical procedures are performed in the United States in a wide variety of clinical settings and with variation in clinical outcomes. In May 2012, the Task Force for Children's Surgical Care, an ad hoc multidisciplinary group comprising physicians representing specialties relevant to pediatric perioperative care, was convened to generate recommendations to optimize the delivery of children's surgical care. This group generated a white paper detailing the consensus opinions of the involved experts. Following these initial recommendations, the American College of Surgeons (ACS), Children's Hospital Association, and Task Force for Children's Surgical Care, with input from all related perioperative specialties, developed and published specific and detailed resource and quality standards designed to improve children's surgical care (https://www.facs.org/quality-programs/childrens-surgery/childrens-surgery-verification). In 2015, with the endorsement of the American Academy of Pediatrics (https://pediatrics.aappublications.org/content/135/6/e1538), the ACS established a pilot verification program. In January 2017, after completion of the pilot program, the ACS Children's Surgery Verification Quality Improvement Program was officially launched. Verified sites are listed on the program Web site at https://www.facs.org/quality-programs/childrens-surgery/childrens-surgery-verification/centers, and more than 150 are interested in verification. This report provides an update on the ACS Children's Surgery Verification Quality Improvement Program as it continues to evolve.

INTRODUCTION

An estimated 5 million ambulatory and inpatient operations are performed on infants and children annually at thousands of sites in the

United States.[1,2] Evidence suggests that some operations are performed in environments lacking the optimal levels of expertise and/or resources.[3]

Studies since the early 1960s comparing outcomes at different ages have consistently demonstrated increased perioperative morbidity and mortality in infants younger than 1 year, with infants younger than 1 month demonstrating the highest risk.[4,5] Both the incidence of perioperative cardiac arrest and death were more than 20-fold higher in infants younger than 30 days compared with children older than 10 years.[6] Pediatric-specific anesthesiology training was subsequently associated with reductions in anesthesia-related morbidity.[7,8] In one survey in which respondents self-reported pediatric anesthesia-related complications such as inadequate ventilation, overdose of anesthetic, cardiac arrest, pulmonary aspiration, complications attributable to regional anesthesia, and acute pulmonary edema, anesthesiologist-specific annual pediatric anesthesia case volume was inversely correlated with the incidence of complications, with the best-achieving practitioners performing >250 pediatric anesthesia cases annually.[9]

In 1999, given concerns that many pediatric patients were undergoing surgery in environments without pediatric-specific expertise and equipment available, the American Academy of Pediatrics (AAP) Section on Anesthesiology and Pain Medicine published guidelines for the pediatric perioperative anesthesia environment.[10] These guidelines were subsequently updated in 2015 and specifically aligned with the American College of Surgeons (ACS) Children's Surgery Verification (CSV) standards.[3] The updated guidelines included recommendations that younger children and children with significant comorbidities should be cared for by board-certified or -eligible pediatric anesthesiologists. In 2012, the American Board of Anesthesiology established board certification standards for pediatric anesthesia in the form of a certificate of added qualifications in pediatric anesthesiology (Table 1). As of 2015, more than 4000 pediatric anesthesiologists in the United States have obtained this certification, and 191 pediatric anesthesia fellowship training positions are available (up 162% from 2002 to 2015).[11] Projections based on current trends suggest that more than 7000 pediatric anesthesiologists will be practicing in the United States by 2035.[11]

Compelling evidence exists that some degree of regionalization of complex children's surgical care improves outcomes. Using statewide hospital discharge databases for the states of California in 1988 and Massachusetts in 1989, Jenkins et al[13] demonstrated that children undergoing surgery for a congenital heart defect were at much lower risk of dying in the hospital if the surgery was performed at a high-volume institution (>300 cases annually).[13] Using discharge data for the state of California from 1995 to 1997, Chang and Klitzner[14] modeled a statewide system in which cases from low- and medium-volume centers were transferred to a small number of high-volume and high-performing centers and demonstrated a significant theoretical decrease in deaths associated with surgery for a congenital heart defect.[14] Similarly, using data from the California Perinatal Quality Care Collaborative from 2005 to 2011, Kastenberg et al[15] showed lower risk-adjusted mortality in very low birth weight infants with necrotizing enterocolitis in high-volume level III NICUs compared with low-volume level III NICUs. Using data from the 2010 National Trauma Data Bank, Webman et al[16] showed that the risk-adjusted mortality rate for injured adolescents was lower when treated at pediatric trauma centers compared to adult trauma centers. These data again indicate that mortality outcomes are improved when care is delivered in centers with

TABLE 1 Verification and Quality Improvement Programs

Program	Year Established	Description
ACS Committee on Trauma	1950	The committee develops and implements programs that support injury prevention and ensure optimal patient outcomes across the continuum of care incorporating advocacy, education, trauma center and trauma system resources, best practice creation, outcome assessment, and continuous quality improvement.
ACS NSQIP-Pediatric	2008	Participating hospitals collect clinical data and compare their surgical outcomes with the outcomes of other participants in the program.
American Board of Anesthesiology Pediatric Anesthesiology Certification	2012	The American Board of Anesthesiology establishes initial pediatric subspecialty certification as well as maintenance of certification to ensure quality anesthetic management of infants and children.
ACS CSV Quality Improvement Program	2015	To ensure pediatric surgical patients have access to high-quality care, the program verifies that resources required to achieve optimal patient outcomes for children receiving surgical care at health care facilities are met.
AAP NICU Verification Program	2016	The program reviews NICUs to verify whether standards for a specific level of care as established by the policy statement "Levels of Neonatal Care"[12] are met.

appropriately matched expertise and resources.

Children who receive care for less complex surgical problems at hospitals with more robust pediatric resources also have better clinical outcomes than those treated at less well-resourced facilities. For instance, although patients had more severe disease related to intussusception, the rate of bowel resection was lower in pediatric facilities compared to nonpediatric facilities in the state of Washington.[17] Similarly, risk of complications related to surgical treatment of appendicitis and pyloric stenosis was lower for children at pediatric hospitals compared with nonpediatric hospitals.[18] These studies demonstrate that management of children with certain surgical conditions at centers with greater expertise and/or resources generally results in fewer adverse outcomes.

Programs have been developed on national and state levels to promote regionalization and establish criteria for a range of care levels with the goal of optimizing disease-specific outcomes. In 1976, the ACS established criteria for categorizing hospitals on the basis of availability of resources for the care of traumatic injuries. In 1987, in an effort to regionalize systems care for trauma patients, the ACS Committee on Trauma established the trauma site verification program (https://www.facs.org/quality-programs/trauma) (Table 1). After the regionalization of trauma care,[19] MacKenzie et al[20] demonstrated that mortality risk for similarly injured adults was significantly lower in trauma centers compared with nontrauma centers.

In 2004, an AAP policy statement proposed a classification system that was based on the functional capabilities of NICUs with the goal of matching the acuity and complexity of a neonate with the expertise and resources of the treating unit.[21] The AAP proposed that regionalized systems should be organized on the basis of defined capabilities of the various units to optimize the care of newborn infants. This policy has been reaffirmed twice since the original statement, most recently in 2012, at which time levels of care were restratified as I through IV (level IV being the highest).[12] In the latest policy statement, additional literature was cited demonstrating superior survival outcomes for very low birth weight (<1500 g) and extremely low birth weight (<1000 g) infants in level III NICUs compared to level I and II NICUs as well as superior survival outcomes in higher-volume centers of equivalent level. In 2016, the AAP initiated a NICU Verification Program (https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/nicuverification) (Table 1). This program initially was developed to verify adherence to the Texas regulations regarding NICU levels of care (https://dshs.texas.gov/emstraumasystems/neonatal.aspx), which were developed on the basis of attributes of each level, as described in the AAP policy statement "Levels of Neonatal Care."[12]

ESTABLISHING CHILDREN'S SURGICAL VERIFICATION

The ad hoc Task Force for Children's Surgical Care was established in 2012 to address the potential mismatch of resources and an individual child's surgical needs in the United States. This multidisciplinary group comprising children's general and specialty surgeons, pediatric anesthesiologists, and others relevant to comprehensive perioperative care of infants and children met on 4 occasions and worked continuously between 2012 and 2015 to develop a consensus approach to matching resources with children's surgical needs and prepare an initial report.[22] This report included components of optimal resources for basic, advanced, and comprehensive children's surgical centers. Participants in the task force included representatives from the AAP, ACS, the American Pediatric Surgical Association, Children's Hospital Association, the Committee on Pediatric Anesthesia of the American Society of Anesthesiologists, and the Society for Pediatric Anesthesia.

Given the task force's white paper, the ACS CSV Quality Improvement Program was modeled after the well-established ACS verification programs that support a quality portfolio including trauma, colorectal cancer, breast cancer, and bariatric surgery. In 2015, the ACS released final standards for the CSV Quality Improvement Program as its fifth quality improvement program (Table 1). ACS CSV–verified programs are stratified from I through III (level I is the highest) on the basis of available resources and demonstrable commitment to pediatric surgical care (Table 2).

The main principles that form the foundation for the ACS CSV Program include the development of standards based on research, definition of infrastructure, a robust performance improvement process, rigorous data collection, and an external peer review verification process. Level I verification requires the presence of a wide range of pediatric subspecialists along with a level IV NICU and a PICU. In addition to pediatric general and specialty surgeons, pediatric proceduralists, including gastroenterology, pulmonary medicine, and interventional radiology, are also required in this multidisciplinary effort. A level III NICU is the minimum requirement for level II ACS CSV status. Institutional membership in the ACS National Surgical Quality Improvement Program Pediatric (NSQIP-Pediatric) (https://www.facs.org/quality-programs/pediatric) is required for standardized data collection for level I and level II ACS CSV centers; although this is not a requirement for level III ACS CSV status, institutional data collection is still

TABLE 2 Criteria for Children's Surgical Centers by Level

Criteria	Level I	Level II	Level III
Graduate medical education (any type)	Desired	No	No
Freestanding children's hospital or comprehensive pediatric care unit within general hospital organization	Yes	Yes	No
Children's surgical services	Yes	Yes	Yes
Pediatric surgeons	≥2	≥1	Pediatric expertise[a]
Pediatric anesthesiologists	≥2	≥1	Pediatric expertise[b]
Pediatric emergency medicine physicians	Yes	Desired	Pediatric expertise[c]
Pediatric radiologists	≥2	≥1	Pediatric expertise[d]
Other children's surgical specialists	Mandatory	Within scope	Variable
Pediatric rapid response team[e]	Yes	Yes	Yes
Surgery-specific children's CME for children's surgery medical director and liaisons	Yes	Yes	Yes
NICU	AAP level IV	AAP level III or greater	No
Neonatologists	Yes	Yes	No
Pediatric emergency department	Yes	Yes	"Expertise" facility
PICU	Yes	Desired	No
Pediatric critical care medicine physicians	Yes	Yes, within scope	No
Pediatric acute care unit[f]	Yes	Yes	No
Pediatric resuscitation equipment in all appropriate patient-care areas	Yes	Yes	Yes
Children's surgical program manager or coordinator	Yes	Yes	Yes
Surgical data collection	Yes	Yes	Yes, limited
Child-life and family-support programs	Yes	Yes	No
Pediatric social work and/or child protective services	Yes	Yes	Yes
Community outreach programs	Yes	Yes	Yes
Children's education programs	Yes	Yes	Yes
Surgical research	Yes	Desired	No
Minimum number of annual surgical procedures for children younger than 18 y	1000	—	—
Children's surgical performance improvement and patient safety program	Yes	Yes	Yes

CME, continuing medical education; —, not applicable.

[a] A general surgeon with pediatric expertise is defined as a surgeon either eligible for certification or certified by the American Board of Surgery or an equivalent body in general surgery. All surgeons who care for children will demonstrate ongoing clinical engagement and expertise in children's surgery, as evidenced by the performance of 25 or more procedures annually in patients younger than 18 years, as well as completion of 10 or more pediatric category 1 CME credit hours annually.[23]

[b] An anesthesiologist with pediatric expertise is defined as an anesthesiologist either eligible to certify with, or with a current certificate from, the American Board of Anesthesiology or equivalent. He or she will demonstrate continuous experience with children younger than 24 months, defined as 25 patients per anesthesiologist per year. In addition, this individual will demonstrate ongoing pediatric clinical engagement with patients younger than 18 years and will complete 10 or more pediatric category 1 CME credit hours annually.[23]

[c] An emergency medicine physician with pediatric expertise is defined as an individual certified by the American Board of Emergency Medicine, the American Board of Pediatrics, or equivalent and who has demonstrable pediatric experience and training to support the actual scope of emergency medicine practice, as well as 10 h annually of pediatric category 1 CME.[23]

[d] A radiologist with pediatric expertise is defined as a radiologist with certification by the American Board of Radiology or equivalent with demonstrable pediatric experience to support the scope of actual practice and 10 or more pediatric category 1 CME credit hours annually.[23]

[e] A pediatric rapid response and/or resuscitation team is required for level I verification (CD 2–35). There must be a 24/7 physical presence of a pediatric physician or surgeon who has current pediatric advanced life support certification (CD 2–36). The NICU should have a neonatal rapid response and/or resuscitation team with a 24/7 presence of a pediatric provider who has current Neonatal Resuscitation Program certification.[23]

[f] Staffed by pediatricians and/or pediatric hospitalists.

required. ACS NSQIP-Pediatric is a nationally validated, risk-adjusted outcomes assessment program used to measure and improve the quality of children's surgical care among more than 100 participating centers by reporting of institution's adverse events rates compared with those of peer institutions. As with all ACS verification programs, a dedicated administrative team, comprising a surgeon (NSQIP-Pediatric champion) and support staff, is vital to the success of the program. The current annual fees to participate in CSV and ACS NSQIP-Pediatric are listed at https://www.facs.org/quality-programs/childrens-surgery/fees. Reverification is performed every 3 years.

An up-to-date list of all verified centers is listed on the program Web site at https://www.facs.org/quality-programs/childrens-surgery/childrens-surgery-verification/centers. An additional 150 centers have expressed interest in verification. After receipt of a CSV application and submission of the prereview questionnaire, a reviewer team is selected. The team is a combination of 3 reviewers. The team always includes a specialty-qualified children's surgeon(s) and a pediatric anesthesiologist. The team may also include a pediatric nurse. The reviewers are selected by the ACS CSV Program staff. The review team is provided relevant documents and an organized agenda in advance of the site visit. Guidelines ensure consistent and appropriate conduct of the review. After the site visit, a standardized report is generated and reviewed by the ACS CSV Committee, which makes the final decision regarding verification.

Lessons learned from completed verification visits include the importance of developing institution-wide, multidisciplinary process improvement structures, and the need for robust resource commitments that prioritize pediatric patient safety and encourage quality improvement initiatives. In addition, establishing and maintaining pediatric-specific resources (nursing, operating rooms, etc) and

focused attention on pediatric provider training and availability are essential.

ACS CSV is a voluntary program that, if implemented uniformly, would enable all hospitals to identify and advocate for shortfalls in important resources for optimizing children's surgical care. Without augmentation of resources, Baxter et al,[24] using the 2009 Kids' Inpatient Database, estimated conservatively that more than one-third of all neonates with complex surgical conditions would need to be relocated from level II or III hospitals to a level I hospital.[24] Using propensity score-adjusted logistic regression, the authors further estimated 1 life saved for every 32 neonates relocated, with a median distance traveled of 6.6 miles (range up to >200 miles). The authors did not analyze the implications on morbidity and its associated costs. Although access to care is important, the goal of ACS CSV is ensuring the best care possible for each child requiring surgery, and site review can be used to advocate for pediatric perioperative resources important to achieving this goal.

Going forward, the ACS CSV Program actively collaborates with the AAP NICU Verification Program in Texas. The program also collaborates with Wake Up Safe, an anesthesia quality improvement program supported by the Society for Pediatric Anesthesia. As more hospitals undergo children's surgical verification, outcomes will be assessed to ascertain whether the process results in demonstrable improvements in children's health, as has been documented with trauma program verification.

CONCLUSIONS

The goal of the ACS CSV Program is to improve the quality of care for children requiring surgery by matching individual patient needs (including surgical complexity and comorbidities) with appropriate and optimal perioperative resources (including equipment and personnel). The ACS CSV Program is actively collaborating with the AAP NICU Verification Program. The program, which has been endorsed by the AAP, has already verified several programs, and it is projected that at least 20 additional pediatric perioperative programs will be verified by 2020. Ensuring that hospital resources are matched with children's surgical needs is expected to optimize clinical outcomes.

Participation of Children and Adolescents in Live Crisis Drills and Exercises

- *Policy Statement*

POLICY STATEMENT Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

American Academy of Pediatrics

DEDICATED TO THE HEALTH OF ALL CHILDREN®

Participation of Children and Adolescents in Live Crisis Drills and Exercises

David J. Schonfeld, MD, FAAP,[a] Marlene Melzer-Lange, MD, FAAP,[b] Andrew N. Hashikawa, MD, MS, FAAP,[c] Peter A. Gorski, MD, MPA, FAAP,[d,e] COUNCIL ON CHILDREN AND DISASTERS, COUNCIL ON INJURY, VIOLENCE, AND POISON PREVENTION, COUNCIL ON SCHOOL HEALTH

Children and adolescents should be included in exercises and drills to the extent that their involvement advances readiness to meet their unique needs in the event of a crisis and/or furthers their own preparedness or resiliency. However, there is also a need to be cautious about the potential psychological risks and other unintended consequences of directly involving children in live exercises and drills. These risks and consequences are especially a concern when children are deceived and led to believe there is an actual attack and not a drill and/or for high-intensity active shooter drills. High-intensity active shooter drills may involve the use of real weapons, gunfire or blanks, theatrical makeup to give a realistic image of blood or gunshot wounds, predatory and aggressive acting by the individual posing to be the shooter, or other means to simulate an actual attack, even when participants are aware that it is a drill. This policy statement outlines some of the considerations regarding the prevalent practice of live active shooter drills in schools, including the recommendations to eliminate children's involvement in high-intensity drills and exercises (with the possible exception of adolescent volunteers), prohibit deception in drills and exercises, and ensure appropriate accommodations during drills and exercises based on children's unique vulnerabilities.

BACKGROUND

Historically, children of all ages have generally not been included in crisis preparedness efforts in the United States, including participation in live drills and exercises, and certainly not to the extent that children are represented in the general population. This lack of planning and practice for the needs of children represents a significant oversight that increases the vulnerability of children in the event of a crisis.[1] However, increasing concerns about the risk of mass casualty events in schools throughout the United States have given rise to crisis preparedness efforts that now include

children in high-intensity live crisis exercises such as active shooter drills, which are increasingly held in schools and involving children of all ages, including early elementary school- and preschool-aged children as well as college students. For the purpose of this policy statement, "children" will be used to refer to children and youth of all ages (ie, 0–21 years of age), unless stated otherwise. The American Academy of Pediatrics (AAP) recommends that children be included in exercises and drills only to the extent that their involvement advances adult readiness to meet the unique needs of children in the event of a crisis and/or furthers their own preparedness or resiliency. However, there is also a need to be cautious about the potential psychological risks of directly involving children in live exercises and drills. These risks are especially a concern when children are deceived so that they believe there is an actual attack and not a drill and/or for high-intensity active shooter drills.

A lockdown is an emergency procedure to minimize risk of harm to students and staff when a significant threat of violence within (or near) the school is present. A lockdown generally involves the immediate movement of students and staff into rooms in which doors are locked and students remain quiet. Other security measures are often followed, including darkened lights, shades on exterior windows, and covered doors, and children moving to an area that is not visible from hallways. Lockdown drills are when lockdown procedures are practiced in the absence of a threat, including as a form of preparation for a possible armed assailant (in which case, some people may refer to this as an active shooter drill). High-intensity active shooter drills may involve the use of real weapons, gunfire or blanks, theatrical makeup to give a realistic image of blood or gunshot wounds, predatory and aggressive acting by the individual posing to be the shooter, or other means to simulate an actual attack, even when participants are aware that it is a drill.[2]

STATEMENT OF PROBLEM

The majority of school districts currently require active shooter drills, among other emergency drills and exercises within schools and other community settings.[3] If planned and conducted thoughtfully with sufficient attention to the potential emotional impact of participation and conducted in a manner that is developmentally appropriate, exercises such as lockdown drills may be completed without a major negative impact to most children.[4] However, in practice, active shooter drills are often planned and conducted without guidance from those familiar with the unique needs and vulnerabilities of individual or groups of children, which is critical to inform best practices. The unique needs of young children (eg, those in early care and education settings), children who suffered traumatic events in the past, and those with physical, intellectual, and neurodevelopmental disabilities are rarely considered and addressed in live exercise planning. Preparedness initiatives and approaches need to be evaluated to ensure that they are effective, and research is needed to demonstrate that these initiatives do not cause untoward distress or other unintended consequences for individual or groups of children and school staff or other adult participants.

EVIDENCE BASE

Although there is general agreement that the direct involvement of children should be based on the value of including them in crisis drills and exercises, their age and developmental capabilities, and their personal vulnerabilities, there is a limited evidence base on how to make these assessments. Mass shootings in schools, although highly visible in the media and social consciousness, are rare events. These events, therefore, provide limited opportunities to test the efficacy of interventions in real-life situations. School safety, especially related to school shootings, has generated opportunities for products and services that together represent major financial investments, without much or any evidence of efficacy.[5] Products promoted for purchase by schools now include bulletproof barriers or shelters intended to accommodate the full class and teacher that can be used as panic rooms in the event of a school shooting.[6] These types of training and interventions proposed have rarely been evaluated, despite an escalating demand for both.

Recently, researchers have begun to question the efficacy of some popular training approaches. For example, Dorn[7] conducted more than 8000 one-on-one controlled video and audio simulations and, in the study, found that school personnel who completed active shooter training designed to train people to make decisions among various crisis response options (eg, whether to run, hide, or physically attack a shooter) were almost twice as likely to misjudge many critical action steps in simulations compared with untrained school staff who relied on common-sense actions. For example, adults who completed the training were more likely to attack a child who was holding a gun and threatening suicide or run from a classroom when staying within the room was the safer alternative.

It is possible, and even likely, that other well-intentioned preparedness efforts may inadvertently cause children and adults to place themselves in additional danger in a crisis situation. Children (and adults) might be taught to fight a heavily armed intruder, when fleeing or hiding would be a more appropriate response. Children taught to provide first aid to a bleeding peer or remain near an injured person to comfort them may remain in harm's way in an

active shooter event and place themselves at increased risk of becoming a casualty.

Some students and school personnel may feel empowered by being able to actively participate in live exercises because they may feel that it better prepares them for possible events. These individuals may, however, underestimate how others with different personalities, coping styles, personal histories, and individual vulnerabilities may respond. Children and adults who receive training to respond to a crisis may feel comforted because it provides them an illusion of control. However, such efforts could result in increased guilt if the individual is not able to respond in the idealized fashion in a real event. For example, children taught to fight back against an armed intruder or adult staff who are armed with a weapon to shoot a potential attacker may feel substantial guilt if they end up fleeing (appropriately) or are unable to save the life of a child or peer in an actual attack. These and other unintended consequences need to be carefully considered, and programs need to be evaluated more strategically for efficacy before being widely implemented. Even initiatives with good intentions may cause serious harm.

Unfortunately, there is not much evidence to guide best practices. Survivors or family members of individuals who died in crisis events may be powerful advocates for preparedness efforts and feel passionately about the need to take active steps to protect students and staff from school crisis events. Parents and other community members may simply be unwilling to wait until preparedness approaches are adequately evaluated. Pediatricians and other pediatric health care providers can provide important insights into the developmental needs and vulnerabilities of children of all ages that can help inform best practices.

Law enforcement personnel who place their own lives in jeopardy have the unenviable responsibility of protecting children from such acts of violence and may understandably suggest taking virtually any action that may save a child's life, thereby leading them to recommend involving children in high-intensity drills. Their passion may need to be balanced with concerns of unintended mental and physical consequences and/or the lack of evidence about the efficacy of certain approaches.

Law enforcement personnel benefit from regular and realistic opportunities to practice critical skills, much as physicians do. It, therefore, stands to reason that these professionals would seek opportunities to identify and then practice how best to respond to active shooter scenarios in schools and other settings. The question is whether and in which situations children and adolescents should be actively engaged in such live exercises and how the exercises should be conducted to minimize the negative impacts on students. Guidelines developed by the National Association of School Psychologists and National Association of School Resource Officers recommend that schools follow a hierarchy of preparedness strategies, beginning with simple discussion-based exercises, before even considering complex (in-person or live) operations-based drills. These organizations also recommend the inclusion of school mental health professionals in both the planning and implementation of drills so that careful consideration can be given to the appropriate involvement of children and potential means to minimize distress for all participants.[8,9]

In contrast, some schools have conducted active shooter exercises without advance notice and misled students and/or staff members that it was an actual shooting event, complete with a police response and, in at least one situation, armed weapons pointed at school-aged children. This is based on the belief that simulations that evoke the same level of distress as real events better prepare participants to act appropriately at a time of true crisis.[2] During one recent live exercise in which high school students were deceived to believe it was a real event, children sobbed hysterically, vomited, or fainted, and some children sent farewell notes to parents. Children risked physical harm when a stampede ensued, and students jumped over fences to escape.[10] In one situation, staff were intentionally shot at close range with pellets as part of the training.[11]

High-intensity crisis preparedness efforts may contribute to a distorted sense of risk in children and perspective that adults and peers need to be viewed as potential killers. More broadly, these activities can increase children's anxiety and fear that the world is a threatening place.[12] This atmosphere of a continuous threat of violent death is likely to increase anxiety further among children when frequent threats directed at the school or present in the community lead to lockdown procedures. It should not be a surprise that there are reports of young children writing frantic notes while in lockdown, including one 7-year-old who wrote "Love mom and dad" with marker on her arm and later explained to her mother that it was "In case the bad guy got to us and I got killed, you and daddy would know that I love you" after her body was discovered.[10,13] Even infants and toddlers in early child care settings, who will have little understanding of the implications of gun violence, may nonetheless react negatively with increased anxiety, stress, and helplessness to the stressful context, loud noises, and disruptive environment of active shooter drills, especially when the adults are themselves distressed. Stakeholders can instead be focused on equipping children with the skills

needed and expectations of peaceful coexistence rather than an expectation for and preparation to recover from mass violence. Resources directed to prevention efforts are more cost-effective and have wider benefits to potential victims, survivors, and society.

The December 2018 report of the Federal Commission on School Safety[14] included the following statement: "While there is some disagreement over whether it is appropriate to subject students to active shooter training, as school shootings become more prevalent, more schools are opting to drill their students on how to respond to an active shooter situation. According to a 2016 US Government Accountability Office report, an estimated 67% of school districts conduct active shooter drills involving their students. Whether to conduct active shooter drills with the student population is something each community must determine for itself. For those that do elect to conduct active shooter drills with students, they should ensure that the training is age-appropriate and designed in a manner not to unduly traumatize any of the participants."

The determination of what is generally age-appropriate and/or likely to be traumatizing to children when conducting a live crisis exercise or drill is something that can be determined at a national level. There is a general lack of national recommendations on whether to include children in active shooter exercises and other crisis drills. This policy statement aims to provide those recommendations.

CONCLUSIONS

The AAP supports advocacy efforts at the national and state levels to ensure that the unique needs of children are fully considered in crisis preparedness efforts, including, when appropriate, the involvement of children in live exercises and drills. However, the AAP also recognizes the importance of ensuring that preparedness efforts are effective but do not cause children untoward psychological distress or lead to other unintended consequences.

RECOMMENDATIONS

1. Eliminate children's routine involvement in high-intensity drills and exercises. Children should generally only be involved in crisis exercises when their involvement is of direct benefit to them and/or other children, rather than only of benefit to adult professionals. If the goal of a high-intensity drill or exercise is for adult responders to practice their roles (eg, to train law enforcement and/or medical personnel), then alternatives such as manikins or adults playing the roles of children should be sufficient, or the activity can occur outside of the hours when students are present in schools or preschools. First responders may need to practice being in a high-stress situation involving active shooters, but the same is not true for school-aged children. Therefore, only adolescents who have a personal desire to participate (eg, volunteers from a drama club or teenagers who plan a career in law enforcement or as an emergency medical technician) should have the option to be included in high-intensity drills and exercises until evidence is gathered that such drills or exercises are of sufficient benefit to warrant the likely distress of other participants.
2. Obtain active consent/assent of adolescent volunteer participants. If adolescents volunteer to be involved in high-intensity live exercises, they should be carefully briefed on what will be involved and the feelings that the experience may engender (including for those with undisclosed personal vulnerabilities, such as anxiety or past traumatic experiences) and told that they are under no pressure to volunteer. For this reason, active consent (for those youth able to provide consent) or active consent from a legal guardian and assent from the adolescent should generally be required for live high-intensity exercises, rather than the use of passive consent procedures. Children who are of an age and developmental ability to provide consent/assent for procedures that may cause modest physical discomfort or modest emotional distress to an average child (eg, donating blood in a blood drive for example) may be permitted to provide consent/assent to participate in such exercises; younger children should not be allowed to participate. Even adolescents who have been appropriately briefed and are capable of providing consent/assent may still not disclose personal vulnerabilities and/or may underestimate the distress that participation may ultimately cause.
3. School personnel or other adults present during drills should remain vigilant for psychological distress. It is critical to minimize the distress children may experience throughout any exercise. Simulations involving real weapons, gunfire or blanks, theatrical makeup to give a realistic image of blood or gunshot wounds, predatory and aggressive acting by the individual posing to be the shooter, or other means to accurately simulate an actual attack are likely to still be traumatic to some and should require careful justification. Even if children have agreed to participate in an exercise, they ought to be instructed to discontinue participation if it is causing any physical or emotional

distress and explicitly given permission to take a break from the exercise for any reason. Adult monitors should be observing children's reactions and checking on them periodically throughout the exercise. Even when exercises or drills do not include any elements that may be felt likely to engender distress, some children and adults may nevertheless experience distress. For this reason, adults should carefully monitor the reactions of children and adults to any exercises and drills, with oversight by an experienced member of the team planning the exercise or drill, and provide supportive services as indicated.

4. Eliminate deception in drills and exercises. Notice of drills should be provided to parents, students, and staff members. Students, staff, and families of students should not be led to believe that an exercise is a real event or misled about the injury to or death of others. Such a practice is harmful and unethical and is not justified by a theoretical benefit of evaluating people's response under extreme levels of stress. State AAP chapters can advocate that schools and emergency response agencies prohibit the use of deception in live drills and exercises and any related simulations (eg, mock death notifications and funerals). Instead, it should be mandatory to notify parents, students, and staff members of planned live crisis drills and exercises. Pediatricians can review the policies of local school districts, inquire about their current practices related to drills and exercises, and offer guidance as described in this policy.
5. Focus on teaching skills rather than simulating distressing crisis events. The goal of live exercises and drills is to teach skills before actively testing them in a more pressured context that may degrade performance, thereby helping to promote and demonstrate competence rather than overwhelming people by their failures. Stakeholders planning drills and exercises should articulate that the learning objectives for adult and child participants are different and ensure that the drills and exercises highlight or teach specific behaviors that promote safety rather than simply being used to highlight potential dangers or convey the seriousness of a crisis event. Feedback from all stakeholder groups, including students and staff, should be obtained after exercises and drills to identify any remaining gaps in knowledge and skills and ascertain if participation caused any distress or other unintended consequences.
6. Make accommodations that are based on children's unique vulnerabilities. In most situations, active shooter drills should be conducted as fire drills are generally conducted (without simulation of there being an active fire) using a well-discussed, calm approach to the safe movement of students and staff in the school building. In general, adults should avoid referencing these drills with names that may engender further distress, such as calling them "active shooter drills"; instead, terms such as "lockdown," "shelter in place," or "safety drills" are preferable. Children with a high level of personal vulnerability (eg, students with an anxiety disorder, previous traumatic experience, or physical disability) may require particular accommodations, including being excused from certain drills or exercises when such participation may be overwhelming.[15,16] Parents and/or guardians can be notified at the start of a school year about the likely drills that will be held and invited to bring any concerns about their child's participation to the school's attention. Pediatricians who become aware of such concerns should encourage and assist parents to communicate them directly to school authorities. In some situations, the accommodations may be part of a 504 Plan or incorporated into a student's Individualized Education Program. School personnel must be conscious of the unique needs of early childhood, child care, Head Start and Early Head Start, or preschool programs located on campus and consider ways to exclude or mitigate the impact on this vulnerable population.
7. Seek and incorporate student input. School personnel can give thought as to how to incorporate the input of students into safety discussions and planning for exercises and drills. Students can provide important insight into the risks that students may face in the event of a crisis, vulnerabilities that adults may not anticipate, and how best to prepare peers for exercises and drills and minimize their distress while participating. It is important, though, to remember that some students and staff may feel empowered by opportunities to engage actively in exercises and underestimate the distress it may cause other students with different personalities, coping styles, or preexisting vulnerabilities. Adults can talk with students after conducting drills and exercises to obtain their feedback about the experience and suggestions on how to optimize future exercises and drills.
8. Obtain multidisciplinary input into exercise and/or drill planning. To give careful consideration to the needs of all children in drills and

exercises, planning teams should be multidisciplinary and include pediatricians or other professionals with expertise in child development and behavioral health, such as school mental health providers (eg, school counselors, psychologists, and social workers). Such planning teams should also explore how best to incorporate the input of students, school and/or preschool staff of different professions, parents, and other community partners. Teachers and other school professionals care deeply about protecting children and may, therefore, have more emotional reactions to such exercises and drills than planners anticipate, even in the absence of any personal vulnerabilities such as preexisting trauma or loss. The impact of drills and exercises on adults should be given careful consideration as well.

9. Emphasize the role of prevention. Sufficient emphasis should be placed on the prevention of violence, including the necessary financial resources and professional efforts. These efforts include, among others, efforts in social-emotional learning, positive school climate and culture, early identification and effective and readily accessible treatment of behavioral health concerns and mental illness, educator and school administration training, deployment of sufficient mental health and support personnel in schools, and interdisciplinary threat assessment.[5] The AAP and its members can work with others nationally to balance the rights of gun ownership with the need to protect the safety of children in a way that does not allow society to view mass shootings involving children as inevitable or as a "new normal" in society.
10. Promote legislative advocacy. All legislation requiring active shooter drills in schools should be required to follow best-practice guidelines, such as those from the National Association of School Psychologists and the National Association of School Resource Officers.[8] Among other recommendations, these guidelines recommend that schools begin with simple discussion-based exercises (ie, tabletop exercises) before considering complex live drills.
11. Conduct research on the impact of exercises and drills. Funding for research is needed to evaluate the goals, efficacy, and potential unintended consequences of crisis preparedness activities involving children. Strategies that are likely to cause significant distress or other unintended consequences, such as high-intensity live exercises, should be evaluated before they are implemented, especially in the absence of evidence of their efficacy.

Pediatric Readiness in Emergency Medical Services Systems. *Pediatrics.* 2020;145(1): e20193307

Prehospital emergency care typically involves emergency medical technicians, paramedics, and other licensed medical providers who work in emergency medical services (EMS) systems in ground ambulances and fixed- or rotor-wing aircraft that are dispatched to an emergency when either a bystander calls 9-1-1 or when a patient requires interfacility transport for a medical illness or traumatic injury. Because prehospital emergency care of children plays a critical role in the continuum of health care, which also involves primary prevention, hospital-based acute care, rehabilitation, and return to the medical home, the unique needs of children must be addressed by EMS systems.[1–5] Pediatric readiness encompasses the presence of equipment and medications, usage of guidelines and policies, availability of education and training, incorporation of performance-improvement practices, and integration of EMS physician medical oversight to equip EMS systems to deliver optimal care to children.[6–8] It has been shown that emergency departments are more prepared to care for children when a pediatric emergency care coordinator is responsible for championing and making recommendations for policies, training, and resources pertinent to the emergency care of children.[9,10] The specialty of EMS medicine has the potential to derive similar benefits when members of the EMS community are personally

invested in pediatric patient care. Although a critical aspect of pediatric readiness in EMS involves strong EMS physician oversight of these investments, a discussion of physician oversight of pediatric care in EMS is outside the scope of this article. This topic is, however, well addressed in the National Association of Emergency Medical Services Physicians position statement "Physician Oversight of Pediatric Care in Emergency Medical Services."[1] This policy statement is accompanied by a technical report published simultaneously in this issue of *Pediatrics*.[11]

RECOMMENDATIONS

To provide infrastructure designed to support the prehospital emergency care of children, the American Academy of Pediatrics, American College of Emergency Physicians, Emergency Nurses Association, National Association of Emergency Medical Services Physicians, and National Association of Emergency Medical Technicians believe that EMS systems and agencies should do the following:

- Include pediatric considerations in EMS planning and the development of pediatric EMS dispatch protocols, operations, and physician oversight (for example, as outlined in the National Association of Emergency Medical Services Physicians position statement "Physician Oversight of Pediatric Care in Emergency Medical Services").[1]
- Collaborate with medical professionals with significant experience or expertise in pediatric emergency care, public health experts, and family advocates for the development and improvement of EMS operations, treatment guidelines, and performance-improvement initiatives.[2]
- Integrate evidence-based, pediatric-specific elements into the direct and indirect medical oversight that constitute the global EMS oversight structure.[4]
- Have pediatric-specific equipment and supplies available, using national consensus recommendations as a guide, and verify that EMS providers are competent in using them.[3,4,12–15]
- Develop processes for delivering comprehensive, ongoing, pediatric-specific education and evaluating pediatric-specific psychomotor and cognitive competencies of EMS providers.[13,14,16–18]
- Promote education and awareness among EMS providers about the unique physical characteristics, physiologic responses, and psychosocial needs of children with an illness or injury.[19–21]
- Implement practices to reduce pediatric medication errors.[22,23]
- Include pediatric-specific measures in periodic performance-improvement practices that address morbidity and mortality.[4]
- Submit data to a statewide database that is compliant with the most recent version of the National Emergency Medical Services Information System and work with hospitals to which it transports patients to track pediatric patient-centered outcomes across the continuum of care.[4]
- Develop, maintain, and locally enforce policies for the safe transport of children in emergency vehicles.[4]
- Develop protocols for the destination of pediatric patients, with consideration of regional resources and weighing of the risks and benefits of keeping children in their own communities.[4]
- Collaborate, along with receiving emergency departments, to provide pediatric readiness across the care continuum.[4–10]
- Include provisions for caring for children and families in emergency preparedness planning and exercises, including the care and tracking of unaccompanied children and timely family reunification in the event of disasters.[3,4,24]
- Promote overall patient- and family-centered care, which includes using lay terms to communicate with patients and families, having methods for accessing language services to communicate with non–English-speaking patients and family members, narrating actions, and alerting patients and caregivers before interventions are performed. In addition, allow family members to remain close to their children during resuscitation activities and to practice cultural or religious customs as long as they are not interfering with patient care.[19]
- Have policies and procedures in place to allow a family member or guardian to accompany a pediatric patient during transport when appropriate and feasible.[19]
- Consider using resources compiled by the Emergency Medical Services for Children program when implementing the recommendations noted here.[25]

CONCLUSIONS

Ill and injured children and their families have unique needs that can be magnified when the child's ailment is serious or life-threatening. Resource availability and pediatric readiness across EMS agencies are variable. Providing high-quality EMS care to children requires an infrastructure that is designed to support the care of pediatric patients and their families. Therefore, it is important that EMS physicians, administrators, and personnel collaborate with pediatric acute care experts to optimize EMS care through the development of care models to minimize morbidity and mortality in children as a result of illness and injuries.

Ill and injured children have unique needs that can be magnified when the child's ailment is serious or life-threatening. This is especially true in the out-of-hospital environment. Providing high-quality out-of-hospital care to children requires an emergency medical services (EMS) system infrastructure designed to support the care of pediatric patients. As in the emergency department setting, it is important that all EMS agencies have the appropriate resources, including physician oversight, trained and competent staff, education, policies, medications, equipment, and supplies, to provide effective emergency care for children. Resource availability across EMS agencies is variable, making it essential that EMS medical directors, administrators, and personnel collaborate with outpatient and hospital-based pediatric experts, especially those in emergency departments, to optimize prehospital emergency care for children. The principles in the policy statement "Pediatric Readiness in Emergency Medical Services Systems" and this accompanying technical report establish a foundation on which to build optimal pediatric care within EMS systems and serve as a resource for clinical and administrative EMS leaders.

DEFINITIONS

- Emergency medical services (EMS): An intricate and comprehensive system, which in a coordinated response, provides the arrangements of personnel, facilities, and equipment for the effective, coordinated, and timely delivery of health and safety services to provide emergency care.[1,2]
- Out of hospital: A term used in emergency medicine to mean "in the field," "in the community," "at the patient's home or workplace," or "prehospital." Assessments performed and treatments given out of

hospital often stabilize a patient or initiate critically needed care.[3]

INTRODUCTION

Emergency care for children occurs along a continuum from primary prevention to prehospital, hospital-based acute care, and rehabilitation services. In 2009, the American Academy of Pediatrics (AAP), the American College of Emergency Physicians (ACEP), and the Emergency Nurses Association collaborated to produce a document focused on the emergency department (ED), "Guidelines for Care of Children in the Emergency Department,"[4] recently revised and published as "Pediatric Readiness in the Emergency Department."[5] Alongside the ED policy statement, the National Association of EMS Physicians (NAEMSP) and National Association of Emergency Medical Technicians (NAEMT) joined those organizations in authoring a policy statement[6] on pediatric readiness in EMS systems. This technical report supports these policies with evidence for the need for pediatric services to be embedded into the EMS segment of the continuum of emergency care for children. This report identifies areas where improvements can be made in EMS systems and provides resources and references for clinical and administrative EMS leaders to use to transform health care for pediatric patients. Recommendations for integrating pediatric-specific components into EMS systems are noted in Table 1.

BACKGROUND

In 2011, the National Association of State EMS Officials (NASEMSO) published the results of the National EMS Assessment. At the time, 826 111 credentialed EMS professionals in 19 971 licensed EMS agencies cared for more than 35 million patients annually in the United States.[7] Children represented only 10% of EMS encounters,[8] raising concerns that even well-trained EMS providers can face challenges in the maintenance of their cognitive knowledge and psychomotor skills given the range of acuity in pediatric patients they encounter.[8–19] These challenges underscore the importance of establishing activities in EMS agencies and systems to ensure pediatric readiness in the EMS environment.[19–24]

Pediatric Readiness

In 2006, the Institute of Medicine (IOM), now called the National Academies of Sciences, Engineering, and Medicine, published a report titled, "Emergency Care for Children: Growing Pains," which described multiple deficiencies and gaps in the ability of our emergency care system to meet the needs of children.[25] For example, the IOM noted that the workforce providing emergency care must have the knowledge and skills to take care of children to minimize devastating health consequences. As evidence of deficiencies in this necessary knowledge and skill, the authors noted significant gaps in both clinical and administrative areas as well as a paucity of research on best practices, clinical outcomes, and patient safety for the prehospital care of children. The report had several recommendations including the need for the EMS industry to establish defined pediatric emergency care competencies and provide initial and continuing pediatric-specific education for providers.[4–25]

The 2013 National Pediatric Readiness Project assessment evaluated various foundational elements based on the joint policy statement "Guidelines for Care of Children in the ED." The fundamental elements of readiness included administration and coordination; physicians, nurses, and other health care providers; quality improvement (QI); patient safety; policies, procedures, and protocols; support services; and equipment, supplies, and medications.[4,26] This study demonstrated that although pediatric readiness had improved in EDs, 80% still reported some barriers to implementing the recommendations in the guidelines. Studies examining pediatric readiness and a pediatric facility verification program found that activities in EDs that achieve higher scores of pediatric readiness are linked to improved outcomes such as a decreased pediatric mortality rate, timeliness of pain management and reduced radiation for fractures, and improved simulation care for pediatric sepsis.[4,26–30]

Evidence from the National Pediatric Readiness Project supports that EDs are more prepared to care for children when guidelines are adhered to for the care of children in EDs.[26,27] Several of the elements of pediatric readiness assessed recommended a pediatric liaison in the EMS environment. EMS medicine has the potential to see similar benefits in readiness to care for children with established guidelines for the care of children in EMS systems.[5,24]

The Impact of Population-Specific Oversight Practices on Improving Care

Attention to sufficient cognitive and psychomotor training, provider experience, and physician oversight aids EMS success. An example of success for a condition-specific population is advanced airway management, in which focused oversight has been shown to improve performance.[31,32] Researchers in Rochester, New York, studied the effect of a redesigned rapid sequence intubation program that was consistent with recommendations published by the NAEMSP.[33] They were able to demonstrate significant gains in cognitive performance, most notably proper

TABLE 1 Integration of Pediatric Components Into EMS Systems

Medical oversight
Ensure pediatric representation in EMS planning, operations, and oversight as outlined in the NAEMSP position statement "Physician Oversight of Pediatric Care in EMS"
Provide direct and indirect medical oversight that integrates pediatric-specific elements into the global EMS system
Operations
Include pediatric-specific guidance and expertise in the development and improvement of EMS operations
Have pediatric-specific equipment and supplies available and ensure that prehospital providers are competent in their use
Develop processes for evaluating pediatric-specific psychomotor and cognitive competencies of prehospital providers
Have policies that ensure the safe transport of children and families in emergency vehicles
Collaborate with outpatient and hospital-based pediatric experts, especially those in EDs
Facilitate destination determination of patients by weighing the risks and benefits of transport to a higher level of care
Collaborate with local EDs to promote basic pediatric readiness of all facilities
Include considerations for care of children and families in emergency preparedness planning and exercises, including family repatriation, in time of disasters
Provide situational awareness to caregivers by encouraging providers to designate a person to narrate and preempt actions to the bystander on the scene, using lay terms to communicate with patients and families, and allowing bystanders to maintain a line of sight with the child as long as they are not interfering with patient care
Education
Ensure that prehospital providers receive periodic pediatric-specific education
Ensure pediatric assessment and recognition of respiratory distress or failure, cardiac failure, and shock
Competency in neonatal and pediatric resuscitation
Ensure updated psychomotor skills and practice in pediatric airway management (focusing on basic airway management) and venous and intraosseous placement and access
Provide education tools to improve proper pain and wt assessment and pain management
Research, data management, and QI
Implement practices to reduce pediatric medication errors
Include pediatric-specific measures in QI and quality assurance processes
Submit data to a statewide database that is compliant with the most recent version of the NEMSIS and work with local hospitals to track pediatric patient-centered outcomes across the continuum of care

Physician oversight of pediatric care in emergency medical services. *Prehosp Emerg Care.* 2017;21(1):88 and Ayub EM, Sampayo EM, Shah MI, Doughty CB. Prehospital providers' perceptions on providing patient and family centered care. *Prehosp Emerg Care.* 2017;21(2):233–241.

patient selection.[33] This serves as an example of the effect that recommendations from professional organizations can have on increasing EMS agency attention toward special populations or conditions and how adding close physician oversight can improve provider performance.

ADMINISTRATION AND COORDINATION FOR THE CARE OF CHILDREN IN EMS SYSTEMS

Many publications have called for the coordination and integration of patient care throughout EMS systems. In 1993, the NASEMSO and NAEMSP published a position statement on physician oversight, emphasizing that quality patient care depends on a commitment to the development and operation of an integrated and comprehensive EMS system.[34] High-quality leadership is a critical element in developing such a high-functioning EMS agency or system, especially with regard to physician oversight of EMS. In 2017, the NAEMSP provided clear descriptions of the role and duties of the EMS medical director, which were intended to help system administrators integrate medical direction throughout EMS systems.[35] The NAEMSP has published a position statement specifically outlining the critical elements of "Physician Oversight of Pediatric Care in EMS."[36] In another policy statement that discussed the role of pediatricians in rural communities, the AAP described how pediatricians' expertise can help close gaps in pediatric care for EDs and EMS agencies that have limited resources.[37] In the EMS Agenda 2050 document, which is a collaborative effort to create a plan for the next several decades, there is an emphasis on patient-centered care, as follows: "EMS medical oversight for specific patients and populations includes close collaboration with the physicians who make up the patients' medical home," including input from various specialists such as pediatricians. Collaboration is an intrinsic component to system-wide EMS care tailored to the individual patient.[38]

Pediatric Leadership in EMS

As previously noted, the 2006 IOM report stated the importance of having a pediatric emergency care coordinator (PECC) designated at the EMS agency level to facilitate continued pediatric emergency education; ensure QI for pediatric patients; enhance the availability of pediatric medications, equipment, and supplies; represent the pediatric perspective in the development of EMS protocols; and participate in pediatric research.[25] The 2017 NAEMSP position statement on the importance and oversight of pediatric care in EMS also discussed how PECC oversight could be incorporated into existing roles (eg, an agency's EMS physician medical director) or established as a new role that is

collaborative within the EMS leadership team (eg, PECC or EMS system pediatric advisory committee).[36] The PECC could be incorporated into an EMS system as a single provider or team of providers. A person and/or team in this role would be expected to oversee the system-based care of pediatric patients and would promote the integration of pediatric elements into day-to-day services as well as local and/or regional disaster planning.[25,36] The PECC also can serve as a pediatric health care liaison among the EMS agency, community pediatricians, and medical home in addition to the local health care facilities. The recommended qualifications and responsibilities of an EMS PECC are noted in Table 2, which as previously noted, can be incorporated into an existing role already within the EMS agency or established as a stand-alone role.[5,25,36] The importance of a PECC within EMS agencies was further exemplified by the Emergency Medical Services for Children (EMSC) program adding this supportive role as a performance measure.[39] Analysis of pediatric readiness assessment data demonstrated that having a PECC in an ED increased the likelihood of a higher readiness score overall and improved pediatric QI processes.[40] A recent study showed interest among EMS agency administrators in integrating a PECC into their systems, and in addition, pediatric-specific psychomotor skills testing was more common in EMS agencies that respond to a higher pediatric call volume and have a PECC. The presence of a PECC can potentially increase provider confidence and safety for all pediatric prehospital patients regardless of volume and location.[41] Regardless of how this role is incorporated into the structure of EMS, it is important that each agency include pediatric-specific guidance and expertise in the development and improvement of their operations.

Pediatric Emergency Care Coordinator Learning Collaborative

There is currently an initiative to strategize integrations of PECCs within EMS agencies, known as the Pediatric Emergency Care Coordinator Learning Collaborative. This initiative is being led by the Emergency Medical Services for Children Innovation and Improvement Center (EIIC). The purpose of this project is to form a cohort of EMSC state partnership grant recipients to participate in a learning collaborative that will demonstrate effective and replicable strategies for local EMS agencies with a PECC. Results from this project will inform and advance efforts within all 58 EMSC state partnership recipient sites to increase the adoption of PECCs within local EMS agencies.[42]

COMPETENCIES FOR PROVIDERS

Considering the challenges associated with low patient volumes, a number of experts in the field have recommended mandated skills testing or ongoing education in pediatric emergency care programs such as Pediatric Advanced Life Support, Pediatric Education for Prehospital Professionals (PEPP), Advanced Pediatric Life Support, and the Emergency Nursing Pediatric Course.[9–19,43–46]

EMS Education

EMS agencies have an important role in integrating pediatric-specific elements into all aspects of prehospital care, including oversight, education, protocol development, and performance improvement. Only 10% of the EMS patient volume involves pediatric patients,[8] underscoring the recognition that additional methods of exposure are needed to help EMS providers maintain clinically relevant cognitive and psychomotor competencies. One of these alternatives includes an annual educational and skill assessment of provider competency in the following domains:

- pediatric assessment, including recognition of respiratory distress or failure, shock, and cardiac failure[43,47–49];
- neonatal and pediatric cardiopulmonary resuscitation[43–46];
- pediatric airway management with an emphasis on basic airway intervention skills[10–14,17];
- pediatric vascular access, including intravenous access and intraosseous access;
- pain assessment and management, using age-appropriate pain scales; and
- pediatric weight assessment, equipment sizing, and medication dosing.[48–51]

Pediatric Clinical Care Within EMS: Pediatric Assessment

Critical illness and injury do not always manifest in children in the same way as they do in adults. EMS agencies should ensure that providers have access to tools that can help them recognize critically ill or injured pediatric patients. Structured pediatric assessment tools, such as the Pediatric Assessment Triangle (PAT),[47–49] which is taught in the PEPP course,[44] allow EMS providers to develop a standardized approach to pediatric assessment. Evidence has shown that the PAT is a proven triage tool for EMS and has become a foundation for rapid pediatric assessment.[46,49–51] Such assessment tools have been incorporated into most standardized life support courses in the United States, including Pediatric Advanced Life Support, Advanced Pediatric Life Support, and the Emergency Nursing Pediatric Course.[43–46] The PAT includes an observational assessment of a child's respiratory status, circulatory status, and mental status and, when paired with measurement of a child's vital signs, can help

TABLE 2 Responsibilities of an EMS PECC

Recommended Qualifications	Responsibilities
A clinical provider (physician, nurse, physician assistant, or nurse practitioner) with experience in EMS medicine and who works in an ED with active clinical practice in pediatric emergency medicine or a paramedic with some experience in pediatric prehospital or pediatric emergency medicine	Education
Strong interest in and desire to improve pediatric emergency care within the EMS system	To enhance pediatric proficiency for all EMS providers by facilitating both initial and continuing pediatric education for all providers
Experience in emergency medical care of children as demonstrated by training, clinical experience, and/or focused continuing education	To verify and promote EMS provider competency in providing pediatric emergency care through periodic training and evaluation of both cognitive and psychomotor competencies
Maintenance of competency in pediatric emergency care	To provide resuscitation skills training that includes concepts related to both trauma and medical care for neonates through adolescents
Provider may already be working within the EMS system	To promote opportunities for additional pediatric emergency care education and advancement within the EMS organization including, where available, collaboration with academic institutions
	Clinical care
	To actively provide pediatric-based input in the development and revision of EMS protocols
	To assess compliance with pediatric emergency care protocols and policies
	To observe and measure the quality of pediatric emergency care
	To equip the EMS agency to care for all children through the availability of pediatric-sized equipment and supplies, including medications required to treat common conditions in children
	To integrate pediatric needs into EMS disaster and emergency preparedness plans
	To serve as a liaison between hospitals, the local community, and EMS to establish local destination determination guidelines that ensure that pediatric patients are transported to appropriate regional facilities on the basis of the patient's clinical needs
	Research and QI
	To oversee pediatric QI, patient safety, injury and illness prevention, and clinical care initiatives
	To identify potential sources of funding for pediatric EMS research at local, state, or federal levels
	To integrate pediatric-specific quality metrics into the EMS agency that are either based on the national EMS Compass Initiative or are evidence based
	To establish a mechanism for electronic data collection that captures pediatric-relevant information in accordance with the most recent version of the NEMSIS data dictionary
	To analyze system efficacy and cost-effectiveness with respect to pediatric patient outcomes
	To identify local pediatric public health and operational issues in need of scientific evaluation and provide leadership to develop pediatric EMS research

a provider rapidly identify a child with significant illness or injury.[47–49]

The PEPP course and textbook is an additional EMS resource for pediatric assessment of abnormal respiratory and circulatory status and includes evaluating a child's lung sounds and work of breathing, noting the oxygen concentration and route of delivery required to improve oxygenation, and signs of perfusion such as skin color and capillary refill time.[44] Assessment of mental status can be achieved by using the "alert-verbal-pain-unresponsive" (also known as AVPU) scale or the Glasgow Coma Scale.[44]

Age-related changes in ranges of normal pediatric vital signs can add to the challenges EMS providers face in recognition of critically ill or injured children.[15] Initial and ongoing assessment and documentation of pediatric vital signs include evaluation of respiratory rate, heart rate, blood pressure, temperature, pulse oximetry, mental status, weight, and pain.[43–49] Current weight assessment tools in EMS include length-based tape[52] and age-based weight applications standardized in kilograms.[45,50–52] Pain assessment with age-appropriate tools and documentation before and after medication administration is consistent with evidence-based guidelines and defined EMS Compass quality metrics.[53,54] Understanding and recognizing critical departures from normal values can guide providers in detecting unstable

children early.[15] Processes for identifying abnormal vital signs and reporting them to receiving facilities as part of prearrival notification can enhance patient care and should be incorporated into EMS-based policies and clinical protocols.

In addition to these vital assessment findings, pediatric readiness also includes developing processes to include training on the recognition of child sex trafficking and interventions in cases of suspected child physical and/or sexual abuse and/or neglect.[5,55] Such processes should be incorporated into each EMS agency's pediatric-specific policies and protocols.

QI AND PERFORMANCE IMPROVEMENT

In 2006, the federal EMSC program established performance measures to evaluate the status of pediatric emergency care capabilities in each state and territory. The performance measures included benchmarks for EMS access to direct and indirect pediatric-specific medical oversight and suggested pediatric equipment guidelines for ground ambulances. This document also recommended hospital benchmarks to establish standardized systems for identifying facilities that are equipped to stabilize and manage children with medical or traumatic emergencies and to establish interfacility transfer guidelines and agreements among hospitals.[39]

A 2013 assessment of the EMSC performance measures revealed that approximately 90% of basic life support (BLS) and Advanced Life Support (ALS) agencies have direct pediatric-specific medical oversight. Indirect medical oversight, provided as written pediatric protocols, was available to 72% of BLS and 94% of ALS EMS agencies. In addition, both BLS and ALS agencies carried more than 90% of the nationally recommended pediatric equipment.[39] After this assessment, the EMSC program worked with the National EMS for Children Data Analysis Resource Center to develop the next generation of "EMS for Children" performance measures, which were implemented for assessment in 2017[39]:

- submission of National Emergency Medical Services Information System (NEMSIS)–compliant version 3 data,
- pediatric emergency care coordination at the EMS agency level, and
- evaluation of psychomotor competencies using pediatric equipment.

PEDIATRIC-SPECIFIC ELEMENTS OF EMS QI

EMS QI involves the continuous monitoring of EMS system performance by using measures to identify opportunities for improving patient care. Such improvements can include changes in policies, addition or revision of clinical protocols, and ensuring access to appropriate resources and health care facilities.

Pediatric EMS QI includes several important elements, starting with the integration of pediatric-relevant content into prearrival dispatch instructions. Other components are the inclusion of pediatric data elements into prehospital patient care charts and data-reporting technology and collaboration with pediatric content-matter experts in off-line protocol development. Of critical importance are the development of relationships and a communication process between EMS and hospitals to facilitate the exchange of QI information including patient outcomes and case reviews and to include both EMS and hospitals in system data analysis.[5,56] The EIIC is spearheading a QI collaborative to assist state programs in accelerating their progress in improving the pediatric readiness of EDs through new interventions. The EIIC hopes to demonstrate how leveraging QI science and the expertise of multiple professional societies and federal organizations can improve and transform health care outcomes for children in the United States.[57] Evaluation of EMS as part of the trauma QI program is a requirement for trauma centers by state designation, the American College of Surgeons verification process, or both. Integration of prehospital care and children's hospital transport services in the QI process is also an essential component of the American College of Surgeons Optimal Resources for Children's Surgical Care Verification Program.[58]

Pediatric-specific EMS QI programs should consider the following clinical areas for inclusion in both concurrent reporting and peer review with medical oversight and in a written plan that incorporates quality metrics that use NEMSIS-based data elements:

- neonatal assessment, resuscitation, and transport;
- respiratory distress and failure, including airway management;
- cardiovascular assessment and management;
- trauma, including burns and head injury;
- child abuse and neglect;
- pain assessment and management;
- hypoglycemia and hyperglycemia assessment and management;
- seizure assessment and management;
- environmental exposure hypothermia and hyperthermia; and
- toxicology assessment and management.

In 2014, NASEMSO launched an initiative known as EMS Compass. This initiative was funded through a cooperative agreement with the National Highway Traffic Safety

Administration with the focused goal of helping EMS systems (local, regional, and state) measure EMS care delivery and improve the quality of care at all 3 levels.[54] The quality metrics proposed by this program are linked to NEMSIS data variables to allow individual EMS agencies to assess quality and benchmark their care against other EMS agencies. As pediatric-relevant quality metrics are developed through EMS Compass, it is important to integrate them into local QI processes at the EMS agency level. The first pediatric-specific quality metrics focus on pediatric respiratory assessment, the administration of β-agonists for asthma, and the documentation of weight in kilograms with the use of various methods and applications, such as length-based tape. To ensure sustainability of the initial work of the EMS Compass initiative, the Joint National Emergency Medical Services Leadership Forum is working with the National Highway Traffic Safety Administration to create the National EMS Quality Alliance.[59]

POLICIES, PROCEDURES, AND PROTOCOLS

Use of prehospital guidelines will assist EMS entities in achieving recommendations from the IOM that "EMS systems should implement evidence-based approaches to reduce errors in emergency and trauma care for children."[25] Integration of these guidelines into operational practice requires the involvement of EMS medical directors and administrators, EMS educators, state health entities, emergency physicians, pediatricians, and nurses who are involved in the prehospital care of children.[5,36,56]

Pediatric Refusals

Refusal of medical aid is a challenging element of EMS care for patients of any age and can be especially difficult when the refusal of aid involves pediatric patients. A NAEMSP and ACEP joint position statement recommends that each EMS agency and system include key elements in their policies surrounding refusal of medical aid and that such policies specifically address the issue of nontransport of minors. It also recommends that nontransport occur only in the presence of online medical direction or detailed off-line protocols.[60] These specific guidelines are useful tools to help EMS systems prepare for the special needs of their pediatric population.

Existing Guidelines for Policies, Procedures, and Protocols

Local or statewide EMS policies, procedures, and protocols lay the foundation for providing optimal care to ill and injured pediatric patients in the prehospital setting. The development of policies, procedures, and protocols that are evidence based, when possible, and inclusive of EMS system stakeholders at the local, regional, and state levels will make EMS care more effective for children.

Implementation of procedures that integrate QI activities and include education within the system has the potential to enhance care. Suggested prehospital pediatric policies, procedures, and protocols could include, but are not limited to, the following:

- appropriate level of care (BLS, ALS, or critical care);
- appropriate mode of transport (ground, rotor wing, or fixed wing);
- pediatric field triage and facility destination decision-making;
- refusal of medical aid (nontransport decision-making and documentation);
- prehospital determination of death and withholding of resuscitation;
- physician medical direction;
- dispatch prearrival instructions for children and families;
- children with special health care needs;
- child maltreatment, including recognition and criteria and processes for mandated reporting;
- evidence-based guidelines for clinical care and, when not available, vetted consensus-based guidelines, such as the NASEMSO Model EMS Clinical Guidelines[61];
- development of new guidelines based on the pediatric community's health care needs by using rigorous methods for guideline development;
- children and disaster management planning[62–67]; and
- key support services.

PATIENT AND MEDICATION SAFETY

Unlike adults, for whom a "one-dose-fits-most" approach can be an effective method of dosing medications, dosage of medications for pediatric patients requires an accurate assessment of a child's weight to avoid significant over- and underdosing.[45,50–52] Estimation of children's weight by using a specific pediatric validated tool for weight and documenting the weight in kilograms in the EMS record can enhance safety.[45,50–52] Medication dosages are based on weight in kilograms, and adjuncts, such as smartphone applications that provide decision support for precalculated doses, can minimize dosing errors.[50–52] Online medical direction from a physician with pediatric expertise can provide important guidance when EMS personnel have reached the limit of what is specified in their agency's protocols. A method to identify, prevent, and report medication errors, including a policy for timely reporting and tracking of adverse events, can enhance safety.[68] Including pediatric weight measurement tools, use of weight-based dosing tools, education in the use of those tools, and developing QI projects surrounding the accuracy of pediatric-based medication dosing

are necessary components of pediatric readiness that should be incorporated in the activities of each EMS agency.[45,50–52,68–70]

Patient- and Family-Centered Care in EMS

Policies and/or protocols that promote family presence, participation in care, and safe transport of children have been recommended by the NAEMT.[71] Methods for the identification of the child receiving treatment and transport during a disaster that includes contact information for a responsible adult can enhance the ability of EMS systems and/or hospitals to reunify children with adult caregivers. Planning for the reunification of children and families is often an overlooked element of disaster planning but is an important consideration in disaster response plans for both EMS and receiving facilities.[67,72]

Part of providing patient- and family-centered care also involves using effective communication strategies and technology. In a qualitative study of EMS providers who participated in simulated resuscitations of pediatric patients, providers identified several strategies to promote patient- and family-centered care. These included providing emotional support to caregivers, maintaining a calm demeanor, empowering families to feel involved, designating a person to narrate and preemptively describe interventions in lay terms, summarizing between interventions, allowing a line of sight between the caregiver and child, and allowing the bystander the opportunity to return if temporarily removed for interfering with patient care.[72]

The diversity of languages that EMS providers encounter continues to grow, and methods for accessing language services can enhance the ability of EMS personnel to communicate with non–English-speaking patients and family members. Organizations such as the NAEMT have recommended that EMS agencies adopt procedures to ensure effective communication in culturally diverse communities.[71]

Policies on advanced directives for withholding or terminating prehospital resuscitation efforts in children are also an important consideration for local protocols and should be considered as part of an EMS agency's pediatric readiness activities. State protocols for the declaration of death in the field and termination of resuscitation vary widely and often differ between adults and children. For childhood victims of out-of-hospital cardiac arrest attributable to blunt trauma, there is evidence that children and adults have similar outcomes, although the current recommendations for termination of resuscitation in children are more conservative, recommending at least 30 minutes of resuscitation efforts compared with 15 minutes in adults. The recommendations in children also advocate for a family-centered approach under guidance from medical control, especially in remote areas that are far from a hospital.[73–77]

Guidance for prehospital providers on how to disclose that a child is dead of any cause, next steps in the care of the family, and prevention of secondary trauma in themselves are all challenges of encountering pediatric death in the field.[75]

Pediatric Safe Transport

Safe transport for children has been a significant problem that is now being recognized. Given the unique features of children, including their smaller size and different anatomic proportions, the National Highway Traffic Safety Administration published guidelines for the safe transport of children in ground ambulances, including specific guidance regarding requirements for pediatric-passenger restraint.[78] Previously, there were no federal standards or protocols for the best method of pediatric transport in ambulances. It is estimated that up to 1000 ambulance crashes involve pediatric patients per year, with approximately 4 fatalities occurring per year.[79] In addition, in a collision at 35 mph, an unrestrained 15-kg child is exposed to the same forces as in falling from a fourth-story window.[79] The NASEMSO released interim guidance in 2017 on the safe transport of children by EMS, and this organization specifically highlighted the need for further research to establish a Society of Automotive Engineers standard for pediatric restraint recommendations through crash testing of different types of equipment.[80] The interim guidance emphasized that safe transport for children should be considered standard of care equivalent to EMS airway, breathing, and circulation maintenance. The guidance strongly states that all EMS agencies should have pediatric safe transport policies and procedures for evidence-based and appropriately sized and positioned child-restraint systems. Children should not be transported in ambulances unrestrained (eg, held in laps and/or arms).[80]

Children With Special Health Care Needs

Children with special health care needs are defined as "children who have or are at increased risk for a chronic physical, developmental, behavioral, or emotional condition and who also require health and related services of a type or amount beyond that required by children generally."[81] Given that the number of children with special health care needs or dependence on health technologies has been steadily increasing, EMS systems have always

faced the need to provide quality prehospital care to children with special needs. A report from Utah found that these children were more likely to receive ALS and prehospital clinical interventions than children who are not technology dependent.[82] Up to 78% of ED encounters for children with special health care needs are also more likely to use EMS for interfacility transport.[83]

It is important to have access to key information to care for patients, especially those with special needs. Professional organizations such as the ACEP and AAP have recommended that families maintain an emergency information form (EIF).[84] Paper and electronic versions of the form are available from both organizations' Web sites. The development of electronic, remotely accessible health-information exchanges available to EMS providers in real time may someday reduce the need for paper copies of EIFs. Until then, EMS-applicable patient-specific care plans, EIFs, and off-line guidelines are each important elements of pediatric prehospital readiness programs. In addition to key information and medical history for this population, it is equally important to ensure specific training for pediatric technology such as ventilators, tracheostomies, and gastrostomy tubes.[84]

Health Disparities in Pediatric Prehospital Care

Significant health disparities exist in pediatric prehospital care. EMS personnel are often the initial contact for many children who do not have insurance or access to emergency care. EMS serves as a health care safety net for this population. Rural areas are a setting in which EMS can act as a primary source of health care. Rural EMS systems face operational and clinical challenges in meeting the prehospital needs of their communities and more specifically the vulnerable population of children. These challenges include geographic isolation, lack of qualified physicians to serve as medical directors, insufficient staffing of EMS providers, substandard road conditions, inadequate landing areas for air transport, and radio communication dead zones.[85–87]

In addition, the health disparity gap is widened for pediatric minority populations such as African American, American Indian, Alaskan native, and Hispanic children. Children of minority populations experience myriad disparities in prehospital care, medical care, access to health care, and use of health care services. Some of these health disparities include suboptimal health status; higher levels of obesity, asthma, and behavioral problems; lack of mental health services and medical insurance; transportation barriers to care; and increased frequency of ED visits. Language and cultural differences can lead to barriers to care in the prehospital environment. African American children and children in urban residences are more likely to arrive at the ED by EMS.[86,87] In a recently published abstract, pediatric patients with severe asthma who were transported by regional EMS agencies were predominantly older, of male sex, and African American.[88] In addition, in a recent study assessing statewide EMS management of pediatric asthma, 49% of the patients were African American, and there was a geographic disparity of EMS asthma encounters involving African American children living in rural areas.[89] American Indian and Alaskan native children are disproportionately burdened by injuries and diseases and often live in rural areas geographically far from hospitals.[90–92] A study focusing on prehospital care for rural American Indian children concluded that Indian Health Service EMS agencies do not have the infrastructure to treat pediatric patients during day-to-day operations as well as disaster situations. Indian Health Service agencies were markedly overwhelmed and unable to provide pediatric continued medical education.[93] Mobile integrated health (MIH) and community paramedicine is a way for EMS systems to provide patient-centered and integrated health care with social services, subsequently improving the overall health of the community. MIH programs improve and enhance care by sending EMS personnel to patients' home to aide in chronic disease management (eg, asthma) and education, follow-up, and rehabilitation care as well as preventive care.[94] A PECC can serve as a pediatric liaison within an EMS MIH system to provide much needed health care to children in minority and rural populations where they live. Integration of PECCs within EMS systems could help to overcome health care barriers and obstacles for these patients and serve as a possible solution to help coordinate pediatric emergency care for these particularly vulnerable populations.

Mental Health and Pediatric Prehospital Care

Mental health disorders are one of the most common diseases of childhood. Children with mental health disorders are at increased risk for substance use, residing in juvenile detention, and suicide and homicide. There continues to be an increasing number of children with mental health disorders seen in the ED and a decreasing number of available mental health facilities.[95] As a result, there is growing evidence revealing increased use of EMS services for children with mental health disorders to obtain care related to these disorders.[95] In a study of a statewide EMS system, a large proportion of pediatric patients with behavior-related disorders within mental health disorders was associated with an increase in EMS resource use because of limited behavioral

health infrastructure.[96] Interventions are key to training EMS providers on the recognition and management of pediatric mental health disorders.

INTERACTION WITH SYSTEMS OF CARE

Trauma

Trauma accounts for approximately 20% of pediatric EMS encounters.[97] The care of the pediatric trauma patient in the prehospital setting involves rapid assessment of hemodynamic status; focused and measured assessment and management of airway patency, oxygenation, and ventilation; evaluation of pain and provision of analgesia; consideration of cervical spine injury and provision of appropriate spinal motion restriction; and making appropriate destination determination decisions.[98–100] Verification or state designation of a trauma center does not mean that the facility has also achieved a high degree of overall pediatric readiness.[101] In regions where both trauma center and pediatric facility designation programs exist, a trauma center does not equate to pediatric readiness, further highlighting the potential benefits of regionalizing pediatric care.[101] Pediatric readiness in EMS systems will therefore need to include an assessment of appropriate destination facilities with respect to pediatric-focused protocols, equipment, and training to optimally manage the pediatric trauma patient.[5] Most children's hospitals that are also pediatric trauma centers will have the requisite resources for the care of the injured child, and EMS providers who use a destination determination triage tool such as the one developed by the Centers for Disease Control and Prevention will triage children to a pediatric trauma center if one is available.[102] Coordination with the regional trauma system as well as any pediatric facility verification program, where it exists, will be critical.[102,103]

Mass Casualties and Disasters

Few position statements regarding mass casualty events address infants and children. The NAEMSP has position statements on both the role of EMS in disaster response and mass gathering medical care,[64,65] with neither document specifically addressing children. In a survey of EMS agencies, only 13% had pediatric-specific mass casualty incident plans.[66] Several organizations have worked or are now working to develop resources for EMS agencies to incorporate children into their disaster preparedness plans, including educational resources.[67–69] These resources can be leveraged by EMS agencies to prepare for the care of children and families during disasters as part of their prehospital pediatric readiness activities.

EQUIPMENT, SUPPLIES, AND MEDICATIONS

Even with the best leadership and well-trained providers, without appropriate equipment, optimal care cannot be provided to pediatric patients in the field. The policy statement "Equipment for Ground Ambulances" addresses this issue and serves as a standard for the minimum equipment and supplies needed for both ALS and BLS ground ambulances in the United States.[104]

CONCLUSIONS

Numerous publications have indicated the need for improved integrated pediatric care within the prehospital setting.[4,5,25,26,36] EMS systems can adopt policies, practices, and procedures that guide provider prehospital pediatric emergency care. Pediatric-specific components that will aid in improving care include pediatric-specific education, equipment, QI, data collection and management, and research. Designation of a PECC, EMS provider access to pediatric direct and indirect medical direction, and safe transport of pediatric patients are particularly important components of a well-integrated pediatric prehospital care system.

Pediatrician Guidance in Supporting Families of Children Who Are Adopted, Fostered, or in Kinship Care

Veronnie F. Jones, MD, MSPH, FAAP,[a] Elaine E. Schulte, MD, MPH, FAAP,[b] Douglas Waite, MD, FAAP,[c] COUNCIL ON FOSTER CARE, ADOPTION, AND KINSHIP CARE

The child welfare system strives to provide children and adolescents in foster care with a safe, nurturing environment through kinship and nonkinship foster care placement with the goal of either reunification with birth parents or adoption. Pediatricians can support families who care for children and adolescents who are fostered and adopted while attending to children's medical needs and helping each child attain their developmental potential. Although this report primarily focuses on children in the US child welfare system, private and internationally adopted children often have similar needs.

THE FACES OF CHILD WELFARE IN THE UNITED STATES

The child welfare system strives to protect the safety of children while supporting families whose children are placed in foster care. In this document, the term "child" includes infants, children, adolescents, and young adults. The child welfare system also serves as a bridge to the primary goal of permanency through reunification or adoption. On September 30, 2018, the Adoption and Foster Care Analysis and Reporting System reported that 437 283 children and adolescents were in foster care.[1] Of these children, 262 956 entered foster care during the fiscal year of 2018, with 250 103 exiting foster care. The number of children served in the foster care system during 2018 was 687 345. There were 125 422 children waiting to be adopted, with 71 254 having parental rights terminated and 63 123 subsequently being adopted from care. Primary reasons for entering foster care include neglect (62%), parental substance use (36%), poor coping skills of the caregiver (14%), physical abuse (13%), and inadequate housing (10%). Other reasons that account for less than 10% in each category include child behavior problems, parental incarceration, parental alcoholism, abandonment, sexual abuse, child disability, relinquishment, parental death, and child alcohol and other substance use.[1] A growing number of children, estimated to be 5% to 10%

of the total foster care population, are specifically placed because of complex medical needs.[2] In many cases, a combination of these factors leads to foster care placement.

The 2018 Adoption and Foster Care Analysis and Reporting System reports the mean age of children in foster care is 8.3 years of age, with 42% of children 5 years or younger. Of note, adolescents 13 to 20 years of age account for 21% of the population in foster care.[1] Black or African American children account for 23% of the foster care population, and Hispanic and Latino children make up 21%. Children who identify as ≥2 races account for 8% of the foster care population, and children of American Indian or Alaskan native, Asian American, and Native Hawaiian or other Pacific or unknown ethnicity represent 4% of the population.[1] Forty-six percent of children are placed in nonrelative foster care, with another 32% placed in a relative or kinship foster home. Other placement categories include institutional (6%), group home (4%), trial home discharge (5%), preadoptive home placement (4%), supervised independent living (2%), and runaways (1%). Fifty-nine percent of children exiting foster care in 2018 returned to a parent or primary caregiver, and 25% were adopted, 7% were emancipated, 7% were living with other relatives, 11% were placed in guardianship care, and 1% transferred to another agency.[1] In 2017, a report by the National Council of Juvenile and Family Court Judges revealed Black and African American and American Indian and Alaska Native children constitute 27.5% and 2% of the population in care, respectively, although African American and American Indian and Alaska Native children represent approximately 14% and 1%, respectively, of the general population.[3] Although the data during the time period did not reveal overrepresentation for Hispanic and Latino children nationally, they did reveal disproportionate representations in several states.[3] These disproportionate rates of children in the child welfare system may result from social factors related to poverty, race, and class bias in initial reporting and subsequent processing of children in the child welfare system.[3–6] The effects of structural racism in the child welfare system also should be acknowledged and addressed in the disproportionate rates of minority children in the system.[7,8]

LEGISLATION SUPPORTING THE CARE OF CHILDREN IN FOSTER CARE AND ADOPTION

In 2018, the Family First Prevention Services Act was signed into law.[9–11] This law evolved in response to an increase in child welfare placements as a result of the opioid epidemic. The current increase in placements is similar to increases observed in 1999 at the height of the crack cocaine epidemic, when 567 000 children were in foster care.[12] The Family First Act allows reallocation of annual foster care funding to states, territories, and tribes to be redirected toward evidence-based preventive programs for mental health services, substance use treatment, and in-home parenting skill training with the goal of keeping children with their families, focusing especially on families affected by substance use and psychiatric illness.[9–11] The Family First Act also seeks to improve the well-being of children in foster care by placing children in the least restrictive environment within the child welfare system while setting standards of care for children with special needs placed in residential treatment programs, including timely assessments and periodic reviews to ensure continued need for a high level of care.[9–11,13] Summaries of the Family First Prevention Services Act and other significant federal legislation passed to protect children in foster care are highlighted in Table 1.[13–15]

KINSHIP CARE

Approximately 4% of all children in the general population are cared for by extended family members. Although the vast majority of these more than 2.7 million children in the United States live in extended family homes without involvement of the child welfare system, approximately 104 000 of these children have been formally placed in kinship care as part of the state-supervised foster care system.[23] One-quarter of all children who have been removed from their homes by the child welfare system are subsequently placed in a kinship home. Over the past decade, the number of children in kinship care has grown 6 times faster than the number of children in the general population (18% vs 3%, respectively). It is estimated that 1 in 11 children live in kinship care for at least 3 consecutive months at some point before the age of 18 years. The likelihood that African American children will experience kinship care is more than double that of the overall population, with 1 in 5 African American children spending time in kinship care at some point during their childhood.[23] The passage of the Adoption and Safe Families Act in 1997 promoted placement in kinship care as a means of shortening length of child placement in foster care while continuing a child's relationship with his or her birth parent.[20] Kinship care is relatively cost-effective and may keep children more connected with their families, communities, and cultures compared with nonkinship care.[24,25]

Multiple studies suggest specific advantages when children are placed with members of their birth family.[26–32] In a systematic review, authors found that children placed in kinship foster care experienced fewer behavioral problems, mental health

TABLE 1 Federal Mandates for Adopted and Foster Children

	Description
Family First Prevention Services Act of 2018 (Pub L No. 115-123)[13]	This act reforms the federal child welfare financing streams Title IV-E and Title IV-B of the Social Security Act to provide prevention services, including mental health services, substance use treatment, and in-home parenting training. Allows IV-E funds to support inpatient substance use disorder treatment settings that allow the placement of children with their parents when those settings can treat the needs of both the parent and child. Reauthorizes the Regional Partnership Grant program, which supports multidisciplinary approaches to addressing the effects of parental substance use on child welfare. Mandates that services be trauma informed and evidence based. Seeks to improve the well-being of children already in foster care by incentivizing states to reduce placement of children in congregate care while raising standards for residential treatment programs.
Fostering Connections to Success and Increasing Adoptions Act of 2008 (Pub L No. 110-351)[16–18]	States must make reasonable efforts to place siblings in the same foster home unless doing so would be contrary to the safety or well-being of any of the siblings. If siblings are not placed together, the state must make reasonable efforts to provide frequent visitation or other ongoing interaction between siblings unless this interaction would be contrary to a sibling's safety or well-being. Ensure that children have permanency goals to improve the well-being of children served by public child welfare agencies. Child welfare agencies are required to notify relatives of the child's removal from the custody of the parent. Promote permanent placement with relatives. Maintain connections with siblings and family. Increase the number of adoptions for waiting children. Improve outcomes and transition for older youth. Improve outcomes for American Indian and Alaska Native children. Improve competencies of individuals working with children involved in the child welfare system. Improve education stability and coordination of medical needs.
Child and Family Services Improvement and Innovation Act of 2011 (Pub L No. 112-34)[19]	Requires states to monitor children removed from the home for emotional trauma States must track and enact protocols for appropriate use of psychotropic medications States must report on steps taken to ensure developmental health for young children in state care
Adoption and Safe Families Act of 1997 (Pub L No. 105-89)[20]	Provides a fundamental change in child welfare philosophy from a primary focus of reunification with the biological parents as the principal goal without regard to parental history, to a process of considering child well-being related to the child's health and safety in permanency planning. Improves the safety and promotes permanency for fostered children through adoption or the establishment of other permanent homes. Gives preference to the placement of abused and neglected children with relatives. Provides provisions to ensure family support. Places an emphasis on timeliness to permanency.
Indian Child Welfare Act of 1978 (Pub L No. 95–608).[21,22]	Enacted "to protect the best interests of Indian children and to promote the stability and security of Indian tribes and families by the establishment of minimum federal standards for the removal of Indian children from their families and the placement of such children in foster or adoptive homes which will reflect the unique values of Indian culture, and by providing for assistance to Indian tribes in the operation of child and family service programs." Gives greater authority to tribal governments to collaborate in decision-making in child custody proceedings. When a child lives on a reservation or is a ward of the tribe, tribal leadership can assert exclusive decision-making power.

disorders, and placement disruptions compared with their counterparts in nonkinship care.[26] Thirty-two percent of children placed in early kinship care showed behavioral problems 36 months after placement, compared with 46% of children placed in nonkinship homes when controlling for baseline behavior before placement.[27] Children also experienced less stigma and trauma from the separation from parents and were more likely to remain connected to siblings and maintain family cultural traditions.[28–32] Researchers have consistently shown that relative caregivers are more likely to be single, poorer, and older; to have less formal education than nonkin foster parents; to care for large sibling groups; and to have chronic health conditions or disabilities because of their age.[33,34] Children who come to the attention of child protection and

are placed with a relative but are not taken into state custody (voluntary kinship care) are more likely to be cared for by a grandparent (87%) than children placed in kinship foster care after being taken into state custody (43%). Conversely, children in kinship foster care are more likely to be in the care of an aunt or uncle (37%) than those in voluntary kinship care (10%).[33] Children in kinship care are more likely to be removed from the birth parent's home because of parental substance use and neglect than children in nonkinship care.[34] For kinship families, unexpected placement of children with relatives may exacerbate financial and daily life stress. A report by the Annie E. Casey Foundation revealed 38% of children living in kinship care live below the federal poverty threshold, and 63% live below 200% of the poverty level.[23] A recent report by Generations United revealed that of the 2 572 146 grandparents responsible for their grandchildren, 57% were in the workforce, with 20% living below the poverty line.[35]

Despite these challenges, voluntary and kinship foster caregivers are less likely to be aware of financial benefits and other support services available to children in nonkinship foster care.[23,36,37] The Annie E. Casey Foundation reports that fewer than 12% of kin caregivers receive help from Temporary Assistance for Needy Families program, although the majority of families are eligible to receive benefits.[23,37] Fifty-eight percent of low-income kinship families do not receive Supplemental Nutritional Assistance Program benefits (food stamps) or Medicaid health coverage.[23,37] Only 17% of families receive child care assistance, with a mere 15% seeking housing cost support.[23] These statistics highlight how little our current child welfare system and communities support kinship families, especially those outside of the child welfare system, and why pediatricians, through referral to benefit resources and simple acknowledgment of the dedication of kinship parents, can be an important part of a support network to kinship families who care for children who would otherwise be placed in a nonkinship home.

The Families First Act has several provisions to support kinship families by extending Title IV-E eligibility requirements at the end of 12 months while ensuring that programs provided to children are not counted against a kinship caregiver's eligibility for other programs.[9–11,13] The Family First Act funds the development of an electronic interstate database to help facilitate placement of children with relatives who live in states other than the child's state of origin. Additionally, the Family First Act allows states to receive funding for up to 50% of the state's expenditures on kinship navigator programs that work to help locate potential kinship placements for children in the child welfare system.[9–11,13]

In addition to placement in kinship care, placement of siblings in the same foster home helps maintain ties to a child's family of origin. Approximately two-thirds of children in the child welfare system have a sibling in care.[38,39] The Fostering Connections to Success and Increasing Adoptions Act of 2008 was the first federal law to address the placement and welfare of siblings and promote ongoing relationships with siblings, requiring:

[S]tates to make reasonable efforts to place siblings in the same foster care, kinship guardianship, or adoptive placement, unless doing so would be contrary to the safety or well-being of any of the siblings. If siblings are not placed together, the state must make reasonable efforts to provide frequent visitation or other ongoing interaction between the siblings, unless this interaction would be contrary to a sibling's safety or well-being.[16–18]

Efforts to maintain sibling placement can be complicated because of inaccurate contact information after sibling separation.[40] Furthermore, specialized medical and psychiatric needs of a child may require an exceptional foster home placement, which further complicates attempts to keep siblings together.[41] Maintaining contact with siblings and other members of a kinship family in such cases helps ameliorate the strains such separations put on ties to a child's birth family.

An often-forgotten venue of kinship care and placement of siblings is the adult sibling caregiver, which is the third largest relative caregiver group behind grandparents and aunts and uncles.[42] In their study, Denby and Ayala[42] reported adult sibling caregivers have the same unmet service needs as other kinship caregivers, and the emotional toll may be even greater because of their unique sibling relationship to the child's birth parents. Although sibling caregivers who express a relatively high degree of parenting ability report strong support systems, others with low levels of family involvement and social support report a dissatisfaction with available services.[42] Additionally, when younger siblings have special health care needs, the adult sibling caregiver is more likely to commit to adopt their siblings.[42] Pediatricians can help adult sibling caregivers connect with peer-aged parents and caregivers to support parenting skills. By educating sibling caregivers on the developmental abilities of their younger siblings, pediatricians can ease unrealistic caregiver expectations while encouraging activities to promote child development.[42]

Kinship caregivers report significantly fewer support services than other foster caregivers, such as parent training, peer support, and respite care.[43] Grandparents who become adoptive parents may have

the additional burden of grieving lost expectations of their own children becoming parents while coping with the stresses of raising another generation of children and managing the ongoing challenges that led to their grandchild's placement in care.[35] In some cases, the stress of taking in a grandchild may cause problems within a marriage, exacerbate preexisting health issues, and increase financial strain within the family. Kinship parents may experience guilt or resentment over the birth parents' inability to be primary caregivers for their children.[35] At the same time, kinship parents may face challenges from birth parents who may express anger over the circumstances that led to their children being placed in foster care and feel the kinship parent conspired against them to obtain custody.[35,44] In addition, children may not understand or may resent the kinship parent, blaming them for their inability to live with their birth parents.[28] Boundaries must be set regarding the type of contact, timing, and granting of parental responsibility to the birth parents. All family members may need to be reminded that the guardian or adoptive parent is the responsible parent.

ADOPTION AND PERMANENCY

Approximately 2.4% of the child population in the United States is adopted, accounting for 2.1 million children.[45] In 2014, there were a total of 110 373 adoptions, with 41 023 (37%) adoptions with at least 1 adoptive parent related to the child by blood or marriage, and 69 350 (63%) family-unrelated adoptions.[46] The number of children who are adopted in the United States has steadily declined, primarily because of a decrease in international adoptions. In 2004, 22 989 children were adopted internationally. In 2013, 7092 international adoptions occurred, dropping to 4714 in 2017.[47] Although this clinical report is focused on children who are served through the child welfare system, awareness of other venues for adoption is important, because many of the same issues exist for both groups.

Additional demographic data collected by the Children's Bureau at the Department of Health and Human Services Administration for Children and Families provide a broader picture of adoptive families.[48] Data reveal that the predominant family structures are married couples (68.8%) and female-headed households (26.5%). Previous families of fostered youth account for almost half of adoptions, with relatives making up 31% of adoptive families. Eighty-one percent of children adopted from the foster care system are classified as having special needs. Ninety-one percent of families receive an adoption subsidy. White children account for most adoptees (49%), whereas African American and Hispanic children represent 19% and 22%, respectively.[48] Younger children are more likely to be adopted than teenagers. According to a report from the Children's Bureau through a partnership with the Ad Council, AdoptUSKids, youth in the foster care system between the ages of 15 and 18 years represent 43% of all children with active photograph listings on AdoptUSKids.org, but only 5% of all children adopted in 2015 were in that age range.[49]

Two different forms of adoption influence a child's subsequent relationship to his or her family of origin. Closed adoption allows no sharing of identifying parental information with the adoptive parent, leaving large amounts of information and details of an adopted child's family of origin and birth unknown to the adoptive parent. In contrast to closed adoptions, open adoption allows a continuum of communication between birth families, adoptive parents, and the adopted child.[50] Open adoption may be restricted to birth parents' participation in the selection of the adoptive parents or may extend to regular communication between, or face-to-face meetings with, the adoptive parents, adopted child, or both.[51,52] Open adoption is a dynamic and fluid process with the goal of child-centered integration of a child's family of origin with the adoptive family that ensures the child's awareness of his or her origins and culture. Open adoption may be particularly important to an older child or adolescent with long-standing bonds to members of his or her birth family. Postadoption contact between families is typically unregulated; in rare cases, a judge may order postadoption contact with birth family relatives, even over the adoptive parents' objection. Although these statutes are present in most states, their implementation is varied.[53]

As children age into adolescence and adulthood, they often wish to seek out more information about their biological families.[54] In attempting to gain information about their birth parents, adopted individuals who joined their families through intercountry adoption may choose to make a trip to their country of birth. Others seek information about their birth parents through commercially available DNA testing that matches an individual with those who share a similar DNA inheritance.[55] Advancements through social media have also made it much easier to locate relatives of their family of origin.[56] Other available routes include exploration of reunion registries, reestablishment of ties in a lapsed open adoption, or restoration of other ties that have connections to the child's family.

Although some adoptive parents may view their child's searching for his or her birth family as a sign of rejection, this transition is a normal sign of healthy emotional growth and

establishment of identity. The experience of a reunion with the biological family may be rewarding but may also cause the child to re-experience his or her loss. In preparing for contact and reunion, those who have been adopted or experienced foster care may need to anticipate a whole range of realities, including rejection by the birth parent(s) and family members.[57,58] Pediatricians need to be aware of the feelings children may have after meeting a sibling, either one who is older or who remained with the birth parent(s) or one who was born after the child was placed. Adoptive parents may fear birth parents will interfere in the adoptive family's life or affect the child's bond with the adoptive family. All members of this triad may need the help of mental health professionals to work through these situations. An adoption-competent social worker and/or counselor can discuss the extent of communication between the adoptive family and birth family and provide needed support by identifying benefits and drawbacks to the relationship. Pediatricians are encouraged to become aware of local community resources, support groups, conferences, services, and mental health professionals to which families confronting these difficult issues can be referred. Some available resources are included later in the article.

MEDICAL ISSUES

Children, adolescents, and young adults involved in the child welfare system often have multiple health care needs.[59–66] Because children who have been in foster care may move through multiple placements, the resulting fracture of medical care places children at risk for having medical, developmental, and psychiatric needs that remain either unaddressed and/or untreated. In addition to developmental delays and behavioral issues that can occur because of neglect and early environmental deprivation, physical and sexual abuse can lead to marked behavioral challenges at any age. The effects of toxic stress in early childhood on the neuroendocrine–immune system not only leads to psychological and psychiatric morbidity but also can result in higher risks for later medical morbidity. Additional information on the effects of early life adversity on brain development and both physical and mental health can be found in the 2012 American Academy of Pediatrics (AAP) policy statement and technical report on early childhood adversity and toxic stress in addition to the AAP Trauma Toolkit (https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/resilience/Pages/Training-Toolkit.aspx).[67,68]

Among the multiple factors associated with removal of a child from a parent's home, parental substance use is one of the most common. Although 36% of children in the child welfare system are referred because of documented parental substance use, children referred for neglect (62% of child welfare referrals) often have parental substance use that has not been documented at the time of intake.[1] Although parental substance use is often reported on foster care intake, the co-occurrence of alcohol use by the parents is often overlooked. This is especially important in caring for children born with neonatal abstinence syndrome. The prevalence of fetal alcohol spectrum disorders (FASDs) among children in foster care has been estimated to be 16.9%.[63] A recent study of children in foster care referred for developmental evaluation provides further evidence of the prevalence of FASD in foster care and lack of diagnosis of this disorder. Eighty percent of children subsequently diagnosed with an FASD had not been previously diagnosed with this disorder.[64] Given this prevalence, all children entering foster care should be screened for prenatal alcohol exposure. The AAP has created an implementation guide for pediatric primary care providers to increase screening for prenatal alcohol exposure (https://www.aap.org/en-us/Documents/FASD_PAE_Implementation_Guide_FINAL.pdf). In addition, a comprehensive medical evaluation, including behavioral health assessment by using validated tools to identify needs, is most effective when completed soon after placement.[61,62,66] An early evaluation allows the pediatrician to identify and address existing medical diagnoses, uncover issues unaddressed before placement, discuss developmental and behavioral concerns with parents, and make appropriate referrals when appropriate.[61,62,66] Other issues for exploration, particularly in the adolescent and young adult population, include a history of their own substance use, mental health history, and the potential of the adolescent or young adult to be involved in sex trafficking.

Review of past medical records allows successful coordination of the child's medical, developmental, and mental health needs. Children in foster care may arrive at the office or hospital with little or no documented medical history. Despite reasonable efforts to obtain past records, information may be incomplete or uncomprehensive in scope. Barriers to obtaining consent from birth parents can make these efforts frustrating. Determining who has legal authority to give consent to care and allow access to past medical records is critical. Access to a child's medical history is particularly important for children with complex health care needs. At the time of admission to the child welfare system, the person with legal custody of the child signs consent for general and emergency medical care. Consent for further medical intervention beyond routine care must be obtained from the legal guardian. Foster parents

may not be authorized to sign consent for medical care. Many states have passed medical consent laws that allow kinship caregivers to make health decisions on the child's behalf with parental consent and without having to obtain legal custody.[69] In cases in which, despite diligent efforts, obtaining consent is not possible or in cases of parent refusal to sign consent, local child welfare authorities or the family court system can override custody rights in acting toward the best interests of the child.[70] Such situations may include the need for surgery, medical tests, psychotropic medication, and developmental evaluation and intervention. These legal issues often require pediatricians to act as advocates for the child while working with the foster care agency and family court system. After adoption, adoptive parents gain the right to be legal guardians and make decisions separate from the birth parent. The AAP Council on Foster Care, Adoption, and Kinship Care has provided further guidance related to consent in "Health Care Issues for Children and Adolescents in Foster Care and Kinship Care"[61] and at the AAP Fostering Health Web site: https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/healthy-foster-care-america/Pages/Fostering-Health.aspx.

Particularly relevant parts of the health care record include past medical history; complications of pregnancy; late recognition of pregnancy; lack of prenatal care; prenatal exposures to maternal alcohol, substances, and/or tobacco; poor maternal nutrition; preterm birth; maternal and paternal psychiatric illness; and genetic diseases within the family. Important history also includes the number of previous placements, significant past relationships, developmental delays, abnormalities in growth, behavioral challenges, mental health history, substance abuse, and any traumatic events such as physical and sexual abuse, including sex trafficking.[61,62,65,66] Pediatricians can use the time a child is in foster care to integrate the medical, developmental, and psychiatric history within an electronic health record that can be easily forwarded to new placements while working with their state child welfare system to advocate for centralized or portable records that can travel with the child across foster care placements. Examples of categories within such records may include birth and developmental history, prenatal drug and/or alcohol exposure risk factors, immunization records, past psychiatric treatment, and ongoing diseases and medications. When reviewing medical records, informed interpretation of the Health Insurance Portability and Accountability Act allows proper sharing of information to improve continuity and coordination of medical care. The Health Insurance Portability and Accountability Act contains several provisions that encourage information sharing regarding children in foster care.[71]

In collaboration with members of child welfare services, pediatricians can develop treatment recommendations that support caregivers in planning to best meet their child's physical and mental health needs while anticipating future challenges. Pediatricians without expertise in this area may seek resources through the AAP Council on Foster Care, Adoption, and Kinship Care to assist in this effort.[72] For internationally adopted children, this evaluation includes, but is not limited to, infectious disease and developmental screening tests and assessment of immunization status, as recommended in the AAP *Red Book*[73] and the Centers for Disease Control and Prevention *Yellow Book*.[74] The following AAP resources are also available to guide pediatricians: *Addressing Mental Health Concerns in Primary Care: A Clinician's Toolkit*,[75] *Developmental and Behavioral Pediatrics*,[76] and *Adoption Medicine: Caring for Children and Families*.[77]

Finally, identification and documentation of a child's medical diagnoses may be necessary in establishing eligibility for financial subsidies to support the child's needs. Although the type and amount of assistance vary by state and typically are negotiated before the adoption is finalized, financial subsidy may specifically support medical and/or psychiatric care, counseling or therapy, special equipment, tutoring programs, or other support services that may help children who have special needs.[78–80] Community services, such as early child intervention programs, quality early childhood learning centers, parent support groups, financial assistance, respite care, trauma-informed care, and community organizations, including local child welfare agencies, can also help support families. Organizations such as the Child Welfare League of America[81] and Generations United[82] may be valuable resources for pediatricians and families.

COMMUNICATING WITH CHILDREN AND ADOLESCENTS ABOUT PLACEMENT AND PERMANENCY

Even before a child understands the words "adoption," "adopted," "foster care," "kinship care," "guardianship," and "biological family" or "birth family," these words should become a part of a family's natural conversation, whether the adoption is open or confidential, kinship, or foster-adoptive placement.[83,84] Positive language lays a foundation for a child's later understanding of the abstract concepts of foster care, adoption, and separation from birth parents. It is generally not advisable for families to wait until "just the right minute" to talk to children about their permanency status, because this

may leave children feeling betrayed and wondering what else their parents may have hidden from them. Early communication that shares these sensitive histories, starting with placement or early childhood, helps maintain trust between the parent and child. Encouraging an honest, nonjudgmental discussion of a child's birth family and the placement or permanency process will give a child permission to ask questions and express thoughts and feelings that not only serve to develop trust and a feeling of security but also help ameliorate the shame and the stigma associated with being in the child welfare system.[85–87]

Some information in a child's past may be difficult to discuss, such as previous sexual or physical abuse or having been conceived in the context of rape or incest, and should be discussed on the basis of the child's questions and developmental ability to understand these difficult thoughts, feelings, and memories. Furthermore, for older youth and adolescents, discussion of parental psychiatric history, substance use disorder, and life challenges that might have hindered a parent from being a greater part of the child's life can help open future questions and dialogue. Pediatricians, potentially with the collaboration of a mental health specialist, may help the family decide how and when to disclose this information. Open discussion with a child is essential in building bridges of trust and security within a family, but it is also important that the discussion be framed with developmentally appropriate language.[87] Effective communication nurtures a child's self-esteem as he or she grows in the understanding of what it means to join a family and integrate disparate parts of their lives. A child's understanding of the meaning of permanency changes with his or her cognitive development. The pediatrician can counsel parents about the need to understand the child's specific questions surrounding placement and permanency in the context of the child's current development and answer questions in a way that supports a child's sense of self and self-efficacy (Table 2).

Children placed in families at a young age may not understand that they have another family besides the family with whom they live. For many children and adolescents, separation anxiety and other internalizing and externalizing disorders may be pronounced, especially with children who remember the loss of birth or foster parents, siblings, or other relatives. Children may fear that their current family will abandon them in the same way once their "hidden flaws" are discovered. Some children may express yearnings to have been "in the belly" of their mother with whom they are presently living.[86] By kindergarten, many children realize that most of their peers are not in foster care, kinship care, or adopted, which may lead children to feel responsible for their birth parents' inability to raise them as well as for the repeated losses through moves in and out of foster care. This feeling of responsibility is especially true when a foster placement does not advance to adoption of the child.[89–93]

Pediatricians are encouraged to model positive adoption language for all families. Adoptive, foster care, and kinship care families are "real" families; siblings who joined a family through any of these channels are "real siblings." Birth parents do not "give up a child for adoption," which might imply to the child that he or she was of less worth and was given away. Rather, they "make an adoption plan for a child." Furthermore, in modeling positive language, pediatricians can use vocabulary that reflects respect and permanency about children and their families.[84] A "life book," that compiles both happy and difficult periods of a child's life experiences can be an effective tool for parents in helping a child process their thoughts and feelings.[94] Some families choose to develop rituals with their child to honor the child's birth parents on birthdays or holidays or as a special prayer to commemorate the birth family. Rituals like these allow children to acknowledge and remember their past but also to honor their present status.[84]

LOSS, GRIEF, AND TRAUMA ASSOCIATED WITH FOSTER CARE PLACEMENT

Although birth parents may anticipate the loss of their parental rights or loss of their child through adoption, the surrendering of their child often precipitates grief and a sense of loss manifested as denial, sorrow, depression, anger, and guilt. Birth parents may grieve the loss of their role as a parent and of playing a significant part in their child's life. The later birth of other children may be a reminder of the loss of the child that they did not raise.[95] In cases in which change of custody is kept secret, friends and family may not even be aware of this loss or not understand the extent of the birth parent's loss.

Foster parents can experience loss and grief with each child for whom they care. In many instances, foster parents interact with birth families to support reunification of the family. Although reunification may be the mutually desired goal, the resulting separation can be traumatic to both the foster parent and child.[96] Moreover, other children in the home may experience loss and undergo their own grieving process. Birth children of foster parents report feelings of guilt, sadness, and blame at the departure of a child who had been fostered in their childhood home.[97] Anniversary reactions often occur for children with each passing year. Anniversaries may trigger thoughts of the birth family, and children may wonder whether their birth parents still love them or even

TABLE 2 Developmental Tasks and Issues Specific to Adopted and Foster Children

Age and Developmental Stage	Erikson's Psychosocial Stages of Development[88]	Issues That May Be Intensified for Adopted and Foster Children	Strategies for Families and Pediatricians
Birth to 16 mo	Trust versus mistrust	Difficulty or failure to develop a trusting, reliable attachment to caregivers Children may present with feeding problems, anxiety, depression, aggression, sleep disorders, and lack of trust[56]	Educate caregivers of the need to provide a consistent, sensitive, and responsive environment Caregivers should be vigilant for behavioral dysregulation that can be a sign of previous trauma and toxic stress[36]
18 mo to 3 y	Autonomy versus shame and doubt	A child's emerging self-centered perception of the world can become fragmented from experiences of multiple caregivers, previous neglect, and physical or sexual abuse	Caregivers should be aware of the manifestations of early childhood adversity and toxic stress[56,57] Create a highly structured, calm environment that provides a feeling of safety and security Address a child's questions and fears with acknowledgment tempered with reassurance of the child's current safety Be vigilant for developmental delays and behavioral problems, especially in cases of known or suspected prenatal alcohol or drug exposure and in such cases facilitate referral for evaluation for fetal alcohol spectrum disorders Refer to early intervention for developmental delays and behavioral concerns
3–5 y	Initiative versus guilt Problem-solving; attempts to understand permanency and past and current living arrangements	Children who have experienced trauma or been placed with multiple caregivers may exhibit anger, withdrawal, aggression, or sadness because of feelings of insecurity about their environment or caregivers Children who come into families by foster care or adoption experience loss in multiple areas of their life; loss should be viewed as a form of trauma and may manifest in variety of ways depending on the child's developmental level, the type of placement (temporary versus permanent), familiarity of surroundings and support systems[82–85]	Keep a daily, consistent routine Understand a child's current concerns and behaviors in the context of their past experiences and meet these challenges with acknowledgment and reassurance Validate a child's feelings while setting limits on problematic behavior Refer to mental health services when appropriate Refer for speech and other developmental or behavioral problems Consider referral to developmental-behavioral pediatrician and/or referral for evaluation for fetal alcohol spectrum disorders in cases of developmental or behavioral challenges Provide opportunities to nurture intellectual curiosity by allowing preschoolers to explore their environment through imaginative play and social engagement Encourage preschoolers to plan and participate in new activities of their own choosing within the bounds of a safe environment
Middle childhood	Industry versus inferiority Peer groups have increased influence over a child's self-esteem	Fostered or adopted children may experience low self-esteem and feelings of inferiority or rejection as they become aware of their differences from their peers. Such issues may be especially difficult for children placed in homes of a different racial or cultural background In addition to loss of their family of origin, fostered children may experience the loss of friends, surroundings, culture, and disruption of past routines	Caregivers can help their child integrate past experiences into their current life Caregivers can help a child begin to understand how current feelings and thoughts may be related to past experiences while grounding the child to their present life circumstances Refer to mental health services when appropriate Refer for educational support services if indicated Consider referral to developmental-behavioral pediatrician and/or referral for evaluation

TABLE 2 Continued

Age and Developmental Stage	Erikson's Psychosocial Stages of Development[88]	Issues That May Be Intensified for Adopted and Foster Children	Strategies for Families and Pediatricians
			for fetal alcohol spectrum disorders in cases of learning and/or behavioral challenges Caregivers can be encouraged to educate their child about their cultural history while being sensitive to nonverbal clues that they communicate about race and cultural differences
Adolescence	Identity versus role confusion Autonomy Abstract thought; concepts like adoption and permanency may be internalized and adolescents might go through an intense period of self-reflection in an attempt to define their identities. As adolescents develop and begin the task of separation and individuation, permanency issues commonly become important, changing relationships between the adolescent and family	Early life trauma and toxic stress can worsen as a child moves from childhood to adolescence, especially when compared with peers who have had more stable childhoods Adopted adolescents or adolescents in foster care often struggle to integrate their past life into their current life and their future Adolescents may challenge authority within and outside the family, which may result in conflict; Youth may "test" caregivers by challenging their commitment to their relationship Risk-taking or unhealthy peer relationships can place adolescents at high risk for substance use, chronic truancy, and/or involvement in the juvenile justice system; such behaviors are sometimes precipitated by contact with or identification with birth parents who may have had similar difficulties	Caregivers should be aware of the manifestations of past traumatic events and losses and meet challenging behaviors with understanding but age-appropriate limit setting Encourage diary and creative writing or other art forms as a path for integrating past and present experiences into a life story Ensure appropriate support services are provided in school Refer for mental health or substance use treatment services when indicated Consider referral for evaluation for fetal alcohol spectrum disorders Pediatricians can screen for and directly address risks for substance use, depression, suicidality, and criminal behavior in one-on-one conversations with the adolescent In cases in which adolescent risk-taking behavior becomes a risk to an adolescent's future or placement stability, caregivers can consider pursuing a person-in-need-of-supervision petition in family court
Young adulthood[86]	Experiment and exploration: love, work, and worldviews	Housing instability Educational dropout Unemployment Lack of trust, expectation of failure in life trials, and social acceptance Engagement in criminal activities	Support transition with extension of foster care to age 21 y Supportive housing Job placement Funding for college opportunities Social networks and mentoring

think about them. The Child Welfare Information Gateway provides useful resources for families on separation and grief.

FAMILY DIFFERENCES

Although all children, especially in adolescence, face the normal developmental task of clarifying their identity, adopted children and children living in foster care with parents of a different race, ethnicity, or cultural background face the additional challenges of assimilating disparate parts of their lives. Children as young as 3 or 4 years are aware of differences between themselves and members of other racial groups.[98–102] When children live in communities where they are members of an ethnic minority, the differences in racial identity will be easily apparent to classmates, other parents, and strangers. These differences may provoke a child's sense of confusion about their racial, ethnic, or cultural origins.[102]

Children may encounter racist remarks for the first time, particularly in situations in which they are not physically or emotionally safeguarded by their parents. Role-playing with children with respect to stereotypes and racist statements may help them to feel in control when they encounter comments from strangers, friends, or extended family members.[103,104] Parents who have not experienced racism personally may need to pay extra attention to teaching their children effective ways to respond to racism. Families should openly acknowledge racial differences while providing the child with relationships with others of the same race or ethnic group, including adults and children.[104] The child should also be given the opportunity to learn more about the heritage of

his or her racial and ethnic group and country of origin.

An estimated 220 000 children are being raised by more than 111 000 same-sex couples, with approximately 12% of children identified as adopted or in the foster care system.[105,106] Gates et al[107] reported that same-sex couples are 4 times more likely to adopt and are 6 times more likely to foster children than their different-sex counterparts. Additionally, approximately 25% of same-sex couples raising children are involved in kinship care arrangements. In the past, same-sex couples raising adopted children were typically older, more educated, and had more economic resources compared with other adoptive parents.[107] More recently, however, this trend may be changing secondary to the evolving societal acceptance and legal climate within the United States.[108,109] Between 2014 and 2016, 16.2% of all same-sex couples were raising children.[109] The majority (68%) of the couples were raising biological children; however, same-sex couples were more likely to have a child who was adopted (21% vs 3.0%) and/or a child in foster care (2.9% vs 0.4%) compared with male-female couples.[109]

In 2002, the AAP published a policy statement and technical report supporting coparent or second-parent adoption and reaffirmed the policy statement in May 2009.[110,111] Regardless of the sexual identity of the parent, children thrive best when raised in a home that provides a caring, supportive, and secure home environment. Children who grow up with gay or lesbian parents show the same emotional, cognitive, social, and sexual development as children who grow up with heterosexual parents.[112] Authors of a recent study exploring the perspectives of youth who were adopted by gay and lesbian parents reported that although many children experienced more bullying and teasing than their counterparts, children of gay or lesbian parents were more accepting, had greater understanding, and were more compassionate toward people and individual differences than their counterparts raised by heterosexual parents.[113] This growing literature supports pediatricians in their advocacy for all capable individuals to have the opportunity to become foster and adoptive parents.

EDUCATIONAL CHALLENGES

Information from a 2018 multistate study reveals that 65% of foster youth had had more than 1 foster care placement, 34% had experienced 5 or more school placements; up to 47% had been placed in special education, and 65% completed high school by age 21.[114] Additionally, 17- to 18-year-old youth in the child welfare system are 2 times more likely to be suspended and 3 times more likely to be expelled from school.[114] Researchers in the 2005 Midwest study of 736 foster care alumni found that although 57.8% of former foster youth earned a high school diploma and 5% completed a general equivalency diploma (GED), 37% had attained neither a high school diploma nor GED.[115] Youth who earn a high school diploma are 1.7 times more likely to complete an associate's degree and 3.9 times more likely to complete a bachelor's degree and have higher incomes than those with a GED credential.[115] A 2018 multistate study found that although 70% to 84% of high school graduates wished to pursue further college education, only 32% to 45% actually enrolled in college, and only 3% to 11% attained a bachelor's degree.[114]

Researchers have shown that a higher incidence of exposure to one or more traumatic adverse childhood experiences affects educational achievement.[116–118] Maltreatment experienced before kindergarten was associated with negative academic and behavioral outcomes by second grade.[117,118] Kovan et al[119] report children involved with the child welfare system had poorer outcomes than their peers with no involvement with the child welfare systems on measures of receptive vocabulary, math reasoning, and teacher ratings of anger or aggression and anxiety or withdrawal. These findings support previous studies with similar conclusions of poor outcomes of children who have experienced neglect in early childhood.[117] Similarly, poor science outcomes have also been reported for children who experience neglect before kindergarten compared with their peers.[117] Thus, disproportionate representation of children from minority populations in the child welfare system helps maintain disparities in academic outcomes.[3–6] Quality early child care and early education programs, such as Head Start and prekindergarten programs, can partially mitigate the effects of maltreatment on school readiness and child development.[118–121] For children younger than 3 years, referral to a federally funded early intervention program may be warranted. For children older than 3 years, Individualized Education Program and 504 plans under the Individual with Disabilities Act can be mechanisms to obtain services and resources to help meet the special needs of children in foster care or those who have been adopted.[122] In addition, the Uninterrupted Scholars Act (Pub L No. 112-278), passed in 2013, allows information sharing between schools, child welfare agencies, and tribal organizations without parental consent.[123]

TRANSITION CARE TO ADULTHOOD: BARRIERS AND OPPORTUNITIES

Most young adults not in foster care continue to receive ongoing financial and social support from their parents beyond age 18.[124] In 2018, approximately 19 000 young adults aged out of foster care, potentially

losing the financial, educational, and social support services of state foster care overnight when they turned 18 to 21 years old, depending on the state in which they resided.[1,125] Adolescents in foster care enter the world of adulthood all too often ill prepared, their prospects compounded by mental health problems, substance use, and underemployment.[126,127] The Midwest outcome study revealed that fewer than half of young adults leaving foster care were currently employed at age 26, approximately half of the young adults who had worked during the past year reported annual earnings of $9000 or less, and more than one-quarter had no earnings at all.[127] Researchers in a study of aged-out youth found that 20% were chronically homeless, with housing instability associated with emotional and behavioral problems, physical and sexual victimization, criminal conviction, and high school dropout.[128]

Title IV-E of the Social Security Act was amended in 1986 to create the Independent Living Program, allowing states to receive funds to provide independent living services.[129] State child welfare agencies are required to develop a transition plan in collaboration with the youth aging out of foster care that includes housing, health insurance, education, local opportunities for mentors and continuing support services, workforce supports, and employment services.[16–18,129,130] The age limit for foster care varies by state, with some states extending care to 21 years of age. The Fostering Connections to Success and Increasing Adoptions Act of 2008 amended Title IV-E to extend the age of Title IV-E eligibility from 18 to 21 years.[16–18,129] In one study, youth living in a state that extended the age of foster care to 21 years were nearly twice as likely to complete at least 1 year of college education.[126] Awareness of state-specific age limits on foster care placement allows early transition planning for all adolescents in the medical home.[131] Youth who remain in care past age 18 attain higher educational credentials, which translate into better employment outcomes.[126,127,132,133] Furthermore, even when the level of educational achievement is controlled for, the number of years in care after the age of 18 positively affects employment and higher wages of the youth.[134] This study suggests a window of opportunity within transition planning for obtaining employment before discharge from foster care. It also supports the extension of foster care from age 18 to age 21.[134]

Youth transitioning out of foster care report that the most important support for working toward their educational and employment goals are job preparation skills, transportation, child care, educational services, and overall life skills.[135] Yet, former fostered youth who currently live independently overwhelmingly describe a lack of resources in the areas of employment, education, finances, housing, access to independent living classes, personal care, and networking.[135] Although parents outside the foster care system often contribute to the development of young adult independence by advancing important skill-building activities early in life, empowering youth to make decisions for their own lives, and reinforcing the youth's ability to learn and cope with the consequences of those decisions in a supportive environment, this support often fails to be included in the transition care of children in foster care.[136]

Mental health challenges further complicate transition planning from foster care. More than half of young adults leaving care (54.4%) have current mental health problems, compared with less than one-quarter of the general population (22.1%).[137] The prevalence of posttraumatic stress disorder within the previous 12 months is higher among young adults in foster care (25.2%) than among the general US population (4.0%) and nearly twice the rate of that experienced by American war veterans (Vietnam: 15%; Afghanistan: 6%; and Iraq: 12–13%).[137] The prevalence of major depression within the previous 12 months is significantly higher among foster alumni (20.1%) than among the general population (10.2%).[137] Although mental health challenges might be thought to be solely linked to foster care placement, researchers of studies among US adoptees suggest otherwise. Among 96% of the adopted children placed before 1 year of age and all children adopted before their second birthday, adoptees were 4 times more likely to attempt suicide than nonadoptees.[138] Potential contributing factors for the increased risk of suicide attempt include early trauma before adoption, prenatal substance and alcohol exposure, and genetic predisposition to psychiatric illness.[138]

In the face of these adversities lie barriers to medical and psychiatric care. In a study of foster care alumni, only 47% of young adults had health insurance as they prepared to leave foster care.[139] Young adults in foster care are more likely to have health conditions that limit their daily activities, report more emergency department visits and hospitalizations during the previous 5 years than their peers, and suffer medical problems that are left untreated because of lack of health insurance.[61,140] Pediatricians can help youth prepare to transition their health care needs by identifying medical issues that require regular follow-up and educating youth on how to use health insurance benefits and nonemergent medical care.[133] Information on billing for the delivery of health care transition services can be found in the 2017 Transition Coding and Reimbursement Tip

Sheet, as well as other resources, on the Got Transition Web site.[141]

Finally, children placed in foster care are at risk for "crossing over" to the juvenile justice system, and inversely, many juvenile justice–involved youth later become involved in the child welfare system. These youth are commonly referred to as crossover youth, whereas youth with concurrent involvement in both the child welfare and juvenile justice system are described as dually involved or dually adjudicated youth.[142,143] Children who have experienced maltreatment average a 47% greater risk for future delinquency relative to children who have not experienced abuse or neglect.[144] An estimated 56% of crossover youth have mental health problems. A growing body of research indicates that running away from foster care increases the probability of subsequent involvement in the juvenile and/or adult justice system, especially for male individuals, with 42% of youth with runaway histories in one study having at least 1 juvenile and/or adult conviction.[145] Approximately 16% of children placed into foster care experience at least 1 delinquency court involvement compared with 7% of all maltreatment victims who are not removed from their family.[144] Other characteristics related to delinquency include age at first child welfare placement, years in placement, number of placements, total length of time in residential care, and sex, race, and recurrence of maltreatment.[144,146] African American youth involved in the child welfare system are up to 13 times more likely than white fostered youth to become involved in the juvenile justice system.[147] Reasons for this disparity are complex; however, structural racism should be considered.[7,8,147] Structural racism refers to the policies and practices that reinforce racial group inequity by allowing privilege associated with race, in this case white-colored skin, while withholding those same privileges from communities of color. Structural racism is insidious and embedded within historical, cultural, and ideological norms of organizations and systems.[8] Norms around language, behavior, and practices, such as policing and court judgments, are typically based on white middle class expectations and contribute to the disproportionate involvement of youth of color in both the child welfare and juvenile justice systems.[147] Recognition of structural racism in current systems allows for education and interventions to be put in place to mitigate its effects.

One of several promising approaches to juvenile court involvement is multisystemic therapy.[148] Multisystemic therapy interventions target problems identified by the child, family, and worker within and between the multiple systems of the home, school, and neighborhood to problem-solve challenges and support success.[146,148] Pediatricians can affect the outcomes of these youth by participating in a multidisciplinary team that includes members from the juvenile justice system, child welfare organizations, and the family. This coordinated approach provides opportunities to change the trajectory of children with judicial involvement and affect the long-term outcome of their lives.[149]

THE LAST WORD: RESILIENCE

Resilience is the developmental process by which an individual can use internal and external resources to negotiate and adapt to current challenges while developing skills to aid future challenges. Resilience implies the presence of adaptive capacities to negotiate life challenges effectively.[150] In a study of 164 young adults emancipated from foster care, nearly half (47%) managed challenges in education, employment, civic engagement, relationships, self-esteem, and mental health, and 16.5% had low educational and low occupational competence, low civic engagement, problematic interpersonal relationships, low self-esteem, and high depressive symptoms. Yet among those youth having difficulties in their external life, 30% exhibited internal resilience, characterized by psychological well-being, despite having difficulties in external circumstances such as education, employment, homelessness, early parenthood, drug use, and criminal activity. In contrast, 6.5% of youth showed significant emotional difficulties despite the appearance of external competence.[151] Thus, young adults can demonstrate resilience in one area of their lives even as they struggle in others. The greatest association with improvement in resilience is having more than one strong network (biological family, peers, foster care), with multiple strong social networks ameliorating the psychological stress of life struggles.[152] In addition to biological family, foster parents, extended family, and peers, support can come from child welfare case workers, therapists, teachers, mentors, coaches, and pediatricians, many of whom often continue to be a resource after the formal placement has ended.[149] For this reason alone, pediatricians can never underestimate the effect of the day-to-day interactions they share with fostered youth. Conversations for even a simple medical concern can affect a child or foster parent in ways we can never foresee.

Further information on the care of children in foster care and children who have been adopted can be found on the AAP Council on Foster Care, Adoption, and Kinship Care Web site.

KEY POINTS AND RECOMMENDATIONS OF CLINICAL REPORT

- Children and adolescents involved in the child welfare system,

whether formally or informally, often have multiple health care needs that require an interdisciplinary team to maximize their well-being. See the AAP Fostering Health Web site for further information: https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/healthy-foster-care-america/Pages/Fostering-Health.aspx.

- Children and adolescents in foster care and those who have been adopted are at far greater risk than the general population for neurodevelopmental disorders, such as fetal alcohol spectrum disorders. Pediatricians can provide surveillance and screening of socioemotional well-being using validated tools and being aware of developmental and mental health issues common among children and adolescents in foster care. See the AAP Fetal Alcohol Spectrum Disorders Toolkit for further information: https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/fetal-alcohol-spectrum-disorders-toolkit/.
- Many children and adolescents experience social and emotional issues during periods of transition. It is important for pediatricians to counsel and provide information to parents in the recognition and management of current and future medical, developmental, and behavioral problems.
- Pediatricians can advocate for the development of a standardized process for consent and transfer of health information with their local Department of Social Services.
- Pediatricians can address the effects of adverse childhood experiences, early childhood adversity, and trauma on early brain development and life course trajectory for both physical and mental health, as recommended by AAP policy.[39] See the AAP Trauma Toolkit for further information: https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/resilience/Pages/Training-Toolkit.aspx.
- Pediatricians can encourage parents to have developmentally appropriate discussions using developmentally appropriate language with their child or adolescent. Words such as "adoption," "adopted," "foster care," "kinship care," "guardianship," and "biological family" or "birth family" should become a part of a family's natural conversation, whether the adoption is open or confidential, kinship, or foster-adoptive placement.[84,85] Positive language lays a foundation for a child's later understanding of the abstract concepts of foster care, adoption, and separation from birth parents and facilitates the formation of an integrated identity.
- Pediatricians can help parents acknowledge racial and cultural differences and support children and adolescents in coming to an understanding of these differences. See HealthyChildren.org for further information for pediatricians Talking to children about racial bias https://www.healthychildren.org/English/healthy-living/emotional-wellness/Building-Resilience/Pages/Talking-to-Children-About-Racial-Bias.aspx Teaching children cultural and racial pride https://www.healthychildren.org/English/family-life/family-dynamics/Pages/Teaching-Children-Cultural-and-Racial-Pride.aspx
- Pediatricians can be aware of the complexity of losses experienced by children and adolescents in foster care or kinship care or adopted, in addition to losses experienced by foster, adoptive, and birth parents, while facilitating mental health referral as needed.
- Pediatricians can advocate for young adults who are transitioning out of care and/or involved in the juvenile justice system, because they are at risk for poor physical and mental health outcomes, low socioeconomic status, and lower educational attainment.

Physical Activity Assessment and Counseling in Pediatric Clinical Settings

- *Clinical Report*

CLINICAL REPORT Guidance for the Clinician in Rendering Pediatric Care

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Physical Activity Assessment and Counseling in Pediatric Clinical Settings

Felipe Lobelo, MD, PhD,[a] Natalie D. Muth, MD, MPH, FAAP, FACSM,[b] Sara Hanson, PhD,[c] Blaise A. Nemeth, MD, FAAP,[d] COUNCIL ON SPORTS MEDICINE AND FITNESS, SECTION ON OBESITY

Physical activity plays an important role in children's cardiovascular health, musculoskeletal health, mental and behavioral health, and physical, social, and cognitive development. Despite the importance in children's lives, pediatricians are unfamiliar with assessment and guidance regarding physical activity in children. With the release of the 2018 Physical Activity Guidelines by the US Department of Health and Human Services, pediatricians play a critical role in encouraging physical activity in children through assessing physical activity and physical literacy; providing guidance toward meeting recommendations by children and their families; advocating for opportunities for physical activity for all children in schools, communities, and hospitals; setting an example and remaining physically active personally; advocating for the use of assessment tools and insurance coverage of physical activity and physical literacy screening; and incorporating physical activity assessment and prescription in medical school curricula.

INTRODUCTION AND RATIONALE FOR PHYSICAL ACTIVITY ASSESSMENT AND COUNSELING

The 2017 Youth Risk Behavior Survey (YRBS) revealed that only 26.1% of American adolescents reported levels of activity consistent with current guidelines, and 15.4% of students reported not being physically active for at least 1 hour on a single day in the previous week.[1] With the exception of increased sports participation among high school female students, overall youth physical activity levels have decreased.[2] The lowest rates of physical activity occur among adolescent girls, children and youth with special health care needs (CYSHCN), and youth of minority status; rates of inactivity increased with age.[1,3] Although only approximately one-fourth of children report meeting physical activity guidelines, objective measurement of activity by accelerometer reveals that less than half of children and 8% of adolescents were meeting the 2008 Physical Activity Guidelines from the US Department of Health and Human Services of 60 minutes daily of moderate-to-vigorous physical activity (MVPA) as

recently as 2016.[1,4,5] With rates of obesity rising over the last decades, annual relative increases of 4.8% in the incidence of type 2 diabetes mellitus,[6] and declines in estimated life expectancy at time of birth since 1993, the role of physical activity on child, and later adult, health remains an important component of preventive care and disease treatment.[7,8]

In 2006, the American Academy of Pediatrics (AAP) published the policy statement "Active Healthy Living: Prevention of Childhood Obesity through Increased Physical Activity."[9] That statement addressed not only the role of physical activity in obesity but also identification of individuals at risk for decreased physical activity, age-appropriate activity recommendations, and the role of schools in promoting activity.[9] Since that time, the AAP and other organizations have published statements on the assessment, prevention, and treatment of pediatric obesity that include recommendations to promote improved nutrition and sleep, decreased sedentary time, and increased physical activity, although details regarding how to achieve physical activity recommendations are limited.[10–13] Unfortunately, 5 years after the 2008 Physical Activity Guidelines were released, only 23% of family physicians and 33% of pediatricians were able to correctly identify current physical activity guidelines for children 6 to 18 years of age.[14,15] Physical activity is a "priority topic" in *Bright Futures: Guidelines for Health Supervision of Infants, Children and Adolescents, Fourth Edition*, for every health supervision visit starting at 18 months of age, with inclusion of recommending meeting the Physical Activity Guidelines beginning at 5 years of age.[16] The 2018 Physical Activity Guidelines outline the recommended physical activity levels for children and adolescents, provide guidelines for children younger than 6 years, and support the role of physical activity on not just physical health but also in development, mental health, and school performance (Table 1).[17] As such, this clinical report replaces the previous statement on active healthy living, augments existing statements, highlights the role of physical activity in all children's health, and provides guidance for physicians to better assist families in increasing physical activity.

PHYSICAL ACTIVITY AND HEALTH OUTCOMES IN CHILDREN AND YOUTH

The relationships between physical activity, cardiovascular health, and body composition have been well established. Morris et al[18] demonstrated decreased rates of adult coronary heart disease in active versus sedentary employees of the London Transport Executive in 1953. In the absence of longitudinal studies assessing the impact of childhood physical activity on adult mortality, studies have confirmed the benefit of physical activity on children's cardiorespiratory fitness, lipid profiles, insulin sensitivity, and serum glucose concentrations in individuals with obesity as well as associations with more optimal cardiovascular profiles in the most physically active children.[19–24] Importantly, for the developing child, aerobic activity and strength training result in increased muscle mass and decreased fat mass.[21,22,25] Physical activity also increases bone density and improves balance, protecting against falls and injury both in childhood and later in life.[26–30] Overall, strong evidence supports that MVPA improves cardiovascular and muscular fitness, bone health, weight status, and cardiometabolic risk factor status in children and adolescents, as outlined by the 2018 Physical Activity Guidelines Advisory Committee.[31]

Less widely appreciated, physical activity benefits behavioral, cognitive, and social aspects of child health. Increased physical activity has also been shown to be associated with decreased rates of smoking and fewer symptoms of depression, and increased rates of inactivity and sedentary activity can predict future alcohol and drug use in adolescents.[32–34] Both randomized controlled trials and systematic reviews support the effect of physical activity on academic performance, possibly even in a dose-response relationship.[35–41] Children who are provided opportunities to be physically active during school focus and behave better, including children with attention-deficit/hyperactivity disorder.[42–44] Benefits may be even greater in children with autism spectrum disorder who show decreased perseverative behavior and easier redirection after a bout of physical activity.[45,46] The 2018 Physical Activity Guidelines Advisory Committee concluded that in children ages 5 to 13 years, acute bouts of physical activity and regular MVPA

TABLE 1 2018 Physical Activity Guidelines Applicable to Children

Age	Activity Amount	Intensity
3–5 y	3+ h/d	Light, moderate, vigorous
6–17 y	≥60 min/d	Moderate or vigorous aerobic activity daily
		Vigorous at least 3 d/wk
		Muscle-strengthening activities at least 3 d/wk
		Bone-strengthening activities at least 3 d per wk
Children not meeting guidelines	Gradually increase activity in ways the child enjoys	Moderate-vigorous; increase time per d and No. days per wk; use multiple, smaller time increments in activity that are additive throughout the day

Adapted from US Department of Health and Human Services. *Physical Activity Guidelines for Americans*. 2nd ed. Washington, DC: US Department of Health and Human Services; 2018. Available at: https://health.gov/paguidelines/second-edition/pdf/Physical_Activity_Guidelines_2nd_edition.pdf. Accessed December 10, 2018.

improve cognition, including memory, processing speed, attention, and academic performance.[31]

Even more concerning than the rates of inactivity among children overall is the low rate of physical activity among CYSHCN.[3] CYSHCN represent a wide range of children with chronic physical, developmental, behavioral, or emotional conditions.[47] The benefits of physical activity for CYSHCN are substantial. Physical activity plays a vital role in strength, endurance, and bone health for all children and especially for children with neuromotor disorders such as spina bifida, muscular dystrophy and other myopathies, Prader-Willi syndrome, and cerebral palsy.[48–54] Beyond musculoskeletal benefits, activity may play a role in speech and fine motor development, possibly through opportunities for social interaction, postural control and positioning, and use of orofacial muscles required for breathing during physical activity.[55–60] Despite its pronounced benefits, rates of physical activity in CYSHCN are much lower than in health-normative peers.[3,61] Any successful effort to increase physical activity requires approaches tailored to an individual's unique needs.[62]

Physical activity may also create unexpected benefits in children with other chronic health conditions. Children with a history of cancer experience increased rates of cardiovascular events, and physical activity has been shown to improve cardiovascular risk factors in this population.[63–65] Physical activity also improves immune function, which may decrease pulmonary infection, and improves weight gain in children with cystic fibrosis.[66–69] Physical activity benefits cardiorespiratory function in, and may be engaged in safely by, children with congenital heart disease under properly advised and supervised programs.[70–72]

CURRENT PHYSICAL ACTIVITY GUIDELINES IN YOUTH

The 2018 Physical Activity Guidelines Advisory Committee reaffirmed the 2008 Physical Activity Guidelines, which recommend children and adolescents (6–17 years of age) engage in at least 60 minutes of physical activity every day, including vigorous-intensity as well as muscle- and bone-strengthening activities, at least 3 days per week (Table 1).[31] The AAP has advised that physical activity should also include a muscle-strengthening program that targets all major muscle groups, starts with no load and incrementally may add load once exercise technique is mastered, involves 2 to 3 sets of 8 to 15 repetitions, and is performed 2 to 3 days per week for at least 8 weeks.[73]

The 2018 Physical Activity Guidelines Advisory Committee concluded there is strong evidence that a greater volume of physical activity among children ages 3 to 5 years of age is associated with a decreased risk of excessive weight gain and improved bone health.[31] The committee concluded these children should aim to achieve at least the median level of physical activity of children this age, which is 3 hours or more of physical activity per day.[31] This is consistent with other guidelines that suggest that adults should provide opportunities for free play and unstructured physical activity for children 3 to 5 years of age,[15,74] including at least 180 minutes of physical activity throughout the day (approximately 15 minutes every hour while awake) that helps to develop movement skills in a variety of activities and in a variety of environments. The higher volume of activity recommendation for children 3 to 5 years of age is based on the nature of their activity being intermittent and typically of lower intensity than older children.[75] Infants should be physically active several times per day, mostly through interactive floor-based play.[75] The AAP clinical report "The Power of Play: A Pediatric Role in Enhancing Development in Young Children" offers guidance on appropriate approaches for young children.[76] *Caring for Our Children: National Health and Safety Performance Standards; Guidelines for Early Care and Education Programs* is another AAP publication providing guidance for child care settings.[77]

For all children and adolescents, it is important that activities are appropriate to a child's age, enjoyable, and varied.[75] Examples of child and youth physical activities as well as recommendations based on the principles of frequency, intensity, time, and type of activity are included in Tables 2 and 3.

THE IMPORTANCE OF PHYSICAL LITERACY IN SHAPING PHYSICAL ACTIVITY PARTICIPATION

Attention to physical literacy, defined by the Aspen Institute as "the ability, confidence, and desire to be physically active for life" may provide an opportunity to increase and sustain physical activity across childhood and adolescence.[85] Ability includes competence in fundamental movement skills including throwing, catching, jumping, striking, running, kicking, agility, balance, and coordination. Fundamental movement skills emerge starting with gross motor skill development in infancy and early childhood, progress throughout early and midchildhood, and are honed in preadolescence and adolescence (see Table 4).[85] Competency in fundamental movement skills is a strong predictor of both current and future physical activity levels, cardiovascular fitness, BMI, and risk of overweight and obesity.[86–88] Confidence, or self-efficacy in one's ability to play sports or enjoy physical activity, develops from early positive experiences with physical play and a variety of sports that are inclusive and welcoming of

TABLE 2 Examples of Types of Physical Activity

	MET	Physical Symptoms	Examples of Activities
Rest	1	—	—
Light	<3	Easily able to converse	Household chores
			Walking
		No sweating or shortness of breath	Playing catch
			Fishing
Moderate	3–6	Some difficulty talking	Yardwork
		Feeling warm	Jogging or fast walking
		Light sweating	Tag
		Slight shortness of breath	Movement portion of ball sports
Vigorous	>6	Unable to talk	Manual labor
		Short of breath	Run
		Face red	Skipping rope
		Sweating	Skiing, skating
Wheelchair use or use of assistive devices (crutches or ankle-foot orthoses)	Comparable METs expended for comparable examples noted above (eg, wheeling on a smooth surface = light; wheeling fast or up an incline or as part of ball sports = moderate; wheelchair racing or sit-skiing = vigorous) (use of crutches or ankle-foot orthoses involves higher METs but usually not enough to increase the level of PA, eg, from light to moderate)	—	—
Muscle strengthening	—	Pushing and/or pulling one's body or an object	Climbing
			Pushups, curl-ups, or resistance training
			Wheeling a wheelchair
Bone strengthening	—	Increased impact	Jumping rope
			Tumbling
			Running

Data are from references 78–82. MET, metabolic equivalent of task; PA, physical activity; —, not applicable.

all children, regardless of their abilities.[85] Desire encompasses the interest and enjoyment in physical activity and movement.[85]

Teenagers report the strongest facilitators of physical activity include a favorable attitude toward physical activity; motivation; perception of competence and body image; fun; influence of friends, family, and physical education teachers; and environmental physical activity opportunities.[91] Higher physical literacy is associated with higher physical activity levels and cardiorespiratory fitness in children and adolescents.[92,93] On the other hand, children who do not develop fundamental movement skills are unlikely to develop the confidence and desire to be active and are at increased risk for sedentary lifestyle and its associated risks, as demonstrated by children with developmental coordination disorder who experience increased rates of obesity.[94,95]

Children who do not engage in regular physical activity miss out on important benefits such as improved self-esteem, leadership and team building skills, decreased stress and anxiety, decreased depression, and fun, as well as improved physical and brain health.[74] Because physical activity is essential to normal pediatric development and health, the term "exercise deficit disorder" has been proposed to identify children who, for a variety of reasons, do not engage in sufficient physical activity to promote overall health.[96]

Many groups experience barriers to being physically active and developing fundamental movement skills, such as girls, children of minority status, children from low-income households (rural and urban), and CYSHCN.[85] If these skills do not develop, the likelihood of being physically inactive later in life increases, creating an integral role for the pediatrician in screening for physical literacy, physical activity opportunities, and exercise deficit disorder[97] and referring to a youth fitness specialist, physical education teacher, or physical and/or occupational therapist because structured programming improves fitness, strength, and functional movement skills.[98,99] National standards outline physical literacy as the primary purpose of physical education classes in schools.[100]

The role of early physical activity and literacy on later adult health may play a role in fracture risk beyond effects of impact activities on bone density and geometry.[101] Multidirectional ball sports earlier in life appear to protect against stress fractures in adolescent runners.[102] Physical function or, rather, dysfunction has been found to be a contributor to adult "fragility"

TABLE 3 Age-Appropriate Recommendations for Increased Physical Activity

	Infant (0–1 y)	Toddler (1–3 y)	Preschool (3–5 y)	Elementary (5–10 y)	Middle School (11–14 y)	Adolescence (15–18 y)
Frequency	Daily	Daily	Daily	Daily	Daily	Daily
Intensity	Any	Any	Any, including some moderate to vigorous	Moderate to vigorous	Moderate to vigorous	Moderate to vigorous
Time	Several times per day	At least 180 min/d	At least 180 min/d, of which at least 60 min are moderate-to-vigorous intensity	At least 60 min/d	At least 60 min/d	At least 60 min/d
Type	Interactive floor-based play and at least 30 min of tummy time spread throughout the day while awake	Activities that develop gross motor skills; examples include walking in the neighborhood, unorganized free play outdoors, walking through a park or zoo, or playing on a playground for toddlers	Activities that develop gross motor skills; unorganized free play in a safe environment; activities include walking, running, swimming, tumbling, throwing, and catching	Aerobic daily; vigorous activity, muscle, and bone- strengthening at least 3 d/wk; include free play with opportunities for fundamental movement skill development through walk, dance, jump rope. Introduce organized sports with flexible rules and short instruction time with a focus on enjoyment rather than competition	Aerobic daily; vigorous activity, muscle, and bone-strengthening at least 3 d/wk; incorporate activities that are enjoyable and encourage socialization; avoid sports specialization	Aerobic daily; vigorous activity, muscle, and bone-strengthening at least 3 d/wk; incorporate activities that are enjoyable and encourage socialization and competition, when appropriate

Data are from references 9, 15, 73, 75, 83, and 84.

fracture risk.[103] Because osteopenia only explains part of fracture risk, the role of sarcopenia, the loss of muscle, especially with aging, has been proposed as an important risk factor to the extent that, similar to exercise deficit disorder, the term "dysmobility syndrome" has been coined for adults, both resulting from dynapenia, the loss of muscle.[104,105]

INACTIVITY AND SEDENTARY TIME

The typical preschooler spends more than 6 hours per day in sedentary activity and just under 15 minutes per day in MVPA.[106] More than 20% of children watch 3 or more hours of television per day on school days,[1] and the average 8- to 18-year-old spends more than 7 hours per day in front of a screen.[107]

The health effects of a sedentary lifestyle are an area of intense research and emerging concern. For adults, physical inactivity is associated with increased all-cause mortality, cardiovascular disease incidence and mortality, cancer incidence and mortality, and diabetes incidence,[108] among other harmful health consequences. The 2018 Physical Activity Guidelines Advisory Committee concluded that there is limited available scientific evidence linking sedentary behavior to health outcomes; however, given the high prevalence of physical inactivity in youth, especially CYSHCN, replacing some sedentary time with MVPA could improve health, given the strong association.[31,109] More research is needed to better understand the effects of time spent sitting and in light-intensity physical activity among children and adolescents.[110]

Although the advent of exergaming, or active video games, pose an attractive option to promote physical activity in children drawn to electronic media and video games and averse to traditional physical activity, exergaming primarily

TABLE 4 Supporting Physical Literacy

Infancy: supporting rudimentary motor skill development
Grasping (3–4 mo)
Offer toys to support hand-eye coordination
Roll over (4–6 mo)
Tummy time to build core strength
Sitting (6 mo)
Tummy time to increase strength and coordination
Crawling (7–10 mo)
Place toys to help build strength and balance
Cruising (9 mo)
Offer a safe environment to explore which increases strength and balance
Walking (12 mo)
Create a safe environment to explore which improves balance and coordination
Toddler or preschool age: support development of fundamental skills
Encourage fun and socialization, incorporating activities preferred by the child, family walks, and chores (picking up, retrieving items, helping clean)
Running (by 2 y)
Play chase, visit parks, and offer a safe environment to practice
Throwing (2 y)
Play catch with easy-to-grasp foam or fabric balls
Catching (2+ y)
Create a "basket" with arms to catch
Kicking (2 y)
Play soccer with light, foam balls
Swimming (1–4 y)
Enroll in swimming lessons
Skating (4 y)
Elementary school age: improve fundamental skills and develop self-efficacy
Encourage fun and socialization, incorporating fitness preferences (such as dance, yoga, running, hiking, sports), active transportation (walking, cycling to school and activities), and chores (walking the dog)
Running
Build fitness and skills with tag, introduce sports like soccer by age 6
Throwing and catching
Falling and tumbling
Helps decrease injury by learning to tuck head, knees, and arms
Hopping and jumping
Hopscotch and jump rope
Cycling
Teach a child to ride a bike
Striking sports
Practice at home with a plastic ball and bat, hockey stick, etc; introduce sports programs
Dribbling sports
Fine motor skills develop through practice and repetition
Gymnastics
One of the best activities for agility, balance, coordination, strength, and flexibility
Skiing
Low center of gravity makes it easier; it helps with balance
Preadolescence and adolescence: honing physical literacy
Encourage fun and socialization, incorporating fitness preferences (such as dance, yoga, running, hiking, sports), active transportation (walking, cycling to school and activities), and chores (walking the dog)
Identify gaps in fundamental movement skills development, confidence, or desire to be active and devise a plan to remedy (eg, motivational interviewing, physical therapy, community program)
Introduce skill development and strategy through coaching and camps
Introduce more complex sports that incorporate multidirectional movement and attention (eg, sports with equipment and strategy and/or plays)
Introduce resistance training with supervision and instruction on proper technique
Avoid sports specialization until mid-to-late teenaged years

Data are from references 16, 76, 83–85, 89, and 90.

promotes only light physical activity, with few games demonstrating effectiveness in increasing activity to moderate or vigorous levels.[111] Although MVPA occurs with specific games in structured settings, applicability to home settings and the ability to achieve sustained, or cumulative, durations necessary to meet physical activity guidelines has not been demonstrated.[112,113]

The AAP advises that parents develop a family media use plan to help children limit screen time activities to ensure they do not replace adequate sleep, physical activity, and other behaviors essential to health.[114] Likewise, *Bright Futures: Guidelines for Health Supervision of Infants, Children and Adolescents, Fourth Edition*, recommends physical activity and play as alternatives to screen time, as well as a way to promote family routine and social interaction, in addition to benefitting normal growth and development.[16]

EVIDENCE IN SUPPORT OF PHYSICAL ACTIVITY PROMOTION IN PEDIATRIC CARE SETTINGS

Among adults, substantial international evidence supports the use of multiprong physical activity counseling and referral strategies, particularly those linking health care and community-based resources, to improve physical activity levels.[115,116] Meta-analyses and systematic reviews have shown that physician counseling (odds ratio, 1.42; 95% confidence interval, 1.17–1.73) and exercise referral systems (relative risk, 1.20; 95% confidence interval, 1.06–1.35) promote improvements in adult patients' physical activity for up to 12 months,[117–120] with evidence supporting the notion that physical activity counseling can be successfully implemented in routine clinical practice[121,122] and that protocols are acceptable among health care providers.[123] Integration of physical activity counseling and referral strategies into adult primary

care settings has also been found to be cost-effective,[124–128] provide early return on investment because of lower health care use and costs,[129,130] and have been successfully scaled to national levels with adequate sustainability.[128]

Although the experience from adult medicine shows that multicomponent intervention approaches can be effectively implemented within established primary care practices making use of existing resources and personnel, evidence on the effectiveness of physical activity promotion in pediatric settings is more limited.[131] To date, most interventions have been centered on multiple health behaviors including sedentary time and healthy diet in the context of weight management. For example, the Patient-Centered Assessment and Counseling for Exercise Plus Nutrition (PACE+) intervention showed that computer-assisted, individually tailored counseling for physical activity in children 11 to 15 years of age can be effective in reducing sedentary time and improving compliance with physical activity guidelines at 12 months, particular among boys.[132]

The Physical Activity Guidelines for Americans Midcourse Report assessed evidence-based recommendations to increase youth physical activity across multiple sectors.[31] In this report, the authors found insufficient evidence to support specific strategies for physical activity promotion in the clinical setting.[31] The 2018 Physical Activity Guidelines Advisory Committee remarked that this could be improved with more robust and standardized strategies incorporating additional team members and tools such as motivational interviewing and a specific exercise prescription.[31] The committee also noted that individually focused interventions delivered in a variety of settings can successfully increase youth physical activity, especially when families and schools are incorporated into the interventions.[31]

The Healthcare Effectiveness Data and Information Set measure on Weight Assessment and Counseling for Nutrition and Physical Activity for Children/Adolescents assesses the percentage of patients 2 to 17 years of age who had an outpatient visit with a primary care provider and who had evidence of BMI percentile documentation, counseling for nutrition, and counseling for physical activity during the measurement year.[133] Depending on insurance type, 60% or fewer pediatric visits contained documentation of counseling for physical activity or referral for physical activity on the basis of administrative data or medical record review that included a note indicating the date and at least one of the following activities: (1) discussion of current physical activity behaviors (eg, exercise routine, participation in sports activities, examination for sports participation); (2) checklist indicating physical activity was addressed; (3) counseling or referral for physical activity; (4) member received educational materials on physical activity; or (5) anticipatory guidance for physical activity. Examples of notations that do not count toward this requirement include "notation of 'cleared for gym class' alone without any documentation of a discussion" or "notation of 'health education' or 'anticipatory guidance' without any specific mention of physical activity."[133]

The US Preventive Services Task Force recommends that clinicians screen children 6 years and older for obesity and offer them or refer them to comprehensive, intensive behavioral intervention that includes physical activity and nutritional counseling to promote improvement in weight status. Rated as a "B" recommendation, this strategy must be included in health plans under the Affordable Care Act's Prevention and Health Promotion activities.[134] Similarly, the AAP clinical report on obesity prevention also underscores the importance of physical activity promotion by pediatricians and other health care providers.[10] Given the critical importance of play in childhood, of which physical play is one type, the AAP recommends that clinicians write a "prescription for play" at well-child visits in the first 2 years of life.[76] *Bright Futures: Guidelines for Health Supervision of Infants, Children and Adolescents, Fourth Edition*, encourages play as a way to decrease screen time starting at 18 months of age, promoting behavioral management and social development starting at 2 years of age, and advancing to promotion of physical activity guidelines at 5 years of age for growth and development.[16] As such, physical activity is a component of the *Bright Futures* health supervision priorities of social and emotional well-being, school readiness and performance, and risk-behavior reduction.[16]

ROLE OF PARENTS IN PHYSICAL ACTIVITY FOR CHILDREN

Early in life, opportunities for the development of physical literacy occur at home. Parents are integral, not only in role-modeling movement, but also in playing with their children to allow for acquisition of necessary skills.[76] The role of parents is even more important in CYHSCN given the complexity of needs and barriers to participation that children with disabilities face.[135] Free-play is the primary exposure of necessity.[76] Playing catch, climbing structures and natural elements, such as boulders and trees, and tag address skills in travel, hand-eye coordination, and balance and strength through natural exploration and fun play. Organized sports are unnecessary at early ages but are beneficial for more specific skill development once a child is ready on the basis of physical,

cognitive, and behavioral readiness.[136] Children who engage in a variety of different activities and sports, especially those that help build fundamental movement skills such as gymnastics, swimming, and track will be more likely to develop physical literacy as well as enjoyment of physical activity and attain recommended levels of MVPA.[85] Sport specialization, as outlined in the AAP statement "Sports Specialization and Intensive Training in Young Athletes," is discouraged before puberty because there is no evidence that young children will benefit from early sport specialization in the majority of sports, and some data suggest that early specialization leads to higher rates of overuse injury and burnout from concentrated activity.[83,137,138] Exposure to nature has also been shown to have its own benefits on health; thus, opportunities for play and movement outdoors, even in the smallest of green spaces, are important and create an increased appreciation of movement and nature.[139,140]

ROLE OF SCHOOLS IN PROMOTING PHYSICAL ACTIVITY IN YOUTH

In many areas, school provides the primary opportunity for physical activity and acquisition of physical literacy. In fact, the 2018 Physical Activity Guidelines Advisory Committee found strong evidence that interventions that affect multiple components of schools are effective for increasing youth physical activity, particularly among those at highest risk of physical inactivity, such as adolescent girls and children with limited access to safe and affordable activity opportunities outside of school.[31] The American Heart Association calls for schools to become the central element in a community system that ensures that students participate in enough physical activity to develop healthy lifestyles.[141] Developing physical education curricula that promotes enjoyment of movement and skill development is important, especially including CYSHCN, as is providing opportunities for movement before, during, and after school.[142] National standards outline the role of physical education classes in physical literacy.[100] It is important to recognize that in physical education classes at school, a number of factors have been shown to result in children spending less than 50% of class time engaged in MVPA.[143,144] Opportunities for additional movement throughout the day through active classrooms benefit not only the child through increased physical activity but also the learning environment as a result of improved behavior.[36,42,145] Opportunities for recess and physical education during school that maximize movement and minimize sedentary and/or standing time and encourage social interaction are critical.[146,147] Schools also provide a safe place for physical activity before and after school that many children do not have at home, especially outside, increasing the time spent in MVPA.[148–150] SHAPE America, the Society of Health and Physical Educators, discourages the use and withholding of physical activity as punishment in schools.[100]

TOOLS FOR ASSESSING PHYSICAL ACTIVITY IN PEDIATRIC CLINICAL SETTINGS

In a nationally representative sample (N = 811) of US primary care physicians caring for children and adolescents (pediatrics and family medicine), most physicians reported assessing physical activity in youth using general questions about the amount of physical activity (98%).[14] However, a lower proportion (66%) asked specific questions about duration, intensity, and type of physical activity, and only a minority reported using a standardized questionnaire (7%) or other written physical activity assessments (6%).[14] In comparison, 98% of physicians reported regularly measuring weight objectively on a scale in the office setting.[14] That the majority of pediatric primary care physicians report somehow assessing physical activity levels in their clinical practice is encouraging, but the study by Huang et al[14] that revealed fewer than one-third of pediatricians could correctly identify guidelines calls into question the degree to which providers are correctly screening for insufficient physical activity or adequately counseling adolescents and their families on the recommended "dose" of physical activity for health.

Several methods have been used to assess physical activity in children and adolescents including questionnaires, activity logs, pedometers, and research-grade and consumer-oriented accelerometers. Practicality, validity, and reliability are important considerations when deciding appropriate methods to assess physical activity levels in clinical settings.[120] Although physical activity is important, assessment of physical literacy (Table 4) is first necessary to quantify current activity, create appropriate goals for improvement, and allow for dose-response relationships to changes in other health parameters (and subsequent studies to demonstrate benefit or lack thereof) (Table 5). In the absence of opportunities to directly assess movement, quantification of physical activity may serve as a surrogate measure for younger children in representing opportunities for development of physical literacy. Simply asking children about their enjoyment of movement may provide insight into their physical literacy.[105]

In the adult population, systematic assessment of physical activity levels in clinical settings has been established through the integration of a self-reported physical activity vital sign (PAVS) into electronic health records (EHRs).[151] The PAVS has

TABLE 5 Steps Toward Integrating Physical Activity Assessment and Counseling Into Clinical Practice

1. Ask about current physical activity frequency and duration and enjoyment of movement.
2. If it is an acute or subspecialty visit, connect benefit of physical activity to current health condition and advise on restrictions in physical activity (if applicable).
3. If it is a health supervision visit, assess physical literacy and any gap between current and recommended activity level. Assess the patient and family interest in discussing promotion of physical activity.
   a. If not interested, provide information on the benefit of physical activity to current health, if the patient has any chronic issues, and/or future health (including athletic performance).
   b. If interested, discuss the reason for interest and potential area of change and establish a specific, attainable incremental goal to progress toward physical activity guidelines. Connect patient and/or family to resources to support achievement of goal, such as a physical education teacher, exercise specialist, physical or occupational therapist, or coach.
4. Recommend scheduling an appointment to discuss achievement toward goal; identify obstacles to change and establish new goals.

been promoted through the Exercise is Medicine initiative of the American College of Sports Medicine.[115,152–154] The PAVS consists of 2 questions (Fig 1), adapted from the Behavioral Risk Factor Surveillance System and validated to screen for inactivity in clinical settings.[155–157] Integration of the PAVS into the EHR of large health care systems resulted in greater physical activity–related counseling, weight change in adult patients with obesity, and hemoglobin A1c changes in those with diabetes.[158,159] The Institute of Medicine (now National Academy of Medicine) has supported the inclusion of the PAVS and/or objective assessment of physical activity in EHRs.[160]

Assessment of physical activity levels in youth via self-report is a more complex undertaking because youth are less likely to make accurate self-report assessments than adults because of developmental differences, especially in the ability to perform detailed recall and understand concepts regarding physical activity duration and intensity.[161,162] In addition, youth have an activity pattern that is more variable and intermittent compared with adults.[163] Furthermore, sports practices involve MVPA for only a fraction of the time, and the amount of time varies greatly by sport.[164] A thorough review of physical activity assessment tools is included in the Supplemental Information.

STRATEGIES TO OVERCOME BARRIERS TO PHYSICAL ACTIVITY ASSESSMENT, COUNSELING, AND REFERRAL IN CLINICAL PRACTICE

Physicians face many barriers to implementing physical activity assessment, counseling, and referral in the clinical setting.[151] Clinical visit times are short, and the list of preventive guidance to incorporate into well-child checks is long.[151] Solutions will likely require interprofessional approaches and engagement with community organizations in development of tools to provide interventions and track physical activity, integration of measurements of activity into the EHR, and identification of associations with health outcomes.[151] Regardless, physical activity assessment, counseling, and promotion follows the same approach as used in other areas of lifestyle change for chronic disease, yet it is applicable to all patients (Table 5).[165]

Pediatricians will need efficient workflows to incorporate physical activity assessment, counseling, and referral into the clinical visit. This could be accomplished through a PAVS in the medical record, previsit questionnaires, or screening performed by support staff.[151] EHR companies and health care institutions are encouraged to include tools to measure, document, report, and investigate physical activity measures and association with other health outcomes, including assessing for physical literacy. For example, the Intermountain Healthcare system developed and integrated into their EHR system a pediatric PAVS for use at preventive care visits for children ages 6 to 18 years.[151] This tool combines the PACE+ validated item with the addition of questions to assess activity participation on specific settings and domains (physical education, recreation, sports, transportation, home, after school, sedentary or screen time) in an effort to facilitate compliance assessment and guide goal-setting and domain-specific counseling.[151] Since 2011, the Kaiser Permanente Health System integrated into its EHR system and clinical workflows the pediatric exercise vital sign, modeled after the YRBS questions, for youth 5 to 18 years (Fig 1).[166] Although not yet formally validated in children, implementing the PAVS as a part of the health visit and within the EHR represents a starting point in initiating the conversation around physical activity in primary care and assessing the potential to predict future disease risk[158] as well as determining the validity of the PAVS in pediatric practice.[167] Brief tools for assessing physical activity are included in Table 6 (see the Supplemental Information for a full discussion regarding the tools and methodology used to identify advantages and disadvantages of each).

Similar to adult-based approaches, once the current physical activity level of the child is understood, providers can offer more specific, developmentally tailored physical activity advice or set an appropriate incremental goal for increase in activity and can include further guidance and referral resources in the after-visit summary.[120] For children identified as needing further intervention, a brief follow-up visit could be scheduled, or the patient could be referred to a community

a. ACSM Exercise is Medicine PAVS (minutes per week of MVPA)

Question 1. On average, how many days per week do you engage in moderate-to-strenous exercise (like a brisk walk)?

_____days

Question 2. On average, how many minutes do you engage in exercise at this level?

_____minutes

PAVS (minutes per week) = _____ days × _____ minutes

b. YRBS physical activity question (days per week of ≥60 minutes of MVPA)

During the past 7 days, on how many days were you physically active for a total of ≥60 minutes/day (add up all the time you spent in any kind of physical activity that increased your heart rate and made you breathe hard some of the time)?

_____days

c. Intermountain Healthcare pediatric PAVS

On average, how many days per week does your child get ≥60 minutes of MVPA or play (heart beating faster than normal, breathing harder than normal)?

_____days/week

On most days of the week, does your child

- walk or bike to school? ____Yes ___No
- participate in physical education class at school? ____Yes ___No
- participate in organized physical activity (sports, dance, martial arts, etc) or spend 30 minutes or more playing outside? ____Yes ___No

On average, how many hours per day of recreational screen time (video games, television, Internet, phone, etc) does your child get?

_____hours/day

Is physical activity an area that you want to work on with your family to improve?

____Yes ___No

FIGURE 1

resource (such as a teacher or community center).[120] In addition, support staff could receive appropriate training to elaborate on a provider's physical activity prescription and connect patients with community and technology resources to fill the prescription.[120] Special emphasis on addressing barriers for CYSHCN may be needed to assist patients and families with underlying mobility issues.[168,169] Further guidance for CYSHCN may be found in the AAP clinical report "Promoting the Participation of Children With Disabilities in Sports, Recreation, and Physical Activities."[128]

Institutional support of pediatric physical therapists, occupational therapists, athletic trainers, exercise specialists, social workers, and other professionals is necessary to assist in addressing the needs of the children most at risk for inactivity, such as CYSHCN; children of minority, rural, and urban status who experience insufficient access or resources to physical activity; and adolescent girls.[116,170] Ideal partnerships result in access to programs that are safe, close to home, financially feasible, fun, and culturally appropriate and offer adaptive experiences and intellectually appropriate programming (eg, Special Olympics) so that children facing barriers receive the same opportunities as their peers (Table 6).[168]

Insurance companies can play a role by providing coverage for necessary services and reducing reasons for payment denials because improved physical literacy and physical activity, even for nonambulatory individuals, result in later health benefit and savings in health care expenditures.[171]

ROLE OF PHYSICIANS IN PROMOTING PEDIATRIC PHYSICAL ACTIVITY OUTSIDE OF DIRECT PATIENT CARE

Many patients, families, and community organizations look to pediatricians to provide physical activity recommendations for sports participation, modifications for children with special needs or an acute or chronic injury, and increasingly for management of many physical and behavioral conditions such as prediabetes and attention-deficit/hyperactivity disorder.[172] Yet many pediatricians may feel they do not have the experience or training needed to guide their patients toward meeting physical activity recommendations. In medical school, they likely received little to no training in exercise prescription.[173] Most did not fare any better in residency, with only 26% of pediatric residency programs reported having a curriculum in physical activity counseling, with the greatest barrier being the lack of faculty with training in physical activity counseling, limiting provider knowledge and self-efficacy.[174–176] Encouragingly, training pediatric residents in physical activity counseling has been shown to improve the physical activity of

patients.[177] Implementing curricula and providing education is an effective first step (Table 7), which could be expanded to continuing medical education for practicing clinicians.

Clinicians have a responsibility to model physical activity for their patients and families through their own physical activity and community engagement. Several studies have shown that physicians' personal physical activity behaviors are an important correlate of their attitudes and clinical practice regarding physical activity.[178,179] Interestingly, the greatest predictor of asking about physical activity by pediatricians is being personally "fit and healthy" themselves.[180] In addition, physical activity is integral to personal well-being for the health care professional, improving quality of life and work-life balance and decreasing burnout.[181–184] The AAP has published a clinical report on the subject.[185]

RECOMMENDATIONS

Pediatricians are encouraged to promote physical literacy and activity in children and progress toward recommended physical activity guidelines in one or more of the following ways.

1. Assess and document gross motor skills and physical activity as appropriate at health care visits (Table 5, Fig 1).
   a. Assess gross motor skill development, physical literacy, and physical activity levels at all health supervision visits, with early referral to assess and treat identified delays or deficits (Table 4). A PAVS may be a useful screening tool to guide specific counseling (Fig 1).
   b. For CYSHCN, discuss physical activity prescription and any physical activity limitations with subspecialists who are sharing in a patient's care. Clearly document a patient's individual physical activity prescription so that other providers, therapists, caretakers, and parents can help a child implement the prescription.
   c. For children who are insufficiently active, identify barriers to activity and use behavioral strategies such as motivational interviewing to help patients and families identify doable strategies to increase activity.
2. Discuss the role and benefits of physical activity on physical and social growth and development and management of other health conditions as well as in mental health, school performance, behavioral management, and risk-behavior reduction specifically related to the patient.
3. Encourage parents to not only "do as I say" but also "do as I do" because children who grow up in families with active parents are much more likely to be active themselves.
4. Provide specific tools and resources to help families build skills. Assist families in overcoming barriers to physical activity by referring families to community advocates and community-based activity programs and other places to be active, such as sports clubs, recreation centers, parks, walking and biking trails, skate parks, and playgrounds.
5. Advocate with health care organizations, insurance providers, schools, and community organizations to increase opportunities for physical activity for all children.
   a. Encourage healthy child care centers and preschools to provide ample opportunities for children to move in ways

TABLE 7 Recommendations for Promoting Physical Activity Assessment and Counseling in Medical Education

1. Demonstrate assessment and counseling in practice for learners.
a. Primary care pediatricians and health care providers: general physical activity assessment and screening, counseling and goal-setting, and activity or exercise prescription and referral to community partners and resources.
b. Subspecialists: guidance on physical activity benefits and restrictions as related to relevant medical condition to patient, family, and other physicians involved in the patient's care.
2. Advocate for the inclusion of education regarding physical activity guidelines within medical school and residency training.
3. Advocate for the inclusion of education regarding physical activity counseling and exercise prescription as part of longitudinal curricula within medical school and residency training.

that they were designed to move, that is, in frequent, short bursts.

b. Support education policies that engineer physical education and literacy back into the school day and shared use policies that allow for safe, accessible, affordable access to recreational space.

c. Support the development of programs that provide resources for physical activity of children who are hospitalized (and their siblings) and for children needing additional resources to be physically active, such as CYSHCN and those who experience socioeconomic barriers.

6. Identify opportunities for physical activity assessment and prescription for children facing barriers to activity. Those most at risk for inactivity include children of minority, urban, and rural status, adolescent girls, and CYSHCN. In many cases, school-based physical activity interventions are the most promising approach to increase physical activity.[186]

7. Advocate for the inclusion of physical activity assessments within EHRs and use the assessments to provide patient-specific physical activity recommendations for pediatric patients.

a. Advocate for payment from public and private payers for administration of validated physical activity assessment instruments.

b. Investigate the type and effects of physical activity on health outcomes of pediatric patients.

8. Work with medical schools, residency programs, and health care institutions to develop curricula in exercise prescription and methods for physical activity assessment and prescription that include the recommended frequency, intensity, duration, and type of activity, taking into consideration the child's current health, fitness, and preferences (Table 7).

AAP: American Academy of Pediatrics
CYSHCN: children and youth with special health care needs
EHR: electronic health record
MVPA: moderate-to-vigorous physical activity
PACE+: Patient-centered Assessment and Counseling for Exercise plus Nutrition
PAVS: physical activity vital sign
YRBS: Youth Risk Behavior Survey

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

FINANCIAL DISCLOSURE: Dr Muth receives royalties from the American Academy of Pediatrics and F.A. Davis and previously had a consulting relationship with the American Council on Exercise; Drs Hanson, Lobelo, and Nemeth have indicated they have no financial relationships relevant to this article to disclose.

FUNDING: No external funding.

POTENTIAL CONFLICT OF INTEREST: Dr Muth receives royalties from the American Academy of Pediatrics and F.A. Davis and previously had a consulting relationship with the American Council on Exercise; Drs Hanson, Lobelo, and Nemeth have indicated they have no potential conflicts of interest to disclose.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Principles of Financing the Medical Home for Children

Jonathan Price, MD, FAAP,[a] Mary L. Brandt, MD, FACS, FAAP,[b] Mark L. Hudak, MD, FAAP,[c] COMMITTEE ON CHILD HEALTH FINANCING

A well-implemented and adequately funded medical home not only is the best approach to optimize the health of the individual patient but also can function as an effective instrument for improving population health. Key financing elements to providing quality, effective, comprehensive care in the pediatric medical home include the following: (1) first dollar coverage without deductibles, copays, or other cost-sharing for necessary preventive care services as recommended by *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents*; (2) adoption of a uniform definition of medical necessity across payers that embraces services that promote optimal growth and development and prevent, diagnose, and treat the full range of pediatric physical, mental, behavioral, and developmental conditions, in accord with evidence-based science or evidence-informed expert opinion; (3) payment models that promote appropriate use of pediatric primary care and pediatric specialty services and discourage inappropriate, inefficient, or excessive use of medical services; and (4) payment models that strengthen the patient- and family-physician relationship and do not impose additional administrative burdens that will only erode the effectiveness of the medical home. These goals can be met by designing payment models that provide adequate funding of the cost of medical encounters, care coordination, population health services, and quality improvement activities; provide incentives for quality and effectiveness of care; and ease administrative burdens.

INTRODUCTION

The American Academy of Pediatrics (AAP) originally developed the concept of a medical home in 1967.[1] Since that time, the AAP has continuously refined its vision of the mission, structure, and function of a medical home consistent with evolving best practices. A well-implemented and adequately funded medical home not only is the best approach to optimize the health of the individual patient but can also play a key role in improving population health. As public and private

payers modify traditional ways of paying for medical care or create alternative payment models in an effort to provide greater value (an improved ratio of population health to health care expense), they should recognize the contribution to value that the medical home makes.[2,3] Pediatricians must be knowledgeable about certain basic principles in their work with payers to make the medical home fully effective in improving the health of children and to ensure the medical home's fiscal viability.

DEFINITIONS

The "pediatric medical home" delivers accessible, continuous, comprehensive, patient- and family-centered, coordinated, compassionate, and culturally effective health care. In this venue, well-trained pediatric physicians known to the child and family deliver or direct primary medical care.[4] By extension, a "pediatric medical neighborhood" includes pediatric medical subspecialists, surgical specialists, mental and behavioral health specialists, and others who work collaboratively with the pediatric medical home.

The "triple aim," as adopted by payers, is to improve the value of health care (defined as the ratio of proven benefit or quality of care to the cost of care), to improve the individual patient's experience of care, and to improve community health as a whole. The foundational document that describes the triple aim envisions that payers must undertake or delegate several crucial tasks that include partnering with individuals and families, redesigning primary care, managing population health, managing system financing, and integrating care within large systems.[5] This triple aim has expanded to a quadruple aim by recognizing that improved provider satisfaction is another key goal of the health system enterprise. Attention to how the care team experiences the quality of its work life is required to counter the erosion of provider manpower, efficiency, and empathy resulting from accelerating and often onerous administrative demands.[6]

RECOGNIZING AND DELIVERING VALUE

Approximately one-third of the US population consists of children and young adults younger than 25 years.[7] Despite recent advances, however, the vast majority of health care spending, benefit design efforts, and medical home pilot projects are focused on older adults. In a growing body of evidence, it has been demonstrated that a greater achievable health value lies in identifying, preventing, ameliorating, or treating problems that may begin early in life and have lifelong consequences.[8–12] Prevention and early interventions undertaken between birth and school entry have significant effects on adult health[13–15] and remain important when initiated in later childhood, adolescence, and early adulthood. In this respect, greater investments in medical homes that enable or enhance their unique capabilities may be expected to generate compound long-term returns.

Health insurance, therefore, should cover the full range of essential services for children. These services include the traditionally recognized areas of newborn care; acute, urgent, and emergent outpatient care; inpatient and chronic care services; and prescription drugs. Essential services also include screening and early detection of developmental and behavioral problems and the full range of preventive and wellness services, including anticipatory guidance, habilitative and rehabilitative therapies and devices, oral health and vision care services, behavioral and mental health services, reproductive and pregnancy-related care, substance use disorder treatment, and transition to adult care services as well as home health, palliative, and hospice care services.[16] To achieve the full downstream effects of early-in-life prevention and intervention, payers should also cover other services, many of which can be integrated with the medical home. These include home visitations during pregnancy, infancy, and early childhood, the importance of which to child cognition and health have become well recognized.[17–20] Other evidence-based programs that have been shown to improve important short- and long-term child outcomes include Reach Out and Read, Healthy Steps, the Video Interaction Project, Incredible Years, medical-legal partnerships, and the Triple P Positive Parenting Program.[21–26]

PROVIDING EFFECTIVE COMPREHENSIVE CARE IN THE MEDICAL HOME

Accomplishing the goal of providing effective, comprehensive care in the medical home requires the following.

1. Insurers provide first dollar coverage for the preventive care services recommended in *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents*[13] and for vaccines recommended by the AAP and the Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention. All should be exempt from cost-sharing.
2. Health insurers adopt a uniform definition of medical necessity to include those services that promote optimal growth and development as well as prevent, diagnose, and treat the full range of pediatric physical, mental, behavioral, and developmental

conditions, in accord with evidence-based science or evidence-informed expert opinion.[16,27] Expert pediatric providers must be included in adjudication of disputes over medically necessary services for children.

3. Cost-sharing policies relating to deductibles, copays, and coinsurance focus only on discouraging inappropriate, inefficient, or excessive use of medical services. They should not deter appropriate use of primary care or specialist services. Out-of-pocket limits should be set as a function of family income rather than in absolute terms. Out-of-pocket limits should be minimized for these services. A generous number of primary care visits or, alternately, outpatient visits in general should be available without a deductible and with minimal cost-sharing limitations. A similar approach should apply to medically necessary services and procedures that are typically provided by medical subspecialists, surgical specialists, and mental and behavioral health specialists. High-deductible health plans are not appropriate for the pediatric population because they are not congruent with these principles.[28] A developing body of evidence suggests that high-deductible health plans indiscriminately discourage families from seeking high-value and/or medically necessary medical services. Hence, high-deductible health plans not only decrease inappropriate or excessive use but also restrict access to appropriate care.[29,30]
4. The provider and patient become able to determine from the payer the patient's cost responsibility at the time of service to achieve timely and efficient collections necessary to sustain the medical home.

IMPROVING THE PATIENT AND PROVIDER EXPERIENCE OF CARE

For children to receive accessible, continuous, comprehensive, and coordinated care from the medical home, payment for services must be timely and adequate. For the medical home to plan effective delivery of care, the payment methodology for encounters, coordination of care, quality improvement, and data generation must be understandable, transparent, and verifiable and must incentivize improving the patient experience of care. This can effectively be accomplished by implementation of the following principles, which will also improve provider satisfaction, the fourth item of the quadruple aim.

A. Adequate and Fair Payment for Medical Encounters

1. Base payments for encounters should reflect the complexity of service.[31]
2. Payers should value the additional global services that a practice incurs to effect transition of care, especially from pediatric to adult providers[32] as well as from hospital to home care and from home or hospital to residential or other treatment venues, by paying fairly for existing transition *Current Procedural Terminology* (CPT) codes.
3. Payments for vaccines, medications, and medical supplies should be based on the total costs of acquisition, patient counseling, storage, inventory tracking and reporting, quality control, administration, and documentation. Payments should be updated promptly for changes in purchase cost.
4. Appropriate non–face-to-face encounters via telephone and video and those on digital platforms, such as the Internet, e-mail, electronic health record portals, and other secure encrypted communication, that provide meaningful care should be paid for adequately to facilitate optimal function of the medical home and to improve patient and family satisfaction. These interactions may occur between the patient and family and the medical home or between the medical home and specialty care providers. These visits have their greatest value when they are performed within the medical neighborhood because they facilitate more timely access to care, promote continuity and thereby enhance quality, and prevent use of more-expensive medical venues. Payers should recognize this greater value by incentivizing patients and families to coordinate care through the medical home.

B. Adequate and Fair Payment for Coordination of Care

1. Payment for coordination of care allows services outside of face-to-face encounters that optimize care. This is especially important for children with special health care needs. Examples of these services include providing reminders and other outreach to patients and coordination and communication with medical subspecialists, surgical specialists, therapists, educators, and community resources.
2. Payment should be proportional to the specific services provided in this regard by the medical home and should consider the complexity of the patient panel. It is essential to understand that complexity relates not only to patient-specific medical and psychological factors but also, and especially in pediatrics, factors specific to parents and caregivers as well as overarching household and social factors, such as food and housing insecurity, neighborhood and household

violence, poverty, immigration status, and need for legal services.[33]

3. Coordination payments could be made as enhanced fee-for-service payment or as supplemental per-member per-month payment. Supplemental per-member per-month methodology can also enable providers to establish and maintain health information technology and collect data for quality improvement and population health initiatives. Payers should pay fairly for existing CPT codes that apply to care management of children with chronic and/or complex medical and behavioral conditions.

C. Implementing Well-Designed Incentives and Eliminating Disincentives

1. To achieve the full benefits of the medical home, its financiers should not simultaneously incentivize efforts that undermine it.
2. Vaccines, including the influenza vaccine, provided by the Vaccines for Children program and the Centers for Disease Control and Prevention are properly viewed as an important type of "in-kind" financing. As such, they should be supplied in a way that is as timely and adequate as monetary financing. In particular, release of annual influenza vaccine to accessible medical homes should be prioritized. Delayed delivery relative to other venues, such as pharmacies and retail-based clinics, results in lost opportunities for families to engage the medical home and potentially benefit from other interventions or health education at the same time.
3. Payers should not design cost-sharing to encourage the family to use venues, including retail-based clinics and telehealth ventures, that do not meaningfully communicate with the medical home or that deviate from professional standards of care (eg, fail to adhere to antibiotic stewardship principles or fail to conduct patient evaluations adequate for the complaint). Likewise, payers should not support provision of care to children younger than 2 years by acute care venues that lack pediatric expertise.[34]

D. Easing the Administrative Burden

1. Payers using fee-for-service payments should consistently adhere to CPT definitions of services. Providers waste administrative resources encoding the same service differently for different payers. Resultant errors in billing can reduce revenue. In addition, variant coding enfeebles a practice's ability to conduct internal analyses of its services.
2. Pediatricians choose from among specific quality improvement programs designed by the American Board of Pediatrics or one of its chartered entities for maintenance of certification (MOC). They also separately participate in specific programs designed by health care payers to qualify for incentive payments. Synergy between these programs would ease administrative burden within the medical home and better promote community health. Payers and MOC program administrators, via sponsorship or other means of collaboration, can develop and share large amounts of data, which can increase the impact of these programs on health outcomes. The efficiency of the medical home would benefit from reducing the multiplicity of efforts necessary to satisfy separate MOC and payer incentive rules.

IMPROVING THE HEALTH OF THE POPULATION

Pediatricians and payers can improve community health outside the traditional office encounter in a variety of ways. A venue committed to being a medical home for children and young adults should seek broadly innovative ways of improving health outcomes for children in its practice and can also consider extending its efforts to the greater pediatric community.[35,36] Payers should value and encourage research and initiatives that are likely to elevate health outcome trajectories over the long-term.[37] Continuous real-time sharing of data about patient populations between payers and practices can be a powerful way to help both groups respond to health needs in a timely way. All public and private payers should invest in providers, families, and communities to achieve better short-term health outcomes and to stimulate changes that will result in sustained improvement in the long-term life course.

Payers Have a Unique Opportunity and Ability to Enhance the Effectiveness of the Medical Home and Incentivize Families

A payer that covers both a parent and a child has important timely data about the family unit that may allow the medical home to optimize a child's comprehensive care. Payers and providers should consider sharing such data. Social determinants of health (including parental and socioeconomic factors) largely shape many adverse conditions and experiences affecting vulnerable children. Some childhood adverse conditions begin during fetal development; some are associated with preterm birth. Other conditions involve situations, actions, and deficiencies that cause children to become medically, behaviorally, or emotionally complex. Many social determinants of health culminate with children reaching maturity in socioeconomic conditions and habitual

behavior patterns associated with lifelong chronic and expensive adult conditions.[38] Relevant parental factors include the parents' or caregivers' employment status; past and present physical, mental, or behavioral health; use of tobacco and other substances; previous experience with and attitudes toward medical care; and competencies as parents or caregivers. Knowledge of these parental factors may allow the medical home to tailor medical care and parental education to prevent or mitigate those adverse childhood experiences that are predictable yet potentially modifiable. These same factors also influence whether a parent creates and maintains a relationship with a pediatric medical home for their child. Some payers already incentivize pregnant mothers to remain engaged with their prenatal care, such as by providing portable safe sleepers and play yards or coupons for infant products for those who attend nearly all of their prenatal visits; those with the data and resources should also incentivize parents to engage appropriate services on their own behalf and engage with a comprehensive, coordinated medical home for their children. Resources should also be deployed when necessary to provide or subsidize essential transportation for necessary encounters.

Payers Have a Unique Opportunity and Ability to Shape the Community

For children and youth, and especially for those with special health care needs, high-quality care must support family members, who provide the bulk of day-to-day care and advocacy for the child. Some metrics of quality outcomes pertinent to pediatrics reflect enhancements to the family's ability to support the child. Parents, for example, indicate that a meaningful outcome of a health intervention is reducing the number of school days and workdays that an illness, injury, or condition cause to be missed within the family.[39]

A key factor that impedes delivery of quality care is a lack of appropriate, affordable, community-based family services and supports.[40] In addition, a lack of appropriate pediatric-oriented medical, surgical, mental health, substance use, and other therapeutic services within a geographic area or a payer's network of providers can impose a significant barrier. Payers, public and private, should invest in the necessary infrastructure to support the pediatric medical home and medical neighborhood.

Where they exist, payers should support community-based efforts that identify children and adults in high-risk families, provide care coordination, and measure results in housing, education, employment, and engagement with the health system.[41,42]

Payments for Quality Improvement Activities Should Be Adequate and Fair

Ideally, "pay-for-performance" or similarly named programs can be used to promote high levels of quality, value, and outcomes. These programs reward providers either monetarily or by reducing administrative burdens. Examples of the aims of such programs include reducing inappropriate antibiotic use, promoting cost-effective medications, and rewarding follow-up in the medical home after hospitalizations and emergency department visits. Many of the elements that constitute proper design of such programs are delineated in a forthcoming AAP policy statement, "Beyond Fee-for-Service: New and Evolving Payment Models and Pediatrics" (S. Berman, MD, M.L. Hudak, MD, unpublished observations). Some programs are demonstrating positive results.[43] On the other hand, pay-for-performance programs are still evolving. Many adult programs have features that are not pertinent to improving care provided to children or that cannot easily be translated into pediatric equivalents.

1. Pediatricians should be involved in the creation and revision of performance goals, the metrics used to quantify them, and the process of validating them. Uniquely pediatric performance goals include use of evidence-based or evidence-informed screenings, interventions, and coordination that promote the optimal growth and development of children and youth.
2. The criteria for achieving rewards should be transparent. Incentives are ineffective if a provider does not know how a payment was earned or not earned.
3. A detailed "explanation of payment" document should explain how an incentive payment (or lack thereof) was determined and delineate which encounters or actions led either toward or away from a goal.
4. Providers should be able to use such transparency in an active and timely process to appeal payer errors.
5. Payment models that aim to calibrate fee-for-service payments, distribute incentive payments, or impose financial penalties on the basis of process or medical outcome metrics must incorporate a rational, robust, and validated risk adjustment methodology that accounts for the strong influence of social determinants of health on many metrics. Payment models should not discourage providers from caring for patients who are most in need of expert care. Moreover, payers should choose process or quality metrics in consultation with pediatric providers to ensure that the metrics are relevant to improving the care or outcomes of care in children, meaningful to the pediatrician, and feasible to accomplish within the medical home.

6. A robust electronic health record facilitates effective quality improvement activities within the practice population through its ability to create registries and track process and quality outcomes. Payment models should consider ways to encourage investment in this important yet costly infrastructural need.

CONCLUSIONS

For a medical home for children to be both effective and fiscally viable, payers must adequately finance the full range of services required to optimize the physical, developmental, emotional, and behavioral well-being of children, which critically influence health throughout the life course. Some support is required to engage families initially with the medical home. Once engaged, appropriate support is needed for encounters, care coordination, continuous quality improvement, implementation of an effective electronic health record system, and innovative efforts to improve community health. This support should not impose additional administrative burdens that will erode the effectiveness of the medical home. Payers should consider how best to achieve better health care value without encouraging fragmented care outside the medical home.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

Promoting Optimal Development: Identifying Infants and Young Children With Developmental Disorders Through Developmental Surveillance and Screening

Paul H. Lipkin, MD, FAAP,[a] Michelle M. Macias, MD, FAAP,[b] COUNCIL ON CHILDREN WITH DISABILITIES, SECTION ON DEVELOPMENTAL AND BEHAVIORAL PEDIATRICS

abstract

Early identification and intervention for developmental disorders are critical to the well-being of children and are the responsibility of pediatric professionals as an integral function of the medical home. This report models a universal system of developmental surveillance and screening for the early identification of conditions that affect children's early and long-term development and achievement, followed by ongoing care. These conditions include autism, deafness/hard-of-hearing, intellectual and motor disabilities, behavioral conditions, and those seen in other medical conditions. Developmental surveillance is supported at every health supervision visit, as is as the administration of standardized screening tests at the 9-, 18-, and 30-month visits. Developmental concerns elicited on surveillance at any visit should be followed by standardized developmental screening testing or direct referral to intervention and specialty medical care. Special attention to surveillance is recommended at the 4- to 5-year well-child visit, prior to entry into elementary education, with screening completed if there are any concerns. Developmental surveillance includes bidirectional communication with early childhood professionals in child care, preschools, Head Start, and other programs, including home visitation and parenting, particularly around developmental screening. The identification of problems should lead to developmental and medical evaluations, diagnosis, counseling, and treatment, in addition to early developmental intervention. Children with diagnosed developmental disorders are identified as having special health care needs, with initiation of chronic condition management in the pediatric medical home.

[a]Department of Neurology and Development Medicine, Kennedy Krieger Institute, and Department of Pediatrics, Johns Hopkins School of Medicine, Baltimore, Maryland; and [b]Division of Developmental-Behavioral Pediatrics, Department of Pediatrics, Medical University of South Carolina, Charleston, South Carolina

Drs Lipkin and Macias equally participated in the concept and design, drafting, and revising of the manuscript and approved the manuscript as submitted.

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

All clinical reports from the American Academy of Pediatrics automatically expire 5 years after publication unless reaffirmed, revised, or retired at or before that time.

Promoting Optimal Development: Identifying Infants and Young Children With Developmental Disorders Through Developmental Surveillance and Screening. *Pediatrics*. 2020;145(1):e20193449

Pediatricians and other child health care professionals have made significant progress over the past decade in meeting the goal of early identification and treatment of children with developmental and behavioral disorders. There has been an increase in the practice of formalized developmental screening in primary health care settings. Specific efforts from within the American Academy of Pediatrics (AAP)[1–6] and external to the AAP[7,8] have been focused on improving screening methods. Multiple efforts also have been made to improve implementation.[9–14] These initiatives have included broad guidelines focused on identifying general delays in development[1] as well as others to identify specific disorders or conditions.[2,3,6,15] The 2006 AAP policy statement on developmental surveillance and screening provided the pediatric health care professional with a new paradigm and an accompanying algorithm[1] that focused on the use of general, standardized developmental screening tests with strong psychometric properties, including reliability, validity, sensitivity, and specificity. Discrete ages for use of these tests are recommended in *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents, Fourth Edition* and the accompanying periodicity schedule at the 9-, 18-, and 30-month well-child visits.[16,17,*] The recommendation for screening at discrete ages contrasted with earlier statements in which screening at every visit was recommended. The algorithm was designed to fit within the medical home model of care and with use in the screening of all children during key preventive care visits. The policy statement offered guidance on consultation and referral to other specialty physicians as well as to other child development professionals, early intervention services, and preschool. It also recommended incorporating the principles of care for children with special health care needs in the primary care medical home. The policy statement also considered developmental screening payment issues and worked toward improving pediatric health care professionals' knowledge on billing and coding for the recommended procedures, resulting in improved payment across payers[18] (AAP, 2012, unpublished analysis of 2005 Medstat and 2011 TruvenHealth MarketScan outpatient database).

This developmental surveillance and screening model was incorporated into other initiatives and prompted the writing and revision of several similarly designed guidelines for related conditions, including autism spectrum disorder (ASD),[2] neuromotor disorders,[3] early hearing detection,[6] attention-deficit/hyperactivity disorder (ADHD),[19] and behavioral conditions.[5] These guidelines increased pediatric attention to these conditions and improved screening overall; however, universal screening still has not been achieved. AAP surveys of pediatricians report screening rates of 23% in 2002, 45% in 2009, and 63% in 2016.[20,21] Pediatricians have reported difficulties in incorporating multiple new guidelines for related conditions into their practices[22] and continue to report time limitations and inadequate payment as barriers to implementation.[21]

Although there are similarities among recommended screening strategies for delays and disabilities in cognitive disorders, motor disorders, language disorders, autism, and social-emotional and behavioral disorders, there are also substantive differences in their timing, measurement, and implications for intervention. Thus, this revision of the 2006 policy statement describes only the first category. Future reports will provide detailed recommendations regarding screening for ASD and social-emotional and behavioral disorders. The algorithm is intended to serve as a model for the refinement of a universal system of screening of all children in the primary care setting, as illustrated in Fig 1.

This universal system would include the wide range of neurodevelopmental and behavioral conditions that affect the early and long-term development and achievement of children. These conditions include ASD; language disorders; and deafness or hard-of-hearing, also referred to as deafness, hearing loss (*International Classification of Diseases, 10th Revision* codes H91.90 through H91.93), or hearing impairment (the Individuals With Disabilities Education Act [IDEA])[23]; vision disorders; neuromotor conditions (such as cerebral palsy); neuromuscular disorders (such as Duchenne muscular dystrophy); intellectual and learning disabilities; and behavioral conditions (such as ADHD). At the same time, certain conditions have high rates of co-occurring developmental or behavioral disorders (eg, children born preterm or with other perinatal complications and children with complex congenital heart disease, sickle cell disease, intrauterine alcohol exposure, lead toxicity, congenital infections, and other chronic health conditions). Especially vulnerable to developmental and/or behavioral problems are those negatively affected by the social determinants of health and other adverse childhood or family experiences such as children in poverty[24]; children exposed to racism[25]; and children experiencing toxic stress, including exposure to abuse, neglect, parental mental illness, parental drug or alcohol use,

* Developmental screening has traditionally been recommended at the 24-month well-child visit, and since 2006, has been recommended at the 30-month visit. Screening for ASD is still recommended at the 18- and 24-month visits.

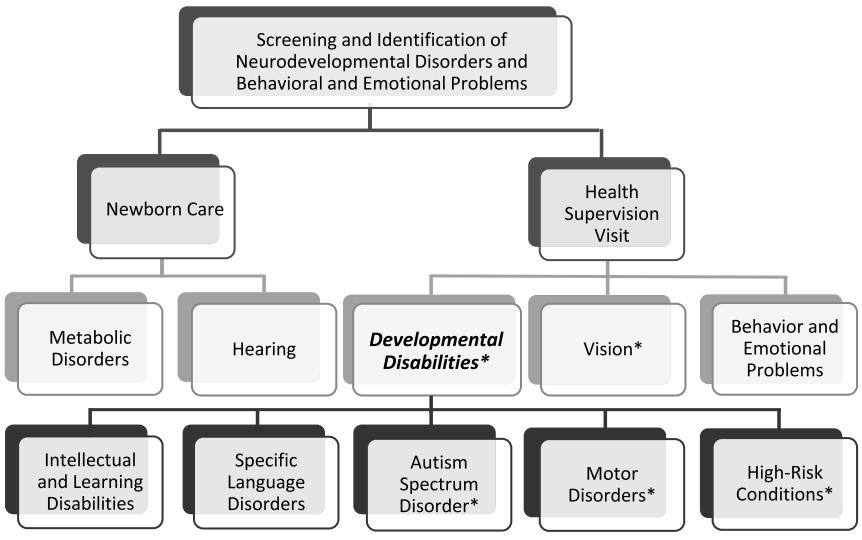

FIGURE 1
Early childhood screening for the identification of neurodevelopmental disorders and behavioral and emotional problems. (Content with an asterisk corresponds to current AAP guidance, using broad categories. This figure may not be inclusive of all specific developmental and behavioral disorders.)

caregiver depression, and foster care. Screening principles being used in developmental surveillance and screening of children without known developmental risks can be applied universally, including use in the identification of developmental and behavioral conditions in children with chronic health conditions. Additionally, given the importance of coordinated patient- and family-centered care in pediatrics, families should be engaged as collaborative partners in developmental screening and surveillance practices. The act of screening itself provides engagement conversations and builds relationships with families. The algorithm and discussion that follow can be used to guide pediatric health care professionals through the surveillance and screening process for the early identification of developmental disorders, including autism; it is important to note that this algorithm is focused on children who do not have already identified risks or developmental problems.

Although this clinical report is focused on children ages 0 to 5 years, these recommendations may be considered a minimum and are not intended to be prescriptive. National and international groups focused on young children concur that early childhood spans ages 0 to 8 years and endorse screening beyond age 3 years. The US Administration for Families, Office of Planning, Research and Evaluation[26] states that to be effective, screening should begin early and be repeated through early childhood. Therefore, it is argued that developmental screening may need to be more frequent to optimize the opportunities for detection of risk and connection to intervention.

NOTE ON TERMINOLOGY

As in the previous policy statement, clear distinctions are drawn within the context of this document among (1) surveillance, the process of recognizing children who may be at risk for developmental delays; (2) screening, the use of standardized tools to identify and refine that recognized risk; and (3) evaluation, a complex process to identify specific developmental disorders that affect a child. "Developmental disorder" and "developmental disability" refer to a childhood mental or physical impairment or combination of mental and physical impairments that result in substantial functional limitations in major life activities.[27]

THE ALGORITHM

The algorithm (Fig 2) presents steps for screening a patient without identified risks for developmental problems at a health supervision visit.

Step 1: Patient Without Identified Risks or Developmental Problems Arrives for Health Supervision Visit

A parent's or professional's developmental concerns should be addressed by the pediatric health care professional as part of developmental surveillance at each pediatric health supervision visit throughout the first 5 years of life, as outlined in the AAP *Bright Futures, Fourth Edition* and related national health promotion and prevention initiative.[16,17] In multiple studies, researchers have shown that developmental disorders are detected at low rates when physicians rely on judgment alone.[28] Including developmental screening tests at targeted ages enhances the precision of the developmental surveillance process.[29]

The recommended ages for developmental screening at the health supervision visit are a starting point for children who are without known identified risks and are not suspected of having a developmental concern. Because development is dynamic in nature and surveillance has limits, periodic screening with a validated instrument should occur so that a developmental concern not detected by surveillance or an earlier screening can be detected by subsequent screening. Using a validated developmental screening test at the 9-, 18-, and 30-month visits is outlined in *Bright Futures, Fourth Edition*.[16,17] Developmental surveillance should continue through childhood, including surveillance at the 4- or 5-year visit as a child prepares to enter elementary school.

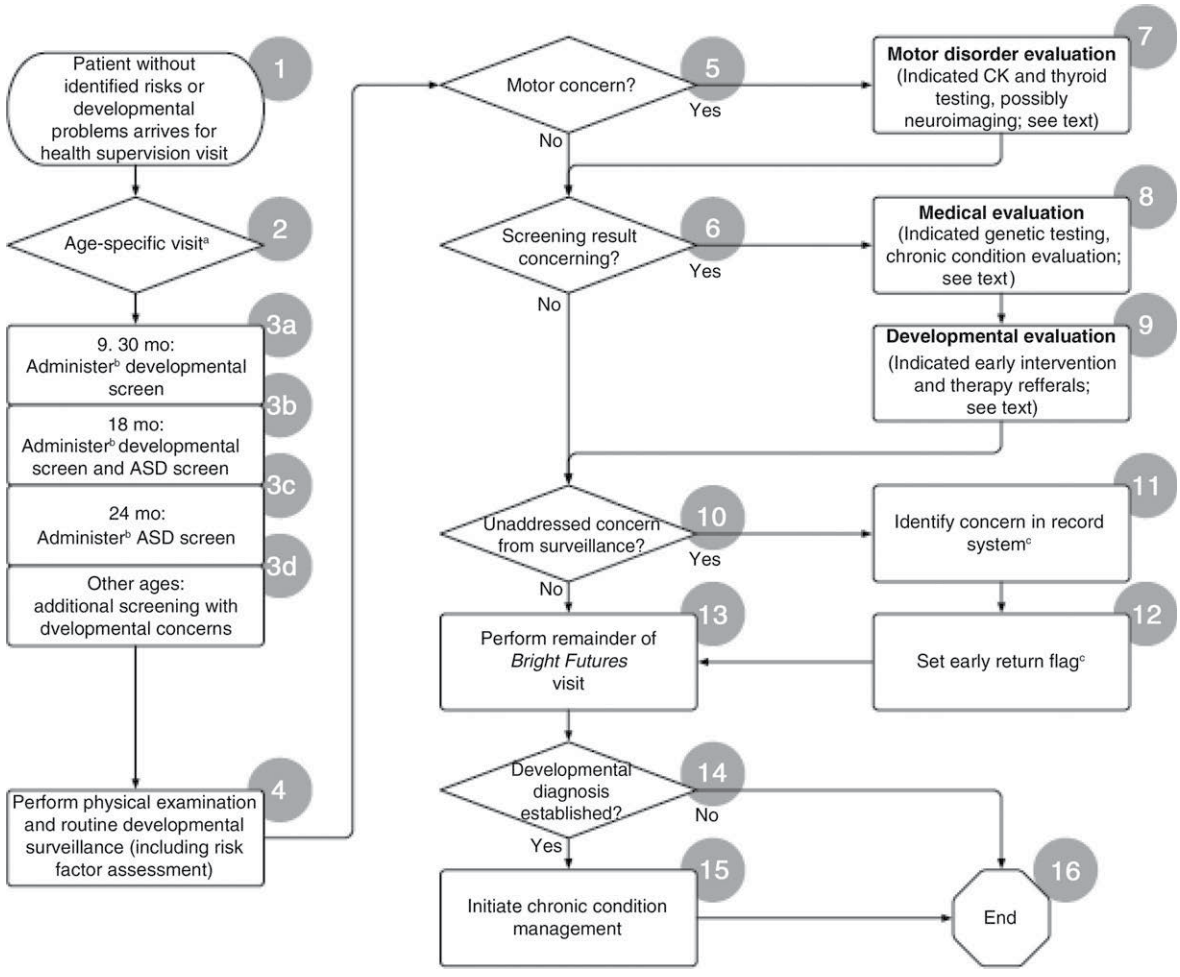

FIGURE 2

Algorithm for screening a patient without identified risks for developmental problems at a health supervision visit. Numbers and headings refer to steps in the algorithm. [a]To identify problems not previously recognized during earlier screenings, clinicians should pay particular attention to developmental surveillance at the age 4- or 5-year visit, before entering kindergarten. Developmental surveillance should continue throughout childhood. [b]Screening instruments may be administered through a previsit process initiated by the practice or by the family. [c]Providers should create methods in their record system (paper or electronic) to ensure that these facts are visible to clinicians in future visits and in the appointment scheduling process. CK, creatine kinase.

Any time that parents, professionals, or others involved in the care of the child raise concerns during surveillance, it is appropriate to perform additional developmental screens using validated tests. These screenings should be recognized separately, with appropriate coding, billing, and payment and with the additional cost acknowledged in capitated expectation (see Supplemental Information).

Given that developmental and behavioral risks increase with age, a child identified with risks or concerns may merit at least annual formal screening if concerns continue to be identified through surveillance.

Step 2: Is This a 9-, 18-, 24-, or 30-Month Visit?

All children should receive periodic developmental screening using a standardized test. In the absence of established risk factors or parental or provider concerns, a general developmental screen continues to be recommended at the 9-, 18-, and 30-month visits. Screening for behavioral and emotional problems is recommended at the same time points, at a minimum.[5] In addition, screening for ASD is recommended at the 18- and 24-month visits.[30]

In addition, to identify problems not previously recognized in earlier screenings and to identify issues with regard to developmental skills necessary for school readiness,[31] surveillance, with close attention to these developmental skills necessary for school readiness, should be performed at the 4- or 5-year visit, with screening performed when concerns are noted. Additional information about the pediatrician's role in promoting school readiness, as well as developmental surveillance

for school readiness, can be found in the AAP policy statement, "The Pediatrician's Role in Optimizing School Readiness."[31] Given the lack of strong evidence validating screening at the 4- to 5-year visit, universal screening is not presently recommended as part of the periodicity schedule.

Step 3: Administer Screening Test

The administration of a brief, standardized screening test helps identify children at risk for a developmental disorder. Well-validated screening tests can be completed by parents and scored by office staff. The pediatric health care professional interprets the screening results.

Developmental screening does not result in a diagnosis but rather identifies areas in which a child's development differs from same-aged norms. Repeated and regular screening is more likely than a single screen to identify problems, especially in skills that develop later, such as language. Waiting until a young child misses a major milestone may result in late rather than early recognition, increasing parental dissatisfaction and anxiety, and can deprive the child and family of the benefits of early identification and intervention.

A table of developmental screening tests is included in this document (Supplemental Table 1), and a discussion of how to choose an appropriate screening test is included in the section below entitled "Implementing the Algorithm."

9- and 30-Month Visits: Administer Developmental Screen

- A screening at the 9-month visit provides an opportunity to attend to the child's motor, visual, and hearing abilities. Early communication skills also are emerging, and symptoms of ASD, such as lack of eye contact, orienting to name being called, or pointing, may be recognizable in the first year of life.[32,33] Infants 9 months of age who have a medical condition that increases risk for developmental disorders, such as a genetic condition or significant perinatal complications, should be referred to early intervention programs, if not previously referred. The 9-month visit also provides an educational opportunity to inform parents about developmental screening and to encourage parents to attend to communication and early language skills. Social and nonverbal communication, including vocalizations and gestures, are important aspects of emerging communication that can be assessed at this visit. Although ASD is not diagnosed at this age, social and emotional delays may qualify a child for early intervention programs (eg, Part C, IDEA [0–36 months])[23,33] and provide valuable support to a family.
- The 30-month visit provides an additional opportunity to identify motor, language, and cognitive problems, including more subtle delays, and represents another opportunity to identify the child with delays qualifying for early intervention services. An early intervention program also assists the child and family in transition to a school-based program as needed.
- As noted previously, this updated clinical report recommends developmental surveillance through childhood, with particular attention to surveillance and administration of a formal screening test at the 4- or 5-year visit when developmental risks, concerns, or problems occur. As age increases, corresponding increases in delays are seen.[34,35] Without routine screening, at least 50% of children with developmental or behavioral disorders are not detected before kindergarten.[36] Therefore, administration of a standardized developmental screen at 4 years of age for children with developmental concerns or risks may improve detection and referral of a child with previously unrecognized learning and attention disorders to the school system or other resources before his or her entry into kindergarten. Additional behavioral surveillance may also help identify ADHD symptoms at preschool age, when behavioral therapy and behavioral parent training may be especially helpful. In addition, symptoms of ASD may become more apparent after children become more verbal and are in the social milieu of preschool. Children 5 years of age who are not yet in kindergarten should receive continued close surveillance followed by screening, if concerns arise.

18-Month Visit: Administer Developmental Screen and ASD Screen

- A developmental screen is recommended at the 18-month visit because delays in fine motor, communication, and language development are often evident by 18 months of age, as are previously undetected gross motor delays. Medical interventions for motor disorders have been shown to be effective in children age 18 months, and effective early intervention for delayed language development also is available.[37]
- In addition to a general developmental screening test, an ASD-specific screen should be administered to all children at the 18-month visit, as originally recommended in 2006.[1] Early symptoms of ASD are often present at this age, and effective early intervention strategies are available.[38,39] Current evidence supports screening for ASD at both the 18- and 24-month visits because ASD symptomatology may be identified after 12 months of age, with accurate screening by 18

months.[40] However, a recent systematic review of primary care screening for ASD by the US Preventive Services Task Force (USPSTF) concluded that insufficient evidence existed on potential benefits and harms of such screening and that, therefore, it was unable to make a recommendation for or against such screening.[41] The USPSTF also called for further research on the screening tests, best ages for screening, and best treatment of those identified.[41] Screening by pediatric health care professionals continues to be recommended for the early identification of and intervention for ASD, while research continues.[42] Children with ASD demonstrate sleep, eating, and behavioral challenges in early childhood, and the pediatric health care professional can help the family manage these issues directly and through appropriate referrals and connect families to valuable peer support organizations.

- Close surveillance and earlier screening remains warranted if a child is at high risk for ASD, for example, if symptoms are present, the child has a sibling with ASD, the child has a genetic condition with known ASD risk, or the child has a history of prematurity or prenatal exposures (such as toxins or infection).[43] Research shows that behaviors concerning for ASD emerge earlier than 18 months of age.[33] Therefore, incorporation of surveillance for "red flags" into health supervision visits before formal screening at the 18- and 24-month visits is recommended.[30] (Note: the USPSTF did not address high-risk individuals.)

24-Month Visit: Administer ASD Screen

- An ASD-specific screen should again be administered to all children at the 24-month visit to further ensure the early identification of children with ASD.

Other Ages: Additional Screening With Developmental Concerns

If parents, pediatric health care professionals, or others involved in the care of the child raise concerns at other times about the child's development, it is appropriate to perform additional developmental screens using validated tests. This screening may require a separate visit and should be conducted as soon as possible.

Additionally, if a child has missed a 9-, 18-, or 30-month visit, a developmental screen should be administered at the next opportunity.

Step 4: Perform Physical Examination and Routine Developmental Surveillance (Including Risk Factor Assessment)

When the results of the periodic screening test are normal, the pediatric health care professional can inform the parents that, at this time, the child is at low risk for a developmental disorder and continue with other aspects of the health supervision visit.[17] Normal screening results provide an opportunity to focus on developmental and behavioral health promotion.[44]

Developmental surveillance continues to be defined with this report as a flexible, longitudinal, continuous, and cumulative process in which knowledgeable health care professionals identify children who may have developmental problems.[1,45] Surveillance also can be useful for determining appropriate referrals, providing patient education and family-centered care to support healthy development, and monitoring the effects of developmental health promotion through early intervention and therapy. Because a great breadth and depth of information, including health and developmental risk factors and previous screening results, is accumulated across a child's life through developmental surveillance, relevant developmental information should be flagged and available for review before or at each visit.

Developmental surveillance has 6 components: (1) eliciting and attending to the parents' concerns about their child's development; (2) obtaining, documenting, and maintaining a developmental history; (3) making accurate and informed observations of the child; (4) identifying risks and strengths and protective factors; (5) maintaining an accurate record of the process and findings; and (6) sharing and obtaining opinions and findings with other professionals, such as child care providers, home visitors, preschool teachers, and developmental therapists, especially when concerns arise.[45] In this updated report, additional emphasis is added to surveillance on the obtaining and sharing of information with professionals from outside of the medical home.

Eliciting and Attending to the Parents' Concerns

By asking about parents' concerns, the pediatric health care professional can elicit important information about the child's development, learning, or behavior.[46–48] A parent also may bring the results of screening or evaluation by an outside professional to the pediatrician's attention, particularly if concerns are noted.[49] In such instances, the pediatric health care professional should seek information on the test performed and its results for review and discussion with the family. Direct discussion with the outside professional about these concerns also may be beneficial. Discussions with the family or outside professionals should be documented in the medical record. The absence of parental or professional concern does not preclude the possibility of serious developmental delays, however.[50]

Obtaining, Documenting, and Maintaining a Developmental History

A developmental history is a vital component of any history taken during a health supervision visit. By asking questions about changes parents have seen in their child's development since the last visit or observing age-specific developmental skill attainment, such as whether the child is walking or pointing, the pediatric health care professional may identify delays or other abnormalities in a child's development that warrant further investigation.[51] Developmental milestones and "red flag" resources are available, including the Centers for Disease Control and Prevention's (CDC) "Learn the Signs. Act Early" program Web site (http://www.cdc.gov/ncbddd/actearly/)[13] and the AAP Screening Technical Assistance and Resource Center Web site (www.aap.org/screening), to engage families and other professionals as collaborative partners in surveillance.

Making Accurate and Informed Observations of the Child

As trained and experienced professionals, pediatricians and other pediatric health care professionals have the expertise and comparative knowledge to identify developmental concerns. A careful physical and developmental examination within the context of the health supervision visit is integral to developmental surveillance.[52] Limited evidence suggests observation of the parent-child interaction also may aid in identifying children with delayed development.[53]

Identifying Risks and Strengths and Protective Factors

A risk assessment is an important part of developmental surveillance. Environmental,[54] genetic, biological,[52,55] social, and demographic factors[56] can increase a child's risk for delays in development. Multiple risk factors can amplify each other.[57,58] Children with established risk factors may be referred directly for developmental evaluation and early intervention services or may require developmental surveillance at more-frequent intervals than children without risk factors.

Some medical conditions can increase a child's risk for developmental delays. These conditions include perinatal complications (eg, preterm delivery, low birth weight, intrauterine alcohol exposure, and hypoxic-ischemic encephalopathy), congenital and other neurologic conditions (eg, myelomeningocele, congenital brain anomalies, and epilepsy), complex congenital heart disease, genetic conditions, and other chronic conditions (eg, sickle cell disease).

Evidence is mounting about the negative effects of early adverse childhood events, which may cause or lead to "toxic stress," on brain architecture and child development and behavior.[59] Poverty and associated risk factors, such as food insecurity and caregiver depression, adds risk for developmental delays. Children who have these adverse experiences would meet the federal Maternal and Child Health definition of being at risk for having special health care needs.[60]

Using the strength-based approach, as exemplified in the AAP *Bright Futures, Fourth Edition*,[17] pediatric health care professionals should identify strengths and protective factors as well as risk factors in children's lives. Strong connections within a loving, supportive family, along with opportunities to interact with other children and grow in independence in an environment with appropriate structure, are important assets in a child's life. These factors, associated with resiliency in children, are important components of healthy development.[61,62] Similarly, strong systems of community supports, including local schools and public, private, and faith-based organizations, can play an important role in supporting the development and well-being of all children, including those with known developmental risks.

Maintaining an Accurate Record of the Process and Findings

Medical records should document the outcome of all surveillance and screening activities during preventive care visits. Additionally, specific actions taken or planned, such as scheduling an early follow-up visit, scheduling a visit to discuss developmental concerns more fully, or referrals to medical specialists or early childhood programs and specialists, also should be noted as part of developmental surveillance and screening. A record might contain a table in which the date of administration and the results of developmental surveillance and formal screens are recorded in relationship to the child's age. If electronic health records are used, developmental findings and plans can be recorded, with automatic prompts created for further action.

Sharing and Obtaining Opinions and Findings With Other Professionals

Although developmental surveillance is performed in the pediatric medical home, the opinions and findings obtained by the pediatric health care professional about the child's development have importance beyond this setting. In particular, a wide range of other professionals may be engaged with the young and developing child and would benefit from conclusions reached by the pediatric health care professional's regular ongoing developmental surveillance. These include child care providers, home visitors, preschool teachers, and developmental therapists. At the same time, some also are likely making observations of their own of the child's development and may be performing their own

developmental screening, as promoted by the "Birth to 5: Watch Me Thrive!" program.[49] Early intervention therapists also may be actively engaged with the child for both evaluation and treatment of developmental concerns. Consistent with the team-based approach, coordination of care with 2-way communication between the patient- and family-centered medical home and entities outside the medical home needs to be systematic and consistent.[63] Any entity outside the medical home that provides screening should have a systematic approach to communication of screen results, both positive and negative, to the medical home. Communication between a member of the medical home staff and these professionals on the child's development is, therefore, a critical part of surveillance to ensure optimal care and coordination of efforts and activities to optimize the child's development.[64–66] When screening or evaluation is performed by another professional, these results must be shared and discussed with the parent and the pediatric health care professional, including the test performed and the results obtained. The "Birth to 5: Watch Me Thrive!" program offers a free screening passport to aid in sharing screening results. Direct communication between the pediatric health care professional and the other professional may be helpful.[64] It should be noted that such communication, particularly electronic communication, is subject to Health Insurance Portability and Accountability Act of 1996 security requirements and must be protected.

This additional information may increase the complexity of the patient encounter. If the screen was recently completed, interpretation, documentation, and related action are recommended, with possible changes in the complexity of the encounter resulting in a higher-level visit. An updated screen may need to be completed if months have elapsed since the outside screening because of rapid changes in the child's development. Pediatric health care professionals should not submit bills for screening processes performed outside the medical home, but the charge for their services could reflect any applicable increase in complexity of medical decision-making.

Step 5: Does the Screening Suggest a Motor Concern?

If the screening results suggest a motor concern, a motor disorder evaluation should be conducted (see Step 7: Perform Motor Disorder Evaluation).

Step 6: Is the Screening Result Concerning?

If screening results are negative or not concerning, the pediatric health care professional can proceed to Step 10: Unaddressed Concern From Surveillance? If there is an unaddressed concern, identify the concern in the record system and set an early return flag before proceeding to Step 13. If there is no concern, proceed to Step 13: Perform Remainder of Health Supervision Visit. If screening results are concerning, a focused history and physical examination should be completed to identify any previously undetected medical conditions (see Step 8: Perform Complete Medical Evaluation below). The physical examination should target physical stigmata suggestive of an underlying genetic abnormality. The neurologic examination may suggest an underlying neurologic condition. The general physical examination may identify undetected medical conditions (eg, cardiac, renal, hematologic disease).

For a child who is determined by the pediatric health care professional to be at increased risk for a developmental disorder on the basis of medical, environmental, or social factors, referral to early intervention (under IDEA Part C[23,67]) or preschool special education (under IDEA Part B)[23,68] is recommended.

Reassurance has a role in the clinical encounter but varies depending on the progress and outcome of developmental surveillance and screening. Reassurance should be rooted in and reference the findings of developmental surveillance and screening. If, for example, developmental surveillance or screening does not identify a concern, specific, simple, age-specific developmental goals can be identified, and parents can be encouraged to schedule follow-up appointments if the child is not attaining those goals. Discussion of normal screening results should also include promotion of developmental and behavioral skills. In reassuring the parents, the pediatric health care professional should emphasize the importance of continual surveillance and screening. Enrollment in Early Head Start or Head Start, child care, or early childhood education should be considered, if appropriate.

Step 7: Perform Motor Disorder Evaluation

The child with motor concerns identified on surveillance and/or screening should undergo a comprehensive neurologic examination. When tone is increased, brain imaging should be considered. The child with normal or decreased tone should have laboratory testing of creatine kinase and thyroid-stimulating hormone.[3] More detailed guidance can be found in the AAP clinical report "Motor Delays: Early Identification and Evaluation."[3]

Step 8: Perform Complete Medical Evaluation

A medical diagnostic evaluation should be undertaken to identify an underlying etiology when the child's development is concerning or a delay is confirmed. This evaluation should consider biological, environmental,

and established risk factors for delayed development.[69–72] Audiologic evaluation should be performed for the child with a developmental concern. Vision screening,[15] review of newborn metabolic screening and hearing screening, growth review, and an update of environmental, medical, family, and social history for additional risk factors are also integral.

Further medical evaluation will vary with the risk factors, and findings may suggest further genetic, neurologic, metabolic, or other medical testing. The child with suspected global developmental delay or intellectual disability should have laboratory testing done, including chromosomal microarray and fragile X testing.[30] Metabolic testing should be considered if indicated by history and physical examination.[73] Further testing may be indicated when a diagnosis is not established with initial laboratory evaluation, including whole exome sequencing and gene panels. Brain imaging should be considered in the presence of abnormal neurologic examination, microcephaly, macrocephaly, or other clinical indicators. The initial genetic workup of the child with suspected ASD is evolving; current recommendations also include chromosomal microarray and fragile X testing.[30] Consultation with a medical geneticist to help guide the genetic workup should be considered. The pediatric health care professional should make additional specialty referrals as needed or when additional testing is warranted.

Identification of an etiology may give parents a greater depth of understanding of their child's disability. It also can affect various aspects of treatment planning, including specific prognostic information, genetic counseling around recurrence risk and heritability, specific medical treatments for improved health and function of the child, and therapeutic intervention programming.[74] This evaluation can be initiated by a general pediatrician or through a pediatric medical subspecialist, such as a neurodevelopmental pediatrician, pediatric neurologist, developmental-behavioral pediatrician, pediatric geneticist, or pediatric physiatrist. The pediatric health care professional within the medical home should develop an explicit comanagement plan with subspecialist(s) and care coordination with the family.

Step 9: Perform or Refer for Developmental Evaluation and Refer to Early Intervention or Early Childhood Education

If screening results performed either in the primary care medical home or in the child's child care or preschool are concerning, the child should have a comprehensive developmental evaluation performed. This evaluation may occur at a different visit or in a series of visits in the primary care medical home or in a different setting by developmental or other medical professionals. The visits should be scheduled as quickly as possible, and professionals should coordinate activities and share findings. Tracking of referrals should be incorporated to ensure follow-up.

Developmental Evaluation

When developmental surveillance or screening identifies a child as being at high risk for a developmental disorder, diagnostic developmental evaluation should be pursued. This evaluation will help to identify the specific developmental disorder or disorders affecting the child, thus providing further prognostic information and allowing prompt initiation of specific and appropriate early childhood therapeutic interventions.

Children with neurodevelopmental disorders often have co-occurring areas of developmental or behavioral problems.[75–77] For example, a child with ASD may have an intellectual or learning disorder, ADHD, anxiety disorder, or a motor coordination disorder. Similarly, the child with cerebral palsy often has problems in these same areas as well as in speech and language development. Identifying these disorders can lead to further evaluation and additional treatments. Pediatric medical subspecialists, such as neurodevelopmental pediatricians, developmental-behavioral pediatricians, pediatric neurologists, and pediatric physiatrists, as well as advanced practice nurses, can perform the developmental diagnostic evaluation, as can other early childhood professionals, in conjunction with the child's pediatric health care professional. These early childhood professionals include early childhood educators, child psychologists, speech-language pathologists, audiologists, social workers, physical therapists, or occupational therapists, ideally working with families as part of an interdisciplinary team and in coordination and communication with the medical home.

Early Developmental Intervention and Early Childhood Education Services

Early intervention programs can be particularly valuable when a child is first identified to be at high risk for delayed development because these programs can provide evaluation services and offer other services to the child and family even before an evaluation is complete.[68,78] Suggestions for effective collaboration and communication between the patient- and family-centered medical home and early childhood education programs are outlined in the AAP policy statement "Patient- and Family-Centered Care Coordination: A Framework for Integrating Care for Children and Youth Across Multiple Systems" (see Supplemental Table 1, Care Coordination Tools and Organizations Supporting Care Coordination).[63]

Early intervention and early childhood education programs include federally funded programs, such as IDEA Part B and C services, Early Head Start, and Head Start, but also encompass quality preschools and parent education programs. These programs provide services that can include developmental therapies, service coordination, social work services, assistance with transportation and related costs, family training, counseling, and home visits.[23] The diagnosis of a specific developmental disorder is not necessary for an early intervention referral to be made. Pediatric health care professionals should realize that a community-based early intervention evaluation may not address children with specific medical risks, and further developmental and medical evaluation will often be necessary for children with established delays. The CDC provides a list of early intervention contact information for US states and territories.[67] Tracking of referrals and good communication with the families should be incorporated to ensure follow-up. This has been found to be problematic in some systems in which a minority of families ultimately connect with early intervention programs, are evaluated, and receive services.[79]

Step 10: Unaddressed Concern From Surveillance?

If concerns were raised during developmental surveillance (see Step 4: Perform Physical Examination and Routine Developmental Surveillance), but a disorder or condition was not identified, the pediatric health care professional should document the concern in the practice's record system (see Step 11: Identify Concern in Record System) and continue to monitor the child's developmental progress. An early return visit is recommended to provide additional developmental surveillance (see Step 12: Set Early Return Flag). Likewise, if concerns were raised during developmental surveillance (Step 4) but developmental screening was unable to be completed, the concern should be noted in the record system (Step 11) and flagged for an early return visit (Step 12), and the return visit should be held as soon as possible. If concerns are significant, then direct referral to early intervention is appropriate.

Step 13: Perform Remainder of Health Supervision Visit

When the results of the periodic screening test are normal (Steps 4 and 6), the pediatric health care professional can inform the parents that at this time, the child is at low risk for a developmental disorder, and continue with other aspects of the preventive visit.[17] Discussion of normal screening results provides an opportunity to focus on developmental and behavioral promotion using a strengths-based approach.

If developmental surveillance did not identify a concern and the child was not at high risk for or identified with a developmental or behavioral disorder or a chronic health condition, the pediatric health care professional should schedule the next health supervision visit after completing the examination and visit.

Steps 14 and 15: Developmental Diagnosis Established? and Initiate Chronic Condition Management

When a developmental disorder has been diagnosed in a child, that child meets the criteria for a child with special health care needs.[60] The child should be identified by the medical home for appropriate chronic condition management and regular monitoring and entered into the practice's registry of children and youth with special health care needs.[60]

The child may be assigned a care coordinator from the practice or from the community who will work with the family to ensure that all needed services can be accessed. Proactive care planning is needed, and routine follow-up with the medical home between health supervision visits may be warranted to assess progress and minimize unmet family needs.

The child health professional should actively participate in all care coordination activities for children who have complex health conditions in addition to developmental problems. Decisions regarding appropriate therapies and their scope and intensity should be determined in consultation with the child's family, therapists, and educators (including early intervention or school-based programs) and should be based on knowledge of the scientific evidence for their use.

Children with established developmental disorders often benefit from referral to community-based family support services, such as respite care, parent-to-parent programs, Parent Training Information Centers (http://www.parentcenterhub.org/find-your-center), and advocacy organizations. Some children may qualify for additional benefits, such as Supplemental Security Income, public insurance, waiver programs, and state programs for children and youth with special health care needs (Title V Maternal and Child Health Block Grant Programs).[80] Parent organizations, such as Family Voices,[81] Family-to-Family Health Information Centers,[82] and condition-specific associations, can provide parents with information and support and can provide an opportunity for advocacy.

IMPLEMENTING THE ALGORITHM

Choosing Developmental Screening Tests

No single screening test is appropriate for all children of all ages. Currently available screening tests vary from broad general

developmental screening tests to those screening for specific conditions, such as ASD, and others that focus on specific areas of development, such as communication skills. Broad screening tests are designed to address all developmental domains, including fine and gross motor development, language and communication, cognitive development, adaptive development, and social-emotional development. Their psychometric properties vary in characteristics, such as their standardization, the comparison group used for determining sensitivity and specificity, and population risk status. Screening tests also need to be culturally and linguistically sensitive.

Many screening tests are available, and the choice of which test to use depends on the population being screened, the types of problems being screened for in that population, administration and scoring time, any administration training time, the cost of the test, ease of fit into practice workflow, and the possibilities for adequate payment.

Screening tests should be both reliable and valid, with good sensitivity and specificity. Positive predictive value (PPV) and negative predictive value (NPV) must also be considered. A test that incorrectly identifies a child as delayed will result in overreferrals. A test that incorrectly identifies a child as typically developing will result in underreferrals. For developmental screening tests, scoring systems must be developed that minimize under- and overreferrals. Trade-offs between sensitivity and specificity occur when devising these scoring systems.[83] All indices (sensitivity, specificity, PPV, and NPV) are dependent on the gold standard used in the clinical evaluation and would vary as a function of the clinical measure(s) used and the cutoff selected (eg, –1 to 1.5 SD). Overidentification of children by using standardized screening tests may indicate that this group of children includes some with below-average development and/or significant psychosocial risk factors.[84] These children may benefit from other community programs to support the family and child as well as closer monitoring of their development by their families, pediatric health care professionals, and teachers or caregivers. Combining developmental surveillance and periodic screening increases the opportunity for identification of undetected delays in early development (Text Box 1).

A list of developmental screening tests and their psychometric testing properties is included in this document (Supplemental Table 1). These screening tests, which are focused on parent-completed tools, have acceptable psychometric properties. The list is not exhaustive, and other standardized, published tests are available. Additional tests are under development. Pediatric health care professionals are encouraged to familiarize themselves with a variety of screening tests and choose those that best fit their populations, practice needs, and skill level. Given the continual evolution of such screening tests, establishing a system for annual review of current and newly available screening tests and the dissemination of the results would be useful to provide guidance to pediatric health care and other professionals on the validity of currently available screening tests for use in the primary care medical home.

Incorporating Surveillance and Screening in the Medical Home

Incorporating developmental surveillance and screening into the pediatric office setting has been successfully achieved through the use of a "whole-office," team-based approach. Implementation projects[9,11,85–92] have demonstrated success with the pediatric health care professional or clinical team leading the office team in integrating the practice into the clinic flow. The process may begin in the child's home or at office visit registration and continue through the child's visit with the pediatric health care professional in the medical office or clinic room. With the assistance of office staff, parents can complete parent-report paper or electronic developmental

TEXT BOX 1 DEVELOPMENTAL SCREENING TEST PROPERTIES

Developmental Screening Test Properties

Reliability: ability of a test to produce consistent results

Validity: ability of a developmental screening test to discriminate between a child at a determined level of risk for delay (ie, high, moderate) from the rest of the population (ie, low risk)

Sensitivity: accuracy of the test in identifying delayed development. Those incorrectly identified as typically developing by the test are false-negatives

Specificity: accuracy of the test in identifying children who are not delayed. Those incorrectly identified as delayed by the test are false-positives

PPV: the proportion of children with a positive test result who are truly delayed; the lower the prevalence or base rate of the disorder, the lower the PPV

NPV: the proportion of children with negative test results who do not have developmental delays; this is also influenced by the prevalence of the disorder

Prevalence rate: No. children in population with a disorder, measured at a given time

Base rate: rate of a given disorder

General screening test: a test that evaluates multiple areas of development

Domain-specific screening test: a test that evaluates one area or domain of development (eg, motor or language)

Disorder-specific screening test: a test aimed at identifying a specific developmental disorder (eg, ASD)

surveillance and screening forms either before the office visit or within the medical office itself. A quality improvement approach may be the most effective means to build surveillance and screening elements into the process of care.[93] In addition to the use of office staff for distribution of surveillance or screening tests to families, team members can help with surveillance through observation of behaviors, interactions, and language. When a concern has been identified, office-based procedures can be used to schedule preventive care or follow-up visits, flag children with established risk factors, and help families with referrals to early intervention, developmental specialists, and pediatric medical subspecialists as needed. With the introduction of developmental screening to child care and early childhood programs, office staff also can serve as links between the family, the programs, and the child's medical home. Nonphysician staff also may score developmental screening tests, with interpretation and discussion with the family by the pediatric health care professional.

Since the publication of the 2006 policy statement, many local, state, and national initiatives have been used to increase developmental surveillance and screening practices in pediatric clinical programs. The results include major increases in screening rates, often with a majority of children screened.[9,21,85–92] However, in one study, rates of screening in family medicine practices for ASD have been reported to be lower.[94] Feasibility and effectiveness of parent-report screening tools also have been verified.[9,21,86,88] However, despite the success of screening, a few studies have shown that rates of referral to early intervention were good but not universal, and referrals to specialists were low.[9,77,86,89,95–97] Establishing an effective and efficient partnership with early childhood professionals is an important ingredient of successful care coordination for children within the medical home.[63] The federal government is supporting these partnerships through its "Birth to 5: Watch Me Thrive!" program,[49] which is particularly centered on universal developmental and behavioral screening for children across settings. The partnership includes early care and education providers, early intervention service and early childhood special education providers, child welfare professionals, home visitors, behavioral health providers, housing and homeless shelter providers, as well as the community and the family. It is built on shared interest in the developmental outcomes of children and recognition of the different skill sets of child health professionals and educators.

Whenever possible, communities should attempt to coordinate resources; this is especially true in preventing delays in care or unnecessary duplication of service. National initiatives that are being implemented to address the low rate of early detection of developmental disorders, much within the context of system-building, also address the problem of successive fall-off between early detection, referral, and initiation of services. The Collaborative Improvement and Innovation Network initiatives[98] include quality improvement projects, home visiting programs, and screening at child care facilities, both public (eg, Head Start, Early Head Start) and private. These Collaborative Improvement and Innovation Network initiatives have evolved from an initial focus on screening to a comprehensive process of engaging families as partners, interpreting screening results in the context of the family, ensuring referral for comprehensive assessment and intervention, and ensuring linkage to services. Use of a computer-based decision support system built into an electronic health record system shows promise as a strategy for increasing screening as well as referral and tracking.[99] Electronic referral systems have also been suggested.[79]

SUMMARY

The early identification of young children with developmental disabilities can be achieved through the combined processes of developmental surveillance and developmental screening in the patient- and family-centered medical home. Developmental surveillance should be a component of every health supervision visit through discussion with a child's parent, with incorporation of information from other child care professionals when appropriate. Screening should be implemented through the use of standardized developmental screening tests with all children at the 9-, 18-, and 30-month visits and when such surveillance identifies concerns about a child's development. Implementation of screening can be performed under the direction of the pediatric health care professional through other clinic or office staff. Children with known high-risk conditions should have close developmental monitoring and intervention, as needed. A child with motor delay also should undergo careful physical examination and have specific laboratory testing performed for treatable neurologic disorders. ASD screening should be performed similarly to general developmental screening using an ASD-specific screening test at the 18- and 24-month visits until the time that accurate measures are validated for other ages.

When a child has a concerning screening result on developmental screening, further developmental and medical evaluations to identify the specific developmental disorders and related medical problems are

warranted. In addition, children who have concerning screening results for developmental problems should be referred to early intervention and early childhood services and scheduled for earlier return visits to increase developmental surveillance.

Children in whom a developmental disorder is diagnosed may be considered as children with special health care needs, and chronic condition management for these children should be initiated, as warranted.

CLINICAL GUIDANCE FOR DEVELOPMENTAL SURVEILLANCE AND SCREENING

For the Medical Home

1. Perform developmental surveillance for the child at every health supervision visit from early childhood through adolescence, and ensure that such surveillance evaluates the child comprehensively.
2. Establish working relationships and dialogue with local child care professionals, early childhood therapists and educators, home visitors, and other early childhood professionals for ongoing developmental surveillance and discussion of a child's screening results in the medical home or elsewhere.
3. Consider direct referral of the child to early intervention or preschool special education for performance of comprehensive developmental and medical evaluations when the child is determined to be at increased risk for a developmental disorder on the basis of medical, environmental, or social factors or when surveillance raises significant concerns for delay.
4. Administer a standardized developmental screening test for all children at the 9-, 18-, and 30-month visits and for those whose surveillance yields concerns about delayed or disordered development. Screening those with concerns observed on surveillance should especially be noted in children seen at the 4- or 5-year visits, at which surveillance may identify concerns not previously noted and that may be of importance on initiation of kindergarten or elementary school.
5. Administer a standardized ASD screening test for children at the 18- and 24-month visits and at any time for those whose surveillance yields concerns about delayed or disordered social development.
6. Undertake a medical diagnostic evaluation of a child when development is concerning to identify an underlying etiology and to provide related counseling and treatment.
7. Schedule early return visits for continued close surveillance of children whose surveillance raises concerns that are not confirmed by a developmental screening test. Such developmental concerns may include those of the parent, the pediatric health care professional, and other medical, educational, or early intervention professionals as well as known high-risk medical or social risk factors.
8. Refer the child for whom screening results are concerning to early intervention and early childhood programs and initiate medical workup, if indicated.
9. Refer the child for whom screening results are concerning for further developmental evaluation to identify a specific developmental disorder.
10. Initiate a program of chronic condition management for any child identified with a developmental disorder.
11. Establish linkages and collaborations with state and local community and government programs, services, and resources for assisting the child in need of special services or assistance.[63]
12. Document all surveillance, screening, evaluation, and referral activities in the child's health record.
13. Family support services (eg, local and national Family Voices organizations [www.familyvoices.org], Parent to Parent USA, state-based Family-to-Family Health Information Centers, and other specific programs) should be offered to families of children identified with special health care needs, and assistance should be provided to access these services.
14. Quality improvement models may be helpful to providers in integrating surveillance and screening into office procedures and for monitoring their effectiveness and outcomes.

For Policy and Advocacy

1. Identify and address barriers to screening in the medical home (such as payment, professional and staff education, and office workflow) to achieve universal screening of all children during early childhood.
2. Provide appropriate payment for developmental screening, testing, evaluation, and treatment. Payment for these separately identifiable and reportable services should not be bundled into the preventive care visit or any other office visit. Payment for follow-up visits to monitor progress and outcomes should also be provided.
3. Provide payment for chronic condition management in the medical home for children identified with a developmental disorder to address the child's ongoing medical, social, and developmental needs and to

identify associated and address newly associated conditions and needs.

4. Continue current unified national efforts to increase early screening and detection rates across health care, education, and social service sectors with refinement and coordination among entities (including the professional associations such as the AAP, American Academy of Family Physicians, American Academy of Physician Assistants, National Association of Pediatric Nurse Practitioners, and the Association of University Centers on Disabilities and federal agencies such as Administration for Children and Families Office of Head Start and Office of Child Care, CDC, and the Maternal and Child Health Bureau and Health Resources and Services Administration). Support for these efforts should continue with a focus on integrated systems for early detection and care coordination to work in a timely, effective way.[100]
5. Guidance on specific ages for behavioral screening should be developed and integrated with developmental and ASD screening, given the close interrelationship of development and behavior and common coexistence of problems in both domains.

For Research and Development

1. Encourage ongoing investigation around screening and referral rates directed to the goal of universal screening of all children, with related referral into systems of medical and developmental care for those identified with specific developmental disorders. Obstacles and barriers to referral and ongoing management should be identified.
2. Support ongoing investigation directed to the goal of earliest identification of all children with developmental disorders and referral into specialty systems of developmental evaluation and care, medical evaluation and care, and education.
3. Expand the evidence base for the effectiveness of developmental surveillance activities, including the long-standing use and validity of developmental milestones for this purpose.
4. Expand the evidence base comparing the effectiveness of developmental surveillance, developmental screening, and their combination in the identification of children with developmental disorders.
5. Identify barriers that limit pediatric health care professionals from conducting medical workup for etiology and known associated medical conditions in children with developmental concerns.
6. Develop information systems and data-gathering tests to automate and operationalize the surveillance and screening processes recommended within this report and its algorithm. These could include integration and documentation into the child's electronic health record of developmental surveillance and screening of all children as well as chronic condition management of those children identified with developmental disorders.
7. Support continued research on the practice of developmental and ASD surveillance and screening, including

   examining the efficacy of surveillance for early identification of developmental concerns in use at nonscreening visits;

   examining the utility and validity of methods of surveillance and current tools;

   establishing the validity of both general developmental and ASD-specific screening;

   expanding the evidence base for the use and effectiveness of optimal ages for recommended developmental screening, including school-readiness screening and associated behavioral screening; and

   investigating the short- and long-term benefits of developmental surveillance and screening, given the current limitations of the evidence base.

   Note that these recommendations are consistent with the recent recommendation from the USPSTF[42] in its review of ASD screening. Although such research continues, developmental surveillance and screening by pediatric health care professionals in the patient- and family-centered medical home continues to be recommended for the early identification and intervention of children with developmental disorders, including ASD, reports of benefit from early and intensive intervention for ASD, and the national legislative mandate for provision of early intervention and special education services to children with developmental disorders.
8. Unification of all current related screenings is recommended, including early hearing screening, motor screening, behavioral and mental health screening, and neurodevelopmental screening in other health conditions (eg, prematurity and congenital heart disease). This would be valuable, considering the multiple screenings recommended for the wide range of health conditions during childhood. Such a vision and schedule would accommodate age and condition overlaps (such as newborn, anemia, hearing, developmental screening), the complexities for their implementation in the pediatric office by pediatric health care professionals and staff, and the need for families and community providers to understand the utility

of such screening. This integration would simplify the process of screening and would benefit affected children, their families, and the pediatric health care professional.

Providing Care for Infants Born at Home

- *Policy Statement*

POLICY STATEMENT Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN®

Providing Care for Infants Born at Home

Kristi Watterberg, MD, FAAP, COMMITTEE ON FETUS AND NEWBORN

The American Academy of Pediatrics (AAP) believes that current data show that hospitals and accredited birth centers are the safest settings for birth in the United States. The AAP does not recommend planned home birth, which has been reported to be associated with a twofold to threefold increase in infant mortality in the United States. The AAP recognizes that women may choose to plan a home birth. This statement is intended to help pediatricians provide constructive, informed counsel to women considering home birth while retaining their role as child advocates and to summarize appropriate care for newborn infants born at home that is consistent with care provided for infants born in a medical care facility. Regardless of the circumstances of his or her birth, including location, every newborn infant deserves health care consistent with that highlighted in this statement, which is more completely described in other publications from the AAP, including *Guidelines for Perinatal Care* and the *Textbook of Neonatal Resuscitation*. All health care clinicians and institutions should promote communications and understanding on the basis of professional interaction and mutual respect.

INTRODUCTION

Women and their families may desire a home birth for a variety of reasons, including cultural or religious beliefs and traditions, hopes for a more family-friendly setting, increased control of the process, and decreased obstetric intervention.[1] The incidence of home birth has increased over the past decade, with the largest increase occurring in white, non-Hispanic women; more than 2% of births to these women now occur at home, with wide variation in incidence among states.[2] However, a woman's choice to plan a home birth is not well supported in the United States. Problems with home birth include wide variation in state laws and regulations, lack of appropriately trained and willing providers, and lack of supporting systems to ensure the availability of specialty consultation and timely transport to a hospital. Geography also may adversely affect the safety of planned home birth because travel times longer than 15 to 20 minutes to a medical facility have been associated with increased risk for adverse

abstract

neonatal outcomes, including mortality.[3,4]

Planned home birth in the United States has previously been reported to be associated with a twofold to threefold increase in perinatal (fetal or newborn) death or an absolute risk increase of approximately 1 to 2 deaths per 1000 live births.[5–7] These findings were recently confirmed in a population-based study by using birth certificates with information on intended place of birth as well as actual place of birth, permitting analysis of birth outcomes after intrapartum transfer to the hospital.[8] This study also confirmed previous findings that infants born at home in the United States have an increased incidence of low Apgar scores and of neonatal seizures.[5,6] There may be an irreducible minimum increase in adverse outcomes with planned home births, even in a well-integrated health care system such as that in England. For example, the English National Institute for Health and Care Excellence recommends that practitioners "advise low-risk nulliparous women that planning to give birth in a midwifery-led unit (freestanding or alongside) is particularly suitable for them because the rate of interventions is lower and the outcome for the baby is no different compared with an obstetric unit. Explain that if they plan birth at home there is a small increase in the risk of an adverse outcome for the baby."[9] This advice is based on the Birthplace in England study, which revealed an increase in composite adverse outcomes of intrapartum stillbirths and early neonatal deaths, neonatal encephalopathy, meconium aspiration syndrome, brachial plexus injury, and fractured humerus or clavicle.[10]

In a recent position statement, the Committee on Obstetric Practice of the American College of Obstetricians and Gynecologists stated, "Although the College believes that hospitals and accredited birth centers are the safest settings for birth, each woman has the right to make a medically informed decision about delivery."[11] In addition, "Women inquiring about planned home birth should be informed of its risks and benefits based on recent evidence."[11] In the statement, the authors reviewed appropriate candidates for home birth and health care system components "critical to reducing perinatal mortality rates and achieving favorable home birth outcomes" (Table 1).

If requested, pediatric health care providers in the United States should be prepared to provide constructive, informed counsel to women considering home birth while retaining their role as child advocates in assessing whether the situation is appropriate to support a planned home birth (Table 1). In addition to apprising the expectant mother of the increase in neonatal mortality and other neonatal complications with planned home birth (Table 1), the health care provider counseling a pregnant woman about planned home birth should make her aware that some women who plan to deliver at home will need transfer to a hospital before birth because of unanticipated complications. This percentage varies widely among reports, from approximately 10% to 40%, with a higher transfer rate for primiparous women.[10,13] The mother should be encouraged to see transfer to a hospital not as a failure of the home birth but rather as a success of the system to provide a healthy outcome for both mother and infant.

Care of the newborn infant born at home is a particularly important topic because infants born at home are cared for outside the safeguards of the systems-based protocols required of hospitals and birthing centers, placing a larger burden on health care providers attending home births to remember and perform all components of assessment and care of the newborn infant. To assist providers, this policy statement addresses the following specific areas: resuscitation and evaluation of the newborn infant immediately after birth and essential elements of care and follow-up for the healthy term newborn infant.

TABLE 1 Planned Home Birth Considerations

Potential candidate for home birth
• Absence of preexisting maternal disease
• Absence of significant disease arising during the pregnancy
• A gestation of 37 + 0/7 to 41 + 6/7 weeks
• A singleton fetus estimated to be appropriate for gestational age
• A cephalic presentation
• Labor that is spontaneous or induced as an outpatient
Reported risks to the newborn associated with planned home birth in the United States
• Increased fetal and/or neonatal mortality[5–8]
• Increased incidence of neonatal seizures[5,6,8]
• Higher incidence of an Apgar score <4 at 5 min[5,6,8]
Systems needed to support planned home birth
• The availability of a physician or a midwife certified by the American Midwifery Certification Board (or its predecessor organizations) or whose education and licensure meet the International Confederation of Midwives Global Standards for Midwifery Education practicing within an integrated and regulated health system
• Attendance by at least 2 care providers, one of whom is an appropriately trained individual (see text) whose primary responsibility is the care of the newborn infant
• Availability of appropriate equipment for neonatal resuscitation[12]
• Ready access to medical consultation
• Access to safe and timely transport to a nearby hospital with a preexisting arrangement

As stated in *Guidelines for Perinatal Care*, fetal malpresentation, multiple gestation, and previous cesarean delivery are considered absolute contraindications to planned home birth.

ASSESSMENT, RESUSCITATION, AND CARE OF THE NEWBORN INFANT IMMEDIATELY AFTER BIRTH

As recommended by the American Academy of Pediatrics (AAP) and the American Heart Association, there should be 2 care providers present at every birth, at least 1 of whom has the primary responsibility to care for the newborn infant.[12] Situations in which both the mother and the newborn infant simultaneously require urgent attention are infrequent but will, nonetheless, occur. Thus, of the 2 care providers who should attend each birth, at least 1 should have the appropriate training, skills, and equipment to perform a full resuscitation of the infant in accordance with the principles of the Neonatal Resuscitation Program.[12,14] To facilitate obtaining emergency assistance when needed, the operational integrity of the telephone or other communication system should be tested before the delivery (as should every other piece of medical equipment), and the weather should be monitored. In addition, access to safe and timely transport to a medical facility should be available, and a previous arrangement with that facility should be in place. Examples of guidelines and forms for maternal and infant transport, developed by the Home Birth Summit organization, can be found at http://www.homebirthsummit.org.

Care of the newborn infant immediately after delivery should adhere to practices described in *Guidelines for Perinatal Care*[15,16] and should include provision of warmth, initiation of appropriate resuscitation measures, and assignment of Apgar scores. Although skin-to-skin contact with the mother is the most effective way to provide warmth, portable warming pads should be available in case a newborn infant requires resuscitation and cannot be placed on the mother's chest. The infant should be monitored closely in the transitional period. Temperature, heart rate, skin color, peripheral circulation, respiration, level of consciousness, tone, and activity should be monitored and recorded at least once every 30 minutes until the infant's condition has remained stable for 2 hours. Infants who receive extensive resuscitation (eg, positive-pressure ventilation for more than 30 to 60 seconds[12]) should be transferred to a medical facility for close monitoring and evaluation. Additionally, any infant who has respiratory distress, continued cyanosis, or other signs of illness should be immediately transferred to a medical facility.

CARE OF THE NEWBORN INFANT

Subsequent newborn care should adhere to that described in *Guidelines for Perinatal Care* as well as the AAP statement regarding care of the well newborn infant.[15–17] Although a comprehensive review of these guidelines would be far too lengthy to include in this statement, a few practice points are worthy of specific mention.

- Transitional care (first 4–8 hours): The infant should be kept warm and should undergo a detailed physical examination that includes an assessment of gestational age and intrauterine growth status as well as a comprehensive risk assessment for neonatal conditions that require additional monitoring or intervention. Temperature, heart and respiratory rates, skin color, peripheral circulation, respiration, level of consciousness, tone, and activity should be monitored and recorded at least once every 30 minutes until the infant's condition is considered normal and has remained stable for 2 hours. A newborn infant who is determined to be $<$37 weeks' gestational age by physical assessment[18] should be transferred to a medical facility for continuing observation for conditions associated with prematurity, including respiratory distress, poor feeding, hypoglycemia, and hyperbilirubinemia.
- Monitoring for early-onset sepsis: As recommended by the Centers for Disease Control and Prevention and the AAP, all pregnant women should be screened for group B *Streptococcus* colonization at 35 to 37 weeks' gestation.[19] Women who are colonized should be given an intrapartum antibiotic (penicillin, ampicillin, or cefazolin) at least 4 hours before delivery. If the mother has received this intrapartum treatment and both she and her newborn infant remain asymptomatic, they can remain at home if the infant can be observed frequently by an experienced and knowledgeable health care provider.[20] If the mother shows signs of intraamniotic infection (chorioamnionitis) but the infant appears completely well, the infant also can remain at home as long as he or she is observed frequently by an experienced and knowledgeable health care provider. A quantitative estimate of the risk of newborn infection (as can be obtained from use of the sepsis risk calculator at https://neonatalsepsiscalculator.kaiserpermanente.org) may help guide the decision to transfer the infant to a medical facility.[21] If the infant does not appear completely well, the infant should be transferred rapidly to a medical facility for further evaluation and monitoring in accordance with AAP guidelines.[20]
- Glucose screening: Infants who have intrauterine growth restriction or whose mothers have diabetes should be delivered in a hospital or birthing center because of the increased risk of hypoglycemia and other neonatal

complications. If, after birth, an infant is discovered to be small or large for gestational age or an infant has required resuscitation, he or she should be screened for hypoglycemia, as outlined in the AAP statement.[22] If hypoglycemia (glucose level <45 mg/dL) is identified and persists after feeding, the infant should be transferred promptly to a medical facility for continuing evaluation and treatment.

- Eye prophylaxis: every newborn infant should receive prophylaxis against gonococcal ophthalmia neonatorum, as directed by local laws and regulations.
- Vitamin K: Every newborn infant should receive a single parenteral dose of vitamin K_1 oxide (phytonadione [0.5–1 mg]) to prevent vitamin K–dependent hemorrhagic disease of the newborn. Oral administration of vitamin K has not been shown to be as efficacious as parenteral administration for the prevention of late hemorrhagic disease.
- Hepatitis B vaccination: For all medically stable infants weighing >2000 g at birth who are born to hepatitis B surface antigen (HBsAg)–negative mothers, the first dose of vaccine should be administered within 24 hours of birth. Only single-antigen hepatitis B vaccine should be used for the birth dose, following proper storage and handling requirements for immunizations. Infants born to mothers who are HBsAg-positive or whose HBsAg status is unknown should also receive hepatitis B immune globulin, as guided by current recommendations.[23]
- Assessment of feeding: A trained caregiver should evaluate at least 1 session of breastfeeding, including observation of position, latch, and milk transfer. The mother should be encouraged to record the time and duration of each feeding, as well as urine and stool output, during the early days of breastfeeding. Nomograms providing hour-specific expected weight loss in the first postnatal week can be found at https://www.newbornweight.org/.
- Screening for hyperbilirubinemia: Infants whose mothers are Rh-negative should have cord blood sent for a Coombs direct antibody test; if the mother's blood type is O and she is Rh-positive, the cord blood may be tested for the infant's blood type and sent for a direct antibody test, but it is not required, provided that there is appropriate surveillance, risk assessment, and follow-up.[24] All newborn infants should be assessed for risk of hyperbilirubinemia and undergo bilirubin screening between 24 and 48 hours after birth. The bilirubin value should be plotted on the hour-specific nomogram to determine the risk of severe hyperbilirubinemia and the need for repeat determinations.[24]
- Universal newborn screening: Every newborn infant should undergo universal newborn screening in accordance with individual state mandates. A list of conditions for which screening is performed in each state is maintained online by the National Newborn Screening and Genetic Resource Center (available at http://genes-r-us.uthscsa.edu/resources/consumer/statemap.htm).
- Hearing screening: the newborn infant's initial caregiver should document arrangements for screening the infant's hearing.
- Pulse oximetry screening: Screening for congenital heart disease should be performed by using oxygen saturation testing, ideally between 24 and 48 hours' postnatal age. Earlier screening can be performed, although the incidence of false-positive screen results may be increased. Helpful information for oximetry screening for planned home births can be found at https://wisconsinshine.org/home-births/.[25,26]
- Provision of follow-up care: Documentation of prenatal care, delivery, and immediate postnatal course, in addition to prompt, comprehensive communication with the follow-up care provider, is essential. Completion of forms such as those found on the AAP Bright Futures Web site (https://brightfutures.aap.org) can help provide such communication. A knowledgeable and experienced health care professional should examine all infants within 24 hours of birth and subsequently within 48 hours of that first evaluation. The initial follow-up visit should include infant weight and physical examination, especially for jaundice and hydration. If the mother is breastfeeding, the visit should include evaluation of any maternal history of breast problems (eg, pain or engorgement), infant elimination patterns, and a formal observed evaluation of breastfeeding, including position, latch, and milk transfer. Results of maternal and neonatal laboratory tests should be reviewed; clinically indicated tests, such as serum bilirubin, should be performed; and screening tests should be completed in accordance with state regulations. The documentation provided by the health care professional attending the birth should include whether tests and vaccinations usually performed as part of hospital protocols have been completed or scheduled.

CONCLUSIONS

The AAP does not recommend planned home birth. However, the AAP recognizes that women may choose to plan a home birth. The AAP concurs with the American College of Obstetricians and Gynecologists statement that "for quality and safety reasons, the College specifically supports the provision of care by

midwives who are certified by the American Midwifery Certification Board (or its predecessor organizations) or whose education and licensure meet the International Confederation of Midwives Global Standards for Midwifery Education. The College does not support provision of care by midwives who do not meet these standards."[11]

In the case of a home birth, as advocates for children, the AAP recommends that provisions for the potential resuscitation of a depressed newborn infant and immediate neonatal care be optimized in the home setting. Thus, each delivery should be attended by 2 care providers, at least 1 of whom has the primary responsibility for the newborn and has the appropriate training, skills, and equipment to perform a full resuscitation of the infant in accordance with the principles of the Neonatal Resuscitation Program.[12,14]

Regardless of the circumstances of his or her birth, including location, every newborn infant deserves health care that adheres to the guidelines highlighted in this statement and more completely described in other AAP publications.[15–17] Continuing efforts by all health care clinicians and institutions should promote communications and understanding on the basis of professional interaction and mutual respect.

POLICY STATEMENT Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

American Academy of Pediatrics

DEDICATED TO THE HEALTH OF ALL CHILDREN®

Recommendations for Prevention and Control of Influenza in Children, 2020–2021

Committee on Infectious Diseases

This statement updates the recommendations of the American Academy of Pediatrics for the routine use of influenza vaccine and antiviral medications in the prevention and treatment of influenza in children during the 2020–2021 season.

The American Academy of Pediatrics (AAP) recommends routine influenza immunization of all children without medical contraindications, starting at 6 months of age. Influenza vaccination is an important intervention to protect vulnerable populations and reduce the burden of respiratory illnesses during the severe acute respiratory syndrome-coronavirus 2 (SARS-CoV-2) pandemic. Any licensed, recommended, age-appropriate vaccine available can be administered, without preference for one product or formulation over another. Antiviral treatment of influenza with any licensed, recommended, age-appropriate influenza antiviral medication is recommended for children with suspected or confirmed influenza who are hospitalized, have severe or progressive disease, or have underlying conditions that increase their risk of complications of influenza. Antiviral treatment may be considered for any previously healthy, symptomatic outpatient not at high risk for influenza complications in whom an influenza diagnosis is confirmed or suspected, if treatment can be initiated within 48 hours of illness onset, and for children whose siblings or household contacts either are younger than 6 months or have a high-risk condition that predisposes them to complications of influenza.

UPDATES FOR THE 2020–2021 INFLUENZA SEASON

1. The composition of the influenza vaccines for 2020–2021 has been updated. The recommended influenza A(H1N1)pdm09 and A(H3N2) components and the influenza B/Victoria component of the vaccine are new for this season. The B/Yamagata component is unchanged from the previous season. All quadrivalent influenza vaccines include these 4 components. The trivalent vaccines do not include influenza B/Yamagata.

2. All pediatric vaccines are quadrivalent. There are no trivalent vaccines available for children.
3. The vaccine formulations available for children 6 through 35 months of age have been updated. Afluria Quadrivalent will be the only vaccine for children 6 through 35 months of age with a dosing volume of 0.25 mL. Fluzone Quadrivalent, which is licensed in a 0.25-mL and a 0.5-mL dosing volume, will likely be available only in a 0.5-mL dosing volume for this age group this season. The dosing volume for the 2 other vaccines available for this age group, Fluarix and FluLaval, is 0.5 mL. The AAP has no preference for one product over another.
4. Children 6 months through 8 years of age who are receiving influenza vaccine for the first time, who have received only 1 dose ever before July 1, 2020, or whose vaccination status is unknown should be offered vaccination as soon as influenza vaccines become available and should receive 2 doses of vaccine, ideally by the end of October. Children needing only 1 dose of influenza vaccine, regardless of age, should also receive vaccination ideally by the end of October.
5. The contraindications for live attenuated influenza vaccine (LAIV) have been updated to harmonize with recommendations of the Advisory Committee on Immunization Practices (ACIP). Although there are no reports of additional safety risks for LAIV in children with immunodeficiencies, anatomic or functional asplenia, cochlear implants, or active cerebrospinal fluid leaks, because the vaccine is a live attenuated product, it is not recommended in these populations.
6. The importance of influenza vaccination during the SARS-CoV-2 pandemic is discussed.

INTRODUCTION

Children consistently have the highest attack rates of influenza in the community during seasonal influenza epidemics. They play a pivotal role in the transmission of influenza virus infection to household and other close contacts and can experience substantial morbidity, including severe or fatal complications from influenza infection.[1] Children younger than 5 years, especially those younger than 2 years, and children with certain underlying medical conditions are at increased risk of hospitalization and complications attributable to influenza.[1] School-aged children bear a large influenza disease burden and are more likely to seek influenza-related medical care compared with healthy adults.[1,2] Reducing influenza virus transmission among children decreases the burden of childhood influenza and transmission of influenza virus to household contacts and community members of all ages.[1,2] Influenza vaccination is particularly important during the severe acute respiratory syndrome-coronavirus 2 (SARS-CoV-2) pandemic to reduce the burden of respiratory illnesses and hospitalizations and preserve the capacity of the health care infrastructure. The American Academy of Pediatrics (AAP) recommends routine influenza vaccination and antiviral agents for the prevention and treatment of influenza in children, respectively.

SUMMARY OF RECENT INFLUENZA SEASONS IN THE UNITED STATES

2017–2018 and 2018–2019 Influenza Seasons

The 2017–2018 influenza season had an important impact in pediatric patients. It was the first classified as a high-severity season for all age groups, with high levels of outpatient clinic and emergency department visits for influenza-like illness, high rates of influenza-related hospitalization, and high mortality.[3–5] Influenza A (H3N2) predominated early, followed by a second wave of influenza B/Yamagata from March 2018 onward. Although hospitalization rates for children that season did not exceed those reported during the 2009 pandemic, they did surpass rates reported in previous high-severity A(H3N2)-predominant seasons. Excluding the 2009 pandemic, the 188 pediatric deaths reported during the 2017–2018 season (approximately half of which occurred in otherwise healthy children) were the highest reported since influenza-associated pediatric mortality became a nationally notifiable condition in 2004.[3–5] Among pediatric deaths of children 6 months and older who were eligible for vaccination and for whom vaccination status was known, approximately 80% had not received influenza vaccine during the 2017–2018 season.[3] Influenza vaccine effectiveness (VE) for the 2017–2018 season in children is shown in Table 1.[4]

The 2018–2019 season was of moderate severity, with similar hospitalization rates in children as during the 2017–2018 season (71/100 000 among children 0 through 4 years old and 20.4/100 000 among children 5 through 17 years old), which were higher than those observed in previous seasons from 2013–2014 to 2016–2017.[7] Among 1132 children hospitalized with influenza and for whom data were available, 55% had at least 1 underlying medical condition; the most commonly reported underlying conditions were asthma or reactive airway disease (26%), neurologic disorders (15.6%), and obesity (11.6%).[8] A total of 144 influenza-associated pediatric deaths were reported. The 2017–2018 influenza season was the longest-lasting season reported in the United States in the past decade, with elevated levels of

TABLE 1 Adjusted Vaccine Effectiveness (VE) in Children in the United States, by Season, as Reported by the Centers for Disease Control and Prevention (CDC), US Influenza Vaccine Effectiveness Network

Influenza Type/Age Group	2017–2018	2018–2019	2019–2020[a]
	H3N2 and B/Yamagata VE% (95% CI)	H1N1 and H3N2 VE% (95% CI)	B/Victoria and H1N1 VE% (95% CI)
Influenza A and B			
Overall all ages	38 (31 to 43)	29 (21 to 35)	45 (36 to 53)

Overall all ages	48 (39 to 55)	Not reported	NA
6 mo–17 y	Not reported	Not reported	NA
6 mo–8 y	77 (49 to 90)	Not reported	NA
9–17 y	28 (1 to 48)	Not reported	NA

Vaccine effectiveness is estimated as 100% × (1 − odds ratio [ratio of odds of being vaccinated among outpatients with CDC's real-time RT-PCR influenza-positive test results to the odds of being vaccinated among outpatients with influenza-negative test results]); odds ratios were estimated using logistic regression. Adjusted for study site, age group, sex, race/ethnicity, self-rated general health, number of days from illness onset to enrollment, and month of illness using logistic regression.

[a] Interim results as of February 21, 2020.[6]

influenza-like illness activity for a total duration of 21 consecutive weeks (compared with an average duration of 16 weeks).[7] Variations in circulating strains affected vaccine efficacy. Influenza A(H1N1)pdm09 viruses predominated from October to mid-February, and influenza A(H3N2) viruses were identified more frequently from February to May. Influenza B (B/Victoria lineage predominant) represented approximately 5% of circulating strains. Most characterized influenza A(H3N2) viruses were antigenically distinct from the A(H3N2) component of the 2018–2019 vaccine. The vaccine's A(H3N2) virus belonged to subclade 3C.2a1. Cocirculation of multiple genetically diverse subclades of A(H3N2) was documented. Circulating viruses identified belonged to subclade 3C.2a1 or clade 3C.3a, with 3C.3a viruses accounting for >70% of the A(H3N2) in the United States. This likely contributed to an overall lower vaccine effectiveness (VE) against influenza A(H3N2) this season, despite achieving the highest vaccination coverage reported in the last decade in children (62.6% overall) (Table 1 and Fig 1).[7,9]

2019–2020 Influenza Season

The 2019–2020 influenza season was unusual and complicated by the emergence of the SARS-CoV-2 pandemic in early 2020. Influenza activity began early in October 2019, continuing through mid-March 2020, with an abrupt decline after the implementation of social distancing measures for mitigation of the pandemic. Although influenza B/Victoria viruses predominated early in the season, influenza A(H1N1)pdm09 viruses were the most predominant circulating strain this season. Influenza A(H3N2) and B/Yamagata lineage represented approximately 4.1% and 0.8% of circulating strains, respectively. The majority of characterized influenza A(H1N1)pdm09 (82.5%) and influenza B/Victoria (59.7%) viruses were antigenically similar to the viruses included in the 2019–2020 influenza vaccine. Less than half (46.5%) of influenza A(H3N2) viruses were antigenically similar to the A(H3N2) component of the 2019–2020 vaccine. During this season, the predominant A(H3N2) circulating clade was 3C.2a, subclade 3C.2a1, with cocirculation of a small proportion of 3C.3a, in contrast to the 2018–2019 season, when 3C.3a strains predominated. Preliminary estimates of the effectiveness of the 2019–2020 seasonal influenza vaccines against medically attended influenza illness from the US Flu VE Network are shown in Table 1.[6] These are preliminary data and are not vaccine specific. Susceptibility to available antiviral agents remains greater than 99% for all circulating strains, but 0.5% of A(H1N1)pdm09 isolates tested by the Centers for Disease Control and Prevention (CDC) exhibited highly reduced inhibition to oseltamivir and peramivir. Reduced susceptibility to baloxavir has not been reported in the United States to date.

The 2019–2020 season was of moderate severity, although 3 peaks of influenza-like illness activity and the highest hospitalization rates in children, 68.2 per 100 000 population overall, were reported this season. The first peak of activity occurred in early January, likely associated with influenza B circulation; the second peak occurred in February, when

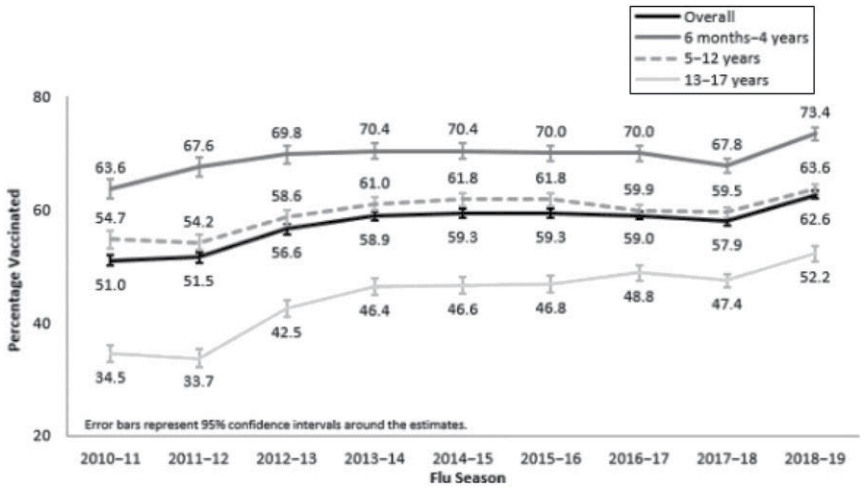

FIGURE 1
Influenza vaccination coverage in children 6 months to 17 years of age in the United States, 2010 to 2019. Source: Centers for Disease Control and Prevention (https://www.cdc.gov/flu/fluvaxview/coverage-1819estimates.htm).

influenza A(H1N1)pdm09 became predominant; and the third peak in March is thought to be associated with cocirculation of influenza and SARS-CoV-2. The CDC has now established a separate surveillance report for novel coronavirus disease 2019 (COVID-19)-like illness.[10] The cumulative influenza hospitalization rates per 100 000 population were 95.1 among children 0 through 4 years old, and 24.8 among children 5 through 17 years old. Hospitalization rates in children 0 to 4 years old were higher than those seen for this age group during the 2009 influenza pandemic, higher than the rate in adults 50 to 64 years old this season (91.8/100 000), and the highest on record for this age group. Among 168 children hospitalized with influenza and for whom data were available, 57.1% had no recorded underlying condition, and 42.9% had at least 1 underlying medical condition; the most commonly reported underlying conditions were asthma or reactive airway disease (19.7%), neurologic disorders (17.0%), and obesity (11.9%).

As of June 6, 2020, the following data were reported by the CDC:

- There were 182 laboratory-confirmed influenza-associated pediatric deaths. Most (63.0%) of those children died after being admitted to the hospital. The median age of the pediatric deaths was 6.1 years (range, 2 months to 17 years).
  - Seventy of the pediatric deaths were associated with influenza A viruses, and 112 were associated with influenza B viruses.
- Among the 168 children with known medical history, 42.9% of deaths occurred in children who had at least 1 underlying medical condition recognized by the Advisory Committee on Immunization Practices (ACIP) to increase the risk of influenza-attributable disease severity. Therefore, most (57.1%) had no known underlying medical conditions.
- The majority of the deaths occurred in children between 2 through 12 years of age: 37.4% were 5- through 11-year-olds, 20.9% were 2- through 4-year-olds, 20.3% were 12- through 17-year-olds, 15.9% were 6- through 23-month-olds, and 5.5% were younger than 6 months.
- Among 63 children who died and were tested, 46.0% had a bacterial coinfection.
- Among 141 children who were 6 months or older at the time of illness onset, and therefore, would have been eligible for influenza vaccination and for whom vaccination status was known, most (74%) were unvaccinated. Only 37 (26%) had received at least 1 dose of influenza vaccine (30 had complete vaccination, and 7 had received 1 of 2 ACIP-recommended doses).

INFLUENZA MORBIDITY AND MORTALITY IN CHILDREN

Influenza viruses are a common cause of acute lower respiratory tract infection (ALRTI) in children. Pediatric hospitalizations and deaths caused by influenza can be substantial. A recent study estimated that globally, influenza virus accounts for 7% of all ALRTIs, 5% of ALRTI hospitalizations, and 4% of ALRTI deaths in children younger than 5 years.[11] In the United States, the rates of influenza-associated hospitalization for children younger than 5 years consistently exceed the rates for children 5 through 17 years of age, and during the 2019–2020 season, they exceeded the hospitalization rates of adults 50 to 64 years of age.[8] Children 5 through 17 years of age also experienced higher than usual hospitalization rates during the 2019–2020 season. The impact of the anticipated SARS-CoV-2 cocirculation with influenza in the 2020–2021 season is unknown at this time. Elevated rates of influenza-like illness hospitalization and mortality were observed toward the end of the 2019–2020 season, suggesting the possibility of comorbidity. It is, therefore, particularly important that children are protected against influenza

through timely vaccination in the 2020–2021 influenza season.

HIGH-RISK GROUPS IN PEDIATRICS

Children and adolescents with certain underlying medical conditions have a high risk of complications from influenza (Table 2). While universal influenza vaccination is recommended for everyone starting at 6 months of age, emphasis should be placed in ensuring that people in high-risk groups and their household contacts and caregivers receive annual influenza vaccine.

EFFECTIVENESS OF INFLUENZA VACCINATION ON HOSPITALIZATION AND MORTALITY

Several studies demonstrate that influenza vaccination can effectively decrease hospitalization in children where universal pediatric immunization has been implemented. In a study during the 2015–2016 season conducted by the United States New Vaccine Surveillance Network (NVSN), among 1653 children enrolled from 7 pediatric hospitals, the adjusted VE in children with complete influenza immunization against any influenza-associated hospitalization was 56% (95% confidence interval [CI], 34% to 71%), against A(H1N1)pdm09 was 68% (95% CI, 36% to 84%), and against B viruses was 44% (95% CI, –1% to 69%).[17] A study in children 6 months to 8 years of age conducted in Israel over 3 influenza seasons from 2015 to 2017 demonstrated that over all seasons, fully vaccinated children had a VE against hospitalization of 53.9% (95% CI, 38.6% to 68.3%), while partial vaccination was not effective (25.6%; 95% CI, –3% to 47%).[18] In this study, a VE against hospitalization as high as 60% to 80% was observed when circulating and vaccine influenza A and B strains matched. After establishing free vaccination for preschool children and children at risk because of comorbid medical conditions in Australia in 2018, VE of influenza vaccine in preventing influenza hospitalization was estimated to be 78.8% (95% CI, 66.9% to 86.4%).[19] In the United Kingdom, during the 2018–2019 season, the overall adjusted VE against influenza-confirmed hospitalization was reported to be 53% (95% CI, 33.3% to 66.8%), with protection varying by strain. Protection was 63.5% (95% CI, 34.4% to 79.7%) against influenza A(H1N1)pdm09, but there was no protection against influenza A(H3N2).[20] Finally, a systematic review and meta-analysis of 28 studies conducted by Kalligeros et al[21] concluded that influenza vaccine offered significant protection against any type of influenza-related hospitalization in children 6 months through 17 years of age, with VE of 57.5% (95% CI, 54.8% to 65.5%). Strain-specific VE was higher for influenza A(H1N1)pdm09 (75.1%; 95% CI, 54.8% to 93.3%) and influenza B (50.9%; 95% CI, 41.7% to 59.9%), compared with influenza A(H3N2) (40.8%; 95% CI, 25.6% to 55.9%). As expected, children who were fully vaccinated were better protected (VE 61.8%; 95% CI, 54.4% to 69.1%) compared with those who were partially vaccinated (VE 33.91%; 95% CI, 21.1% to 46.7%). Notably, VE was higher in children younger than 5 years of age (61.7%; 95% CI, 49.3% to 74.1%) than in children 6 to 17 years old (54.4%; 95% CI, 35.1% to 73.6%). In the United States, the CDC estimates that during the 2018–2019 season, influenza vaccination prevented 20% of projected hospitalizations associated with infection with A(H1N1)pdm09 virus among children 5 through 17 years, and 43% among children 6 months through 4 years.[22]

Historically, up to 80% of influenza-associated pediatric deaths have occurred in unvaccinated children 6 months and older. Influenza vaccination is associated with

TABLE 2 People at High Risk of Influenza Complications

Children <5 y, and especially those <2 y,[a] regardless of the presence of underlying medical conditions
Adults ≥50 y, and especially those ≥65 y
Children and adults with chronic pulmonary (including asthma and cystic fibrosis); hemodynamically significant cardiovascular disease (except hypertension alone); or renal, hepatic, hematologic (including sickle cell disease and other hemoglobinopathies), or metabolic disorders (including diabetes mellitus)
Children and adults with immunosuppression attributable to any cause, including that caused by medications or by HIV infection
Children and adults with neurologic and neurodevelopment conditions (including disorders of the brain, spinal cord, peripheral nerve, and muscle such as cerebral palsy, epilepsy, stroke, intellectual disability, moderate to severe developmental delay, muscular dystrophy, or spinal cord injury)
Children and adults with conditions that compromise respiratory function or handling of secretions (including tracheostomy and mechanical ventilation)[12]
Women who are pregnant or postpartum during the influenza season
Children and adolescents <19 y who are receiving long-term aspirin therapy or salicylate-containing medications (including those with Kawasaki disease and rheumatologic conditions) because of increased risk of Reye syndrome
American Indian/Alaska Native people[b]
Children and adults with extreme obesity (ie, BMI [BMI] ≥40 for adults, and based on age for children)
Residents of chronic care facilities and nursing homes

Source: Adapted from Centers for Disease Control and Prevention. Prevention and control of seasonal influenza with vaccines: recommendations of the Advisory Committee on Immunization Practices—United States, 2020–21 influenza season. *MMWR Recomm Rep.* 2020; in press.

[a] The 2019–2020 CDC recommendations state: Although all children younger than 5 years old are considered at higher risk for complications from influenza, the highest risk is for those younger than 2 years old, with the highest hospitalization and death rates among infants younger than 6 months old.

[b] American Indian/Alaska Native (AI/AN) children have higher rate of influenza complications.[13–16] Most at-risk AI/AN children will also qualify in other high-risk categories to receive appropriate antiviral treatment. In the setting of a shortage, AI/AN children should be prioritized to receive influenza vaccine or anti-viral medications according to local public health guidelines.

reduced risk of laboratory-confirmed influenza-related pediatric death.[23] In one case-cohort analysis comparing vaccination uptake among laboratory-confirmed influenza-associated pediatric deaths with estimated vaccination coverage among pediatric cohorts in the United States from 2010 to 2014, Flannery et al[23] found that only 26% of children had received vaccine before illness onset, compared with an average vaccination coverage of 48%. Overall VE against influenza-associated death in children was 65% (95% CI, 54% to 74%). More than half of children in this study who died of influenza had ≥1 underlying medical condition associated with increased risk of severe influenza-related complications; only 1 in 3 of these at-risk children had been vaccinated; yet, VE against death in children with underlying conditions was 51% (95% CI, 31% to 67%). Similarly, influenza vaccination reduces by three quarters the risk of severe, life-threatening laboratory-confirmed influenza in children requiring admission to the ICU.[24] The influenza virus type might also affect the severity of disease. In a study of hospitalizations for influenza A versus B, the odds of mortality were significantly greater with influenza B than with influenza A and not entirely explained by underlying health conditions.[25]

SEASONAL INFLUENZA VACCINES

The seasonal influenza vaccines licensed for children and adults for the 2020–2021 season are shown in Table 3. More than one product may be appropriate for a given patient, and vaccination should not be delayed to obtain a specific product.

All 2020–2021 seasonal influenza vaccines contain the same influenza strains as recommended by the World Health Organization (WHO) and the US Food and Drug Administration (FDA)'s Vaccines and Related Biological Products Advisory Committee (VRBPAC) for the Northern Hemisphere.[26] Both influenza A(H1N1) and A(H3N2) and the B/Victoria components are different in this season's vaccine. The B/Yamagata component is unchanged. The influenza A strains are different for egg-based versus cell- or recombinant-based vaccines this year on the basis of their optimal characteristics for each platform, but all are matched to the strains expected to circulate in the 2020–2021 season.

1. Quadrivalent vaccines contain:
   a. Influenza A(H1N1) component:
      i. Egg-based vaccines: A/Guangdong-Maonan/SWL1536/2019 (H1N1) pdm09-like virus (new this season)
      ii. Cell- or recombinant-based vaccines: A/Hawaii/70/2019 (H1N1) pdm09-like virus (new this season)
   b. Influenza A(H3N2) component:
      i. Egg-based vaccines: A/Hong Kong/2671/2019 (H3N2)-like virus (new this season)
      ii. Cell- or recombinant-based vaccines: A/Hong Kong/45/2019 (H3N2)-like virus (new this season)
   c. B/Victoria component:
      i. All vaccines: B/Washington/02/2019-like virus (B/Victoria/2/87 lineage) (new this season)
   d. B/Yamagata component:
      i. All vaccines: B/Phuket/3073/2013-like virus (B/Yamagata/16/88 lineage) (unchanged).
2. Trivalent vaccines do not include the B/Yamagata component.

Inactivated Influenza Vaccine

For the 2020–2021 season, all licensed inactivated influenza vaccines (IIVs) for children in the United States are quadrivalent unadjuvanted vaccines, with specific age indications for available formulations (Table 3). Four are egg-based (seed strains grown in eggs), and one is cell culture-based (seed strains grown in Madin-Darby canine kidney cells). All inactivated egg-based vaccines (Afluria Quadrivalent, Fluarix Quadrivalent, Flulaval Quadrivalent, and Fluzone Quadrivalent) are licensed for children 6 months and older and available in single-dose, thimerosal-free, prefilled syringes. The only pediatric cell culture-based vaccine (Flucelvax Quadrivalent) is licensed for children 4 years and older.[1]

A quadrivalent recombinant baculovirus-expressed hemagglutinin influenza vaccine (RIV4, Flublok Quadrivalent) is licensed only for people 18 years and older. A new quadrivalent high-dose inactivated influenza vaccine (HD-IIV4, Fluzone High Dose Quadrivalent) containing 4 times the amount of antigen for each virus strain than the standard dose vaccines, is licensed only for people 65 years and older. A trivalent high-dose formulation is no longer available. Both trivalent and quadrivalent MF-59 adjuvanted inactivated vaccines (aIIV3 Fluad and aIIV4 Fluad Quadrivalent) are now licensed for people 65 years and older. The quadrivalent formulation is new this year (licensed in February 2020).[1] Adjuvants may be included in a vaccine to elicit a more robust immune response, which could lead to a reduction in the number of doses required for children. In one pediatric study, the relative vaccine efficacy of a MF-59 adjuvanted influenza vaccine was significantly greater than nonadjuvanted vaccine in the 6- through 23-month age group.[27] Adjuvanted seasonal influenza vaccines are not licensed for children in the United States.

Children 36 months (3 years) and older can receive any age-appropriate licensed IIV, administered at a 0.5-mL dose containing 15 μg of hemagglutinin (HA) from each strain. Children 6

TABLE 3 Recommended Seasonal Influenza Vaccines for Different Age Groups: United States, 2020–2021 Influenza Season

Vaccine	Trade Name (Manufacturer)	Age Group	Presentation Hemagglutinin Antigen Content (IIVs and RIV4) or Virus Count (LAIV4) per dose for Each Antigen	Thimerosal Mercury Content (μg Hg/0.5-mL dose)	CPT Code
Quadrivalent standard dose – egg-based vaccines					
IIV4	Afluria Quadrivalent (Seqirus)	6–35 mo	0.25-mL prefilled syringe[a] (7.5 μg/0.25 mL)	0	
		≥36 mo	0.5-mL prefilled syringe (15 μg/0.5 mL)	0	90686
		≥6 mo	5.0-mL multidose vial[b] (15 μg/0.5 mL)	24.5	90688
IIV4	Fluarix Quadrivalent (GlaxoSmithKline)	≥6 mo	0.5-mL prefilled syringe (15 μg/0.5 mL)	0	90686
IIV4	FluLaval Quadrivalent (GlaxoSmithKline)	≥6 mo	0.5-mL prefilled syringe (15 μg/0.5 mL)	0	90686 90688
IIV4	Fluzone Quadrivalent (Sanofi Pasteur)	≥6 mo	0.5-mL prefilled syringe (15 μg/0.5 mL)[c]	0	90686
		≥6 mo	0.5-mL single-dose vial (15 μg/0.5 mL)	0	90687
		≥6 mo	5.0-mL multidose vial[b] (15 μg/0.5 mL)	25	90688
Quadrivalent standard dose – cell-based vaccines					
ccIIV4	Flucelvax Quadrivalent (Seqirus)	≥4 y	0.5-mL prefilled syringe (15 μg/0.5 mL)	0	90674
		≥4 y	5.0 mL multidose vial (15 μg/0.5 mL)	25	90756
Standard dose – egg-based with adjuvant vaccines					
aIIV3 MF-59 adjuvanted	Fluad Trivalent Seqirus	≥65 y	0.5-mL prefilled syringe (15 μg/0.5 mL)	0	90653
aIIV4 MF-59 adjuvanted	Fluad Quadrivalent Seqirus	≥65 y	0.5-mL prefilled syringe (15 μg/0.5 mL)	0	90653
Quadrivalent high dose – egg-based vaccine					
IIV4	Fluzone High-dose (Sanofi Pasteur)	≥65 y	0.7-mL prefilled syringe (60 μg/0.7 mL)	0	90662
Recombinant vaccine					
RIV4	Flublok Quadrivalent (Sanofi Pasteur)	≥18 y	0.5-mL prefilled syringe (45 μg/0.5 mL)	0	90682
Live attenuated vaccine					
LAIV4	FluMist Quadrivalent (MedImmune)	2–49 y	0.2-mL prefilled intranasal sprayer (Virus dose: 10 6.5–7.5 FFU/0.2 mL)	0	90672

Data sources: Centers for Disease Control and Prevention. Prevention and control of seasonal influenza with vaccines: recommendations of the Advisory Committee on Immunization Practices (ACIP)—United States, 2020–2021 influenza season. *MMWR Recomm Rep.* 2020; in press. Implementation guidance on supply, pricing, payment, CPT coding, and liability issues can be found at www.aapredbook.org/implementation. (Table has been reformatted and updated).

[a] For Afluria Quadrivalent, children 6 through 35 months of age should receive 0.25 mL per dose; people ≥36 months (≥3 years) of age should receive 0.5 mL per dose.

[b] For vaccines that include a multidose vial presentation a maximum of 10 doses can be drawn from a multidose vial.

[c] The 7.5-μg/0.25-mL dosing volume is no longer available this season.

through 35 months of age may receive any age-appropriate licensed IIV without preference for one over another. Several vaccines have been licensed for children 6 through 35 months of age since 2017 (Table 3). All are quadrivalent, but the dose volume and, therefore, the antigen content vary among different IIV products. In addition to a 0.25-mL (7.5 μg of HA per vaccine virus) Fluzone Quadrivalent vaccine, a 0.5-mL formulation of Fluzone Quadrivalent containing 15 μg of HA per vaccine virus per dose was licensed in January 2019 after these 2 formulations were shown to have comparable safety and immunogenicity in a single randomized, multicenter study.[28–30] Only the 0.5-mL Fluzone product is expected to be available this season. In addition, 2 other vaccines, Fluarix Quadrivalent[31] and FluLaval Quadrivalent,[32] are licensed for a 0.5-mL dose in children 6 through 35 months of age. These 2 vaccines do not have a 0.25-mL dose formulation. Afluria Quadrivalent is the only pediatric vaccine that has a 0.25-mL (7.5 μg of HA per vaccine virus) presentation for children 6 through 35 months of age. Afluria Quadrivalent 0.5 mL (15 μg of HA per vaccine virus) is licensed for children 3 years and older only.[33] Given that different formulations of IIV for children 6 through 35 months of age are available, care should be taken to administer the appropriate volume and dose for each product. In each instance, the recommended volume may be administered from an appropriate prefilled syringe, a single-dose vial, or multidose vial, as supplied by the manufacturer. For vaccines that include a multidose vial presentation, a maximum of 10 doses can be drawn from a multidose vial. Importantly, dose volume is different from the number of doses needed to complete vaccination. Children 6 months through 8 years of age who require 2 doses of vaccine for the

2020–2021 season should receive 2 separate doses at the recommended dose volume specified for each product.

Inactivated influenza vaccines are well tolerated in children and can be used in healthy children as well as those with underlying chronic medical conditions. The most common injection site adverse reactions following administration of IIV in children are injection site pain, redness, and swelling. The most common systemic adverse events are drowsiness, irritability, loss of appetite, fatigue, muscle aches, headache, arthralgia, and gastrointestinal tract symptoms.

IIV can be administered concomitantly with other inactivated or live vaccines. During the 2 influenza seasons spanning 2010–2012, there were increased reports of febrile seizures in the United States in young children who received trivalent IIV (IIV3) and the 13-valent pneumococcal conjugate vaccine (PCV13) concomitantly. Subsequent retrospective analyses of past seasons demonstrated a slight increase in the risk of febrile seizures in children 6 through 23 months of age when PCV13 vaccines were administered concomitantly with IIV.[34] The concomitant administration of IIV3, PCV13, and diphtheria and tetanus toxoids and acellular pertussis vaccine (DTaP) was associated with the greatest relative risk estimate, corresponding to a maximum additional 30 febrile seizure cases per 100 000 children vaccinated, compared with the administration of the vaccines on separate days. In contrast, data from the Post-Licensure Rapid Immunization Safety Monitoring (PRISM) program of the FDA, revealed that there was no significant increase in febrile seizures associated with concomitant administration of these 3 vaccines in children 6 through 59 months of age during the 2010–2011 influenza season.[35] Similarly, in a subsequent sentinel CBER/PRISM surveillance report evaluating influenza vaccines and febrile seizures, there was no evidence of an elevated risk of febrile seizures in children 6 through 23 months of age following IIV administration during the 2013–2014 and 2014–2015 seasons, noting that the risk of seizures after PCV13 or concomitant PCV13 and IIV was low compared with a child's lifetime risk of febrile seizures from other causes.[36] Using a self-controlled interval study design, Baker et al[37] further evaluated the relative risk of febrile seizures following IIV or PCV13 in children 6 through 23 months, using the PRISM health care claims during those same 2 influenza seasons. When the febrile seizure rate was compared in a risk interval (0–1 days post vaccination) versus a control interval (14–20 days after vaccination), adjusting by age, calendar time, and concomitant administration of the other vaccine, an elevated risk of febrile seizures was identified after vaccination with PCV13 (incidence rate ratio [IRR], 1.80; 95% CI, 1.29 to 2.52), but not after IIV (IRR, 1.12; 95% CI, 0.80 to 1.56). Furthermore, in a study of children 12 to 16 months of age vaccinated during the 2017–2018 season, no difference was observed in the occurrence of fever when IIV administration was delayed for 2 weeks after PCV13 and DTaP vaccination (9.3%) compared with PCV13, DTaP and IIV given on the same day (8.1%) (adjusted risk ratio [aRR], 0.87; 95% CI, 0.36 to 2.19).[38] On the basis of these findings, simultaneous administration of IIV with PCV13 and/or other vaccines continues to be recommended for the 2020–2021 influenza season when these vaccines are indicated. Overall, the benefits of timely vaccination with same-day administration of IIV and PCV13 or DTaP outweigh the risk of febrile seizures. Vaccine-proximate febrile seizures rarely have any long-term sequelae, similar to nonvaccine–proximate febrile seizures.

Thimerosal-containing vaccines are not associated with an increased risk of autism spectrum disorder in children. Thimerosal from vaccines has not been linked to any neurologic condition. The American Academy of Pediatrics (AAP) supports the current WHO recommendations for use of thimerosal as a preservative in multiuse vials in the global vaccine supply.[39] Despite the lack of evidence of harm, some states have legislation restricting the use of vaccines that contain even trace amounts of thimerosal. The benefits of protecting children against the known risks of influenza are clear. Therefore, to the extent permitted by state law, children should receive any available formulation of IIV rather than delaying vaccination while waiting for reduced thimerosal-content or thimerosal-free vaccines. IIV formulations that are free of even trace amounts of thimerosal are widely available (Table 3).

Live Attenuated (Intranasal) Influenza Vaccine

The intranasal live attenuated influenza vaccine (LAIV) was initially licensed in the United States in 2003 for people 5 through 49 years of age as a trivalent formulation (LAIV3), and the approved age group was extended to 2 years of age in 2007. The quadrivalent formulation (LAIV4) licensed in 2012 was first available during the 2013–2014 influenza season, replacing LAIV3. The most commonly reported reactions of LAIV in children are runny nose or nasal congestion, headache, decreased activity or lethargy, and sore throat.

The CDC conducted a systematic review of published studies evaluating the effectiveness of LAIV3 and LAIV4 in children from the 2010–2011 to the 2016–2017 influenza seasons, including data from United States and European studies.[40] The data suggested that the

effectiveness of LAIV3 or LAIV4 for influenza A(H1N1)pdm09 strain was lower than that of IIV in children 2 through 17 years of age. LAIV was similarly effective against influenza B and A/H3N2 strains in some age groups compared with IIV. LAIV was not recommended by the CDC or AAP for use in children during the 2016–2017 and 2017–2018 seasons, given concerns about its effectiveness against A(H1N1)pdm09. For the 2017–2018 season, a new A(H1N1) pdm09-like virus strain (A/Slovenia/2903/2015) was included in LAIV4, replacing the prior A/Bolivia/559/2013 strain. A study conducted by the LAIV4 manufacturer evaluated viral shedding and immunogenicity associated with the LAIV4 formulation containing the new A(H1N1) pdm09-like virus among US children 24 to 48 months of age.[41] Shedding and immunogenicity data suggested that the new influenza A(H1N1)pdm09-like virus included in its latest formulation had improved replicative fitness over previous LAIV4 influenza A(H1N1)pdm09-like vaccine strains, resulting in an improved immune response, comparable with that of the LAIV3 available prior to the 2009 pandemic. Shedding and replicative fitness are not known to correlate with efficacy, and no published effectiveness estimates for this revised formulation of the vaccine against influenza A(/H1N1)pdm09 viruses were available prior to the start of the 2018–2019 influenza season, because influenza A(/H3N2) and influenza B viruses predominated during the 2017–2018 Northern Hemisphere season. Therefore, for the 2018–2019 influenza season, the AAP recommended IIV4 or IIV3 as the primary choice for influenza vaccination in children, with LAIV4 use reserved for children who would not otherwise receive an influenza vaccine and for whom LAIV utilization was appropriate for age (2 years and older) and health status (ie, healthy, without any underlying chronic medical condition).

In February 2019, the AAP Committee of Infectious Diseases (COID) reviewed available data on influenza epidemiology and vaccine effectiveness for the 2018–2019 season and agreed that harmonizing recommendations between the AAP and CDC for the use of LAIV in the 2019–2020 season was appropriate. After the February 2020 ACIP meeting, the AAP COID reviewed available epidemiologic and effectiveness data for the previous and current seasons to inform recommendations for the 2020–2021 season. Despite the early circulation of A(H1N1)pdm09 during the 2018–2019 season and its predominance during the 2019–2020 season, low utilization of LAIV4 in the United States population has limited the evaluation of product-specific vaccine effectiveness, and no additional US data on LAIV4 VE are available. Although the proportion of LAIV used for vaccination is unknown, interim overall VE (not specific to a type of vaccine) for the 2019–2020 influenza season shows reassuring protection in children against circulating influenza A and B strains (Table 1).[6] Furthermore, influenza vaccine coverage rates in children are stable.[9] In European surveillance networks where uninterrupted utilization of LAIV has continued from the 2016–2017 through the 2019–2020 seasons, the only country with LAIV VE estimates, the United Kingdom, reported final VE against medically attended influenza for the 2018–2019 season in children 2 through 17 years of age of 49.9% (95% CI, –14.3% to 78.0%) for A(H1N1)pdm09 and of 27.1% (95% CI, –130.5% to 77%) for A(H3N2).[42] The final adjusted VE in the United States (where mostly IIV was used) for 2018–2019 against A(H1N1)pdm09 was 59% (95% CI, 47% to 69%) for children 6 months through 8 years of age but only 24% (95% CI, –18% to 51%) for children 9 through 17 years and for A(H3N2) 24% (95% CI, 1% to 42%) in children 6 months through 8 years of age, and 3% (95% CI, –30% to 28%) in children 9 through 17 years of age.[43] Direct comparisons cannot be made given differences in reporting of VE for various age groups. Other countries that use LAIV (Canada, Finland) have not reported LAIV4-specific VE in past several seasons. Small case numbers and low LAIV use may also limit accurate VE calculations in these countries. In general, as long as use of LAIV is low relative to IIV, it will be difficult to estimate LAIV VE accurately. Furthermore, important variability in VE against all strains is reported for both IIV and LAIV.

Influenza VE varies from season to season and is affected by many factors, including age and health status of the recipient, influenza type and subtype, existing immunity from previous infection or vaccination, and degree of antigenic match between vaccine and circulating virus strains. It is possible that VE also differs among individual vaccine products; however, product-specific comparative effectiveness data are lacking for most vaccines. Additional experience over multiple influenza seasons will help to determine optimal utilization of the available vaccine formulations in children. The AAP will continue to monitor annual influenza surveillance and VE reports to update influenza vaccine recommendations if necessary.

CONTRAINDICATIONS AND PRECAUTIONS

Anaphylactic reactions to any vaccine are considered a contraindication to vaccination. The AAP recommends that children who have had an allergic reaction after a previous dose of any influenza vaccine should be evaluated by an allergist to determine whether future receipt of the vaccine is appropriate. Similarly, consultation

with an infectious disease specialist may be sought to assess potential contraindications and precautions and to determine which influenza vaccine is most appropriate to ensure immunization in special circumstances.

Minor illnesses, with or without fever, are not contraindications to the use of influenza vaccines, including among children with mild upper respiratory infection symptoms or allergic rhinitis. In children with a moderate to severe febrile illness (eg, high fever, active infection, requiring hospitalization, etc), on the basis of the judgment of the clinician, vaccination should be deferred until resolution of the illness. Children with confirmed COVID-19 can receive influenza vaccine when the acute illness has resolved. Children with an amount of nasal congestion that would notably impede vaccine delivery into the nasopharyngeal mucosa should have LAIV vaccination deferred until resolution.

A precaution for vaccination is a condition in a recipient that might increase the risk or seriousness of a possible vaccine-related adverse reaction. A precaution also may exist for conditions that might compromise the ability of the host to develop immunity after vaccination. Vaccination may be recommended in the presence of a precaution if the benefit of protection from the vaccine outweighs the potential risks.

History of Guillain-Barré syndrome (GBS) following influenza vaccine is considered a precaution for the administration of influenza vaccines. GBS is rare, especially in children, and there is a lack of evidence on risk of GBS following influenza vaccine in children. Nonetheless, regardless of age, a history of GBS less than 6 weeks after a previous dose of influenza vaccine is a precaution for administration of influenza vaccine. GBS may occur after influenza infection. The benefits of influenza vaccination might outweigh the risks for certain people who have a history of GBS (particularly if not associated with prior influenza vaccination) and who also are at high risk for severe complications from influenza.

Specific precautions for LAIV include a diagnosis of asthma in children 5 years and older and the presence of certain chronic underlying medical conditions, including metabolic disease, diabetes mellitus, other chronic disorders of the pulmonary or cardiovascular systems, renal dysfunction, or hemoglobinopathies. Although the safety of LAIV has not been definitely established in these situations, IIV can be considered. In a study comparing a large cohort of children 2 through 17 years old with asthma who received LAIV instead of IIV under established practice guidelines from 2007 to 2016, the occurrence of asthma exacerbation within 21 to 42 days of vaccination was not higher compared with children who received IIV.[44] In a prospective open-label phase IV study conducted in the United Kingdom, 478 children aged 2 to 18 years with physician-diagnosed asthma or recurrent wheezing received LAIV, with no significant change in asthma symptoms or exacerbation in the 4 weeks after vaccination.[45] However, 14.7% of patients eventually reported a severe asthma exacerbation after vaccination, requiring treatment. In post-licensure surveillance of LAIV (including LAIV3 and LAIV4), the Vaccine Adverse Event Reporting System (VAERS), jointly sponsored by the FDA and CDC, has not identified any new or unexpected safety concerns, including in people with a contraindication or precaution (https://www.cdc.gov/vaccinesafety/ensuringsafety/monitoring/vaers/).

People who should not receive LAIV are listed below.

People in Whom LAIV is Contraindicated

- Children younger than 2 years.
- Children 2 through 4 years of age with a diagnosis of asthma or history of recurrent wheezing or a medically attended wheezing episode in the previous 12 months because of the potential for increased wheezing after immunization. In this age range, many children have a history of wheezing with respiratory tract illnesses and are eventually diagnosed with asthma.
- Children with new cochlear implants or active cerebrospinal fluid leaks.
- Children who have a known or suspected primary or acquired immunodeficiency or who are receiving immunosuppressive or immunomodulatory therapies.
- Children with anatomic or functional asplenia, including from sickle cell disease.
- Close contacts and caregivers of those who are severely immunocompromised and require a protected environment.
- Children and adolescents receiving aspirin or salicylate-containing medications.
- Children who have received other live-virus vaccines within the previous 4 weeks (except for rotavirus vaccine); however, LAIV can be administered on the same day with other live-virus vaccines if necessary.
- Children taking an influenza antiviral medication and until 48 hours (oseltamivir, zanamivir) and up to 2 weeks (peramivir and baloxavir) after stopping the influenza antiviral therapy. If a child recently received LAIV but has an influenza illness for which antiviral agents are appropriate, the antiviral agents should be given. If antiviral agents are necessary for treatment within 5

to 7 days of LAIV immunization, reimmunization is indicated because of the potential effects of antiviral medications on LAIV replication and immunogenicity.

- Pregnant women.

LAIV and Immunocompromised Hosts

The inactivated influenza vaccine is the vaccine of choice for anyone in close contact with a subset of severely immunocompromised people (ie, those in a protected environment). IIV is preferred over LAIV for contacts of severely immunocompromised people because of a theoretical risk of infection attributable to LAIV strain in an immunocompromised contact of an LAIV-immunized person. Available data indicate a very low risk of transmission of the virus from both children and adults vaccinated with LAIV. Health care personnel (HCP) immunized with LAIV may continue to work in most units of a hospital, including the NICU and general oncology ward, using standard infection control techniques. As a precautionary measure, people recently vaccinated with LAIV should restrict contact with severely immunocompromised patients for 7 days after immunization, although there have been no reports of LAIV transmission from a vaccinated person to an immunocompromised person. In the theoretical scenario in which symptomatic LAIV infection develops in an immunocompromised host, LAIV strains are susceptible to antiviral medications.

INFLUENZA VACCINES AND EGG ALLERGY

There is strong evidence that egg-allergic individuals can safely receive influenza vaccine without any additional precautions beyond those recommended for any vaccine.[46,47] The presence of egg allergy in an individual is not a contraindication to receive IIV or LAIV. Vaccine recipients with egg allergy are at no greater risk for a systemic allergic reaction than those without egg allergy. Therefore, precautions such as choice of a particular vaccine, special observation periods, or restriction of administration to particular medical settings are not warranted and constitute an unnecessary barrier to immunization. It is not necessary to inquire about egg allergy before the administration of any influenza vaccine, including on screening forms. Routine prevaccination questions regarding anaphylaxis after receipt of any vaccine are appropriate. Standard vaccination practice for all vaccines in children should include the ability to respond to rare acute hypersensitivity reactions. Children who have had a previous allergic reaction to the influenza vaccine should be evaluated by an allergist to determine whether future receipt of the vaccine is appropriate.

INFLUENZA VACCINES DURING PREGNANCY AND BREASTFEEDING

Influenza vaccine is recommended by the ACIP, the American College of Obstetrics and Gynecology (ACOG), and the American Academy of Family Physicians (AAFP) for all women, during any trimester of gestation, for the protection of mothers against influenza and its complications.[1,48] Substantial evidence has accumulated regarding the efficacy of maternal influenza immunization in preventing laboratory-confirmed influenza disease and its complications in both mothers and their infants in the first 2 to 6 months of life.[48–53] Pregnant women who are immunized against influenza at any time during their pregnancy provide protection to their infants during their first 6 months of life, when they are too young to receive influenza vaccine themselves, through transplacental passage of antibodies.[50–58] Infants born to women who receive influenza vaccination during pregnancy can have a risk reduction of up to 72% (95% CI, 39% to 87%) for laboratory-confirmed influenza hospitalization in the first few months of life.[56]

It is safe to administer inactivated influenza vaccine to pregnant women during any trimester of gestation and postpartum. Any licensed, recommended, and age-appropriate influenza vaccine may be used, although experience with the use of RIV4 in pregnant women is limited. LAIV is contraindicated during pregnancy. Data on the safety of influenza vaccination at any time during pregnancy continues to support the safety of influenza immunization during pregnancy.[48,50–55,59] In a 5-year retrospective cohort study from 2003 to 2008 with more than 10 000 women, influenza vaccination in the first trimester was not associated with an increase in the rates of major congenital malformations.[60] Similarly, a systematic review and meta-analysis of studies of congenital anomalies after vaccination during pregnancy, including data from 15 studies (14 cohort studies and 1 case-control study) did not show any association between congenital defects and influenza vaccination in any trimester, including the first trimester of gestation.[61] Assessments of any association with influenza vaccination and preterm birth and small-for-gestational-age infants have yielded inconsistent results, with most studies reporting a protective effect or no association against these outcomes.[62,63] A cohort study from the Vaccines and Medications in Pregnancy Surveillance System (VAMPSS) of vaccine exposure during the 2010–2011 through 2013–2014 influenza seasons found no significant association of spontaneous abortion with influenza vaccine exposure in the first trimester or within the first 20 weeks of gestation.[64] One observational Vaccine Safety Datalink (VSD) study conducted during the 2010–2011 and 2011–2012 influenza seasons indicated an association between receipt of IIV containing

H1N1pdm09 and risk of spontaneous abortion, when an H1N1pdm-09-containing vaccine had also been received the previous season.[65] A follow-up study conducted by the same investigators with a larger population and stricter outcome measures did not show this association and further supported the safety of influenza vaccine during pregnancy.[66]

Women in the postpartum period who did not receive influenza vaccination during pregnancy should be encouraged to discuss with their obstetrician, family physician, nurse midwife, or other trusted provider receiving influenza vaccine before discharge from the hospital. Vaccination during breastfeeding is safe for mothers and their infants.

Breastfeeding is strongly recommended to protect infants against influenza viruses by activating innate antiviral mechanisms, specifically type 1 interferons. Human milk from mothers vaccinated during the third trimester also contains higher levels of influenza-specific immunoglobulin A (IgA).[67] Greater exclusivity of breastfeeding in the first 6 months of life decreases the episodes of respiratory illness with fever in infants of vaccinated mothers. For infants born to mothers with confirmed influenza illness at delivery, breastfeeding is encouraged, and guidance on breastfeeding practices can be found at https://www.cdc.gov/breastfeeding/breastfeeding-special-circumstances/maternal-or-infant-illnesses/influenza.html and https://www.cdc.gov/flu/professionals/infectioncontrol/peri-post-settings.htm. Breastfeeding should be encouraged even if the mother or infant has influenza illness. The mother should pump and feed expressed milk if she or her infant are too sick to breastfeed. If the breastfeeding mother requires antiviral agents, treatment with oral oseltamivir is preferred. The CDC does not recommend use of baloxavir for treatment of pregnant women or breastfeeding mothers. There are no available efficacy or safety data in pregnant women, and there are no available data on the presence of baloxavir in human milk, the effects on the breastfed infant, or the effects on milk production.

VACCINE STORAGE AND ADMINISTRATION

The AAP Storage and Handling Tip Sheet provides resources for practices to develop comprehensive vaccine management protocols to keep the temperature for vaccine storage constant during a power failure or other disaster (https://www.aap.org/en-us/Documents/immunization_disasterplanning.pdf). The AAP recommends the development of a written disaster plan for all practice settings. Additional information is available (www.aap.org/disasters). During the COVID-19 pandemic, the AAP recommends that influenza vaccine administration follow CDC guidance for administration of immunizations (https://www.cdc.gov/vaccines/pandemic-guidance/index.html). Vaccination in the medical home is ideal to ensure that pediatric patients receive other vaccinations and routine care in a timely manner and receive catch-up immunizations if delays have occurred because of the pandemic. In general, infection-prevention measures should be in place for all patient encounters, including screening for symptoms, physical distancing, respiratory and hand hygiene, and surface decontamination. In addition to standard precautions and hand hygiene, during the COVID-19 pandemic, it is recommended that vaccine administrators wear a surgical face mask (not N95 or respiratory) at all times and eye protection if the level of community spread is moderate or elevated. Administration of LAIV intranasally is not an aerosol-generating procedure; however, vaccine administrators are advised to wear gloves when injecting LAIV given the potential to coming in contact with respiratory secretions. Gloves used for intranasal or intramuscular vaccine administration should be changed with every patient. Gowns are not required.

Inactivated Influenza Vaccines

IIVs for intramuscular (IM) injection are shipped and stored at 2°C to 8°C (36°F–46°F); vaccines that are inadvertently frozen should not be used. These vaccines are administered intramuscularly into the anterolateral thigh of infants and young children and into the deltoid muscle of older children and adults. Given that various IIVs are available, careful attention should be used to ensure that each product is used according its approved age indication, dosing, and volume of administration (Table 3). A 0.5-mL unit dose of any IIV should not be split into 2 separate 0.25-mL doses. If a lower dose than recommended is inadvertently administered to a child 36 months or older (eg, 0.25 mL), an additional 0.25-mL dose should be administered to provide a full dose of 0.5 mL as soon as possible. The total number of full doses appropriate for age should be administered. If a child is inadvertently vaccinated with a formulation only approved for adults, the dose should be counted as valid.

Live Attenuated Influenza Vaccine

The cold-adapted, temperature-sensitive LAIV4 formulation is shipped and stored at 2°C to 8°C (35°F–46°F) and administered intranasally in a prefilled, single-use sprayer containing 0.2 mL of vaccine. A removable dose-divider clip is attached to the sprayer to facilitate administration of 0.1 mL separately into each nostril. If the child sneezes immediately after administration, the dose should not be repeated.

VACCINE DOSING RECOMMENDATIONS

The number of seasonal influenza vaccine doses recommended for children during the 2020–2021 influenza season depends on the child's age at the time of the first administered dose and vaccine history. The recommendations are unchanged from previous years, as shown in Fig 2.

- Influenza vaccines are not licensed for administration to infants younger than 6 months and should not be used in this age group.
- Children 9 years and older need only 1 dose, regardless of previous vaccination history.
- Children 6 months through 8 years of age:
  - Need 2 doses if they have received fewer than 2 doses of any trivalent or quadrivalent influenza vaccine (IIV or LAIV) before July 1, 2020, or if their vaccination status is unknown. The interval between the 2 doses should be at least 4 weeks. Two doses should be administered to children who receive their first dose before their ninth birthday, even if their ninth birthday occurs during the same season.
  - Require only 1 dose if they have previously received 2 or more total doses of any trivalent or quadrivalent influenza vaccine (IIV or LAIV) before July 1, 2020. The 2 previous doses do not need to have been received during the same influenza season or consecutive influenza seasons.

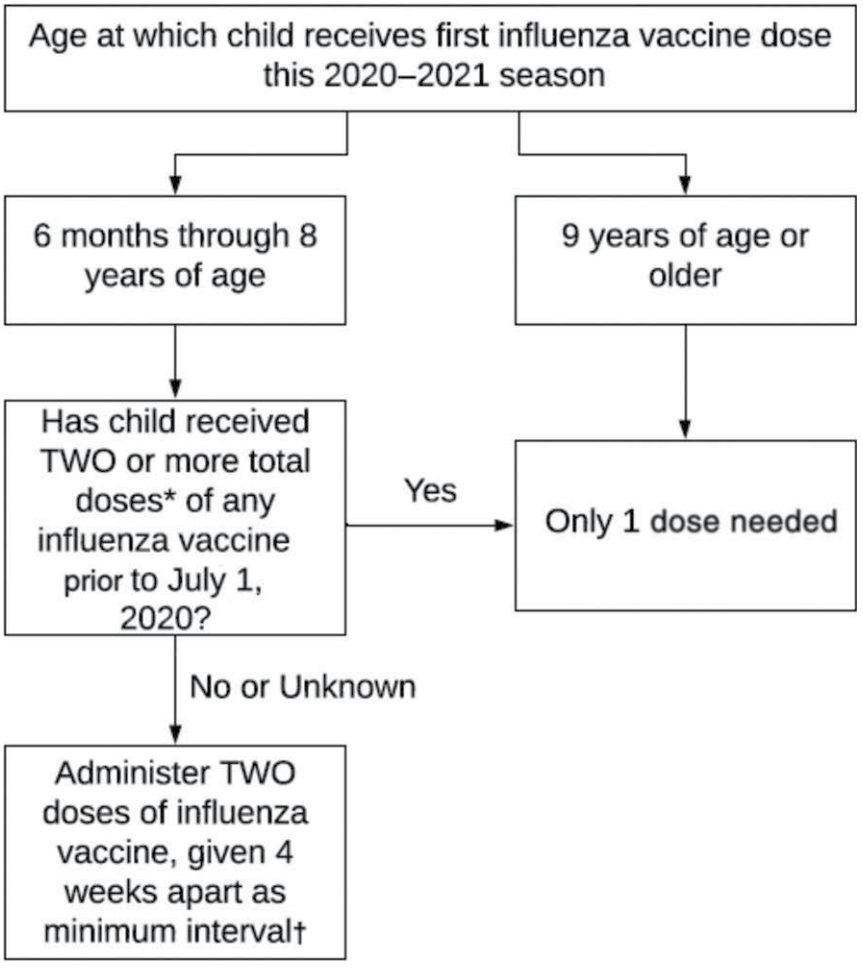

FIGURE 2
Number of 2020–2021 seasonal influenza vaccine doses for children based on age and prior vaccination history. * The 2 doses need not have been received during the same season or consecutive seasons. † Administer 2 doses based on age at receipt of the first dose of influenza vaccine during the season. Children who receive the first dose before their ninth birthday should receive 2 doses, even if they turn 9 years old during the same season.

TIMING OF VACCINATION AND DURATION OF PROTECTION

Although peak influenza activity in the United States tends to occur from January through March, influenza can circulate from early fall (October) to late spring (May), with one or more disease peaks. Predicting the onset and duration or the severity of the influenza season with accuracy is impossible. It is also challenging to balance public health strategies needed to achieve high vaccination coverage with achieving optimal individual immunity for protection against influenza at the peak of seasonal activity, knowing that the duration of immunity after vaccination can wane over time. Initiation of influenza vaccination before influenza is circulating in the community and continuing to vaccinate throughout the influenza season are important components of an effective influenza vaccination strategy, particularly this season, when circulation of SARS-CoV-2 is expected to continue.

Complete influenza vaccination by the end of October is recommended by the CDC and AAP. Children who need 2 doses of vaccine should receive their first dose as soon as possible when vaccine becomes available, to allow sufficient time for receipt of the second dose ≥4 weeks after the first, before the onset of the influenza season. Children who require only 1 dose of influenza vaccine should also ideally be vaccinated by end of October; however, recent data (mostly in adults) suggests that very early vaccination (July or August) might be associated with suboptimal immunity

before the end of the influenza season.

Although the evidence is limited in children, recent reports raise the possibility that early vaccination might contribute to reduced protection later in the influenza season.[68–79] In these studies, vaccine effectiveness decreased within a single influenza season, and this decrease was correlated with increasing time after vaccination. However, this decay in VE was not consistent across different age groups and varied by season and virus subtypes. In some studies, waning VE was more evident among older adults and younger children[71,73] and with influenza A(H3N2) viruses more than influenza A(H1N1) or B viruses.[72,75,77] A multiseason analysis from the US Influenza Vaccine Effectiveness Network found that VE declined by approximately 7% per month for influenza A (H3N2) and influenza B and by 6% to 11% per month for influenza A (H1N1)pdm09 in individuals 9 years and older.[70] VE remained greater than 0 for at least 5 to 6 months after vaccination. A more recent study including children older than 2 years also found evidence of declining vaccine effectiveness with an odds ratio increasing approximately 16% with each additional 28 days from vaccine administration.[80] In another study evaluating VE from the 2011–2012 through the 2013–2014 influenza seasons demonstrated 54% to 67% protection from 0 to 180 days after vaccination.[74] Finally, a multiseason study in Europe from 2011–2012 through 2014–2015 showed a steady decline in VE down to 0% protection by 111 days after vaccination.[75]

Further evaluation is needed before any policy change in timing of influenza administration is made. An early onset of the influenza season is a concern when considering delaying vaccination. Until there are definitive data that determine whether waning immunity influences VE in children, administration of influenza vaccine should not be delayed to a later date, because this increases the likelihood of missing influenza vaccination altogether.[81] Providers may continue to offer vaccine until June 30th of each year when the seasonal influenza vaccine expires, because the duration of influenza circulation is unpredictable. Furthermore, a person may experience more than one influenza infection during a given season because of the various cocirculating strains. Although influenza activity in the United States is typically low during the summer, influenza cases and outbreaks can occur, particularly among international travelers, who may be exposed to influenza year-round, depending on destination.

VACCINE IMPLEMENTATION

The AAP Partnership for Policy Implementation has developed a series of definitions using accepted health information technology standards to assist in the implementation of vaccine recommendations in computer systems and quality measurement efforts. This document is available at www2.aap.org/informatics/PPI.html. In addition, the AAP has developed implementation guidance on supply, payment, coding, and liability issues; these documents can be found at www.aapredbook.org/implementation.

HCP, influenza campaign organizers, and public health agencies are encouraged to collaborate to develop improved strategies for planning, distribution, communication, and administration of vaccines. For example, pediatricians can play a key role in educating and assisting early childhood education centers and schools in educating parents on the importance of influenza immunization. Resources for effective communication and messaging strategies are available on the AAP Web site – promoting vaccinations and providing resources for pediatricians to communicate with patients, families, and the communities they serve (https://www.aap.org/en-us/about-the-aap/aap-press-room/campaigns/immunizations/Pages/default.aspx and https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/immunizations/Influenza-Implementation-Guidance/Pages/Patient-Family-and-Community.aspx).

Pediatricians and other pediatric health care providers should plan to make influenza vaccine easily accessible for all children. Examples include sending alerts to families that vaccine is available (eg, e-mails, texts, letters, patient portals, practice-specific websites, or social media platforms); creating walk-in influenza vaccination clinics; extending hours beyond routine times during peak vaccination periods; administering influenza vaccine during both well child examinations and sick visits as well as in hospitalized patients, especially those at high risk of influenza complications, before hospital discharge (unless medically contraindicated); implementing standing orders for influenza vaccination; considering how to immunize parents, adult caregivers, and siblings (see risk management guidance associated with adult immunizations at http://pediatrics.aappublications.org/content/129/1/e247) at the same time as children; and working with other institutions (eg, schools, child care programs, local public health departments, and religious organizations) or alternative care sites, such as pharmacies and hospital emergency departments, to expand venues for administering vaccine. If a child receives influenza vaccine outside of his or her medical home, such as at a pharmacy, retail-based clinic, or another practice setting, appropriate documentation of vaccination should be provided to the patient to be shared with his or her

medical home and entered into the state or regional immunization information system (ie, registry).

Concerted efforts among the aforementioned groups, plus vaccine manufacturers, distributors, and payers, are necessary to prioritize distribution appropriately to the primary care office setting and patient-centered medical home before other venues, especially when vaccine supplies are delayed or limited. Payers should eliminate remaining "patient responsibility" cost barriers to influenza vaccine where they still exist. Similar efforts should be made to eliminate the vaccine supply discrepancy between privately insured patients and those eligible for vaccination through the Vaccines for Children (VFC) program. American Indian/Alaska Native children, who are eligible for vaccines through the VFC program, are at higher risk for influenza complications and should be prioritized in a vaccine shortage (Table 2).

Population health can benefit from pediatricians' discussions about vaccine safety and effectiveness. Pediatricians and their office staff can influence vaccine acceptance by explaining the importance of annual influenza vaccination for children and emphasizing when a second dose of vaccine is indicated. The AAP and CDC have created communication resources to convey these important messages and to help the public understand influenza recommendations. Resources will be available on *Red Book Online* (https://redbook.solutions.aap.org/selfserve/ssPage.aspx?SelfServeContentId=influenza-resources).

The AAP supports mandatory influenza vaccination programs for all HCP in all settings, including outpatient settings. Optimal prevention of influenza in the health care setting depends on the vaccination of at least 90% of HCP, which is consistent with the national *Healthy People 2020* target for annual influenza vaccination among HCP. Vaccine coverage among HCP was 81.1% during the 2018–2019 season, up from 78.4% the previous year.[82] Influenza vaccination programs for HCP benefit the health of employees, their patients, and members of the community, especially because HCP frequently come into contact with patients at high risk of influenza illness in their clinical settings. Mandatory influenza immunization for all HCP is considered to be ethical, just, and necessary to improve patient safety. For the prevention and control of influenza, HCP must prioritize the health and safety of their patients, honor the requirement of causing no harm, and act as role models for both their patients and colleagues by receiving influenza vaccination annually.

INFLUENZA VACCINE COVERAGE

Although national influenza vaccination coverage among children has not declined in the past several seasons, overall vaccination coverage remains suboptimal (Fig 1). Achieving high coverage rates of influenza vaccine in infants and children is a priority to protect them against influenza disease and its complications. Timely influenza vaccination is particularly important during the 2020–2021 influenza season, given the concurrent SARS-CoV-2 pandemic.

The AAP and CDC recommend vaccine administration at any visit to the medical home before and during influenza season when it is not contraindicated, at specially arranged vaccine-only sessions, and through cooperation with community sites, schools, and Head Start and child care facilities to provide influenza vaccine. The CDC has developed guidance for the planning of vaccination clinics during the COVID-19 pandemic (https://www.cdc.gov/vaccines/hcp/admin/mass-clinic-activities/index.html?deliveryName=USCDC_7_3-DM33813). It is important that annual delivery of influenza vaccine to primary care medical homes should be timely to avoid missed opportunities. If alternate venues, including pharmacies and other retail-based clinics, are used for vaccination, a system of patient record transfer is crucial to maintain the accuracy of immunization records. Immunization information systems should be used whenever available and prioritized to document influenza vaccination. Two-dimensional barcodes have been used to facilitate more efficient and accurate documentation of vaccine administration with limited experience to date. Additional information concerning current vaccines shipped with 2-dimensional barcodes can be found at www.cdc.gov/vaccines/programs/iis/2d-vaccine-barcodes/.

Children's likelihood of being immunized according to recommendations appears to be associated with the immunization practices of their parents. One study found that children were 2.77 times (95% CI, 2.74 to 2.79) more likely to be immunized against seasonal influenza if their parents were immunized.[49] When parents who were previously not immunized had received immunization for seasonal influenza, their children were 5.44 times (95% CI, 5.35 to 5.53) more likely to receive influenza vaccine.

Pediatric offices may choose to serve as a venue for providing influenza vaccination for parents and other care providers of children, if the practice is acceptable to both pediatricians and the adults who are to be vaccinated. Medical liability and payment issues along with medical record documentation requirements need to be considered before a pediatrician begins immunizing adults (see risk management guidance associated

with adult immunizations at http://pediatrics.aappublications.org/content/129/1/e247). Pediatric practices should be aware of payment implications including nonpayment or having the parent inappropriately attributed by a payer as a patient of the pediatrician's office. The AAP supports efforts to overcome these payment barriers with insurance payers to maximize influenza immunization rates. To avoid errors in claims processing and payment and in the exchange of immunization data, pediatricians are reminded that parents should have their own basic medical record, where their influenza vaccination should be documented. Adults should be encouraged to have a medical home and communicate their vaccination status to their primary care provider. Offering adult vaccinations in the pediatric practice setting should not undermine the adult medical home model. Vaccination of close contacts of children at high risk of influenza-related complications (Table 2) is intended to reduce children's risk of exposure to influenza (ie, "cocooning"). The practice of cocooning also may help protect infants younger than 6 months who are too young to be immunized with influenza vaccine.

SURVEILLANCE

Information about influenza surveillance is available through the CDC Voice Information System (influenza update at 1-800-232-4636) or at www.cdc.gov/flu/index.htm. Although current influenza season data on circulating strains do not necessarily predict which and in what proportion strains will circulate in the subsequent season, it is instructive to be aware of 2019–2020 influenza surveillance data and use them as a guide to empirical therapy until current seasonal data are available from the CDC. Information is posted weekly on the CDC Web site (www.cdc.gov/flu/weekly/fluactivitysurv.htm). The AAP offers "What's the Latest with the Flu" messages to highlight those details most relevant for AAP members and child care providers on a monthly basis during influenza season (https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/Pages/What's-the-Latest-with-the-Flu.aspx).

INFLUENZA VACCINATION RECOMMENDATIONS

1. The AAP recommends annual influenza vaccination for *everyone* 6 months and older, including children and adolescents, during the 2020–2021 influenza season.
2. For the 2020–2021 influenza season, the AAP recommends that any licensed influenza vaccine appropriate for age and health status can be used for influenza vaccination in children. Inactivated influenza vaccine (IIV) and live attenuated vaccine (LAIV) are options for children for whom these vaccines are appropriate. This recommendation is based on review of current available data on LAIV and IIV vaccine efficacy (VE). The AAP will continue to review VE data as they become available and update these recommendations if necessary.
3. The AAP does not have a preference for any influenza vaccine product over another for children who have no contraindication to influenza vaccination and for whom more than one licensed product appropriate for age and health status is available. Pediatricians should administer whichever formulation is available in their communities to achieve the highest possible coverage this influenza season.
4. Children 6 through 35 months of age may receive any licensed, age-appropriate IIV available this season, at the dose indicated for the vaccine. No product is preferred over another for this age group. Children 36 months (3 years) and older should receive a 0.5-mL dose of any available, licensed, age-appropriate inactivated vaccine.
5. The number of seasonal influenza vaccine doses recommended to be administered to children in the 2020–2021 influenza season remains unchanged and depends on the child's age at the time of the first administered dose and vaccine history (Fig 2).
6. Children 6 months through 8 years of age who are receiving influenza vaccine for the first time or who have received only 1 dose, before July 1, 2020, or whose vaccination status is unknown should receive 2 doses of influenza vaccine, ideally by the end of October, and vaccines should be offered as soon as they become available. Children needing only 1 dose of influenza vaccine, regardless of age, should also receive vaccination, ideally by the end of October.
7. Efforts should be made to ensure vaccination for children in high-risk groups (Table 2) and their contacts, unless contraindicated.
8. Product-specific contraindications must be considered when selecting the type of vaccine to administer. Children who have had an allergic reaction after a previous dose of any influenza vaccine should be evaluated by an allergist to determine whether future receipt of the vaccine is appropriate.
9. Children with egg allergy can receive influenza vaccine without any additional precautions beyond those recommended for all vaccines.
10. Pregnant women may receive inactivated influenza vaccine at

any time during pregnancy, to protect themselves and their infants, who benefit from the transplacental transfer of antibodies. Women in the postpartum period who did not receive vaccination during pregnancy should be encouraged to receive influenza vaccine before discharge from the hospital. Influenza vaccination during breastfeeding is safe for mothers and their infants.

11. The AAP supports mandatory vaccination of health care personnel as a crucial element in preventing influenza and reducing health care-associated influenza infections, because health care personnel often care for individuals at high risk for influenza-related complications.

INFLUENZA ANTIVIRALS

Antiviral agents available for both influenza treatment and chemoprophylaxis in children of all ages can be found in Table 4 (including doses for preterm infants that have not been evaluated by the FDA) and on the CDC Web site (www.cdc.gov/flu/professionals/antivirals/index.htm). These include the neuraminidase inhibitors (NAIs) (oseltamivir, zanamivir, peramivir) and a selective inhibitor of influenza cap-dependent endonuclease (baloxavir), all of which have activity against influenza A and B viruses.[83]

Oral oseltamivir remains the antiviral drug of choice for the management of illness caused by influenza virus infections. Although more difficult to administer, inhaled zanamivir (Relenza) is an equally acceptable alternative for patients who do not have chronic respiratory disease. Options are limited for children who cannot absorb orally or enterally administered oseltamivir or tolerate inhaled zanamivir. Intravenous (IV) peramivir (Rapivab), a third NAI, was approved in September 2017 as treatment of acute uncomplicated influenza in nonhospitalized children 2 years and older who have been symptomatic for no more than 2 days. The efficacy of peramivir in patients with serious influenza requiring hospitalization has not been established.[83] IV zanamivir is not approved in the United States and has not been available for compassionate use since the 2017–2018 season.[68,69] The FDA-licensed baloxavir marboxil in 2018 for the early treatment of uncomplicated influenza in outpatients 12 years and older who have been ill for no more than 2 days.[84] This antiviral agent for influenza has a different mechanism of action (cap-endonuclease inhibitor) than NAIs and requires only a single oral dose for treatment of uncomplicated influenza. A clinical trial of baloxavir treatment of influenza in hospitalized patients 12 years and older is ongoing (https://clinicaltrials.gov/ct2/show/NCT03684044?cond=baloxavir&rank=6).

INFLUENZA TREATMENT

Randomized controlled trials (RCTs) conducted to date to evaluate the efficacy of influenza antiviral medications among outpatients with uncomplicated influenza have found that timely treatment can reduce the duration of influenza symptoms and fever in pediatric populations.[85–89] Observational studies in pediatric and adult populations suggest that antiviral agents could reduce the risk of certain influenza complications, including hospitalization and death.[90–93] The number of published RCTs in children is limited, and interpretation of the results of these studies needs to take into consideration the size of the study (the number of events might not be sufficient to assess specific outcomes in small studies), the variations in the case definition of influenza illness (clinically diagnosed versus laboratory confirmed), the time of treatment administration in relation to the onset of illness, and the child's age and health status as important variables. A Cochrane review of 6 RCTs involving treatment of 2356 children with clinically diagnosed influenza, of whom 1255 had laboratory-confirmed influenza, showed that in children with laboratory-confirmed influenza, oral oseltamivir and inhaled zanamivir reduced median duration of illness by 36 hours (26%; $P < .001$) and 1.3 days (24%, $P < .001$), respectively.[89] Among the studies reviewed, 1 trial of oseltamivir in children with asthma who had laboratory-confirmed influenza showed only a nonsignificant reduction in illness duration (10.4 hours; 8%; $P = .542$). Oseltamivir significantly reduced acute otitis media in children 1 through 5 years of age with laboratory-confirmed influenza (risk difference [RD], −0.14; 95% CI, −0.24 to −0.04).[89] Another Cochrane review of RCTs in adults and children, which included 20 oseltamivir (9623 participants) and 26 zanamivir trials (14 628 participants),[86] found no effect of oseltamivir in reducing the duration of illness in asthmatic children, but in otherwise healthy children, there was a reduction by a mean difference of 29 hours (95% CI, 12 to 47 hours; $P = .001$). No significant effect was observed with zanamivir. Regarding complications, this review did not find a significant effect of NAIs on reducing hospitalizations, pneumonia, bronchitis, otitis media, or sinusitis in children.[86] More recently, a meta-analysis of 5 new RCTs that included 1598 children with laboratory-confirmed influenza showed that treatment with oseltamivir significantly reduced the duration of illness in this population by 17.6 hours (95% CI, −34.7 to −0.62 hours).[87] When children with asthma were excluded, this difference was larger (−29.9 hours; 95% CI, −53.9 to −5.8 hours). The risk of otitis media was 34% lower in this group as well.

TABLE 4 Recommended Dosage and Schedule of Influenza Antiviral Medications for Treatment and Chemoprophylaxis in Children for the 2020–2021 Influenza Season: United States

Medication	Treatment (5 Days)	Chemoprophylaxis (10 Days)[a]
Oseltamivir[b]		
Adults	75 mg, twice daily	75 mg, once daily
Children ≥12 mo (based on body wt)		
≤15 kg (≤33 lb)	30 mg, twice daily	30 mg, once daily
>15 kg–23 kg (33 lb–51 lb)	45 mg, twice daily	45 mg, once daily
>23 kg–40 kg (>51 lb–88 lb)	60 mg, twice daily	60 mg, once daily
>40 kg (>88 lb)	75 mg, twice daily	75 mg, once daily
Infants 9–11 mo[c]	3.5 mg/kg per dose, twice daily	3.5 mg/kg per dose, once daily
Term infants 0–8 mo[c]	3 mg/kg per dose, twice daily	3 mg/kg per dose, once daily for infants 3–8 mo Not recommended for infants <3 mo old because of limited safety and efficacy data in this age group
Preterm infants[d]		
<38 wks' postmenstrual age	1.0 mg/kg per dose, twice daily	
38 through 40 wks' postmenstrual age	1.5 mg/kg per dose, twice daily	
>40 wks' postmenstrual age	3.0 mg/kg per dose, twice daily	
Zanamivir[e]		
Adults	10 mg (two 5-mg inhalations), twice daily	10 mg (two 5-mg inhalations), once daily
Children ≥7 y for treatment ≥5 y for chemoprophylaxis	10 mg (two 5-mg inhalations), twice daily	10 mg (two 5-mg inhalations), once daily
Peramivir		
Adults	One 600-mg intravenous infusion, given over 15–30 min	Not recommended
Children (2–12 y)	One 12 mg/kg dose, up to 600 mg maximum, via intravenous infusion for 15–30 min	Not recommended
Children (13–17 y)	One 600 mg dose, via intravenous infusion for 15–30 min	Not recommended
Baloxavir		
People ≥12 y who weigh more than 40 kg	40–80 kg: one 40-mg dose, orally ≥80 kg: one 80-mg dose, orally	Not recommended

Sources: 2018 IDSA Guidelines78 and https://www.cdc.gov/flu/professionals/antivirals/summary-clinicians.htm.

[a] CDC recommends for 7 days, and 10 days only if part of institutional outbreak (https://www.cdc.gov/flu/professionals/antivirals/summary-clinicians.htm).

[b] Oseltamivir is administered orally without regard to meals, although administration with meals may improve gastrointestinal tolerability. Oseltamivir is available as Tamiflu in 30-, 45-, and 75-mg capsules and as a powder for oral suspension that is reconstituted to provide a final concentration of 6 mg/mL. For the 6-mg/mL suspension, a 30-mg dose is given with 5 mL of oral suspension, a 45-mg dose is given with 7.5 mL oral suspension, a 60-mg dose is given with 10 mL oral suspension, and a 75-mg dose is given with 12.5 mL oral suspension. If the commercially manufactured oral suspension is not available, a suspension can be compounded by retail pharmacies (final concentration also 6 mg/mL), based on instructions contained in the package label. In patients with renal insufficiency, the dose should be adjusted on the basis of creatinine clearance. For treatment of patients with creatinine clearance 10–30 mL/min: 75 mg, once daily, for 5 days. For chemoprophylaxis of patients with creatinine clearance 10–30 mL/min: 30 mg, once daily, for 10 days after exposure or 75 mg, once every other day, for 10 days after exposure (5 doses). See https://www.cdc.gov/flu/professionals/antivirals/summary-clinicians.htm and IDSA Guidelines.[83]

[c] Approved by the FDA for children as young as 2 weeks of age. Given preliminary pharmacokinetic data and limited safety data, oseltamivir can be used to treat influenza in both term and preterm infants from birth because benefits of therapy are likely to outweigh possible risks of treatment. Of note, the CDC recommends a 3 mg/kg/dose, twice daily, for all infants <12 months old; the IDSA guidelines[83] include both AAP and CDC recommendations.

[d] Oseltamivir dosing for preterm infants. The weight-based dosing recommendation for preterm infants is lower than for term infants. Preterm infants may have lower clearance of oseltamivir because of immature renal function, and doses recommended for full-term infants may lead to very high drug concentrations in this age group. Limited data from the National Institute of Allergy and Infectious Diseases Collaborative Antiviral Study Group provides the basis for dosing preterm infants using their postmenstrual age (gestational age + chronologic age). For extremely preterm infants (<28 wk), please consult a pediatric infectious disease physician.

[e] Zanamivir is administered by inhalation using a proprietary "Diskhaler" device distributed together with the medication. Zanamivir is a dry powder, not an aerosol, and should not be administered using nebulizers, ventilators, or other devices typically used for administering medications in aerosolized solutions. Zanamivir is not recommended for people with chronic respiratory diseases, such as asthma or chronic obstructive pulmonary disease, which increase the risk of bronchospasm.

Overall, efficacy outcomes are best demonstrated in patients with laboratory confirmed influenza. All these studies confirmed vomiting as an occasional adverse effect of oseltamivir, occurring in approximately 5% of treated patients. The balance between benefits and harms should be considered when making decisions about the use of NAIs for either treatment or chemoprophylaxis of influenza.

Although prospective comparative studies to determine the efficacy of influenza antiviral medications in hospitalized patients or pediatric patients with comorbidities have not been conducted, and prospectively collected data to determine the role of antiviral agents in treating severe influenza are limited, on the basis of information obtained from retrospective observational studies

and meta-analyses conducted to date in both adults and children, most experts support the use of antiviral medications as soon as possible to treat pediatric patients with severe influenza, including hospitalized patients.[88,90–94] An observational epidemiologic study conducted in adult patients hospitalized with severe laboratory-confirmed influenza in Spain over 6 influenza seasons (2010–2016) evaluated the effectiveness of NAIs, concluding that when started early after the onset of symptoms (≤48 hours or ≤5 days), NAI treatment was associated with a reduction in influenza-associated deaths (adjusted odds ratio [aOR], 0.37; 95% CI, 0.22 to 0.63; and aOR, 0.50; 95% CI, 0.32 to 0.79, respectively).[90] However, treatment initiation more than 5 days after the onset of influenza symptoms was not associated with reduction in mortality in hospitalized adults.

Importantly, and despite limited evidence from prospectively conducted trials, treatment with oseltamivir for children with serious, complicated, or progressive disease presumptively or definitively caused by influenza, irrespective of influenza vaccination status (the circulating strains may not be well matched with vaccine strains) or whether illness began greater than 48 hours before admission, is recommended by the AAP, CDC, Infectious Diseases Society of America (IDSA),[83] and Pediatric Infectious Diseases Society (PIDS). Earlier treatment provides better clinical responses. However, treatment after 48 hours of symptoms in adults and children with moderate to severe disease or with progressive disease has been shown to provide some benefit and should be offered.[95–97] In a retrospective study of 653 PICU admissions from 2009 to 2012, the estimated risk of death was reduced in NAI treated cases (OR 0.36, 95% CI: 0.16 to 0.83).[95] No additional benefit exists for double-dose NAI therapy on reduction of mortality or virologic clearance, compared with standard-dose therapy, on the basis of a recent systematic review and meta-analysis of 10 published studies[98] (4 RCT and 6 observational studies) involving 20 947 adult and pediatric patients.

Children younger than 2 years are at an increased risk of hospitalization and complications attributable to influenza. The FDA has approved oseltamivir for treatment of children as young as 2 weeks. Given preliminary pharmacokinetic data and limited safety data, the CDC and AAP support the use of oseltamivir to treat influenza in both term and preterm infants from birth, because benefits of therapy of neonatal influenza are likely to outweigh possible risks of treatment.

Oseltamivir is available in capsule and oral suspension formulations. The available capsule doses are 30, 45, and 75 mg, and the commercially manufactured liquid formulation has a concentration of 6 mg/mL in a 60-mL bottle. If the commercially manufactured oral suspension is not available, the capsule may be opened and the contents mixed with simple syrup or Ora-Sweet SF (sugar free) by retail pharmacies to a final concentration of 6 mg/mL.

In adverse event data collected systematically in prospective trials, vomiting was the only adverse effect reported more often with oseltamivir compared with placebo when studied in children 1 through 12 years of age (ie, 15% of treated children versus 9% receiving placebo). In addition, following reports from Japan of oseltamivir-attributable neuropsychiatric adverse effects, a review of controlled clinical trial data and ongoing surveillance has failed to establish a link between this drug and neurologic or psychiatric events.[99,100]

ANTIVIRAL TREATMENT AND INFLUENZA TESTING CONSIDERATIONS

Clinical judgment (on the basis of underlying conditions, disease severity, time since symptom onset, and local influenza activity) is an important factor in treatment decisions for pediatric patients who present with influenza-like illness. Antiviral treatment should be started as soon as possible after illness onset and should not be delayed while waiting for a definitive influenza test result, because early therapy provides the best outcomes. Influenza diagnostic tests vary by method, availability, processing time, sensitivity, and cost (Table 5), all of which should be considered in making the best clinical decision. Positive and negative predictive values of influenza test results are influenced by the level of influenza activity in the population being tested, the characteristics of a test compared with a gold standard, pretest probability, whether the influenza virus is actively replicating in the person, proper collection and transport of specimens, and proper test procedures. Testing should be performed when timely results will be available to influence clinical management or infection control measures. Given the similarities in clinical presentation, testing for influenza and for SARS-CoV-2 infection should be offered to patients with a febrile respiratory illness or influenza-like illness.

Although decisions on treatment and infection control can be made on the basis of positive rapid influenza diagnostic test (RIDT) results, negative results should not always be used in a similar fashion because of the suboptimal sensitivity and potential for false-negative results. An updated list of RIDTs is available at: https://www.cdc.gov/flu/professionals/diagnosis/table-ridt.html. Positive results of RIDTs are helpful, because they may reduce additional testing to identify

TABLE 5 Comparison of Types of Influenza Diagnostic Tests

Testing Category	Method	Influenza Viruses Detected	Distinguishes Influenza A Virus Subtypes	Time to Results	Performance
Rapid molecular assay	Nucleic acid amplification	Influenza A or B viral RNA	No	15–30 min	High sensitivity; high specificity
Rapid influenza diagnostic test	Antigen detection	Influenza A or B virus antigens	No	10–15 min	Low to moderate sensitivity (higher with analyzer devise); high specificity
Direct and indirect immunofluorescence assays	Antigen detection	Influenza A or B virus antigens	No	1–4 h	Moderate sensitivity; high specificity
Molecular assays (including RT-PCR)	Nucleic acid amplification	Influenza A or B viral RNA	Yes, if subtype primers are used	1–8 h	High sensitivity; high specificity
Multiplex molecular assays	Nucleic acid amplification	Influenza A or B viral RNA, other viral or bacterial targets (RNA or DNA)	Yes, if subtype primers are used	1–2 h	High sensitivity; high specificity
Rapid cell culture (shell vial and cell mixtures)	Virus isolation	Influenza A or B virus	Yes	1–3 d	High sensitivity; high specificity
Viral culture (tissue cell culture)	Virus isolation	Influenza A or B virus	Yes	3–10 d	High sensitivity; high specificity

Negative results may not rule out influenza. Respiratory tract specimens should be collected as close to illness onset as possible for testing. Clinicians should consult the manufacturer's package insert for the specific test for the approved respiratory specimen(s). Specificities are generally high (>95%) for all tests compared with reverse transcriptase-polymerase chain reaction (RT-PCR). FDA-cleared rapid influenza diagnostic tests are CLIA-waived; most FDA-cleared rapid influenza molecular assays are CLIA-waived, depending on the specimen. Source: Uyeki.[83]

alternative causes of the child's influenza-like illness, provide the opportunity for early antiviral treatment, promote appropriate antimicrobial stewardship, and allow the timely implementation of appropriate strategies to prevent transmission. Available FDA-approved rapid molecular assays based on nucleic acid detection are highly sensitive and specific diagnostic tests that can provide rapid results. An updated list of these tests is available here: https://www.cdc.gov/flu/professionals/diagnosis/table-nucleic-acid-detection.html. Molecular assays are preferred in hospitalized patients, because they are more sensitive compared with antigen detection. Early detection, prompt antiviral treatment, and infection control interventions can lead to improved individual patient outcomes and allow for effective cohorting and disease containment. This containment strategy is particularly relevant during the SARS-CoV-2 pandemic.

People with suspected influenza who are at higher risk of influenza complications should be offered treatment with antiviral medications (Table 2). Efforts should be made to minimize treatment of patients who are not infected with influenza. Otherwise healthy children who have suspected influenza with an uncomplicated presentation should be considered for antiviral medication, particularly if they are in contact with other children who either are younger than 6 months (as they are not able to receive influenza vaccine) or have high-risk conditions (including age <5 years) that predispose them to complications of influenza, when influenza viruses are known to be circulating in the community. If there is a local shortage of antiviral medications, local public health authorities should be consulted to provide additional guidance about testing and treatment. In previous years, local shortages of oseltamivir suspension have occurred because of uneven drug distribution, although national shortages have not occurred since 2009, particularly given the availability of the capsule formulation that can be made into a suspension for young children if needed (Table 4).

INFLUENZA CHEMOPROPHYLAXIS

Randomized placebo-controlled studies showed that oral oseltamivir and inhaled zanamivir were efficacious when administered as chemoprophylaxis to household contacts after a family member had laboratory-confirmed influenza.[83] There are no data on IV peramivir or oral baloxavir for chemoprophylaxis. Decisions on whether to administer antiviral chemoprophylaxis should take into account the exposed person's risk of influenza complications, vaccination status, the type and duration of contact, recommendations from local or public health authorities, and clinical judgment. Optimally, postexposure chemoprophylaxis should only be used when antiviral agents can be started within 48 hours of exposure; the lower once-daily dosing for chemoprophylaxis with oral oseltamivir or inhaled zanamivir should not be used for treatment of children symptomatic with influenza. Early, full treatment doses (rather than chemoprophylaxis doses) should be used in high-risk symptomatic patients without waiting for laboratory confirmation.

Chemoprophylaxis should not be considered a substitute for vaccination. Influenza vaccine should always be offered before and throughout the influenza season when not contraindicated. Antiviral medications are important adjuncts to influenza vaccination for control and prevention of influenza disease. Toxicities may be associated with antiviral agents, and indiscriminate use might limit availability. Pediatricians should inform recipients of antiviral chemoprophylaxis that risk of influenza is lowered but still remains while taking the medication, and susceptibility to influenza returns when medication is discontinued. Oseltamivir use is not a contraindication to vaccination with IIV, although LAIV effectiveness will be decreased for the child receiving oseltamivir.[83] No data are available on the impact of inhaled zanamivir, IV peramivir or oral baloxavir on effectiveness of LAIV, but it is likely that all antiviral agents will have some impact on effectiveness of LAIV. Among some high-risk people, both vaccination with IIV and antiviral chemoprophylaxis may be considered. Updates will be available at www.aapredbook.org/flu and www.cdc.gov/flu/professionals/antivirals/index.htm.

ANTIVIRAL RESISTANCE

Antiviral resistance to any drug can emerge, necessitating continuous population-based assessment that is conducted by the CDC. During the 2019–2020 season, >99% of influenza A(/H1N1)pdm09 and B/Victoria viruses tested were susceptible to oseltamivir, peramivir, and zanamivir, and all were susceptible to baloxavir. All tested influenza A(H3N2) and B/Yamagata viruses were susceptible to these antiviral agents. Decreased susceptibility to baloxavir has been reported in Japan, where utilization has been more common,[101–105] and surveillance for resistance among circulating influenza viruses is ongoing in Japan and the United States.[106–108] In contrast, high levels of resistance to amantadine and rimantadine persist among the influenza A viruses currently circulating. Adamantane medications are not recommended for use against influenza unless resistance patterns change.[83]

Viral surveillance and resistance data from the CDC and WHO indicate that the majority of currently circulating influenza viruses likely to cause influenza in North America during the 2020–2021 influenza season continue to be susceptible to oseltamivir, zanamivir, peramivir, and baloxavir (https://www.cdc.gov/flu/weekly/). If a newly emergent oseltamivir- or peramivir-resistant virus is a concern, recommendations for alternative treatment will be available from the CDC and AAP. Resistance characteristics can change for an individual patient over the duration of a treatment course, especially in those who are severely immunocompromised. Up-to-date information on current recommendations and therapeutic options can be found on the AAP Web site (www.aap.org or www.aapredbook.org/flu), through state-specific AAP chapter websites, or on the CDC Web site (www.cdc.gov/flu/).

INFLUENZA ANTIVIRALS RECOMMENDATIONS

Treatment recommendations for antiviral medications for the 2020–2021 influenza season are applicable to infants and children with suspected influenza when influenza viruses are known to be circulating in the community, or when infants or children are tested and confirmed to have influenza. Continuous monitoring of the epidemiology, change in severity, and resistance patterns of influenza virus strains by CDC may lead to new guidance. Oseltamivir (oral), zanamivir (inhaled), peramivir (IV), and baloxavir (oral) are FDA-approved for treatment of uncomplicated influenza virus infection in pediatric outpatients; published data exist to support the use of oseltamivir (oral) for hospitalized and children at high risk. For more serious influenza virus infections, particularly in immune compromised children, seeking the advice of an infectious diseases specialist is suggested.

ANTIVIRAL TREATMENT RECOMMENDATIONS

Regardless of influenza vaccination status, antiviral treatment should be offered as early as possible to:

- Any hospitalized child with suspected or confirmed influenza disease, regardless of duration of symptoms.
- Any child, inpatient or outpatient, with severe, complicated, or progressive illness attributable to influenza, regardless of duration of symptoms.
- Influenza virus infection of any severity in children at high risk of complications of influenza, as listed in Table 2, regardless of duration of symptoms.

Antiviral treatment may be considered for the following individuals:

- Any previously healthy, symptomatic outpatient not at high risk for influenza complications in whom an influenza diagnosis is confirmed or suspected on the basis of clinical judgment, if treatment can be initiated within 48 hours of illness onset.
- Children with suspected or confirmed influenza disease whose siblings or household contacts either are younger than 6 months or have a high-risk condition that predisposes them

to complications of influenza as listed in Table 2.

Shared informed decision making between providers and parents/legally authorized caregivers is encouraged to initiate therapy and monitor children for safety and efficacy while receiving antiviral agents. Efforts should be made to minimize treatment of patients who are not infected with influenza viruses.

ANTIVIRAL CHEMOPROPHYLAXIS RECOMMENDATIONS

Although vaccination is the preferred approach to prevention of infection, chemoprophylaxis during an influenza season is recommended in the following situations:

- For children at high risk of complications from influenza for whom influenza vaccine is contraindicated.
- For children at high risk during the 2 weeks after IIV influenza vaccination, before optimal immunity is achieved. Prophylaxis after LAIV may decrease vaccine efficacy.
- For family members or HCP who are unvaccinated and are likely to have ongoing, close exposure to:
  - unvaccinated children at high risk; or
  - unvaccinated infants and toddlers who are younger than 24 months.
- For control of influenza outbreaks for unvaccinated staff and children in a closed institutional setting with children at high risk (eg, extended-care facilities).
- As a supplement to IIV vaccination among children at high risk, including children who are immunocompromised and may not respond with sufficient protective immune responses following influenza vaccination.
- As postexposure antiviral chemoprophylaxis for family members and close contacts of an infected person if those people are at high risk of complications from influenza.
- For children at high risk of complications and their family members and close contacts, as well as for HCP, when circulating strains of influenza virus in the community are not well matched by seasonal influenza vaccine virus strains, on the basis of current data from the CDC and state or local health departments.

These recommendations apply to routine circumstances, but it should be noted that guidance may change on the basis of updated recommendations from the CDC in concert with antiviral availability, local resources, clinical judgment, recommendations from local or public health authorities, risk of influenza complications, type and duration of exposure contact, and change in epidemiology (resistance, antigenic shift) or severity of influenza. Children who have higher rates of influenza complications, including American Indian/Alaska Native children, should be prioritized to receive influenza antiviral agents in the setting of a shortage according to local public health guidelines (Table 2). Chemoprophylaxis is not routinely recommended for infants younger than 3 months given limited safety and efficacy data in this age group.

FUTURE DIRECTIONS

Safety and effectiveness data for influenza vaccines used during the 2020–2021 influenza season will be analyzed as they become available and reported by CDC as they are each season. Continued evaluation of the safety, immunogenicity, and effectiveness of influenza vaccines, especially for at risk populations, is important. The duration of protection, the potential role of previous influenza vaccination on overall vaccine effectiveness, and vaccine effectiveness by vaccine formulation, virus strain, timing of vaccination, and subject age and health status, in preventing outpatient medical visits, hospitalizations, and deaths continue to be evaluated. For the 2020–2021 influenza season, it will be particularly important to understand the effect of SARS-CoV-2 and influenza virus cocirculation on the epidemiology and morbidity of influenza in the pediatric population. Understanding how to better educate parents about influenza symptoms and how to recognize when to seek medical attention would be informative. Additionally, with limited data on the use of antiviral agents in hospitalized children and in children with underlying medical conditions, prospective clinical trials to inform optimal timing and efficacy of antiviral treatment in these populations are warranted. This is particularly relevant as new antiviral agents or new indications for existing antiviral agents become available. At this time, the FDA has accepted supplemental new drug applications for baloxavir marboxil. One application concerns the treatment of acute, uncomplicated influenza in pediatric patients from 1 year of age through 12 years of age. Another application addresses the use of baloxavir marboxil for postexposure prophylaxis (https://www.biospace.com/article/releases/fda-accepts-genentech-s-new-drug-application-for-xofluza-for-the-treatment-of-influenza-in-children-/).

There is also a need for more systematic health services research on influenza vaccine uptake and refusal as well as identification of methods to enhance uptake. Further investigation is needed about vaccine acceptance and hesitancy and methods to overcome parental concerns and improve coverage. This may include evaluating the strategy of

offering to immunize parents and adult child care providers in the pediatric office setting and understanding the level of family contact satisfaction with this approach; how practices handle the logistic, liability, legal, and financial barriers that limit or complicate this service; and most importantly, how this practice may affect disease rates in children and adults. Furthermore, ongoing efforts should include broader implementation and evaluation of mandatory HCP vaccination programs in both inpatient and outpatient settings.

Efforts should be made to create adequate outreach (eg, mobile integrated health care) and infrastructure to facilitate the optimal distribution of vaccine so that more people are immunized. Given the experience with COVID-19, pediatricians should become more involved in pandemic preparedness and disaster planning efforts. A bidirectional partner dialogue between pediatricians and public health decision makers assists efforts to address children's issues during the initial state, regional, and local plan development stages. Additional information can be found at www.aap.org/disasters/resourcekit and https://pediatrics.aappublications.org/content/pediatrics/early/2017/05/11/peds.2016-3690.full.pdf.

Access to care issues, lack of immunization records, and questions regarding who can provide consent may be addressed by linking children (eg, those in foster care/juvenile justice system or refugee, immigrant, or homeless children) with a medical home, using all health care encounters as vaccination opportunities, and more consistently using immunization registry data.

Development efforts continue for universal influenza vaccines that induce broader protection and eliminate the need for annual vaccination. Understanding the establishment of immunity against influenza in early life and the development of a safe, immunogenic vaccine for infants younger than 6 months are essential. Studies on the effectiveness and safety of influenza vaccines containing adjuvants that enhance immune responses to influenza vaccines or that use novel routes of administration are needed. Efforts to improve the vaccine development process to allow for a shorter interval between identification of vaccine strains and vaccine production continue. New antiviral drugs are in various development phases, given the need to improve options for the treatment and chemoprophylaxis of influenza.

Pediatricians can remain informed of advances and other updates during the influenza season by following the CDC Influenza page (www.cdc/gov/flu) and the AAP *Red Book Online* Influenza Resource Page (www.aapredbook.org/flu).

SUMMARY OF RECOMMENDATIONS

1. The AAP recommends annual influenza vaccination for everyone 6 months and older, including children and adolescents, during the 2020–2021 influenza season.
2. For the 2020–2021 influenza season, the AAP recommends that any licensed influenza vaccine appropriate for age and health status can be used for influenza vaccination in children. Inactivated influenza vaccine (IIV) and live attenuated vaccine (LAIV) are options for children for whom these vaccines are appropriate. This recommendation is based on review of current available data on LAIV and IIV vaccine efficacy (VE). The AAP will continue to review VE data as they become available and update these recommendations if necessary.
3. The AAP does not have a preference for any influenza vaccine product over another for children who have no contraindication to influenza vaccination and for whom more than one licensed product appropriate for age and health status is available. Pediatricians should administer whichever formulation is available in their communities to achieve the highest possible coverage this influenza season.
4. Children 6 through 35 months of age may receive any licensed, age-appropriate IIV available this season, at the dose indicated for the vaccine. No product is preferred over another for this age group. Children 36 months (3 years) and older should receive a 0.5-mL dose of any available, licensed, age-appropriate inactivated vaccine.
5. The number of seasonal influenza vaccine doses recommended to be administered to children in the 2020–2021 influenza season remains unchanged and depends on the child's age at the time of the first administered dose and vaccine history (Fig 2).
6. Children 6 months through 8 years of age who are receiving influenza vaccine for the first time or who have received only 1 dose, before July 1, 2020, or whose vaccination status is unknown, should receive 2 doses of influenza vaccine, ideally by the end of October, and vaccines should be offered as soon as they become available. Children needing only 1 dose of influenza vaccine, regardless of age, should also receive vaccination, ideally by the end of October.
7. Efforts should be made to ensure vaccination for children in high-risk groups (Table 2) and their contacts, unless contraindicated.

8. Product-specific contraindications must be considered when selecting the type of vaccine to administer. Children who have had an allergic reaction after a previous dose of any influenza vaccine should be evaluated by an allergist to determine whether future receipt of the vaccine is appropriate.
9. Children with egg allergy can receive influenza vaccine without any additional precautions beyond those recommended for all vaccines.
10. Pregnant women may receive inactivated influenza vaccine at any time during pregnancy, to protect themselves and their infants, who benefit from the transplacental transfer of antibodies. Women in the postpartum period who did not receive vaccination during pregnancy should be encouraged to receive influenza vaccine before discharge from the hospital. Influenza vaccination during breastfeeding is safe for mothers and their infants.
11. The AAP supports mandatory vaccination of health care personnel as a crucial element in preventing influenza and reducing health care-associated influenza infections, because health care personnel often care for individuals at high risk for influenza-related complications.
12. Antiviral medications are important in the control of influenza but are not a substitute for influenza vaccination. Pediatricians should promptly identify their patients suspected of having influenza infection for timely initiation of antiviral treatment, when indicated and based on shared decision making between the pediatrician and child's caregiver, to reduce morbidity and mortality. Although best results are observed when the child is treated within 48 hours of symptom onset, antiviral therapy should still be considered beyond 48 hours of symptom onset in children with severe disease or those at high risk of complications.
13. Antiviral treatment should be offered as early as possible to the following individuals, regardless of influenza vaccination status:
    - Any hospitalized child with suspected or confirmed influenza disease, regardless of duration of symptoms.
    - Any child, inpatient or outpatient, with severe, complicated, or progressive illness attributable to influenza, regardless of duration of symptoms.
    - Influenza infection of any severity in children at high risk of complications of influenza infection (Table 2), regardless of duration of symptoms.
14. Treatment may be considered for the following individuals:
    - Any previously healthy, symptomatic outpatient not at high risk for influenza complications in whom influenza is confirmed or suspected on the basis of clinical judgment, if treatment can be initiated within 48 hours of illness onset.
    - Children with suspected or confirmed influenza disease whose siblings or household contacts either are younger than 6 months or have a high-risk condition that predisposes them to complications of influenza (Table 2).
15. Antiviral chemoprophylaxis is recommended after known or suspected exposure influenza in the following situations:
    - For children at high risk of complications from influenza for whom influenza vaccine is contraindicated.
    - For children at high risk during the 2 weeks after influenza vaccination, before optimal immunity is achieved.
    - For family members or HCP who are unvaccinated and are likely to have ongoing, close exposure to:
    - unvaccinated children at high risk; or
    - unvaccinated infants and toddlers who are younger than 24 months.
    - For control of influenza outbreaks for unvaccinated staff and children in a closed institutional setting with children at high risk (eg, extended-care facilities).
    - As a supplement to vaccination among children at high risk, including children who are immunocompromised and may not respond with sufficient protective immune responses following influenza vaccination.
    - As postexposure antiviral chemoprophylaxis for family members and close contacts of an infected person if those people are at high risk of complications from influenza.
    - For children at high risk of complications and their family members and close contacts, as well as HCP, when circulating strains of influenza virus in the community are not well matched by seasonal influenza vaccine virus strains, on the basis of current data from the CDC and state or local health departments.

Recommended Childhood and Adolescent Immunization Schedule: United States, 2021

- *Policy Statement*

POLICY STATEMENT Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

American Academy of Pediatrics

DEDICATED TO THE HEALTH OF ALL CHILDREN®

Recommended Childhood and Adolescent Immunization Schedule: United States, 2021

COMMITTEE ON INFECTIOUS DISEASES

The 2021 recommended childhood and adolescent immunization schedules have been approved by the Centers for Disease Control and Prevention (CDC), American Academy of Pediatrics, American Academy of Family Physicians, American College of Obstetricians and Gynecologists, American College of Nurse-Midwives, American Academy of Physician Assistants, and National Association of Pediatric Nurse Practitioners. The schedules are revised annually to reflect current recommendations for the use of vaccines licensed by the US Food and Drug Administration.

The 2021 childhood and adolescent immunization schedule has been updated to ensure consistency between the format of the childhood and adolescent and adult immunization schedules. Similar to last year, the cover page includes a table with an alphabetical listing of vaccines, approved abbreviations for each vaccine, and vaccine trade names.

Table 1 contains the recommended immunization schedule from birth to 18 years of age.

Table 2 is the catch-up immunization schedule for persons 4 months to 18 years of age who start late or who are more than 1 month behind the recommended age for vaccine administration.

Table 3 lists the vaccines that may be indicated for children and adolescents 18 years of age or younger on the basis of medical conditions.

Similar to the 2021 schedule, the notes are presented in alphabetical order. The following changes to individual footnotes have been made to the 2021 schedule:

- For influenza vaccines:
  - Updated language about use of influenza vaccines in persons with an egg allergy with symptoms other than hives: if using an influenza vaccine other than Flublok or Flucelvax, administer in a medical setting under the supervision of a health care provider who can recognize and manage severe allergic reactions.

To cite: COMMITTEE ON INFECTIOUS DISEASES. Recommended Childhood and Adolescent Immunization Schedule: United States, 2021. *Pediatrics*. 2021;147(3):e2020049775

- Added information regarding severe allergic reactions.
- Updated information about use of antiviral medications and administering quadrivalent live attenuated influenza vaccine (LAIV4): LAIV4 should not be used if one received influenza antiviral medications oseltamivir or zanamivir within the previous 48 hours, peramivir within the previous 5 days, or baloxavir within the previous 17 days.
- Added "Children younger than 2 years" to the situations in which LAIV4 should not be used[1] (Advisory Committee on Immunization Practices [ACIP] Meeting, June 24, 2020).

- For meningococcal serogroup A, C, W, and Y vaccines:
  - Added meningococcal groups A, C, W, and Y polysaccharide tetanus toxoid conjugate vaccine (MenACWY-TT) as an option for preventing disease attributed to the meningococcal serogroups A, C, W, and Y.
  - Added language for catch-up vaccination for infants who received 1 dose of meningococcal groups A, C, W, and Y oligosaccharide diphtheria CRM_{197} conjugate vaccine (MenACWY-CRM) at an age from 3 to 6 months[2] (ACIP Meeting, June 26–27, 2019).
- For the meningococcal B vaccine (MenB):
  - For persons aged ≥10 years with complement deficiency, complement inhibitor use, or asplenia or who are microbiologists: MenB booster dose 1 year after completion of a MenB primary series, followed by MenB booster doses every 2 to 3 years thereafter, for as long as an increased risk remains.
  - For persons aged ≥10 years determined by public health officials to be at an increased risk during an outbreak: One-time booster dose if it has been ≥1 year since completion of a MenB primary series. A booster dose interval of ≥6 months may be considered by public health officials, depending on the specific outbreak, vaccination strategy, and projected duration of elevated risk[2] (ACIP Meeting, June 26–27, 2019).
- For tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccine (Tdap), ACIP recommendations have been updated to allow either the tetanus and diphtheria toxoids vaccine or Tdap to be used for the decennial tetanus and diphtheria toxoids booster, tetanus prophylaxis for wound management, and additional required doses in the catch-up immunization schedule, if a person has received at least 1 Tdap dose[3] (ACIP Meeting, October 23–24, 2019).

Other notable changes in the 2021 child and adolescent immunization schedule include the following:

- Cover page: changed the abbreviation LAIV to LAIV4; added MenACWT-TT (MenQuadfi) to list of meningococcal ACWY; added DTaP-IPV-Hib-HepB (Vaxelis) to list of combination vaccines.
- Table 1 (Recommended Child and Adolescent Immunization Schedule by Age): changed the abbreviation for live attenuated influenza vaccine (LAIV) to LAIV4. In the hepatitis B vaccine row, arrows were added to second dose.
- Table 3 (Recommended Child and Adolescent Immunization Schedule by Medical Condition): in the LAIV row, changed abbreviation to LAIV4. In the measles, mumps, and rubella (MMR) and varicella (VAR) rows, pregnancy column, an asterisk was added to indicate MMR and VAR vaccines should be administered after pregnancy. In the human papillomavirus (HPV) row, pregnancy column, the pink color for delay until after pregnancy has been replaced with red, which indicates not recommended and contraindicated; an asterisk was also added to indicate the HPV vaccine should be administered after pregnancy.
- Notes (Special Situations): clarifying edits were made to the notes to improve readability and the utility of the schedule for diphtheria and tetanus toxoids and acellular pertussis vaccination, *Haemophilus influenzae* type b vaccination, hepatitis A vaccination, hepatitis B vaccination, HPV vaccination, pneumococcal vaccination, and Tdap vaccination.
- A box within the notes section of the immunization schedules was included that states, "COVID-19 Vaccination- ACIP recommends use of COVID-19 vaccines within the scope of the Emergency Use Authorization or Biologics License Application for the particular vaccine. Interim ACIP recommendations for use of COVID-19 vaccines can be found at www.cdc.gov/vaccines/hcp/acip-recs" on the first page under "Additional Information."

The 2021 version of Tables 1 through 3 and the notes are available on the American Academy of Pediatrics Web site (https://redbook.solutions.aap.org/SS/Immunization_Schedules.aspx) and the CDC Web site (www.cdc.gov/vaccines/schedules/hcp/child-adolescent.html). A parent-friendly vaccine schedule for children and adolescents is available at www.cdc.gov/vaccines/schedules/index.html. An adult immunization schedule is published in February of each year and is available at www.cdc.gov/vaccines/schedules/hcp/adult.html.

Clinically significant adverse events that follow immunization should be reported to the Vaccine Adverse Event Reporting System. Guidance about how to obtain and complete a Vaccine Adverse Event Reporting

System form can be obtained at www.vaers.hhs.gov or by calling 800-822-7967. Additional information can be found in the *Red Book* and at *Red Book* Online (http://aapredbook.aappublications.org/). Statements from the ACIP and the CDC that contain detailed recommendations for individual vaccines, including recommendations for children with high-risk conditions, are available at www.cdc.gov/vaccines/hcp/acip-recs/index.html. Information on new vaccine releases, vaccine supplies, and interim recommendations resulting from vaccine shortages and statements on specific vaccines can be found at www.aapredbook.org/news/vaccstatus.shtml.

Resistance Training for Children and Adolescents

Paul R. Stricker, MD, FAAP,[a] Avery D. Faigenbaum, EdD, FACSM, FNSCA,[b] Teri M. McCambridge, MD, FAAP,[c] COUNCIL ON SPORTS MEDICINE AND FITNESS

Resistance training is becoming more important as an integral part of comprehensive sport training regimens, school physical education classes, and after-school fitness programs. The increasing number of youth who are involved in sport activities, coupled with the health problems of inactivity and being overweight, have resulted in increased interest in resistance training. Secular declines in measures of muscular fitness in modern-day youth highlight the need for participation in youth resistance training for nonathletes as well as athletes. Parents often ask pediatricians to offer advice regarding the safety, benefits, and implementation of an effective resistance-training program. This report is a revision of the 2008 American Academy of Pediatrics policy statement and reviews current information and research on the benefits and risks of resistance training for children and adolescents.

KEY POINTS

1. Positive outcomes of improved strength in youth continue to be acknowledged, including improvements in health, fitness, rehabilitation of injuries, injury reduction, and physical literacy.
2. Resistance training is not limited to lifting weights but includes a wide array of body weight movements that can be implemented at young ages to improve declining measures of muscular fitness among children and adolescents.
3. Scientific research supports a wide acceptance that children and adolescents can gain strength with resistance training with low injury rates if the activities are performed with an emphasis on proper technique and are well supervised.
4. Gains in childhood strength are primarily attributed to the neurologic mechanism of increases in motor neuron recruitment, allowing for increases in strength without resultant muscle hypertrophy.

5. It is important to incorporate resistance training into physical education classes and youth sport programs to increase muscular strength, reduce the risk of overuse injuries, and spark an ongoing interest in this type of exercise.
6. Certain health situations require consultation with a medical professional before starting a program of resistance training.

BACKGROUND

Resistance training and strength training are synonymous terms used to denote a component of sport and exercise training that is designed to enhance muscular strength, muscular power, and local muscular endurance for general exercise or competitive sports. Resistance training is a specialized method of conditioning that involves the use of different modes of training with a wide range of resistive loads, from body weight to barbells. Resistance-training programs may include the use of free weights (barbells and dumbbells), weight machines, medicine balls, kettlebells, elastic tubing, or a person's own body weight to provide the resistance needed to increase strength.

Along with the extremes of inactivity and/or being overweight and the evolution of youth sports into more intense training at younger ages, there is also a change in the landscape of "strength" among children and adolescents. Evidence of decreasing measures of muscular fitness in youth over the years adds importance for involving youth in some form of resistance exercise regardless of whether they are involved in sports.[1–3] On the other hand, some adolescents are increasingly using resistance training in pursuit of muscularity without even being involved in sports.[4] The type, amount, and frequency of resistance exercises are dictated by the specific and unique goals of the sport and training program as well as the individual child's resistance training skill competency (RTSC) and accumulated time of formal resistance training (also referred to as "training age"). Table 1 defines an alphabetical list of common terms used in resistance training.

RESISTANCE-TRAINING BENEFITS

Performance Benefits

The many benefits of resistance training have been increasingly documented in the pediatric sports arena. Although building strength is often a primary goal, the positive sequelae of strength gains in youth continue to be recognized, including improvements in motor skill performance, gains in speed and power, developing physical literacy, reducing the risk of injury, and injury rehabilitation. Children and youth are entering competitive sports at younger ages, and their training programs are becoming more complex and can involve the use of private coaching, personal trainers, and sports psychologists in addition to their routine coaches and teams. Possessing adequate strength to keep up with these increased demands on the body is valuable to help reduce the risk of injury and optimize gains in performance.

TABLE 1 Definitions

Term	Definition
Bodybuilding	Lifting weights with the specific goal of increasing muscle size, symmetry, and definition with the possible goal of entering competitive events that are judged
Concentric muscle action	The muscle shortens during contraction (ie, lifting phase of bicep curl)
Core strengthening	Focusing a strength-building program on the muscles that stabilize the trunk and pelvis of the body; this training emphasizes strengthening the abdominal, low back, and gluteal muscles as well as flexibility of muscular attachments to the pelvis, such as the quadriceps and hamstring muscles
Eccentric muscle action	The muscle lengthens during contraction (ie, lowering phase of bicep curl)
Integrative neuromuscular training	Multimodal exercise program using different types of resistance training to target deficits in strength and motor control by improving both health- and skill-related components of physical fitness
Isokinetic muscle action	This exercise requires special equipment that maintains a fixed speed of muscle contraction throughout the range of motion
Muscular fitness	A global term that includes muscular strength, muscular power, and local muscular endurance
Physical literacy	Moving with confidence and competence in various activities and environments to benefit overall health
Plyometric exercises	Repeated, rapid, eccentric, and concentric muscle actions, such as side-to-side hops or squat jumps
Powerlifting	A competitive sport that involves maximum lifting ability; powerlifting includes the dead lift, back squat, and bench press
Prehabilitation	Strength, flexibility, and functional training aimed at preventing injuries before they happen or reducing the risk of a recurrent injury
Repetition (rep)	One complete movement of an exercise that typically involves lifting and lowering a load
Repetition maximum (RM)	The maximum amount of weight that can be lifted with proper exercise technique using a given resistance; a 1 RM is the maximum resistance that can be used for 1 complete repetition of an exercise, whereas a 10 RM is the maximum resistance that can be used for 10 complete repetitions of an exercise
Set	A group of repetitions performed continuously
Weightlifting	A sport that involves the performance of the snatch and clean-and-jerk exercises in competition
Weightlifting training	The use of weightlifting exercises, movements, and derivatives of these exercises incorporated into a training program

Health Benefits

Healthy lifestyles incorporate regular exercise that provides a balance of activities, including participating in strength-building programs. In addition to increasing muscular strength, muscular power, and local muscular endurance, resistance training has been shown to produce many health benefits, including improvements in cardiovascular fitness, body composition, bone mineral density, blood lipid profiles, insulin sensitivity in youth who are overweight, increased resistance to injury, and mental health.[5–14]

Programs involving resistance training provide positive options to engage children and adolescents with overweight or obesity in physical activity and may be more likely to create a positive and successful experience for these participants, who may have lower levels of physical fitness, poor exercise compliance, and reduced tolerance for aerobic training.[15–17] Evidence does show that participation in a resistance-training program helps increase daily levels of spontaneous activity in school-aged boys,[18,19] which suggests that resistance training may be a good place to start when trying to get inactive kids to be more active. Progressing into a combined program of resistance and aerobic training may generate added benefit because combined programs have shown favorable effects on the reduction of total body fat in youth.[20–22]

Additional Benefits

After years of research, it is now accepted that children and adolescents can increase strength with low injury rates if resistance training is well supervised with an emphasis on correct technique. Early studies successfully demonstrated significant strength gains in children and a lack of injury with proper technique and supervision.[5,7,12,23]

With a preponderance of studies showing positive gains from youth resistance training, perspectives are shifting regarding integrating resistance training into physical education, youth fitness, and injury-reduction programs.

Previous concerns regarding resistance training focused on what would happen if a child lifts weights, but more recent focus has turned toward what will happen if a child does not lift weights, especially in light of the secular declines in measures of muscular fitness over the years. Targeting strength deficits and building strength reserves will continue to be a valuable concept to address.[24,25] The available research supports resistance training in youth with a new perspective of acquiring and maintaining high strength reserves to enhance performance across a wide range of general and specific skills while reducing injury risk. There is a shift from the primary concern of injuries associated with resistance training to the concern of injury and other adverse events because of a lack of adequate strength to keep up with training demands.[14,26,27]

Resistance training is applicable to virtually all children and adolescents for contributions to muscular fitness, resistance to injury, and improved performance. Enhancing muscular strength is an important concept to embrace fully beyond the association with only lifting progressively heavier weights. This clarification may encourage girls and boys to engage in year-round resistance training to increase their strength reserves without fear of getting too muscular or impairing sports performance.

Numerous studies have shown that children and adolescents can gain strength with resistance-training programs involving technique-driven progression along with qualified supervision and instruction.[5,7,12,23,28–30] Adequate supervision may be variable depending on the goals of the resistance-training program, RTSC of the participants, and experience of the teacher, instructor, or coach. An experienced professional may be able to effectively guide a larger number of youth, whereas more individualized instruction may be appropriate for more advanced-level techniques. There are many different variables that contribute to a well-designed youth resistance-training program, including quality of instruction, training environment, training frequency, training age, type of resistance used, intensity of effort, number of sets and repetitions, rest interval between sets and exercises, and duration of training.[26]

Training and Detraining

Recent studies suggest that resistance-training programs lasting $>$23 weeks are most effective in attaining maximal strength gains.[30] Strength gains occur with different types of resistance training for a minimum duration of 8 weeks with a frequency of 2 to 3 times a week. In general, detraining effects can occur after 8 to 12 weeks without resistance training,[5,7,11,15,31,32] but detraining is a more complex process in youth because of developmental improvements in performance, which allows some skills to be retained better than others.[32] Children recover more quickly than adults from resistance-training fatigue; therefore, experts recommend 1 minute of rest between sets for beginners, increasing to 2 to 3 minutes of rest as the intensity of training increases (ie, incorporation of weightlifting movements or plyometric exercises).[33] Training exercises involving the core (abdominals, low back, and gluteal muscles) are foundationally important for sports participation and can provide benefit for sport-specific skill acquisition and postural control.[7,34,35]

One-Repetition Maximum

The one-repetition maximum (1 RM) (see Table 1 for definition) test can be administered by qualified professionals to assess maximal strength, determine an appropriate resistance-training intensity, and evaluate the effectiveness of a resistance-training program.[36] Previous American Academy of Pediatrics (AAP) policy statements have not recommended 1 RM testing in skeletally immature individuals. However, 1 RM testing that is properly administered has been found to be a valid and reliable measure of strength and power in children and adolescents.[36,37] Although 1 RM testing is used in pediatric research settings and youth sport facilities, alternative measures (handgrip strength, long jump, and vertical jump) correlate with 1 RM strength and may be used to evaluate muscular fitness in youth.[38] Research indicates that 1 RM testing in children and adolescents can be safe and efficacious when established testing protocols are followed by qualified professionals.[36,37,39,40]

Mechanisms of Strength Gains

Proper resistance training in children can enhance strength without resultant muscle hypertrophy. These strength gains are attributed primarily to a neurologic mechanism whereby training increases the number of motor neurons that are "recruited" to fire with each muscle contraction.[41,42] This mechanism accounts for the increase in strength in populations with low androgen concentrations, including girls and preadolescent boys. In contrast, resistance training during and after puberty augments muscle growth by actual muscle hypertrophy.[11] Early studies regarding resistance training involved nonathletic children, but an increasing number of studies are being conducted with competitive young athletes.[43,44] Further research is needed in the area of long-term strength improvements with resistance training programs in young athletes and the effect on the neurologic mechanism of motor unit recruitment.

Performance Enhancement and Other Uses of Resistance Training

Increases in strength with resistance programs have shown improvement in some performance measures, such as vertical jump, countermovement jumps, and sprint time[6,45–47] as well as improved maximal oxygen uptake with combined resistance and aerobic training programs.[48] Resistance training combined with aerobic training does not appear to impair strength gains in youth and may be more beneficial than single-mode training.[32,49] Translation of those improvements to overall athletic performance on the field or court may be more difficult because so many variables are involved with actual performance, making it challenging to separate the contribution from resistance training alone. However, positive results in the area of performance measures, along with other aspects of sport, such as injury rehabilitation and injury reduction, make resistance training a valuable piece of the training landscape and foundational to long-term athletic development.[50,51]

Prehabilitation

Preventive exercise (prehabilitation) uses resistance training to address and focus on joints that are commonly at risk for overuse injuries (ie, enhancing rotator cuff and scapular stabilization strength preventively to reduce shoulder injury in athletes who are involved in overhead sports, such as baseball, softball, tennis, volleyball, swimming, and water polo). Research in adolescent athletes has shown resistance training to contribute to decreased injuries.[5–7,14,52,53] Injury prevention programs may have greater effectiveness when started before the period of altered biomechanics that increase injury risk.[54–56]

Various prehabilitation studies are finding positive results in the reduction of anterior cruciate ligament injuries, especially when resistance training exercises are combined with plyometric exercises.[5–7,45,52,57] Plyometric training involves the use of rapid concentric and eccentric muscle actions to enhance muscle strength and power in a relatively short amount of time, such as squat jumps. Plyometric exercises may benefit performance[58–60] and reduce the risk of injury. When combined with proprioceptive training (ie, balance exercises), these programs have also been shown to be beneficial in rehabilitation and reduction of certain injuries, such as ankle sprains.[61]

RESISTANCE TRAINING RISKS

Injury rates in youth resistance training settings that adhere to qualified supervision and proper technique are lower than those occurring in other sports or general recess play at school.[4] On the basis of years of research in this area, there is less concern for injury from supervised, well-designed, and technique-driven resistance training and more concern for injuries that occur because of poor supervision, an inappropriate progression of training loads, or low strength reserves in youth who are not prepared for the demands of sports practice and competition.

Overtraining Risks

Resistance training has more of a place in injury reduction than in the cause of injury. However, prolonged training with heavy loads and resistance training without adequate rest and recovery between sessions have been correlated with increased injuries and illness,[62–64] thus requiring similar attention as with other sources of overtraining and

sensible incorporation into the yearly training schedule. It is important to account for time spent in resistance training as part of total training time to reduce the risk of overuse injuries. Resistance training can be incorporated into a year-round plan that varies in volume and intensity depending on the sport season (eg, preseason, in season, or off season).

The AAP recommends rest from competitive athletics, sport-specific training, and practice by taking at least 1 to 2 days off per week to allow for physical and psychological recovery.[65] Adequate fluid and caloric intake is necessary to provide the fuel to exercise, compete, recover, and grow.[66,67] Athletes participating in high levels of training volume who are underrecovered and undernourished are at risk for overtraining, injury, and illness.[68,69]

Skeletal Risks

Appropriately designed resistance training programs have no apparent negative effect on linear growth, physeal health, or the cardiovascular system.[7,22] Explosive contractions of the muscle-tendon attachment at apophyseal areas during active play, sports, or lifting weights may increase the risk of avulsion fracture until closer to skeletal maturity.[70,71] Resistance training safety is enhanced when teachers, coaches, and instructors ensure a safe training environment and use developmentally appropriate teaching strategies, focus on enhancing RTSC, and have an appropriate instructor/participant ratio. This ratio can vary on the basis of the expertise of the instructor, program design, and training age and RTSC of participants.

National Electronic Injury Surveillance System

Results of the US Consumer Product Safety Commission's National Electronic Injury Surveillance System (NEISS) have raised concerns about injuries from the use of weights and resistance training. The NEISS collects data on injuries related to strength training equipment but does not provide information on supervision, program design, or training experience. This system warrants mentioning in this report to reduce conflicting information among the general public who read NEISS information. Careful interpretation of NEISS data is needed because most injuries reported from resistance training occur on home gym equipment with unsafe behavior in unsupervised settings.[72] These data are in stark contrast to data from well-designed studies with appropriate supervision and technique, making education of parents necessary to reduce confusion about the risks associated with resistance training in the youth population.[12,73–75]

NEISS data suggest that muscle strains account for many of the reported injuries, and areas that are most commonly injured are the hand, low back, and upper trunk; recent NEISS data also suggest that hand injuries are particularly common in children $<$12 years old.[76,77] NEISS data neither specify the cause of the injury (ie, attempting to lift a heavy load with poor technique) nor separate recreational from competitive weightlifting or powerlifting injuries, but the data support the need for qualified supervision and equipment that are appropriate for the size and skill level of youth involved in resistance training.

Various intense metabolic conditioning programs incorporate different types of resistance training, running intervals, and repetitive body weight exercises, such as plyometrics, into training sessions. This type of high-intensity circuit training is typically characterized by the performance of a maximum number of repetitions of selected exercises for a predetermined time interval. In adult metabolic conditioning programs, the shoulder, knee, and low back are most commonly injured,[78] but safety in the pediatric population is undetermined because of a lack of current data. As with any type of resistance training, it is important to have proper exercise technique, qualified supervision, and adequate recovery between intense training sessions.

Medical Conditions

Certain health situations require special attention before beginning a resistance training regimen. Athletes with poorly controlled, preexisting hypertension require consultation with a medical professional because of the risk of marked elevation of blood pressure during resistance training with weights. Using one's own body weight is an acceptable alternative until a consultation can be obtained.[79,80] Consultation with a medical professional regarding resistance training is also required for young athletes with uncontrolled seizure disorders,[81] although resistance training has been determined to be safe in children with underlying seizures that are well controlled on medication.[81,82]

Some children and adolescents may be disqualified from participation in resistance training because of certain medical conditions. Counseling against resistance training is necessary for youngsters with hypertrophic cardiomyopathy who are at risk for worsening ventricular hypertrophy and restrictive cardiomyopathy or hemodynamic decompensation secondary to an acute increase in pulmonary hypertension.[83] Resistance training should be avoided in individuals with pulmonary hypertension because of a risk of acute decompensation during a sudden change in hemodynamics as well as those with Marfan syndrome.[83]

Although exercise interventions that include resistance training may be beneficial for youth with cancer,[84] certain chemotherapeutic agents require caution. Youth with a previous history of cancer treated with anthracycline chemotherapy are at increased risk for cardiotoxicity and acute congestive heart failure during resistance training, as evidenced by case reports associated with doxorubicin, daunomycin or daunorubicin, idarubicin, and possibly mitoxantrone.[85]

Misconceptions and Evidence

The health supervision visit is a good opportunity to explore the topic of resistance training, dispel the myths associated with this type of exercise (Table 2), and discuss the importance of staying physically active and strong. These visits can allow for the identification of risk factors for injury; discussion of family history, medical conditions, medications, previous injuries, as well as training goals; motivation for resistance training; discussion of experience; and discussion of expectations from both the child and parents. It is valuable for pediatricians to counsel families about the multiple health and fitness benefits of resistance training, including improvements in muscular strength, muscular power, sports performance, injury resistance, and long-term athletic development.

Performance-Enhancing Substances

The AAP strongly opposes the use of performance-enhancing substances and vigorously endorses efforts to eliminate their use among children and adolescents.[86] Information is available for health care providers to provide regarding the risks and health consequences of anabolic steroids and other performance-enhancing drugs as well as to discourage youth from considering their use. For instance, the AAP has a training simulation on addressing the use of performance-enhancing substances (available at www.aap.kognito.com).

Integrative Neuromuscular Training

In this era of sedentary pursuits of technology and social media, keeping children and adolescents active and optimally developing motor skills, muscular fitness, and physical literacy is challenging. No longer can it be assumed that children innately know how to run, hop, jump, and throw. Integrative neuromuscular training is a multimodal form of training that uses resistance exercises, dynamic stability, core exercises, and plyometric and agility training performed in short intervals with intermittent periods of rest.[26,87] Integrative neuromuscular training can improve muscular fitness in youth, enhance motor skill development, improve sports performance, and decrease sports injury risk.[12,87]

It is difficult to say at what age a child can begin resistance training because of developmental differences. If a child is able to begin participating in sports activities at 5 years of age, being able to begin some type of resistance training with body weight movements at that age is acceptable because strength gains can be made in ways other than lifting external loads. An age range of 5 to 7 years is when many children are often involved in sports participation, and it is reasonable that they can also benefit from the strength-building process with exercises such as frog jumps, bear crawls, crab walks, kangaroo hops, and one-leg hops.[88] The one-leg hop is a skill most 5-year-olds should be able to perform,[89] although the ability to perform more complex movements will be influenced by the amount of time youth have practiced basic skills and reinforced desired movement patterns. The combination of qualified instruction with technique-driven progression is likely to yield the greatest benefits for youth at any age.

Training Age

The more recent concepts of "training age" and RTSC can be used in the design of a resistance training program. Training age refers to the

TABLE 2 Misconceptions Versus Evidence

Misconceptions	Evidence
A child is unable to increase strength before puberty.	Prepubertal children are able to gain strength by an increase in neurologic recruitment of muscle fibers, and gains in strength can be made with low injury rates if resistance training programs are well supervised with an emphasis on proper technique.
Young boys and girls may get "muscle bound" if they resistance train.	Prepubertal strength gains occur by neurologic mechanisms, and pubertal gains may augment muscle growth by actual muscle hypertrophy enhanced by pubertal hormones.
Resistance training may decrease aerobic performance in youth.	Improvements in aerobic performance have been shown with combined aerobic and resistance training programs, and combined aerobic and resistance programs do not appear to impair strength gains in children.
Resistance training may stunt growth.	Well-designed resistance training programs have not been shown to have a negative effect on physeal (growth plate) health, linear growth, and cardiovascular health in youth.
Children are stronger now than ever before.	There is a need to target strength deficits and build strength reserves due to declining measures of muscular fitness in modern-day youth.
1 RM testing is unsafe for youth.	1 RM testing may be a safe method for assessing muscular strength in youth provided that qualified supervision is present and appropriate testing guidelines are followed.

cumulative amount of time spent in formalized training, and RTSC incorporates the quantity of weight lifted, the quality of the lifting movement, and the emotional maturity of the athlete.[26,90] As the athlete's RTSC advances, higher loads may be used in a technique-driven process, and a gradual progression of incorporating skills requiring higher degrees of technical ability may be included (ie, more advanced weightlifting movements and plyometric exercises).[7] Understanding training age and the importance of RTSC allows for developmentally appropriate, progressive training rather than relying on previous recommendations based solely on chronological age. With earlier participation in well-designed and properly supervised resistance training, a 10-year-old girl may already have 3 years of resistance-training experience versus a 14-year-old boy who is a beginner and has a resistance training age of 0.

Ways and Means of Improving Strength

Gains in strength can be acquired via various types of resistance training methods and equipment, including body weight, free weights, resistance bands, kettlebells, medicine balls, and child-size machines. Most fitness centers use equipment made for adult bodies and greater weight increments, but child-appropriate machines are available in some youth centers across the country. Dumbbells, kettlebells, and medicine balls require good balance control and technique while being small in size, portable, and allowing for sport-specific motions.

The Use of Weightlifting Movements

The competitive sport of weightlifting includes the snatch and the clean-and-jerk exercises, whereas weightlifting movements include derivatives of these exercises. Research has demonstrated that this type of weightlifting training is superior in improving countermovement jumps, horizontal jumps, and 5- and 20-m sprints over traditional resistance training.[47,91] Research has demonstrated that if light loads are used to learn these complex movements, and ongoing quality instruction is available for technique-driven progression, then weightlifting exercises and their derivatives can be incorporated into youth training programs safely.[7] Learning how to perform these multijoint lifts correctly requires considerable time and coaching expertise. Performing these multijoint movements in childhood can help youth gain competence and confidence in performing these skills. If weightlifting movements are going to be incorporated into a youth training program, the following guidelines are to be considered.

- Advance in a gradual fashion, learning the lifts with a wooden dowel then progressing to an unloaded, light barbell and finally to a weighted barbell, focusing on proper form throughout the technique-driven progression. These weightlifting movements can be incorporated into beginner programs but will depend on the goal of the program and quality of instruction available.
- Consider training age and RTSC level, which will vary individually on the basis of cumulative training and level of instruction.
- Perform under the guidance of a professional with requisite coaching certifications, such as a certified strength and conditioning specialist (National Strength and Conditioning Association), accredited strength and conditioning coach (UK Strength and Conditioning Association), or USA weightlifting coach (USA Weightlifting).

Competitive bodybuilding is the application of resistance training principles specifically for the appearance-related purposes of maximizing muscle mass, symmetry, and body definition. Endogenous anabolic hormones are necessary for the increased muscle mass that is the primary goal of bodybuilding. "Late bloomers" are often tempted to try to build muscle mass by increasing the intensity and volume of training; however, there is no substitute for the onset of puberty, and increased training does not hasten the biological clock. Concerns about abnormal eating behaviors, excessive focus on body image, or use of anabolic agents and other performance-enhancing substances warrant careful screening for these behaviors in any adolescent who pursues competitive bodybuilding.

Resistance Training Roadmap

Suggestions for youth who are engaged in a resistance training program are as follows.

- Qualified instructors with appropriate certifications who understand youth resistance-training principles and the physical and psychosocial uniqueness of youth should provide real-time feedback to ensure safe and correct movement development.
- Begin with 1 to 2 sets of 8 to 12 repetitions using a low resistance training intensity (ie, $\leq$60% 1 RM) as proper technique is developed. A low resistance training intensity allows for the completion of 8 to 12 repetitions of a variety of exercises without undue fatigue.
- As RTSC improves and can be demonstrated consistently, it is reasonable to increase weight in 5% to 10% increments and reduce the number of repetitions.
- The program can be progressed to 2 to 4 sets of 6 to 12 repetitions with a low to moderate training intensity ($\leq$80% 1 RM).
- Young athletes can be introduced to periodic phases of lower

repetition ranges (<6) at a higher training intensity (>80% 1 RM) provided that RTSC is high.[30]

- When performing more complex, multijoint exercises, such as weightlifting, the importance of completing all repetitions with proper technique is vital to achieve proper motor control development. During this type of resistance training, fewer repetitions (eg, 1–3) may be productive to aid in motor control development.
- Include all muscle groups, including core muscles, in a resistance training program.
- Perform the various exercises through the full range of motion with proper technique.
- Perform exercises in a particular sequence during training. In general, work large muscle groups before small muscle groups and complex, multijoint exercises before single-joint exercises.
- Achieving strength gains require sessions to be at least 20 to 30 minutes long and performed 2 to 3 times per week on nonconsecutive days while gradually increasing resistance training intensity and volume as strength and RTSC improve.
- Keep the resistance training stimulus effective and enjoyable by periodically varying the exercises, sets, and repetitions.
- Use dynamic warm-up exercises integrated into the training session followed by cool-down periods with appropriate stretching techniques.
- Youth resistance training programs should be technique driven and consistent with the needs, abilities, and maturity level of the participants.

Guidelines have been proposed by the National Strength and Conditioning Association[5] and the 2014 International Consensus position statement on youth resistance training.[7]

Resistance training is highly encouraged as part of a multifaceted approach to physical literacy, exercise, strength building, fitness, and athletic performance in youth. It is valuable to emphasize that combining aerobic training with resistance training also offers long-term benefits for general health and fitness. Important factors concerning child health are fueling the need for resistance training for all youth. Trends of decreasing muscular fitness in youth and the requirement of strength for competency in movement skill development are important and make it meaningful for families to be aware of the benefits of integrating strength-building activities into a well-rounded exercise program for general physical fitness, sports participation, and lifelong health and wellbeing. It is also important for youth who are involved in resistance training to be able to participate in a safe, supportive, and nonabusive environment. Health care providers, parents, and coaches who are interested in learning more are referred to the US Center for SafeSport (www.safesport.org) and the AAP clinical report on organized sports.[92]

RECOMMENDATIONS

The necessity and appropriateness of a youth resistance training program are determined on the basis of the program goals and RTSC of participants. Proper exercise technique and qualified supervision are necessary for youth resistance-training programs to be safe, effective, and enjoyable. With enthusiastic instruction, constructive feedback, and program variation, resistance training can become a lifetime activity. Recommendations for a youth resistance training program are as follows.

1. Obtain consultation with a medical professional before beginning a resistance training program in youth with uncontrolled hypertension, uncontrolled seizure disorders, specific cardiovascular conditions, or a history of treatment with an anthracycline chemotherapeutic agent.
2. Seek consultation with a pediatric cardiologist for children with complex congenital cardiac diseases for guidance on safety and possible modification of participation.
3. Integrate aerobic and resistance training along with other skill-related fitness components into developmentally appropriate exercise training (ie, integrative neuromuscular training) to create a comprehensive fitness program.
4. In youth with overweight or obesity, start with basic resistance exercises over a more aerobically based program to support and encourage successful physical activity both short- and long-term.
5. Include dynamic warm-up exercises in the training session and cool down with less intense stretching.
6. Encourage participants to have an adequate intake of fluids and proper nutrition because both are important for energy storage, recuperation, and competition. Proper fuel is beneficial for the caloric demands of exercise, performance, recovery, and growth.
7. Assess RTSC and provide real-time feedback on exercise technique to minimize risk and maximize benefit from resistance training. This can be achieved by the following.
    - Exercises should be performed initially with little or no load until RTSC improves and proper technique has been mastered.

- Incremental loads may then be added by using either body weight or other forms of resistance as long as proper form can be maintained.
- In youth with more advanced training age, higher loads and intensities will be necessary to increase muscular strength and power in preparation for sports.[30,43,44]
- 1 RM testing may be appropriate to develop an individualized resistance training program and monitor progress.

8. Address all major muscle groups of the upper and lower body along with the core and include multijoint activities, such as squats and weightlifting exercises, for a comprehensive program for building muscular strength and power. These exercises may be complemented by adding more focused exercises to address sport-specific goals.
9. Sensibly incorporate resistance training and account for time spent in resistance training as part of the total training plan to reduce the risk of overuse injuries. Monitoring time spent resistance training in school- and community-based programs in addition to other types of training is important to account for true total training volume.[93]
10. Evaluate any symptom of illness or sign of injury or overuse from resistance training or sport participation before allowing the exercise program to resume.
11. Incorporate weightlifting exercises and their derivatives into an exercise program under the direction of a qualified professional. Progress from a wooden dowel to an unloaded barbell as RTSC improves.
12. Educate athletes about the risks associated with the use of performance-enhancing substances and/or drugs and anabolic steroids to discourage the use of such substances.
13. Enhance resistance training safety by using professionals who are qualified, trained, and aware of the unique aspects of youth and possess a recognized strength and conditioning certification. Instructor/participant ratio is important and depends on the experience of the instructor as well as the training age and RTSC of participants. Licensed physical education teachers and certified fitness professionals with understanding and experience in training youth may provide safe and effective programs for children and adolescents, and young athletes may receive qualified instruction from their high school coaches or strength and conditioning specialists.[94]
14. Use proper technique and supervision by a qualified professional as necessary safety components in any resistance training program involving children and adolescents.

CLINICAL REPORT Guidance for the Clinician in Rendering Pediatric Care

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN®

Resources Recommended for the Care of Pediatric Patients in Hospitals

Kimberly D. Ernst, MD, MSMI, FAAP, COMMITTEE ON HOSPITAL CARE

It is crucial that all children are provided with high-quality and safe health care. Pediatric inpatient needs are unique in regard to policies, equipment, facilities, and personnel. The intent of this clinical report is to provide recommendations for the resources necessary to provide high-quality and safe pediatric inpatient medical care.

In 2016, there were 5.5 million hospitalizations of children 17 years and younger, with a mean length of stay of 4.0 days.[1] The primary indication for inpatient pediatric hospitalizations is respiratory illness, including pneumonia, acute bronchiolitis, and asthma.[2] Other common reasons for pediatric hospital admissions include appendicitis, seizures, infections, and dehydration.[2] Although many of these patients can be appropriately cared for in community settings, there must be a balance between family convenience, safe health care, and resource use. It is widely accepted that a minimum case volume is necessary to maintain competence and is associated with better outcomes; therefore, health care administrators and professionals need to evaluate their ability to care for the unique needs of the pediatric population and determine if they have the diagnostic and treatment capabilities, as well as the equipment and staffing, to provide high-quality and safe health care for these patients. Hospitals need to carefully evaluate their resources and may decide to be proactive in stabilizing and then transferring pediatric patients to facilities with higher pediatric inpatient volumes and more resources.

The intent of this clinical report is to provide recommendations for the resources (policies, equipment, facilities, and personnel) necessary to provide high-quality and safe pediatric inpatient medical care. Although all hospitals are obligated to provide emergency stabilization for children of all ages, including newly born infants,[3] this document's intent is specific to inpatient care after hospital admission, especially those hospitals with lower pediatric volumes that may need additional guidance. For pediatric emergency care, the American Academy of Pediatrics (AAP) provides detailed information in "Joint Policy Statement--Guidelines for Care of Children in the Emergency Department,"[4] and newborn care guidelines can be found in *Guidelines for Perinatal Care*.[5] For pediatric intensive care,

abstract

Section of Neonatal-Perinatal Medicine, Department of Pediatrics, College of Medicine, University of Oklahoma, Oklahoma City, Oklahoma

Dr Ernst was responsible for the literature review, writing the first draft, and revising the final draft with the input of all reviewers and approved the final manuscript as submitted.

Clinical reports from the American Academy of Pediatrics benefit from expertise and resources of liaisons and internal (AAP) and external reviewers. However, clinical reports from the American Academy of Pediatrics may not reflect the views of the liaisons or the organizations or government agencies that they represent.

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

All clinical reports from the American Academy of Pediatrics automatically expire 5 years after publication unless reaffirmed, revised, or retired at or before that time.

the AAP and Society of Critical Care Medicine provide resources in "Criteria for Critical Care Infants and Children: PICU Admission, Discharge, and Triage Practice Statement and Levels of Care Guidance."[6]

POLICIES, PROCEDURES, AND PROTOCOLS

The care of the pediatric inpatient population is sufficiently different from that of the adult inpatient population, and these differences need to be taken into account when caring for this vulnerable population. Hospitals should electively admit only patients for whom they have appropriate resources, such as physical space, size-appropriate equipment, and qualified staff necessary for the unique needs of pediatric patients. In cases in which these resources are not available, policies to assist health care professionals with determining appropriate triage, consultation, and referral decisions are necessary. Hospitals that provide pediatric inpatient or outpatient services need both a plan in place (whether internally or through transport agreements) and resources available to provide urgent and emergent transfer to a facility with a higher level of care to best meet a patient's needs. These policies should address compliance with the Emergency Medical Treatment and Labor Act requirements.[3] A board-certified general pediatrician or pediatric medical subspecialist is strongly recommended to provide a leadership role to ensure all hospital policies, procedures, and protocols sufficiently address care for pediatric patients of all ages. If a pediatrician is not available, then a physician board certified in family or emergency medicine with current pediatric expertise could fulfill that role. Ideally, this physician would also be active in the evaluation of hospital-wide pediatric care and quality improvement efforts.

Regionalization and Interfacility Transfer

Hospitals and/or physicians providing care for children need well-established networks for timely consultation by subspecialists with pediatric expertise and, when necessary, for transfer of a patient to a facility that offers more advanced levels of care. Guidance for regionalization of care, the care of pediatric trauma patients, the care of pediatric critical care patients, and patient transfer has been published by the AAP, the American College of Surgeons, the Society of Critical Care Medicine, and the Emergency Medical Services for Children (EMSC) program.[6–10] Formal written interfacility transfer agreements should be in place for consultation and transport of a pediatric patient to a facility with a higher level of care.[10] These include access to air and ground transportation systems that are responsive and appropriately equipped and staffed on the basis of medical illness severity to care for children of all ages.[11] It is important for these referral relationships to be developed proactively and for protocols to be standardized to facilitate safe and efficient transports.

Regular multidisciplinary review of children transferred out of the facility as well as cases of deterioration can be conducted to reevaluate the hospital's admission, discharge, and transfer criteria. Ideally, this review would occur in collaboration with the regional referral facility. Such review may reveal minor modifications in equipment or training that would allow the facility to safely care for the higher-acuity patients it has previously transferred out, or alternatively, it may identify high-risk diagnoses that warrant immediate transfer on presentation. The goal is to ensure that all children in the facility receive the optimal care most appropriate for their medical and psychosocial needs.

Telehealth care may provide additional opportunities for collaboration between hospitals. In addition to direct patient interactions with pediatric medical subspecialists, tertiary centers may have outreach programs that can provide ongoing educational support for those practicing in the community.[12,13] One example of this model is Project ECHO (Extension for Community Healthcare Outcomes), a telementoring program designed to leverage widely available videoconferencing technology, clinical management tools, and case-based learning to increase workforce capacity by improving quality, reducing variety, and standardizing best practices within a multidisciplinary, team-based approach.[14] Establishing formalized relationships in advance can benefit both the referring hospital and the receiving tertiary care center by creating joint quality improvement teams to optimize patient care. Comprehensive information regarding the use of telehealth care can be found in "American Telemedicine Association Operating Procedures for Pediatric Telehealth."[15]

Patient Safety

The provision of care for hospitalized children should reflect an awareness of the unique patient safety concerns in the pediatric population:

- patient identification strategies that meet Joint Commission standards[16];
- the child's current weight in kilograms documented at admission and at regular intervals;
- a full set of vital signs documented in the medical record with a process for reporting abnormal age-specific vital sign values to the child's medical provider;

- all medication doses prescribed and dispensed by using weight-based dosing in kilograms with checks to ensure doses do not exceed the expected maximum dosages[17];
- precalculated medication dosages based on the child's weight in kilograms for common emergency medications[18];
- radiation safety procedures for imaging by using as low as reasonably achievable ionizing and shielding techniques[19]; and
- a rapid response team with at least 1 person having expertise in pediatric airway management as well as pediatric-specific criteria leading to activation of the team.[20]

The security of pediatric patients should be addressed within individual facilities. The Joint Commission standards require that the facility identifies and implements security procedures to address handling an infant or child abduction.[21] For younger children, the use of security bracelets or umbilical cord tags provide one layer of security, and locked units may provide security for older children. A risk assessment should be multidisciplinary, with each staff member providing input in his or her area of expertise to address actual and potential risks.[21] Not all pediatric patients will have family supervision, and the facility will be responsible for ensuring that children and adolescents do not leave the facility unattended or with a noncustodial parent or guardian. The physical layout, the number and arrangement of exits, the vulnerability of the patient population, intended level of guardian and/or visitor access, and community risk need to be addressed. Abduction and missing patient exercises are effective means to validate pediatric security effectiveness.[21] Facilities will need to address whole-hospital security measures to provide safety to patients, families, and staff in cases of active-shooter or other violent scenarios.[21]

Policies, procedures, and protocols should also be developed and implemented for all-hazards disaster preparedness.[4,22] Because of the complexities and need for advance planning, disaster preparedness is mentioned in this report to remind all facilities to address the issue. Hospital disaster plans are unique to each facility and community depending on the patient populations served as well as local, state, and regional resources and partners. The AAP has published additional information in "Ensuring the Health of Children in Disasters,"[22] and links to additional resources can be found on the AAP Disaster Preparedness Advisory Council and EMSC Web sites.[23,24] The EMSC program has prepared a checklist to assist facilities in incorporating pediatric preparedness into existing disaster policies.[25] Information for special populations, such as infants in the NICU and children with special health care needs, can be found in separate resources.[26,27]

Family-Centered Care

Facilities striving to provide patient- and family-centered care will include active family involvement in decision-making, medication safety processes, patient and family education, and discharge instruction.[28] It is important to address situations such as families with limited English proficiency and/or low general literacy, especially with regard to informed consent and family involvement and education.[29] Tailoring discussions with families by using the principles of health literacy universal precautions is critical for good communication.[30] Religious and cultural considerations may require adjustments to the child's care plan. Hospital policies allowing at least 1 caregiver to remain with the child at all times should be standard practice, especially with younger children. Ethical and legal guidelines for the care of adolescents need to be considered with regard to privacy and medical decision-making. Not only does consent need to be addressed but also assent on the basis of the child's age and developmental understanding.[29,31]

Policies should be developed that specify where children will be placed in the hospital once admitted. Single rooms provide better isolation for the common infectious diseases for which children are hospitalized and should also provide a space for caregivers to sleep and monitor care. If single rooms are not available, guidelines for appropriate age and sex cohorting should be established, taking into account adults who may be accompanying minors. Inviting families in the community to participate in policy making or design of a facility remodel can be a valuable resource for hospital leadership.

As the number of children with chronic illnesses increases, hospitals may care for more pediatric patients with life-limiting illnesses, even if only in an emergency situation. Processes should be in place for dealing with "do not resuscitate" or "allow natural death" orders with the understanding that individual situations require flexibility depending on the family and child's needs. The assessment and management of pain may be challenging because of the developmental and individual differences in experiencing and expressing pain. Several tools exist to provide improved pain control assessment and management.[32] The AAP statement "Patient- and Family-Centered Care and the Pediatrician's Role" can also act as a resource for facilities as they design their policies and processes.[28]

Policies regarding personnel and training will be addressed later in this report under Personnel and Training.

EQUIPMENT

Emergency Resuscitation Equipment

Essential equipment for care of the pediatric patient in hospitals includes resuscitation equipment for patients whose status has deteriorated since admission. All hospitals should be prepared for the emergency occurring in a pediatric patient, whether they routinely admit pediatric patients or not. A child who requires transfer to a facility with a higher level of pediatric care should be stabilized while transport is being arranged. The AAP policy statement "Joint Policy Statement--Guidelines for Care of Children in the Emergency Department" provides specific information for these situations.[33]

Separate pediatric emergency resuscitation carts are preferably located in or near areas such as the emergency department, pediatric inpatient unit, labor and delivery area, imaging area, and operating room. Supplies recommended for these carts include the following:

- inventory checklist;
- standardized code sheets with the medication dosages and Joules precalculated on the basis of weight in kilograms;
- pediatric backboard;
- personal protective equipment (gloves, gowns, masks);
- sharps container;
- cardiorespiratory and pulse oximetry monitors with appropriate alarm limits for pediatric patients;
- automated external defibrillators capable of treating pediatric patients with cardiac defibrillator paddles sized for infants and children;
- airway management equipment that fits children of all sizes (newborn to adolescents):
  - oxygen tanks;
  - pediatric oxygen masks;
  - bag-valve masks and manometers;
  - suctioning equipment;
  - laryngoscope blades;
  - oropharyngeal and nasoharyngeal airways;
  - endotracheal tubes (laryngeal masks are beneficial for health care professionals who rarely have the opportunity to intubate or rarely intubate children);
  - feeding tubes to provide gastric decompression during ventilation; and
  - chest tubes and large needles to evacuate pneumothoraces;
- vascular access devices and supplies:
  - skin preparation supplies and bandages;
  - small needle sizes, including butterfly needles;
  - various sizes of syringes;
  - umbilical line kits; and
  - intraosseous needles and drill;
- pediatric emergency medications, including fluids appropriate for pediatric patients (10% dextrose vials, 5% dextrose, and normal saline [NS] bags); and
- chemical mattress pads to provide warmth for infants.

Maintaining a code sheet with the medication dosages and Joules precalculated on the basis of the child's actual weight in kilograms is desirable in the patient's room (and, ideally, kept at all times with the patient during transport between departments or facilities). An extensive checklist of more specific supply items can be found in the resources and toolkit section on the EMSC Web site.[18]

Routine Hospital Equipment

Essential equipment is necessary to provide for the most common diagnoses seen in hospitals such as respiratory illness, appendicitis, seizure disorders, infections, and dehydration. This equipment should account for the wide differences observed in the pediatric population ranging from newborn infants to adolescents. The following list supplements standard adult equipment:

- infant, standing, and bed scales to measure patients in kilograms;
- appropriately sized respiratory equipment such as oxygen masks, nasal cannulas, bag-valve masks, artificial airways, and suctioning supplies;
- supplemental oxygen delivery systems, including low-flow meters;
- oximeter monitoring supplies that fit infants and small children;
- nebulizers and metered-dose inhalers with masks and spacers;
- "smart" infusion pumps designed for pediatric use with precise administration of low infusion rates with built-in libraries of the standard pediatric concentrations of medications;
- heel warmers to improve peripheral blood flow for sampling in infants;
- topical anesthetics for blood and spinal fluid sampling[34];
- pediatric lumbar puncture trays;
- sterile urine collection supplies in pediatric sizes;
- mercury-free thermometers with measurements in Celsius;
- pediatric-sized blood pressure cuffs;
- common pediatric fluids such as 10% dextrose vials, NS bags, 5% dextrose with 1/2 normal saline (D5-1/2NS), and 5% dextrose with normal saline (D5 NS);
- orogastric and nasogastric feeding tubes in sizes to fit children from newborn infants to adolescents;
- common infant formula types and bottles with nipples;
- pacifiers to provide newborn pain analgesia or soothing for neonatal abstinence;

- dedicated enteral pumps (these provide safety because they prevent inadvertent administration of enteral products via the intravenous route);
- electric breast pumps for mothers of young infants, including labels for storage and accessible storage facilities;
- incubators and/or warmers for infants and cribs with sleeping surfaces meeting safe-sleep guidelines[35];
- Various sizes of diapers;
- age-appropriate restraint devices, including soft wrist and leg restraints and arm and/or wrist immobilizers, to help preserve life-saving equipment such as endotracheal tubes, feeding tubes, and intravenous lines; and
- wheelchairs, crutches, slings, and splints in pediatric sizes.

Electronic Clinical Information Systems

Electronic clinical information systems play an important role in ensuring the safety and quality of pediatric care. A comprehensive AAP resource "Pediatric Aspects of Inpatient Health Information Technology Systems" provides guidance for facilities in understanding the unique aspects of safety, care, and documentation needs with regard to pediatric patients.[36] Although no dedicated pediatric inpatient clinical information system exists, some unique pediatric needs from this resource are highlighted below:

- anthropometric measurements (weight, length, head circumference) in metric units with automatic plotting on appropriate growth charts based on sex and age;
- storage of age-specific data, such as Apgar scores, pediatric pain scales, neonatal abstinence scores, pediatric mortality prediction scores, and ages in hours or days;
- ability to designate an indeterminate gender;
- configuration of access to adolescent patient data based on legal status and state confidentiality laws[37];
- ability to maintain continuity of access to health care information in cases in which children are mobile between various legal or physical custodians, for example, the foster care system;
- linking between infant and maternal medical charts and unlinking in cases of custodial loss or adoption;
- management of immunization data, including the ability to share administration data with the medical home and immunization registries;
- management of age-specific data for handoff reports including the transmission of the report to the medical home[38,39];
- ability to manage newborn screening and hearing screening data;
- availability of age-appropriate normal values for laboratory test results;
- ability to document developmental milestones;
- automated nutritional calculations;
- ability to manage the storage, tracking, and administration of human milk;
- electronic ordering of medications and infusions with weight-based calculations and alerts specific to the pediatric population;
- ability to preadmit patients likely to be admitted (preterm infant going to the NICU) so medications are readily available;
- medication dosing and drug interactions relative to pediatric patients;
- barcode scanning capabilities for medications, blood, and human milk as an additional layer of security for error prevention[40];
- discharge outpatient prescription prescribing with weight-based dosing, including total metric dose, as well as milliliters for liquid medications, name of medication, and reason for use; and
- ability to provide family education in their native language for medical issues as well as medications.

FACILITIES

Patient Care Area Facilities

The Joint Commission provides the *Comprehensive Accreditation Manual for Hospitals* that addresses the standards of hospital facilities to provide safe, quality health care.[41] These standards generally address the physical space and the features that protect patients, visitors, and staff. Caring for children requires additional considerations:

- single- or double-occupancy rooms that comply with guidelines for prevention of hospital-acquired infections (grouping pediatric rooms allows for efficient use of resources);
- pediatric beds allowing for bed rails to be raised;
- rooms with enough space to accommodate caregivers who stay with their children, including a sleeping space for at least 1 caregiver;
- adjustable privacy screens that allow convenient observation and supervision of patients;
- space to accommodate an accompanying adult in elevators and procedural rooms;
- a negative-pressure room for children admitted with suspected infectious illness that require that type of isolation;
- age-appropriate furniture, including cribs equipped with overhead safety devices and beds

having covered mechanical or electrical controls;
- high chairs for infant and toddler mealtimes;
- bookshelves or other large or bulky furniture anchored to the wall and that meet Consumer Product Safety Commission standards with a process in place to monitor for product recalls[42];
- specific safety products, such as electrical outlet covers, window locks, cabinet door safety latches, padding for sharp corners and edges, and toilet latches, for spaces in children's areas;
- cordless window coverings;
- cordless phones;
- magnet-free status communication boards;
- trash cans and sharps containers out of reach of toddlers and small children;
- alcohol-containing hand sanitizer dispensers not accessible to small children;
- age-appropriate spaces where children can feel safe from painful or scary medical procedures[43];
- a separate treatment room for procedures[43];
- entertainment consoles, computers, as well as educational and other age-appropriate activities help to keep children distracted; all toys, equipment, and play surfaces should be regularly cleaned with appropriate germicidal solutions;
- an indoor and/or secure outdoor playground area with equipment that has accommodations for those with impaired mobility;
- Internet access, with appropriate safeguards, available to all patients and families for entertainment, work, and education;
- facilities for families to safely store food and human milk and for personal hygiene (laundry, showers, etc) while they are staying with their children in the facility; and
- affordable or free parking for families with hospitalized children to encourage family involvement.

Although interior design and decor is beyond the scope of this document, additional information about child-friendly, developmentally appropriate environments may be obtained from the Institute for Patient- and Family-Centered Care Web site.[44]

Therapeutic and Diagnostic Facilities

The following therapeutic and diagnostic facilities are necessary, and 24-hour availability is strongly recommended:

- routine radiographic imaging, using techniques to reduce radiation exposure in children,[19] with a radiologist skilled in pediatric assessment available either on-site or by teleradiology for interpreting images;
- clinical laboratory with services appropriate for infant and pediatric needs, including hematologic profiles, blood chemistries (including serum bilirubin levels), blood gas studies, microbiology studies, common locally used antibiotic levels, and standard urine studies:
  - equipment to process all commonly ordered tests, such as complete blood cell counts and blood chemistry levels, by using samples of less than 1 mL ("micro" samples);
  - serum drug concentrations for aminoglycoside antibiotics, for example, known to cause ototoxicity and nephrotoxicity, with results available in a timely manner; send-out testing may not allow appropriate adjustments in dosing; and
  - standard laboratory regulations require appropriate critical reference values based on patient age[45];
- pharmacy services to provide age- and size-appropriate drug administration and dosing that includes both a weight-based dose and a final calculated amount[46]:
  - commonly used oral suspensions, including oral sucrose solutions to use for analgesia with painful procedures in young infants, quickly available[34];
  - supplies and expertise to safely create pediatric liquid formulations at nationally accepted standard concentrations[14];
  - orally administered liquid medications dispensed with metric dosing (milligrams, micrograms) on the label in small-volume milliliter-based dosing devices, such as syringes[47];
  - doses of medications calculated by using computer programs or calculations based on appropriate neonatal or pediatric pharmacokinetic models; and
  - medications for pediatrics stored in a separate location from adult formulations both within and outside of the pharmacy; and
- nutritional services to provide child-friendly meals:
  - common infant and toddler formulas, pediatric nutritional supplements, and rehydration formulas stocked in pediatric areas and readily retrieved for those in the emergency department or other areas where children are treated;
  - in cases in which the hospital cafeteria does not remain open 24 hours, prepackaged meals and patient nutritional supplies

stocked in the pediatric areas before the cafeteria closes for the night;
- nutritious meals and drinking water readily available for breastfeeding mothers; and
- donor human milk, which is becoming more widely available and is a consideration for hospitals treating infants who may benefit from this resource.

PERSONNEL AND TRAINING

Because respiratory illnesses are the most common pediatric diagnoses requiring inpatient admission, the need for health care facilities to have ready access to personnel skilled in airway management as well as specialized equipment in sizes appropriate for children from newborn infants to adolescents is imperative. Respiratory therapists with pediatric expertise are especially important for providing safe pediatric care because pediatric patients tend to experience respiratory arrest rather than the cardiac arrest seen in adults. Health care professionals with expertise in pediatric life support techniques should know the location of carts and equipment for cardiopulmonary resuscitation. Mock codes conducted on a regular basis with debriefings either by pediatric-trained internal staff or by using personnel from tertiary centers are strongly recommended. It is helpful if the multidisciplinary medical team trains together during life support courses so that the team functions optimally in times of emergency. This training complements, but does not replace, real-life experience in caring for hospitalized children. Education sessions, clinical training opportunities, and mock codes should be documented for review by hospital quality assurance committees and The Joint Commission.

Physicians and other health care professionals responsible for the care of inpatient pediatric patients should be licensed and have training in the care of hospitalized children either through a formal training program and/or through supervised experience consistent with the individual facility's bylaws for credentialing. Health care professionals need to maintain professional expertise through continuing education as well as maintenance of active life support credentials, including neonatal and pediatric advanced life support or equivalent training.[48] Those who are in charge of a pediatric patient's care may be either on-site or on-call, depending on the severity of a child's illness, and policies may address an acceptable response time for on-call professionals. Children who require intermediate- or higher-level care need a high-level health care professional who is in-house and readily available to respond to the patient immediately should the child's condition deteriorate.[49] The AAP and Society of Critical Care Medicine publication "Criteria for Critical Care Infants and Children: PICU Admission, Discharge, and Triage Practice Statement and Levels of Care Guidance" helps identify resource needs in those settings.[6] Facilities must have policies in place so that the responsible health care professional is known to all personnel caring for the child, whether it be the primary physician, on-call physician, or an in-house emergency department physician with abilities to care for pediatric patients. Procedures should be in place so that both families and the medical team are able to easily identify this person.

Because a child's age, as well as cognitive level, influences his or her ability to cooperate, sedation in children is often administered to relieve pain and anxiety as well as to provide immobility to allow the safe completion of a procedure. Health care professionals should have an in-depth knowledge of the agents they intend to use and their potential complications. It is important to be able to recognize the various levels of sedation in addition to possessing the skills and age- and size-appropriate equipment necessary to provide appropriate monitoring as well as cardiopulmonary support if needed.[50] Because normal vital sign values differ in younger age groups, instruction on the use of cardiorespiratory monitors and their alarms is necessary for all staff. Competencies and case volumes in pediatric sedation should be reviewed annually.[50] Children younger than 1 year are at a fourfold higher risk of anesthesia-related cardiac arrest than those between 1 and 18 years of age.[51] For this reason, for children younger than 2 years or older children with complex medical diseases, it is preferred that board-certified pediatric surgeons and anesthesiologists supervise all elective surgical procedures.[51] The AAP statement "Critical Elements for the Pediatric Perioperative Anesthesia Environment" has detailed information.[50]

Pediatric nursing experience and training is crucial in determining a facility's ability to provide high-quality and safe pediatric medical care. Because nurses spend more face-to-face time with the patient than any other member of the health care team, it is important that they are able to identify signs of decompensation and are able to intervene in an emergency. They should understand that normal laboratory values may differ in pediatric patients. Nurses must understand the behavioral differences that occur in children to modify their care on the basis of the child's understanding of the situation (eg, the use of age-appropriate pediatric pain scales)[34] or developmental differences in their ability to respond to a neurologic examination. Adolescents require a fine balance between guidance and autonomy, and pediatric nurses need skill in

recognizing signs of abuse or self-harm. In cases in which nurses have relatively low skill in obtaining intravenous access, it is preferable that the most experienced staff member attempt to obtain access to decrease the child's emotional and physical trauma. Although having a pediatric nursing educator is ideal, facilities lacking a pediatric educator should ensure they dedicate time to pediatric competencies. It is important for hospitals to anticipate pediatric personnel shortages or times of higher pediatric census by crosstraining nonpediatric staff, who should only be used after successfully demonstrating the essential duties of nurses caring for pediatric inpatients. If skilled pediatric staff are not available, consideration should be given to transfer of children to a facility that can meet the patients' needs. Baseline and annual evaluations that include age-specific and psychosocial competencies as well as the performance of essential pediatric skills should be verified by qualified personnel.

Similar to medical and nursing staff, pharmacists caring for pediatric patients need experience and specific training in their roles. Pediatric patients are at higher risk for medication error and may experience a more serious consequence should an error occur.[17] It is helpful for pharmacists with pediatric experience to participate in prospective order review, safety and technology committees, protocol development, staff education, quality improvement, and other high-impact patient care duties.[52] Pharmacy technicians who prepare pediatric medications, including parenteral solutions, need to maintain documented pediatric pharmacy competencies. Not all facilities will have a pediatric pharmacist on staff, and a liaison pediatric pharmacist from a children's hospital may be a beneficial resource to assist in minimizing the possibility of adverse consequences.

It is highly recommended that the following health care professionals be available on a routine basis to provide services to the inpatient pediatric patients: radiology technologists, nutritionists, lactation specialists, rehabilitation therapists, child life specialists, mental health specialists, social workers, and medical interpreters. Professionals providing these services should have adequate training and continuing education in the pediatric applications of their respective fields. Baseline and periodic competency evaluations should include competencies specific to the pediatric populations cared for in the individual facility. In many facilities, nurses often fill the role of providing lactation support to mother-infant dyads with common lactation issues. Staff who are asked to fill the gaps when other personnel are not available routinely should be provided continuing education opportunities to ensure competence in the roles they are performing. It is not acceptable to use family members as interpreters of health care information, and hospital staff should practice health literacy universal precautions. Only 12% of US adults are fluent in the language of health care, and the ability to absorb and use health information can be compromised by stress.[30] The Agency for Healthcare Research and Quality's *AHRQ Health Literacy Universal Precautions Toolkit, Second Edition*, can help facilities increase patient and family understanding of health information and enhance support for people of all health literacy levels.[30] Foreign and sign language assistance may be provided by a telephone or telehealth interpretive service, and educational materials may be translated by an off-site service if an interpreter is not available in-house. When it is not feasible to employ full-time personnel or crosstrain staff because of financial or staffing issues, facilities should maintain appropriate consultative relationships with tertiary hospital staff members. These points of contact may provide regular educational sessions, consultations for specific patients, and assistance with policy development.[8,9]

SPECIAL CONSIDERATIONS

Although all health care professionals who provide care to pediatric patients should be familiar with the unique and changing physical and psychosocial needs of children and the core concepts of patient- and family-centered care, having a child life specialist on staff is recommended.[28] If it is not feasible to maintain a dedicated child life specialist, facilities should consult one at a tertiary center to assist with ongoing education of the local hospital staff in the provision of psychosocial care and family- and child-friendly services.[43] The assessment of pain can be difficult in nonverbal children, and health care professionals need training in how to use age-appropriate pediatric pain scales appropriately. Staff may also need training on how to support children with intellectual disabilities or autism spectrum disorder, for example, who present with a medical illness needing treatment. Training in the physical as well as the emotional components of end-of-life situations and palliative care may be helpful for staff because many find it difficult to deal with a child's impending or actual death.

Hospitalized children, especially those with hospital stays anticipated to last more than a week, need a designated hospital liaison (nurse, social worker, discharge planner, child life specialist) to partner with the child's school to ensure the hospitalization does not cause interruption in the child's education endeavors. In some cases, having access to videoconferencing or online attendance at a child's school can keep the child from getting behind in his or her studies.

Children may be seen in the emergency department for medical disorders that can either present as or coexist with psychiatric or behavioral disorders needing appropriate triage. It is important to be sensitive to the needs of adolescent patients by asking nonprejudiced questions in private about sexual partners and substance use. Although toxic ingestions in toddlers may be accidental, those in adolescents may be a sign of suicidal intentions.[53] Sixteen percent of adolescents have seriously considered, and 8% have attempted, suicide in the past year.[54] Certain ethnic groups, those with a family or personal history of suicide attempts or behavioral disorders, and those who identify as a sexual minority are at higher risk.[55] Personnel should be able to recognize these issues and be familiar with the hospital's mental health resources and policies for appropriate triage.

Health care professionals responsible for the care of children should be trained in the recognition and initial management of child abuse, maltreatment, and neglect whether physical, sexual, emotional, or medical. They should be aware of the types of injuries that can occur at various ages and which ones are unlikely to have occurred in the manner in which they are described by the child or accompanying adult.[56,57] Children who have experienced physical or sexual abuse, children who have experienced violence in the home, or children who are diagnosed with a psychological disorder should have timely intervention with a child maltreatment team and/or mental health specialist. There should be policies in place to ensure proper reporting of allegations to authorities for further investigation as well as appropriate transfer to a facility with mental health services with expertise in pediatric care if not available locally. Guidance in the area of child maltreatment can be found on the AAP Council on Child Abuse and Neglect Web site.[58]

CONCLUSIONS

Inpatient facilities caring for the unique pediatric population should be well resourced to provide high-quality and safe health care by providing the appropriate policies, equipment, facilities, and personnel as outlined in this clinical report.

Routine Neuroimaging of the Preterm Brain

Ivan L. Hand, MD, FAAP,[a] Renée A. Shellhaas, MD, MS, FAAP,[b] Sarah S. Milla, MD, FAAP,[c] COMMITTEE ON FETUS AND NEWBORN, SECTION ON NEUROLOGY, SECTION ON RADIOLOGY

Neuroimaging of the preterm infant is a common assessment performed in the NICU. Timely and focused studies can be used for diagnostic, therapeutic, and prognostic information. However, significant variability exists among neonatal units as to which modalities are used and when imaging studies are obtained. Appropriate timing and selection of neuroimaging studies can help identify neonates with brain injury who may require therapeutic intervention or who may be at risk for neurodevelopmental impairment. This clinical report reviews the different modalities of imaging broadly available to the clinician. Evidence-based indications for each modality, optimal timing of examinations, and prognostic value are discussed.

INTRODUCTION

Central to the assessment of the preterm infant is identifying the presence and extent of brain injury. Preterm infants are at significant risk of intraventricular hemorrhage (IVH), periventricular leukomalacia (PVL), posthemorrhagic ventricular dilatation, and other neurologic injuries that may or may not have imaging corollaries. Through neuroimaging, the neonatologist may initiate interventions and plan for supportive care and assess the risk of future neurologic impairment.

In 1968, Abraham Towbin[1] described the frequent finding of IVH at necropsy in preterm infants, with abnormalities almost universally present in those born at less than 28 weeks' gestation. Not until 10 years later did Papile at al[2] describe the computerized tomography (CT) findings of 46 consecutive very low birth weight (VLBW) infants and demonstrate a much higher incidence of IVH than was clinically suspected. That report described 4 separate grades of hemorrhage: "Grade I–subependymal hemorrhage, Grade II–intraventricular hemorrhage without ventricular dilatation, Grade III–intraventricular hemorrhage with ventricular dilatation, and Grade IV–intraventricular hemorrhage with parenchymal hemorrhage." Since the initial report, the Papile classification has been modified to grade I, indicating minimal IVH; grade II, with IVH occupying

10% to 50% of the ventricular area; grade III, representing IVH with >50% of ventricular area; and last, parenchymal hemorrhage, most likely attributable to hemorrhagic venous infarction.[3]

These findings led to one of the earliest outcomes studies,[4] in which authors described the association of major developmental and neuromotor handicaps with the findings of more severe (grade III and IV) IVH on CT scan performed between 3 and 10 days of age. On the basis of these and other studies, the American Academy of Neurology (AAN) released practice parameters in 2002 suggesting universal cranial ultrasonographic screening for all infants born at less than 30 weeks' gestation.[5] The AAN also recommended that initial screening ultrasonography be performed at 7 to 14 days after birth and repeated at near term corrected age. In 2001, the Canadian Pediatric Society recommended screening all infants born at less than 32 weeks' gestation at 2 weeks after birth, with a repeat screening 6 weeks after birth.[6] Since the publication of those guidelines, cranial ultrasonography capabilities have evolved, and modern ultrasonography technology, along with the use of supplementary acoustic windows, can now provide good structural imaging of the preterm infant brain.[7]

Imaging the entire brain was once performed by using CT scanning. Use of head CT has given way to improved cranial ultrasonography as well as MRI, which yields better detail and avoids the use of ionizing radiation.[8] However, routine use of MRI for screening the preterm infant has been identified as being of questionable value in the Choosing Wisely campaign of the American Academy of Pediatrics.[9] The aim of this clinical report is to provide guidance to clinicians for an evidence-based approach to neuroimaging for the preterm infant.

INITIAL SCREENING EXAMINATIONS

The VLBW (ie, birth weight <1500 g) infant is at high risk for germinal matrix and IVH as well as ischemic white matter injury as identified by cranial ultrasonography. Risk of severe IVH is inversely related to gestational age, with infants born at less than 24 weeks' gestation at highest risk.[10] In 2017, the Vermont Oxford Network database demonstrated an overall 24.6% incidence of IVH and an 8.1% rate of severe IVH, defined as grade III or IV among more than 50 000 VLBW infants.[11] In a recently published survey of the California Perinatal Quality Care Collaborative, 63% of infants born at 22 to 23 6/7 weeks' gestation had IVH, with 36% demonstrating severe IVH.[12] This incidence decreased to 14% of infants whose gestational age at birth was 30 to 31 6/7 weeks having any IVH and 1.4% having a severe grade. Less severe grades of IVH (grades I and II) may have less prognostic influence on clinical outcomes. In a National Institute of Child Health and Development study of 1472 infants born at less than 27 weeks' gestational age,[13] there was no significant difference in neurodevelopmental outcomes at 18 to 22 months of those infants with and without these low-grade hemorrhages.

PVL is a disorder of the periventricular cerebral white matter that may be cystic or diffuse in nature. Most cystic PVL occurs in infants born between 26 and 30 weeks' gestation, initially appearing as periventricular increased echogenicity (eg, a blush or flare) with cystic evolution over the course of a few weeks. Periventricular hemorrhagic infarcts (PVHIs) (ie, formerly grade 4 IVH) occur mainly in infants born at <26 weeks' gestation[14] and occur infrequently in infants born beyond 30 weeks' gestation.[15] A PVHI is a parenchymal lesion usually associated with a large IVH and, on the basis of current understanding, believed to be caused by venous infarction. A PVHI is not, as once believed, an extension of the IVH into the parenchyma.

Severity of IVH in the most immature infants is consistent with the developmental changes of the subependymal germinal matrix as it decreases in size from 2.5 mm in the 24-week preterm infant to involution at about 36 weeks' gestational age.[3] For these and other reasons affecting vascular integrity, the more moderate and late preterm infants (those born between 32 and 36 6/7 weeks' gestation) are at less risk for significant intracranial injury. In a retrospective study of moderately preterm infants born between 29 and 33 weeks' gestation, 60% of a cohort of 7021 infants underwent cranial imaging, and 15% of these 4184 infants had ultrasonographic abnormalities.[16] The rates of severe IVH and cystic PVL were 1.7% and 2.6%, respectively, in this population.[15] The authors noted that low Apgar scores, maternal risk factors, lack of antenatal steroids, and vaginal delivery were associated with ultrasonographic abnormalities, including intracranial hemorrhage, PVL, and ventriculomegaly. The presence of risk factors such as abnormal neurologic examination, intrauterine growth restriction, abnormal head circumference, low Apgar scores, and need for ventilation or surfactant increased the chance of detecting an abnormality by fourfold in a group of more mature preterm infants born at 33 to 36 weeks' gestational age.[17] In a similar study, infants born at >30 weeks' gestation who were found to have significant ultrasonographic abnormalities typically had clinically significant events, such as placental abruption, seizures, hypotension, and hydrocephalus, which warranted the cranial ultrasonographic investigations.[18] Risk factors also play a role in the more immature preterm

infants as well. In a study of 303 infants born at <30 weeks' gestation, no asymptomatic infants required clinical intervention solely on the basis of screening ultrasonography performed at 7 to 14 days.[19] All infants who required clinical interventions had factors precipitating an ultrasonographic study, including anemia, metabolic acidosis, pulmonary hemorrhage, and hypotension. Similar results have been reported for infants born at <32 weeks' gestation with risk factors for severe IVH including lack of antenatal steroids, outborn status, asphyxia, significant acidosis, and/or hypotension.[10] Thus, the risk for severe IVH is associated with gestational age ≤30 weeks' gestation, with the highest risk in infants born at <24 weeks' gestation. Infants born at >30 weeks' gestation have a low risk of severe IVH unless they have additional clinical risk factors.

TIME OF IVH OCCURRENCE

The overwhelming majority of IVH in the preterm infant occurs within the first 3 days of life.[20–24] Of those, approximately 50% of hemorrhages occur within the first 5 hours, and approximately 70% occur within the first 24 hours of life. By 7 days, 95% of IVH will have occurred, with a small percentage appearing at 7 to 10 days.[21,22] In an analysis of infants requiring neurosurgical intervention for posthemorrhagic hydrocephalus, the average age of IVH development was 2 days, with ventriculomegaly apparent by 3 days of age.[24] In this study, temporizing neurosurgical procedures were performed 3 weeks after IVH development. Thus, frequent follow-up of significant IVH until resolution or stabilization will likely allow for early determination of ventricular dilation and the potential need for therapy.

REPEAT BRAIN IMAGING

PVL may initially be observed during the first week of life in the VLBW infant as increased echogenicity of the periventricular white matter, sometimes described as an echogenic "blush" or "flare." Because the periventricular white matter may normally have slight increased echogenicity, the echogenic choroid plexus can be used as an internal comparison for increased echogenicity.[25] Normal periventricular white matter should be less echogenic than the choroid plexus. These areas of white matter abnormality may become cystic on ultrasonography within 2 to 5 weeks and/or lead to ventriculomegaly from white matter volume loss, which can be visible on repeat ultrasonography at term equivalent age (TEA). In light of these findings, the Canadian Pediatric Society recommended screening at 6 weeks of age, whereas the AAN suggested a near term study.[5,6] These varying suggested time frames can lead to different timing of studies in the extremely preterm infant. Because 4- to 6-week screening is sensitive for identifying PVL and term equivalent cranial ultrasound findings are associated with adverse neurodevelopmental outcomes, we recommend screening during both time periods.

Sequential ultrasonography appears to have the best yield for identifying lesions associated with cerebral palsy. In infants with cerebral palsy, almost one third were found to have PVL on ultrasonography performed after 4 weeks of age.[26] Among 12 739 preterm infants who were screened at 4 weeks of age and again at near TEA, notably, 14% had cystic PVL that was only visible on the early imaging and had resolved by the time of the later study.[27] Subgroup analysis revealed that in infants born at <26 weeks' gestation, 18.5% of PVL cases were missed by a single ultrasonographic examination performed at TEA. However, a follow-up study demonstrated that infants who had cystic PVL at any time on ultrasonographic imaging had a significantly higher primary outcome of late death or neurodevelopmental impairment than those who never had such findings.[28] Thus, even if the findings were transient, infants with cystic PVL warrant close follow-up observation for neurodevelopmental impairment. Communication regarding neuroimaging results and follow-up plans are recommended between inpatient and outpatient providers.

STANDARD CRANIAL ULTRASOUND IMAGING TECHNIQUE

Cranial ultrasound imaging has traditionally made use of the anterior fontanelle as an acoustic window and should be performed by an American Registry for Diagnostic Medical Sonography board-certified sonographer. Images of the brain are taken in the coronal plane with anterior to posterior views and in the sagittal plane with appropriate angulation on the left and right.[7,29] Use of the posterior fontanelle may allow more detailed assessment of the periventricular white matter and occipital lobes. These views allow excellent visualization of supratentorial structures but limited views of the posterior fossa and cerebellum. The cerebellum has been shown to be a frequent site of injury, with significant hemorrhage occurring in as many as 9% of preterm infants with a diagnosis made by appropriately performed ultrasonography.[30,31] For this reason, additional imaging through the mastoid fontanelle is recommended. In cases of limited cerebellar hemorrhage, there was much better imaging sensitivity when mastoid views were obtained (86%) than when only the anterior fontanelle was assessed (16%).[32] However, mastoid views are unable to detect cerebellar microhemorrhages, which can only be visualized with MRI. Apart from hemorrhage, cerebellar hypoplasia is also associated with motor and

TABLE 1 Neuroimaging the Preterm Infant

Modality	Clinical Notes	Timing
Cranial ultrasonography	Routine anterior and mastoid fontanelle, optional posterior fontanelle, and vascular images	1. Initial scan within 7 d of age 2. Repeat scan at 4–6 wk of age 3. Scan near term or discharge
MRI	Ideally nonsedated	Optional, based on physician-family discussion; TEA
CT	Should be avoided in most instances	—

Preterm infants ≤30 wk or >30 wk with significant risk factors (see text). —, not applicable.

cognitive deficits.[31] Although most cases of cerebellar hypoplasia have been associated with cerebral white matter injury, other factors, including genetic and neurodegenerative syndromes, medications, infarction, and nutrition, play a role in cerebellar growth and affect neurologic outcomes. Thus, cerebellar imaging may have important diagnostic and prognostic value as part of the screening ultrasonographic examination. The addition of high-resolution linear color Doppler images obtained through the anterior fontanelle can be used to evaluate for patency of the superior sagittal sinus. If there is concern for venous sinus thrombosis, the posterior and mastoid windows can additionally help to evaluate the sagittal and transverse sinuses. Many centers are also measuring the resistive index of the anterior cerebral artery as a marker for vascular compliance and to document normal waveforms and diastolic flow.

MRI

MRI has become increasingly popular as a means of identifying brain injury in the preterm infant. MRI provides the most detailed imaging of the brain and avoids the radiation risks associated with CT.[33] Specific absorption rates (a measure of power of radiofrequency fields) in patients undergoing magnetic resonance procedures appear to be much lower in neonates than adults and within a safe and acceptable range.[34] MRI studies may be successfully performed in the preterm population at TEA without the use of any sedating medications.[35,36] Protocols that rely on feeding the infant 20 to 30 minutes before the scan and swaddling to limit movement have generally been successful in avoiding significant sedation in the majority of cases. With the use of nonsedated MRIs and the increasing availability of MRI-compatible equipment, this imaging has become more readily obtainable. Yet, controversy persists regarding which infants should receive MRI studies at TEA. Abnormal findings on MRIs performed at TEA in a group of infants born at <30 weeks' gestation have been shown to be predictive of psychomotor delay and cerebral palsy at 2 years of age.[37] The predictive value of MRI at TEA for school-aged neurocognitive outcomes is less clear. One study reported that abnormal brain MRI at TEA was predictive of adverse neurodevelopmental outcomes at 7 years of age.[38] This association with adverse neurodevelopmental outcome at 7 years of age was particularly striking for abnormalities in the white matter, deep gray matter, and cerebellum. However, other studies have reported[39,40] that adding MRI to early and late cranial ultrasonography did not improve prediction of severe intellectual disability or neurodevelopmental impairment at 6 to 7 years of age. Obtaining routine MRI has also not been shown to have a clinically significant effect on maternal anxiety or improve quality of life, although it may increase the cost of care.[41] As the Choosing Wisely[9] campaign identified, there is insufficient evidence that routine brain MRI at TEA improves long-term outcomes, and the effects the results may have on an individual family may not be predictable.[42,43]

RECOMMENDATIONS (TABLE 1)

- Infants born at a gestational age of ≤30 weeks and selected infants with a gestational age of >30 weeks who are believed to be at increased risk for brain injury on the basis of identified risk factors are recommended to be screened for IVH with appropriately performed cranial ultrasonography. These risk factors may include, but are not limited to, placental abruption, need for vigorous resuscitation, hypotension requiring pressor support, severe acidosis, prolonged mechanical ventilation, confirmed sepsis, or pneumothorax.
- Routine cranial ultrasonographic screening is recommended by 7 to 10 days of age for infants born at ≤30 weeks' gestational age. Screening before 7 days of age may be indicated for infants with clinical signs and symptoms suggestive of significant brain injury. Repeat cranial ultrasonographic screening is recommended to be performed at 4 to 6 weeks of age and at TEA or before hospital discharge.
- Infants with abnormal cranial ultrasonography findings are recommended to have repeat serial cranial ultrasonography as clinically indicated on the basis of chronological as well as gestational age.

- Standard cranial ultrasonographic screening includes views from the anterior and mastoid fontanelles. Additional posterior fontanelle and vascular imaging can be performed for additional information.
- CT is no longer considered a part of routine imaging techniques of the preterm brain.
- On the basis of available evidence, MRI for infants born at <30 weeks' gestational age is not indicated as a routine procedure. MRI may be offered at TEA to the high-risk infant after a conversation with the family regarding the limitations of this test for estimation of long-term prognosis. When possible, it is recommended that the brain MRI be performed without contrast in the nonsedated state by using a "feed and wrap" technique.

DEDICATED TO THE HEALTH OF ALL CHILDREN™

Runaway Youth: Caring for the Nation's Largest Segment of Missing Children

Thresia B. Gambon, MD, MPH, MBA, FAAP,[a] Janna R. Gewirtz O'Brien, MD, FAAP,[b] COMMITTEE ON PSYCHOSOCIAL ASPECTS OF CHILD AND FAMILY HEALTH, COUNCIL ON COMMUNITY PEDIATRICS

The largest segment of missing children in the United States includes runaways, children who run away from home, and thrownaways, children who are told to leave or stay away from home by a household adult. Although estimates vary, as many as 1 in 20 youth run away from home annually. These unaccompanied youth have unique health needs, including high rates of trauma, mental illness, substance use, pregnancy, and sexually transmitted infections. While away, youth who run away are at high risk for additional trauma, victimization, and violence. Runaway and thrownaway youth have high unmet health care needs and limited access to care. Several populations are at particular high risk for runaway episodes, including victims of abuse and neglect; lesbian, gay, bisexual, transgender, and questioning youth; and youth in protective custody. Pediatricians and other health care professionals have a critical role to play in supporting runaway youth, addressing their unique health needs, fostering positive relationships within their families and with other supportive adults, and connecting them with available community resources. This report provides clinical guidance for pediatricians and other health care professionals regarding (1) the identification of adolescents who are at risk for running away or being thrown away and (2) the management of the unique medical, mental health, and social needs of these youth. In partnership with national, state, and local resources, pediatricians can significantly reduce risk and improve long-term outcomes for runaway youth.

INTRODUCTION

The largest segment of missing children in the United States includes runaways, children who run away from home, and thrownaways, children who are told to leave or stay away from home by a household adult.[1,2] This report aims to provide clinical guidance for pediatricians regarding (1) the identification of adolescents who are at risk for running away or being thrown away and (2) the management of the unique medical, mental health, and social needs of these youth.

There has been a considerable amount of research conducted in the area of runaway and thrownaway youth since the 2004 publication of the previous clinical report "The Pediatrician's Role in the Prevention of Missing Children."[3] This clinical report expands on the previous report's discussion of youth who run away in the United States. Although estimates of the prevalence of running away vary depending on definitions, methodology, and population, the 2013 National Incidence Studies of Missing, Abducted, Runaway, and Thrownaway Children (NISMART-3), released by the US Office of Juvenile Justice and Delinquency Prevention in 2017, estimated that 413 000 children ran away or were thrown away in 2013, at a rate of 5.3 per 1000 children, comparable to previous NISMART cycles.[2,4] Other studies have estimated that between 5% and 8% of adolescents run away every year.[5–8] It is important that pediatricians understand this population so they can better serve these youth and families in clinical practice and in the community setting.

Unaccompanied adolescents who run away or who are asked to leave home have unique health needs. Before running away, many have learning disabilities, struggle with mental illness, experience school failure, or engage with peer groups who participate in high-risk behaviors.[9] Many have experienced abuse or neglect before running away.[10–13] While away, these unaccompanied minors are at high risk for victimization and violence; substance use; risky sexual behavior, including survival sex; further absenteeism from school; and other associated negative health consequences.[9–11,14–19]

DEFINITIONS

According to the Office of Juvenile Justice and Delinquency Prevention, a runaway episode occurs when a child leaves home without permission and stays away overnight for at least 1 night (for children younger than 15 years) or 2 nights (for children 15 years or older). A thrownaway episode occurs when a child is asked or told to leave the home by a household adult or is prevented from returning home by a household adult for at least 1 night when no adequate alternative care is arranged.[2]

Runaway and thrownaway episodes are grouped together because youth often fall into both categories. Information varies depending on who is interviewed regarding the circumstances; youth do not always view the circumstances the same way as the guardians and/or parents do.[20] Twenty-two percent of youth described the episode as a combination of running away and being thrown out.[20] In this report, the term "runaway" is used to refer to both categories, although the term "thrownaway" is occasionally used to be consistent with the data.

Runaways may not always be classified as missing children, making it difficult to quantify the problem. Many runaways are not considered missing because guardians and/or parents know the whereabouts of the youth. Youth who run away may stay with friends or other family members.[1,20] In addition, some runaways may not be reported missing because the guardians and/or parents are not looking for them. There is a small category of children who are permanently abandoned and are often not included in data because they may not be reported as missing.[1]

DEMOGRAPHICS

The total number of youth who run away is difficult to measure for a number of reasons, including inconsistent definitions and difficulty with sampling.[4] The data regarding the incidence of running away vary by state and by study population. As noted previously, NISMART-3 estimated a prevalence of running away of 5.3 per 1000 children.[2] In another study, published in 2006 on the basis of data from the 1996 wave of the National Longitudinal Study of Adolescent Health, authors reported that 6.4% of youth (nearly 850 000) had run away in the 12 months before the 1996 survey.[6] By using the data from the National Longitudinal Survey of Youth (1997 cohort), it was found that nearly 1 in 5 youth ran away before age 18. A school-based survey of Minnesota youth in grades 8 through 11 revealed that between 4% and 7% of students had run away at least once in the previous year.[7,8]

Each report of a missing child made to law enforcement is required by federal law to be entered into the Federal Bureau of Investigation National Crime Information Center (National Center for Missing and Exploited Children [NCMEC]).[21] Some of the reports may be regarding the same child because a report can be made each time a child is missing. In 2017, 464 000 reports were made into this database. One role of the NCMEC, the national clearinghouse and resource center for missing and exploited children, is to help with finding these children. In 2017, the NCMEC assisted with more than 27 000 cases, including 25 000 runaways (missingkids.org).[21]

The Runaway Safeline, (1–800-RUNAWAY), formerly known as the National Runaway Switchboard, is a federally funded national resource that provides services to youth and their families (https://www.1800runaway.org/). The Safeline allows runaway and homeless youth or their parents to call for assistance or guidance; attain 24-hour referrals to community resources, including shelter, food banks, legal assistance, and social services agencies; and seek crisis intervention counseling.[20] The Safeline handled more than 70 000 calls and electronic contacts in

2017.[22] Of those contacts, 31% of contacts were about youth who were contemplating running away, 16% were about youth who had run away, 5% were about youth asked to leave home or prevented from returning home (thrownaway), and 9% were about youth experiencing homelessness. Approximately three-fourths of the calls came from the affected youth.[22] Research compiled by the National Opinion Research Center found that more than 70% of youth left home on the spur of the moment, 36% of youth planned to run in advance, and 23% of youth who were thrown out said they expected to be thrown out.[20] This information was compiled from calls to the National Runaway Switchboard from 2000 to 2009, a comprehensive review of research on runaways, and new research conducted on youth in the streets and shelters in Chicago and Los Angeles between October 2008 and January 2010.[20] More than half of the adolescents reported that friends knew where they were, and 26% said that their parents knew their whereabouts. Only 13% of youth interviewed said that no one knew where they were.[20]

The NISMART-3 response rate was not high enough to be able to break down the characteristics of the runaway episodes.[2] Data from NISMART-2, conducted in 1999, reveal that 68% of runaways were between 15 and 17 years of age, 28% were 12 to 14 years of age, and 4% were 7 to 11 years of age.[1] Runaway episodes are most likely to occur during the summer; runaways usually go between 10 and 50 miles from home. Twenty-three percent traveled more than 50 miles from home. Most were gone from 24 hours to 1 week. Seven percent of runaways were missing for 1 to 6 months.[9]

The data regarding the distribution of runaway youth from racial and ethnic minority backgrounds are inconsistent.[1] Although racial and ethnic distributions have not been reported for NISMART-3, NISMART-2 data suggest that youth of color may be slightly overrepresented among runaway youth.[1,2] Research published in 2006 exploring the demographic profile of runaway youth in the United States using data from the National Longitudinal Study of Adolescent Health did not reveal significant differences in running away among racial and ethnic groups.[6] However, more recent data from the National Runaway Safeline reveal that youth of color seem to be overrepresented among runaway youth in crisis who are connecting with the Safeline; 23% of those youth connecting identify as black or African American, compared with 14% of the general population.[22] Morton et al[23] found similar results in 2018, revealing that black or African American youth were more likely to be homeless (including runaway episodes) than their peers. Although data on American Indian/Alaska Native youth who have run away are limited, an estimated 1 in every 130 American Indian/Alaska Native children go missing each year.[24] The number missing is likely to be higher, but estimates of American Indian/Alaska Native youth are limited because there is no centralized reporting system in tribal communities.[24]

The data regarding the gender distribution of runaway youth are also mixed but consistently reveal that girls run away more often than boys.[6] Sanchez et al[6] reported that female-identifying youth were more likely to have runaway. Data from the National Runaway Safeline reveal a similar trend. Among those youth connecting with the National Runaway Safeline in 2017, 69% identified as female, 29% identified as male, and 3% identified as either transgender or gender nonconforming.[22]

More than a decade of data suggest that lesbian, gay, bisexual, transgender, and questioning (LGBTQ) youth are disproportionately represented among runaway and thrownaway youth. An estimated 20% to 40% of teenagers who are homeless identify as LGBTQ, compared with 4% to 10% of nonhomeless peers.[25–28] In a 2015 study of 434 homeless youth in Texas, 25% of youth identified as lesbian, gay, bisexual, transgender, or something else.[25] The unique runaway experiences and health care needs of LGBTQ runaway youth are discussed in detail later in this report.

HEALTH IMPACTS

A generation of research reveals that runaways are at high risk for adverse health outcomes, including disease, crime (both as victims and perpetrators), injuries, alcohol use, illegal drug use and sales, and sexual contact including abuse and activity.[1,9,10,15–17,29] It is critical that pediatricians are aware of the health implications of runaway episodes so that they can better care for these children. Many, but not all, runaways are homeless while away. The American Academy of Pediatrics (AAP) policy statement "Providing Care for Children and Adolescents Facing Homelessness and Housing Insecurity" details the health risks associated with homelessness.[30] This section focuses on health risks associated with running away, although there is some overlap.

While away from home, youth are at high risk for poor sexual health outcomes, including pregnancy, sexually transmitted infections, and sexual exploitation and abuse.[17,31–35] Nearly half of female street youth and one-third of female youth living in emergency shelters report a history of pregnancy.[33,36] Although not the focus of this report, runaways may become involved in sex trafficking or exploitation, including survival sex, which is sex in exchange for food, clothing, or housing.[1,15] Readers are referred to the AAP policy "Child Sex

Trafficking and Commercial Sexual Exploitation: Health Care Needs of Victims" and other publications for additional information on this critical topic.[37,38] For youth who have been victims of abuse or neglect before running away or while away from home, pediatricians are mandated reporters. In states where sex trafficking is considered a form of abuse, pediatricians must make a formal report of suspected exploitation to law enforcement and to child protective services as well, if indicated.

Youth who run away are more likely to engage in substance use.[1,9] In addition to the health consequences associated with substance use alone, substance use increases the risk of sexual assault and mental health consequences dramatically for runaway adolescents.[38] In urban areas, these youth often join gangs or are involved in violent and/or drug-related criminal activity.[1,39] They have a high likelihood of being affected by violence while away from home.[1,11]

Youth who run away experience higher rates of mental illness, including anxiety, depression, and suicidality.[1,9,14,40] Edinburgh et al[14] showed that among runaway youth presenting to a child advocacy center, nearly a quarter had a history of a suicide attempt, compared with 13.7% of youth who had not run away. Older data from NISMART-2 revealed that 4% of endangered runaway and thrownaway youth had attempted suicide previously, but these data were not updated in NISMART-3.[1] A 2004 study measuring the prevalence of mental health disorders among runaway and homeless youth in small- to midsized cities in 4 Midwestern states revealed significantly higher rates of mental health disorders when compared with age-matched peers.[41]

Unfortunately, runaways frequently risk further trauma while away, including physical or sexual assault.[1,14,15,42] Poor mental health is believed to be associated with street victimization among homeless and runaway youth.[38] Running away puts youth at risk for exposure to additional trauma, further limits their social supports, and makes it difficult to access the necessary medical help for these disorders.[38]

There is a strong association between substance use and runaway episodes, although a causal link has not been established.[9,14,43] It is unclear whether the use of drugs and/or alcohol precipitates running away or being asked to leave home or whether the circumstances associated with the episodes lead to increased substance use, although longitudinal studies suggest that the association is likely bidirectional.[9] A 2013 study by Edinburgh et al[14] of youth presenting at a child advocacy center revealed that 1 in 3 runaway youth met criteria for problem substance use, whereas 1 in 10 nonrunaway youth met criteria. NISMART-2 data revealed that 17% of runaway youth reported using "hard drugs"; 18% were in the company of someone known to be using drugs while away, and 19% of runaway and thrownaway youth surveyed were substance dependent.[1]

Running away also has long-term effects on educational success. Youth who run away multiple times are 18% more likely to drop out of high school.[44] Youth who run away from home are less likely to graduate from high school. Seventy-five percent of runaway or homeless youth drop out of school.[19]

IDENTIFYING YOUTH WHO ARE AT RISK FOR RUNNING AWAY

There is no current, validated screening tool for runaway episodes, but practices should consider assessing for previous runaway episodes and risk factors for running away using a trauma-informed approach, which involves being aware of trauma and adverse childhood experiences that can affect health. "A trauma informed practice is defined as an organizational structure and treatment framework that involves understanding, recognizing, and responding to the effects of all types of trauma."[45] The AAP Trauma Toolbox for Primary Care contains resources on implementation for a primary care practice to become trauma informed.[45]

Many factors drive adolescents to run away or to be asked to leave home. The most common reason youth give for running away is fleeing a negative home environment.[9] In a study conducted by Tucker et al[9], several factors were found to be common in the runaway population. These factors included a perception of low parental support in the ninth grade, school disengagement, substance use, and depressive affect.[9] Disruption of the family structure and dysfunction and disorganization of homes are known risk factors for running away.[9,10]

Runaway behavior is more common in youth who have been exposed to violence, had a poor parent-child relationship, and/or had a history of delinquent behavior or depressive symptoms. Some studies have shown that economic problems in the home may lead to more youth running away.[19] Tyler and Bersani[46] noted that youth living in disadvantaged neighborhoods were also more likely to run away.

Disengagement from school is a significant risk factor for a child running away or becoming homeless. Tucker et al[9] reviewed an analysis of more than 15 000 youth in crisis shelters or transitional living programs and found that 47% had irregular school attendance and 22% had dropped out or been expelled.

Youth who are asked to leave home may include youth who are pushed out of their homes for different

reasons, some because the family cannot provide for their specific mental health or disability needs, some because parents cannot afford to provide care, and many because of poor relationships between parents and youth.[1,19]

Implementation of various screens during health care visits can assist to identify family stressors, school problems, and other social determinants of health that may increase the risk of running away. Screening tools such as the Well Child Care, Evaluation, Community Resources, Advocacy, Referral, Education survey instrument (WE CARE) and Safe Environment for Every Kid (SEEK) parent screening questionnaire screen families for problems related to education, housing, child maltreatment, domestic violence, and more. More information is available on the AAP Poverty and Child Health Web site.[47] For, adolescents, pediatricians should conduct a thorough, confidential psychosocial assessment, such as the HEEADSSS assessment (home environment, education and employment, eating, peer-related activities, drugs, sexuality, suicide/depression and safety).[48] Routine depression screening is also recommended for teenagers. Pediatricians should also assess for protective factors, including whether adolescents consider themselves to have several sources of support at home, at school, and in the community.[14]

When an adolescent at high risk for running away is identified, early intervention to prevent runaway episodes is recommended. Use of practice- and community-based resources to address any modifiable risk factors, support the psychological and behavioral health needs of the child and family, and ensure safety can be helpful. Pediatricians can share information regarding national resources for runaways and their families, including the National Runaway Safeline and the NCMEC (see Resources). Pediatricians can ask adolescents where they would go if they were to run away or be forced out, specifically assessing for other safe, supportive adults who might be able and willing to provide shelter and support in a crisis. Pediatricians can refer families to local resources for behavioral health, family therapy, and support and assistance with other issues.

Several high-risk populations deserve additional attention, including victims of abuse and neglect, LGBTQ youth, and youth in protective custody. Each of these populations is discussed in further detail in the sections that follow. Adolescents in these subgroups are at high risk for running away and may experience significant health effects while away.

VICTIMS OF ABUSE AND NEGLECT

Among runaway and thrownaway youth surveyed as part of NISMART-2, 21% (estimated 350 400) reported being physically or sexually abused at home in the year before the episode or were afraid of abuse if they returned.[1] Across multiple studies of homeless youth, rates of sexual abuse ranged from 17% to 35% and physical abuse ranged from 40% to 60%.[19,26] Approximately 20% of street youth have, at some point, been removed from their homes by authorities because of neglect or abuse.[32] Runaway youth consistently report family conflict as a primary reason for leaving the home.[32,49] Thrane et al[10] studied the impact of family abuse on running away, deviance, and street victimization and found that adolescents who had been exposed to neglect and sexual abuse ran away sooner and were more likely to be victimized on the street. Although most runaway youth are missing for less than 1 week and remain close to home, those who go missing for longer periods of time and who travel farther from home are more likely to have been abused previously.[10] As previously noted, while youth are away, they are at risk for further victimization.[14,38]

LGBTQ YOUTH

As noted previously, a decade of research suggests that an estimated 20% to 40% of teenagers who are homeless identify as LGBTQ, compared with 4% to 10% of nonhomeless peers.[25–28] In a 2012 survey of service providers for homeless youth and youth at risk for homelessness, Durso and Gates[50] explored reasons for homelessness among LGBTQ youth and found that nearly half (46%) of LGBTQ youth reported running away because of rejection relating to sexual orientation or gender identity, and 43% reported being forced out by parents because of sexual orientation or gender identity. Nearly one-third of these youth (32%) attributed their homelessness to physical, sexual, or verbal abuse at home.[50] To the authors' knowledge, there are no specific data that are focused on LGBTQ runaway youth; thus, the literature on LGBTQ homeless youth is used more generally in this discussion given the significant overlap in this population.

LGBTQ youth are more likely to be affected by the many health risks associated with homelessness.[41,50,51] LGBTQ youth who are homeless report higher rates of survival sex, substance use, and victimization when compared with non-LGBTQ homeless youth.[41,51–53] A survey by Cochran et al[51] comparing LGBT homeless youth and heterosexual homeless youth revealed that LGBT youth reported, on average, 7.4 more acts of sexual victimization than their heterosexual counterparts and had significantly higher rates of psychopathology.[50] LGBTQ youth also experience higher rates of depression and suicidality.[41,53,54] In a multistate single-day survey of homeless youth

by Van Leeuwen et al,[54] 62% of LGBTQ homeless youth reported a previous suicide attempt, compared with 29% of non-LGBTQ homeless youth.[54] In the same study, homeless LGBTQ youth had higher rates of sexually transmitted infections, including HIV, than heterosexual homeless youth.[54]

YOUTH IN PROTECTIVE CUSTODY

Data on runaway youth living in protective custody, including foster care, vary depending on the source of the data.[55–57] In 2017, 4734 (1.1%) of the 442 995 children in foster care in the United States ran away from their foster care placements, consistent with data reported by the US Department of Health and Human Services in 2016. Data from 2010 include all runaways in foster care from birth to 18 years of age, but because young children do not have the capability to run away, the estimate of children who run away increases with age, with approximately 30% of youth 12 years or older in out-of-home care placements having run away.[58,59] In 2013, Benoit-Bryan[59] reported that older youth in foster care were more than 2.5 times more likely to run away than youth who do not live in foster care. Lin[58] found that most foster youth who run away run to their family of origin and/or their friends out of a desire to maintain relationships with their community of origin.

One study from 2015 reported that youth in foster care who run away have often experienced emotional or psychological problems that began before entering foster care.[55] Experiences such as parental incarceration and personal history of substance use were associated with a higher number of runaway episodes.[55]

While in out-of-home care, children with developmental and cognitive disabilities were less likely to run away, whereas children with mental and behavioral health problems were more likely to run away.[57] Courtney and Zinn[57] found that some mental and/or behavioral disorders, such as schizophrenia and other psychoses, were associated with lower risk of running away, but alcohol- and other substance-related disorders were associated with increased risk. Data from the 2009 Adoption and Foster Care Analysis and Reporting System (AFCARS), a federally mandated data collection system that includes case-level information on (1) all children in foster care for whom child welfare agencies have responsibility for placement, care, and supervision and (2) children adopted through child welfare agencies, found that autism spectrum disorder was associated with a decreased incidence of running away.[55]

Child welfare system–related characteristics, including the type of placement, permanency plan while in care, reason for placement, number of placements, and the quality of care received in placements were also found to be factors associated with runaway behaviors.[58] The instability of foster care placements is a predictor of youth running away behavior, and multiple placements are related with an increased risk of running away.[58] Children who ran away experienced an average of 6 placement settings.[58] Stabilization of foster care placement is associated with fewer runaway episodes.[58] Placement type is also important; youth in foster homes, especially if placed with a relative, are less likely to run away than those placed in residential care.[57] In addition, children who are placed in the same foster home as a sibling are less likely to run away.[57] Youth who know they are unlikely to be reunified with family or relatives and/or be adopted are more likely to run away.[55] Of note, youth with a history of running away are 92% more likely to run away again.[58]

Children who run away from out-of-home care are at increased risk of negative consequences similar to all runaway youth, such as criminal victimization, sexual exploitation, and substance or alcohol use.[55]

For youth in protective custody, pediatricians should discuss stability of placement with the foster parent, case manager, and/or child, and a confidential discussion with the child should take place about how the child feels about where he or she is living and any concerns. For all children in foster care, it is critical that pediatricians recommend that their behavioral health needs be met. Pediatricians and other health care providers for youth in out-of-home custody can refer to the multiple resources available through the AAP on the Healthy Foster Care America Web page (https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/healthy-foster-care-america/Pages/default.aspx).

ROLE OF TECHNOLOGY AND SOCIAL MEDIA

The rapid expansion of social media has influenced the experiences of runaway youth in several ways. Early data exploring the nature of Internet-initiated crimes suggest that online relationships may increase the risk of running away.[60] However, the evolving social media landscape makes the effects difficult to measure, and available follow-up data are limited. A study conducted from October 2001 to July 2002 of a random sample of law enforcement agencies described the characteristics of episodes in which juveniles became victims of sex crimes committed by people they met through the Internet.[61] This study revealed that victims in these crimes were primarily 13- to 15-year-old girls who met adult male offenders and developed romantic relationships with them for 1 month or longer. In most cases, offenders did not deceive victims regarding their age or sexual

motives. Of 129 cases studied, 5% involved violent offenses and 3% involved brief abductions in the setting of sexual assaults. Notably, 29% of the victims who attended face-to-face meetings were reported missing to police, with 24% being runaways and 5% who had misinformed parents regarding where they were going.[61] In a 2014 study of law enforcement perspectives on the role of technology in child sexual exploitation, investigators working on child sexual exploitation cases report that technology has played a significant role in the majority of cases.[62]

Recognizing the potential links between runaway youth, sexual exploitation, and technology, in April 2018, the Family and Youth Services Bureau added a tool titled "Online Recruitment of Youth Via Social Media and the Internet" to its "Human Trafficking and Runaway and Homeless Youth: Practical Tools for Grantees." This tool explores the role of social media trafficking recruitment, lists red flags, and recommends prevention strategies for youth-serving agencies.[63]

Innovative work has also emerged exploring the potential use of technology to improve health and access to services for homeless youth.[64–68] A 2016 study by Harpin et al[69] of homeless youth in Denver, Colorado, revealed that 71.9% of youth consistently used social media. Tyler and Schmitz[68] reported on using texting technology for data collection and explored potential opportunities for interventions leveraging technology. Buccieri and Molleson[64] explored the use of a youth-developed application for homeless youth. In their study of law enforcement, Mitchell and Boyd[62] discussed the potential opportunity for technology to be used to connect with difficult-to-reach populations that may be at risk for commercial sexual exploitation, including homeless and runway youth. Although much of this work has focused on homeless youth specifically, it has potential implications for runaway youth and requires further study.

MANAGEMENT OF RUNAWAY EPISODES

For children who have run away, pediatricians can conduct a thorough assessment of mental health concerns; substance use; previous history of abuse, violence, or victimization while away; exposure to trauma; and sexual and reproductive health needs and treat accordingly. Pediatricians should provide comprehensive care, including psychological and social support, to families who have a child or adolescent who has recently returned home after running away. Often, these children are targeted for punishment for the act of running away or for the associated misdeeds of substance use, theft, or prostitution when what is needed is medical and psychological treatment, family realignment, or placement in protective custody.[3]

Pediatricians can support and maintain awareness of programs that serve runaway youth and build connections with these programs through the medical home. Pediatricians may also consider sharing information regarding national resources for runaways and their families listed below, including the National Runaway Safeline and the NCMEC (see Resources).

OPPORTUNITIES FOR FUTURE RESEARCH AND ACTION

Additional research on the recognition, management, and prevention of runaway episodes is critical. Specifically, the development of well-validated screening tools for identifying children who are at high risk for running away or being thrown away would help pediatricians and other health care providers better identify this high-risk population of adolescents. Innovative, evidence-based interventions aimed at the prevention of runaway and thrownaway episodes in the clinical and community setting should also be developed and studied to guide practice- and community-based intervention.

Another potential area of study is the role of the Internet and social media in episodes of runaway youth, including further exploration of safe media use and applications of social media and technology to better support youth who have run away.

Finally, policies and programs that improve health care access for runaway youth are essential. Federal legislation supporting the Runaway and Homeless Youth Program, initially passed in the 1970s and revised as recently as 2017, recognizes this need and provides funding for services that support runaway and homeless youth. This legislation includes grant funding for programs that target mental and physical health among runaway youth and integrate health care into existing services for youth.[70,71] Shelter-based clinics, clinics for runaway youth, health care services for street youth, and free youth clinics all may serve as options to meet the health care needs of this population but must provide readily accessible, culturally competent, trauma-informed, and confidential care.[72–75] The Runaway Intervention Program in Minnesota represents an innovative nursing-led intervention targeting runaway youth with promising outcomes.[73,76,77] Community-based interventions that improve health care access and outcomes in a cost-effective manner should be studied and supported. Policy strategies are needed that improve access to health insurance and health care for runaway youth.

CONCLUSIONS

Runaway and thrownaway youth, the largest category of missing children, require ongoing support and

continued engagement with pediatricians and other health care providers and community resources to prevent recurrence and address their unique health needs.

RECOMMENDATIONS FOR CLINICAL PRACTICE

- Identify youth who are at high risk for running away or being thrown away.
  - Conduct a thorough, confidential social history and home environment, education and employment, eating, peer-related activities, drugs, sexuality, suicide and/or depression, and safety (HEEADSSS) assessment for all adolescents, including surveillance for risk factors known to be associated with running away.[48] Routine depression screening is recommended for children 12 and up by using standardized tools such as the Patient Health Questionnaire for Adolescents (PHQ-A) and the primary care version of the Beck Depression Inventory (BDI).[78]
  - Assess whether adolescents consider themselves to have sources of support, including the pediatrician, so that they do not need to resort to running away. Ask them to identify an adult they feel comfortable confiding in and recommend they go to that adult if they are having any issues.
- Consider posting and sharing information regarding national resources for runaways and their families in waiting or examination rooms.
- If an adolescent is believed to be at high risk for running away or has run away before, discuss a safety plan for future runaway episodes, including a plan for accessing safe housing. Review potential health and behavioral risks associated with running away and provide necessary health care to mitigate risk, such as reliable contraception and access to mental health care.
- If risk factors are identified, intervene early to prevent runaway episodes by using practice- and community-based resources to address any modifiable risk factors, support the psychological and behavioral health needs of the child and family, and ensure safety.
- Consider counseling special populations as follows:
  - Victims of abuse and neglect: For children with a known or suspected history of abuse or neglect, confirm that they feel safe in their current living situation.
  - LGBTQ youth: Help support sexual minority children and youth and their families, particularly about the process of coming out regarding nonconforming gender expression or sexual orientation.
  - Youth in protective custody: For youth in protective custody, discuss stability of placement with the foster parent, case manager, and/or child. Discuss with the child how he or she feels about where he or she is living and any concerns.
  - Youth with mental health and/or substance use issues: Recommend appropriate ongoing mental health support and services. For substance use, consider using the screening, brief intervention, and referral to treatment (SBIRT) outlined in the AAP policy statement and clinical report.[79,80]
- Support and maintain awareness of programs that serve youth who have run away or are homeless, including hotlines, shelters, and other resources to provide for basic needs while youth are away (see Resources).
- For youth who have run away, conduct a thorough assessment of mental health concerns; substance use; previous history of abuse, violence, or victimization while away; exposure to trauma; and sexual and reproductive health needs and treat accordingly. Youth who have run away may run away again. Refer at-risk youth to programs that are focused on self-empowerment, healthy sexuality, and relationships and safety planning with the goal of increasing youth resilience.
- Provide comprehensive care through a trauma-informed lens, including psychological and social support, to families who have a child or adolescent who has recently returned home after running away.
- Although the prevention of runaway episodes has not been well studied, prevention likely depends on the development of strong, nurturing, reciprocal relationships from early childhood. Building on existing approaches within Bright Futures for health supervision visits and validated community programs, the AAP supports efforts to promote positive relationships and positive parenting strategies early on.
- In states where sex trafficking is considered a form of abuse, pediatricians must make a formal report of suspected exploitation to law enforcement and to child protective services as well, if indicated.

RESOURCES

- The National Runaway Safeline, formerly known as the National Runaway Switchboard (1–800-RUNAWAY; https://www.1800runaway.org/), serves as a hotline for children considering running away and those who have run away.
- NCMEC (www.missingkids.com): If a child runs away, the parent or

guardian should contact the NCMEC at 1-800-THE-LOST in addition to reporting the incident to law enforcement. Any information about a missing child or suspected sexual exploitation should be reported to NCMEC.

- Strengthening Families (www.strengtheningfamilies.net) provides resources for building resilience in parents and children.
- National Network for Youth (www.nn4youth.org) is a public education and policy advocacy organization dedicated to the prevention and eradication of youth homelessness.

Truth, Reconciliation, and Transformation: Continuing on the Path to Equity

- *Policy Statement*

POLICY STATEMENT Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

American Academy of Pediatrics

DEDICATED TO THE HEALTH OF ALL CHILDREN®

Truth, Reconciliation, and Transformation: Continuing on the Path to Equity

American Academy of Pediatrics Board of Directors

One year ago, the American Academy of Pediatrics (AAP) published a landmark policy statement identifying racism as a core social determinant of health and a driver of health inequities.[1] Seventy-five years ago, the AAP admitted its first Black members, Drs Alonzo deGrate Smith and Roland Boyd Scott. As the AAP continues to evolve its equity agenda, it is essential that the tortuous experiences of Drs deGrate Smith and Scott on their pathway to AAP membership be truthfully acknowledged and reckoned with.

At the time of their initially rejected applications in 1939, both Drs deGrate Smith and Scott were busy clinicians and well-established leaders in the pediatric academic community as faculty at the Howard University College of Medicine in Washington, DC. Dr deGrate Smith, through the practice pathway, and Dr Scott, via examination, were among the earliest pediatricians to achieve certification under the Advisory Board of Medical Specialties (ABMS) when the American Board of Pediatrics (ABP) was established in 1933. However, the ABMS required American Medical Association (AMA) membership to honor certification, and the local AMA chapter, the Medical Society of the District of Columbia, was segregated.[2] According to the oral history interview of Dr Melvin E. Jenkins Jr, advocacy on the part of the inaugural ABP president, Dr Borden Veeder, was necessary to permanently eliminate this exclusionary barrier and to make certification possible for all eligible candidates regardless of race or ethnicity.[3] Drs deGrate Smith and Scott faced other systemic barriers, including the inability to gain admitting privileges to care for even their own patients at local hospitals in the District of Columbia. This was a hurdle that Dr Scott was not able to overcome until 1955, fully 6 years after he had already been appointed Chair of Pediatrics at Howard University.[4]

Although AAP bylaws did not explicitly prohibit physicians of color from membership, and Drs deGrate Smith and Scott were finally admitted in 1945, it is clear that the AAP Executive Board struggled with unbiased consideration of their applications. The characterizations related to Drs deGrate Smith and Scott in the following passages excerpted directly from meeting transcripts of AAP Executive Board meetings in November 1939,

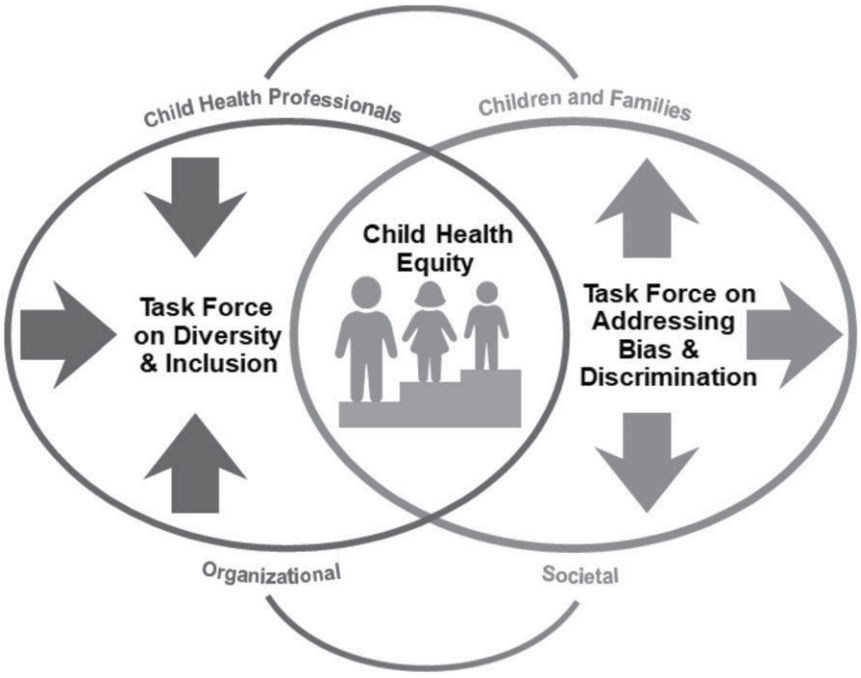

FIGURE 1
AAP Equity Agenda.

November 1944, and June 1945 are elucidating, instructive, and painful to read. The verbatim dialogue and proceedings highlight the racist attitudes and beliefs from which early AAP leaders were clearly not immune.

November 1939—American Academy of Pediatrics Executive Board

[Region I Chairman] then presented the application of Dr Alfred [sic] deGrate Smith. Motion made by [Region I Chairman] that this application not be accepted and that a letter be sent to his sponsor outlining the educational advancements being outlined by the American Academy of Pediatrics for negro physicians; motion seconded by [Region I Associate Chairman] and carried.[5]

[Region III Chairman] moved that all of these [Region III] applications, with the exception of Dr Scott, be accepted into membership; motion duly seconded and carried. Motion made by [Region I Chairman] that the same action be taken on Dr Scott as had been taken on Dr Smith; motion seconded and carried.[5]

November 1944—American Academy of Pediatrics Executive Board

"I know Smith and he is a very nice fellow. Scott has for a year or two attended the Sunday morning clinical conferences at Children's Hospital. He has taken part in the discussion of cases at Freedman's Hospital. I think the local men in Washington would like to have something to say about men taken into the Academy from that particular location. I think they would rather resent an effort being made to put these men in. I would like to hear what [Region II Chairman] has to say."[5]

"We allow negroes to come to our meeting and we fix a separate place for them to sit. They do not become members. If they became members they would want to come and eat with you at the table. You cannot hold them down."[5]

June 1945—American Academy of Pediatrics Executive Board

"We talked with them for about a half hour and they conducted themselves as gentlemen. They said their only interest in wishing to join the Academy was for educational purposes. They said they would not attend any meetings held South of the Mason and Dixon line. They would attend meetings in other parts of the country, but under no circumstances enter into the social side for the reason that they did not want to get hurt themselves. I impressed upon them the importance should they be elected, of their being leaders and not pushers, and their acceptance in the Academy would be guidance for those who would come at a later time."[6]

"I think the problem is of much more concern to us than it needs to be. In the first place, we have a definite responsibility to these negro representatives and to the negro population of the country. The only trouble is the social implication. The burden lies much heavier upon Smith and Scott than upon us. As the President (of the Academy) says, we have the authority to say who will not be admitted. In the event that either of these men transgress the social lines, they completely stop the advancement of the negro."[6]

In the United States there is a tendency to be ahistorical when it comes to race. The lack of acknowledgment, or worse, the intentional whitewashing of history and the longitudinal relationship of 400 years of oppression on the present-day expression of racism is not uncommon. As the AAP turns the corner toward the 2030 centennial anniversary of its founding, we cannot do so without authentically acknowledging, owning, and reconciling past discriminatory transgressions like the shameful gauntlet to membership experienced by Drs Alonzo deGrate Smith and Roland Boyd Scott.

In honoring the memory of these two trailblazers and their contributions to pediatrics and the AAP,[7] be it resolved that, we, the Board of Directors of the AAP:

1) Apologize for the racism that contributed to the inequities that Drs deGrate Smith, Scott, and other pediatricians have endured, and;
2) Commit to a bylaws referendum to explicitly codify that AAP membership does not discriminate on the basis of race, ethnicity, religion, sex, sexual orientation, gender identity, disability, or national origin.

The AAP as an organization is on a firm pathway to broadly establishing an equity agenda through meaningful diversity and inclusion and a societal commitment to combating bias and discrimination

in all its forms, including structural and systemic anti-Black racism (Fig 1). This country is already majority represented by children of color when it comes to the pediatric population.

Embracing racial and ethnic socialization is critical for *all* children and families as well as for the pediatricians who care for them. Healing starts at home with truth, reckoning, and honest reconciliation.

The AAP is proud to transparently acknowledge, proud to publicly reconcile, and proud to continue to lead on behalf of the best interests of children, adolescents, and young adults and the people who care for them.

2020 RECOMMENDATIONS FOR PREVENTIVE PEDIATRIC HEALTH CARE

Committee on Practice and Ambulatory Medicine and Bright Futures Periodicity Schedule Workgroup

ABSTRACT. The 2020 Recommendations for Preventive Pediatric Health Care (Periodicity Schedule) have been approved by the American Academy of Pediatrics (AAP) and represents a consensus of the AAP and the Bright Futures Periodicity Schedule Workgroup. Each child and family is unique; therefore, these recommendations are designed for the care of children who are receiving competent parenting, have no manifestations of any important health problems, and are growing and developing in a satisfactory fashion. Developmental, psychosocial, and chronic disease issues for children and adolescents may require frequent counseling and treatment visits separate from preventive care visits. Additional visits also may become necessary if circumstances suggest variations from the normal. (2/20)

AAP DIVERSITY AND INCLUSION STATEMENT

American Academy of Pediatrics

ABSTRACT. The vision of the American Academy of Pediatrics (AAP) is that all children have optimal health and well-being and are valued by society and that AAP members practice the highest quality health care and experience professional satisfaction and personal well-being. From the founding of the AAP, pursuing this vision has included treasuring the uniqueness of each child and fostering a profession, health care system, and communities that celebrate all aspects of the diversity of each child and family. ABUSIVE HEAD TRAUMA IN INFANTS AND CHILDREN

Sandeep K. Narang, MD, JD, FAAP; Amanda Fingarson, DO, FAAP; James Lukefahr, MD, FAAP; and Council on Child Abuse and Neglect

ABSTRACT. Abusive head trauma (AHT) remains a significant cause of morbidity and mortality in the pediatric population, especially in young infants. In the past decade, advancements in research have refined medical understanding of the epidemiological, clinical, biomechanical, and pathologic factors comprising the diagnosis, thereby enhancing clinical detection of a challenging diagnostic entity. Failure to recognize AHT and respond appropriately at any step in the process, from medical diagnosis to child protection and legal decision-making, can place children at risk. The American Academy of Pediatrics revises the 2009 policy statement on AHT to incorporate the growing body of knowledge on the topic. Although this statement incorporates some of that growing body of knowledge, it is not a comprehensive exposition of the science. This statement aims to provide pediatric practitioners with general guidance on a complex subject. The Academy recommends that pediatric practitioners remain vigilant for the signs and symptoms of AHT, conduct thorough medical evaluations, consult with pediatric medical subspecialists when necessary, and embrace the challenges and need for strong advocacy on the subject. (3/20)

ACCESS TO OPTIMAL EMERGENCY CARE FOR CHILDREN

Committee on Pediatric Emergency Medicine

ABSTRACT. Millions of pediatric patients require some level of emergency care annually, and significant barriers limit access to appropriate services for large numbers of children. The American Academy of Pediatrics has a strong commitment to identifying barriers to access to emergency care, working to surmount these obstacles, and encouraging, through education and system changes, improved levels of emergency care available to all children. ACHIEVING QUALITY HEALTH SERVICES FOR ADOLESCENTS

Committee on Adolescence

ABSTRACT. This update of the 2008 statement from the American Academy of Pediatrics redirects the discussion of quality health care from the theoretical to the practical within the medical home. This statement reviews the evolution of the medical home concept and challenges the provision of quality adolescent health care within the patient-centered medical home. Areas of attention for quality adolescent health care are reviewed, including developmentally appropriate care, confidentiality, location of adolescent care, providers who offer such care, the role of research in advancing care, and the transition to adult care. (7/16)

ACHIEVING THE PEDIATRIC MENTAL HEALTH COMPETENCIES (TECHNICAL REPORT)

Cori M. Green, MD, MS, FAAP; Jane Meschan Foy, MD, FAAP; Marian F. Earls, MD, FAAP; Committee on Psychosocial Aspects of Child and Family Health; and Mental Health Leadership Work Group

ABSTRACT. Mental health disorders affect 1 in 5 children; however, the majority of affected children do not receive appropriate services, leading to adverse adult outcomes. To meet the needs of children, pediatricians need to take on a larger role in addressing mental health problems. The accompanying policy statement, "Mental Health Competencies for Pediatric Practice," articulates mental health competencies pediatricians could achieve to improve the mental health care of children; yet, the majority of pediatricians do not feel prepared to do so. In this technical report, we summarize current initiatives and resources that exist for trainees and practicing pediatricians across the training continuum. We also identify gaps in mental health clinical experience and training and suggest areas in which education can be strengthened. With this report, we aim to stimulate efforts to address gaps by summarizing educational strategies that have been applied and could be applied to undergraduate medical education, residency and fellowship training,

continuing medical education, maintenance of certification, and practice quality improvement activities to achieve the pediatric mental health competencies. In this report, we also articulate the research questions important to the future of pediatric mental health training and practice. (10/19)

ADDRESSING EARLY CHILDHOOD EMOTIONAL AND BEHAVIORAL PROBLEMS

Council on Early Childhood, Committee on Psychosocial Aspects of Child and Family Health, and Section on Developmental and Behavioral Pediatrics

ABSTRACT. Emotional, behavioral, and relationship problems can develop in very young children, especially those living in high-risk families or communities. These early problems interfere with the normative activities of young children and their families and predict long-lasting problems across multiple domains. A growing evidence base demonstrates the efficacy of specific family-focused therapies in reducing the symptoms of emotional, behavioral, and relationship symptoms, with effects lasting years after the therapy has ended. Pediatricians are usually the primary health care providers for children with emotional or behavioral difficulties, and awareness of emerging research about evidence-based treatments will enhance this care. In most communities, access to these interventions is insufficient. Pediatricians can improve the care of young children with emotional, behavioral, and relationship problems by calling for the following: increased access to care; increased research identifying alternative approaches, including primary care delivery of treatments; adequate payment for pediatric providers who serve these young children; and improved education for pediatric providers about the principles of evidence-based interventions. (11/16)
http://pediatrics.aappublications.org/content/138/6/e20163023

ADDRESSING EARLY CHILDHOOD EMOTIONAL AND BEHAVIORAL PROBLEMS (TECHNICAL REPORT)

Mary Margaret Gleason, MD, FAAP; Edward Goldson, MD, FAAP; Michael W. Yogman, MD, FAAP; Council on Early Childhood; Committee on Psychosocial Aspects of Child and Family Health; and Section on Developmental and Behavioral Pediatrics

ABSTRACT. More than 10% of young children experience clinically significant mental health problems, with rates of impairment and persistence comparable to those seen in older children. For many of these clinical disorders, effective treatments supported by rigorous data are available. On the other hand, rigorous support for psychopharmacologic interventions is limited to 2 large randomized controlled trials. Access to psychotherapeutic interventions is limited. The pediatrician has a critical role as the leader of the medical home to promote well-being that includes emotional, behavioral, and relationship health. To be effective in this role, pediatricians promote the use of safe and effective treatments and recognize the limitations of psychopharmacologic interventions. This technical report reviews the data supporting treatments for young children with emotional, behavioral, and relationship problems and supports the policy statement of the same name. (11/16)
http://pediatrics.aappublications.org/content/138/6/e20163025

ADMISSION AND DISCHARGE GUIDELINES FOR THE PEDIATRIC PATIENT REQUIRING INTERMEDIATE CARE (CLINICAL REPORT)

Committee on Hospital Care and Section on Critical Care (joint with Society of Critical Care Medicine)

ABSTRACT. During the past 3 decades, the specialty of pediatric critical care medicine has grown rapidly, leading to a number of pediatric intensive care units opening across the country. Many patients who are admitted to the hospital require a higher level of care than routine inpatient general pediatric care, yet not to the degree of intensity of pediatric critical care; therefore, an intermediate care level has been developed in institutions providing multidisciplinary subspecialty pediatric care. These patients may require frequent monitoring of vital signs and nursing interventions, but usually they do not require invasive monitoring. The admission of the pediatric intermediate care patient is guided by physiologic parameters depending on the respective organ system involved relative to an institution's resources and capacity to care for a patient in a general care environment. This report provides admission and discharge guidelines for intermediate pediatric care. Intermediate care promotes greater flexibility in patient triage and provides a cost-effective alternative to admission to a pediatric intensive care unit. This level of care may enhance the efficiency of care and make health care more affordable for patients receiving intermediate care. (5/04, reaffirmed 2/08, 5/17, 2/20)
http://pediatrics.aappublications.org/content/113/5/1430

ADOLESCENT AND YOUNG ADULT TATTOOING, PIERCING, AND SCARIFICATION (CLINICAL REPORT)

Cora C. Breuner, MD, MPH; David A. Levine, MD; and Committee on Adolescence

ABSTRACT. Tattoos, piercing, and scarification are now commonplace among adolescents and young adults. This first clinical report from the American Academy of Pediatrics on voluntary body modification will review the methods used to perform the modifications. Complications resulting from body modification methods, although not common, are discussed to provide the pediatrician with management information. Body modification will be contrasted with nonsuicidal self-injury. When available, information also is presented on societal perceptions of body modification. (9/17)

ADOLESCENT DRUG TESTING POLICIES IN SCHOOLS

Sharon Levy, MD, MPH, FAAP; Miriam Schizer, MD, MPH, FAAP; and Committee on Substance Abuse

ABSTRACT. School-based drug testing is a controversial approach to preventing substance use by students. Although school drug testing has hypothetical benefits, and studies have noted modest reductions in self-reported student drug use, the American Academy of Pediatrics opposes widespread implementation of these programs because of the lack of solid evidence for their effectiveness. (3/15)
http://pediatrics.aappublications.org/content/135/4/782

ADOLESCENT DRUG TESTING POLICIES IN SCHOOLS (TECHNICAL REPORT)

Sharon Levy, MD, MPH, FAAP; Miriam Schizer, MD, MPH, FAAP; and Committee on Substance Abuse

ABSTRACT. More than a decade after the US Supreme Court established the legality of school-based drug testing, these programs remain controversial, and the evidence evaluating efficacy and risks is inconclusive. The objective of this technical report is to review the relevant literature that explores the benefits, risks, and costs of these programs. (3/15)

ADOLESCENT PREGNANCY: CURRENT TRENDS AND ISSUES (CLINICAL REPORT)

Jonathan D. Klein, MD, MPH, and Committee on Adolescence

ABSTRACT. The prevention of unintended adolescent pregnancy is an important goal of the American Academy of Pediatrics and our society. Although adolescent pregnancy and birth rates have been steadily decreasing, many adolescents still become pregnant. Since the last statement on adolescent pregnancy was issued by the Academy in 1998, efforts to prevent

adolescent pregnancy have increased, and new observations, technologies, and prevention effectiveness data have emerged. The purpose of this clinical report is to review current trends and issues related to adolescent pregnancy, update practitioners on this topic, and review legal and policy implications of concern to pediatricians. (7/05)
http://pediatrics.aappublications.org/content/116/1/281

ADOLESCENT PREGNANCY: CURRENT TRENDS AND ISSUES—ADDENDUM

Committee on Adolescence

INTRODUCTION. The purpose of this addendum is to update pediatricians and other professionals on recent research and data regarding adolescent sexuality, contraceptive use, and childbearing since publication of the original 2005 clinical report, "Adolescent Pregnancy: Current Trends and Issues." There has been a trend of decreasing sexual activity and teen births and pregnancies since 1991, except between the years of 2005 and 2007, when there was a 5% increase in birth rates. Currently, teen birth rates in the United States are at a record low secondary to increased use of contraception at first intercourse and use of dual methods of condoms and hormonal contraception among sexually active teenagers. Despite these data, the United States continues to lead other industrialized countries in having unacceptably high rates of adolescent pregnancy, with over 700 000 pregnancies per year, the direct health consequence of unprotected intercourse. Importantly, the 2006–2010 National Survey of Family Growth (NSFG) revealed that less than one-third of 15- to 19-year-old female subjects consistently used contraceptive methods at last intercourse. (4/14)
http://pediatrics.aappublications.org/content/133/5/954

ADOLESCENTS AND HIV INFECTION: THE PEDIATRICIAN'S ROLE IN PROMOTING ROUTINE TESTING

Committee on Pediatric AIDS

ABSTRACT. Pediatricians can play a key role in preventing and controlling HIV infection by promoting risk-reduction counseling and offering routine HIV testing to adolescent and young adult patients. Most sexually active youth do not feel that they are at risk of contracting HIV and have never been tested. Obtaining a sexual history and creating an atmosphere that promotes nonjudgmental risk counseling is a key component of the adolescent visit. In light of increasing numbers of people with HIV/AIDS and missed opportunities for HIV testing, the Centers for Disease Control and Prevention recommends universal and routine HIV testing for all patients seen in health care settings who are 13 to 64 years of age. There are advances in diagnostics and treatment that help support this recommendation. This policy statement reviews the epidemiologic data and recommends that routine screening be offered to all adolescents at least once by 16 to 18 years of age in health care settings when the prevalence of HIV in the patient population is more than 0.1%. In areas of lower community HIV prevalence, routine HIV testing is encouraged for all sexually active adolescents and those with other risk factors for HIV. This statement addresses many of the real and perceived barriers that pediatricians face in promoting routine HIV testing for their patients. (10/11, reaffirmed 9/15)
http://pediatrics.aappublications.org/content/128/5/1023

THE ADOLESCENT'S RIGHT TO CONFIDENTIAL CARE WHEN CONSIDERING ABORTION

Committee on Adolescence

ABSTRACT. In this statement, the American Academy of Pediatrics reaffirms its position that the rights of adolescents to confidential care when considering abortion should be protected. Adolescents should be encouraged to involve their parents and other trusted adults in decisions regarding pregnancy termination, and most do so voluntarily. The majority of states require that minors have parental consent for an abortion. However, legislation mandating parental involvement does not achieve the intended benefit of promoting family communication, and it increases the risk of harm to the adolescent by delaying access to appropriate medical care. This statement presents a summary of pertinent current information related to the benefits and risks of legislation requiring mandatory parental involvement in an adolescent's decision to obtain an abortion. ADVANCED PRACTICE IN NEONATAL NURSING

Committee on Fetus and Newborn

ABSTRACT. The participation of advanced practice registered nurses in neonatal care continues to be accepted and supported by the American Academy of Pediatrics. Recognized categories of advanced practice neonatal nursing are the neonatal clinical nurse specialist and the neonatal nurse practitioner. (5/09, reaffirmed 1/14)

ADVOCACY AND COLLABORATIVE HEALTH CARE FOR JUSTICE-INVOLVED YOUTH

Mikah C. Owen, MD, MPH, FAAP; Stephenie B. Wallace, MD, MSPH, FAAP; and Committee on Adolescence

ABSTRACT. Children and adolescents who become involved with the justice system often do so with complex medical, mental health, developmental, social, and legal needs. Most have been exposed to childhood trauma or adversity, which both contribute to their involvement with the justice system and negatively impact their health and well-being. Whether youth are held in confinement or in their home communities, pediatricians play a critical role in promoting the health and well-being of justice-involved youth. Having a working knowledge of the juvenile justice system and common issues facing justice-involved youth may help pediatricians enhance their clinical care and advocacy efforts. This policy statement is a revision of the 2011 policy "Health Care for Youth in the Juvenile Justice System." It provides an overview of the juvenile justice system, describes racial bias and overrepresentation of youth of color in the justice system, reviews the health and mental health status of justice-involved youth, and identifies advocacy opportunities for juvenile justice reform. ADVOCACY FOR IMPROVING NUTRITION IN THE FIRST 1000 DAYS TO SUPPORT CHILDHOOD DEVELOPMENT AND ADULT HEALTH

Sarah Jane Schwarzenberg, MD, FAAP; Michael K. Georgieff, MD, FAAP; and Committee on Nutrition

ABSTRACT. Maternal prenatal nutrition and the child's nutrition in the first 2 years of life (1000 days) are crucial factors in a child's neurodevelopment and lifelong mental health. Child and adult health risks, including obesity, hypertension, and diabetes, may be programmed by nutritional status during this period. Calories are essential for growth of both fetus and child but are not sufficient for normal brain development. Although all nutrients are necessary for brain growth, key nutrients that support neurodevelopment include protein; zinc; iron; choline; folate; iodine; vitamins A, D, B_6, and B_{12}; and long-chain polyunsaturated fatty acids. Failure to provide key nutrients during this critical period of brain development may result in lifelong deficits in brain function despite subsequent nutrient repletion. Understanding the complex interplay of micro- and macronutrients and neurodevelopment is key to moving beyond simply recommending a "good diet" to optimizing nutrient delivery for the developing child. Leaders in pediatric health and policy

makers must be aware of this research given its implications for public policy at the federal and state level. Pediatricians should refer to existing services for nutrition support for pregnant and breastfeeding women, infants, and toddlers. Finally, all providers caring for children can advocate for healthy diets for mothers, infants, and young children in the first 1000 days. Prioritizing public policies that ensure the provision of adequate nutrients and healthy eating during this crucial time would ensure that all children have an early foundation for optimal neurodevelopment, a key factor in long-term health. (1/18)

ADVOCATING FOR LIFE SUPPORT TRAINING OF CHILDREN, PARENTS, CAREGIVERS, SCHOOL PERSONNEL, AND THE PUBLIC

James M. Callahan, MD, FAAP; Susan M. Fuchs, MD, FAAP; and Committee on Pediatric Emergency Medicine

ABSTRACT. Out-of-hospital cardiac arrest occurs frequently among people of all ages, including more than 6000 children annually. Pediatric cardiac arrest in the out-of-hospital setting is a stressful event for family, friends, caregivers, classmates, school personnel, and witnesses. Immediate bystander cardiopulmonary resuscitation and the use of automated external defibrillators are associated with improved survival in adults. There is some evidence in which improved survival in children who receive immediate bystander cardiopulmonary resuscitation is shown. Pediatricians, in their role as advocates to improve the health of all children, are uniquely positioned to strongly encourage the training of children, parents, caregivers, school personnel, and the lay public in the provision of basic life support, including pediatric basic life support, as well as the appropriate use of automated external defibrillators. (5/18)
http://pediatrics.aappublications.org/content/141/6/e20180704

ADVOCATING FOR LIFE SUPPORT TRAINING OF CHILDREN, PARENTS, CAREGIVERS, SCHOOL PERSONNEL, AND THE PUBLIC (TECHNICAL REPORT)

Susan M. Fuchs, MD, FAAP, and Committee on Pediatric Emergency Medicine

ABSTRACT. Pediatric cardiac arrest in the out-of-hospital setting is a traumatic event for family, friends, caregivers, classmates, and school personnel. Immediate bystander cardiopulmonary resuscitation and the use of automatic external defibrillators have been shown to improve survival in adults. There is some evidence to show improved survival in children who receive immediate bystander cardiopulmonary resuscitation. Pediatricians, in their role as advocates to improve the health of all children, are uniquely positioned to strongly encourage the training of children, parents, caregivers, school personnel, and the lay public in the provision of basic life support, including pediatric basic life support, as well as the appropriate use of automated external defibrillators. AGE LIMIT OF PEDIATRICS

Amy Peykoff Hardin, MD, FAAP; Jesse M. Hackell, MD, FAAP; and Committee on Practice and Ambulatory Medicine

ABSTRACT. Pediatrics is a multifaceted specialty that encompasses children's physical, psychosocial, developmental, and mental health. Pediatric care may begin periconceptionally and continues through gestation, infancy, childhood, adolescence, and young adulthood. Although adolescence and young adulthood are recognizable phases of life, an upper age limit is not easily demarcated and varies depending on the individual patient. The establishment of arbitrary age limits on pediatric care by health care providers should be discouraged. The decision to continue care with a pediatrician or pediatric medical or surgical subspecialist should be made solely by the patient (and family, when appropriate) and the physician and must take into account the physical and psychosocial needs of the patient and the abilities of the pediatric provider to meet these needs. (8/17)

AGE TERMINOLOGY DURING THE PERINATAL PERIOD

Committee on Fetus and Newborn

ABSTRACT. Consistent definitions to describe the length of gestation and age in neonates are needed to compare neurodevelopmental, medical, and growth outcomes. The purposes of this policy statement are to review conventional definitions of age during the perinatal period and to recommend use of standard terminology including gestational age, postmenstrual age, chronological age, corrected age, adjusted age, and estimated date of delivery. (11/04, reaffirmed 10/07, 11/08, 7/14)

ALCOHOL USE BY YOUTH

Joanna Quigley, MD, FAAP, and Committee on Substance Use and Prevention

ABSTRACT. Alcohol use continues to be problematic for youth and young adults in the United States. Understanding of neurobiology and neuroplasticity continues to highlight the potential adverse impact of underage drinking on the developing brain. This policy statement provides the position of the American Academy of Pediatrics on the issue of alcohol and is supported by an accompanying technical report. (6/19)
https://pediatrics.aappublications.org/content/144/1/e20191356

ALCOHOL USE BY YOUTH (TECHNICAL REPORT)

Sheryl A. Ryan, MD, FAAP; Patricia Kokotailo, MD, MPH, FAAP; and Committee on Substance Use and Prevention

ABSTRACT. Alcohol use continues to be a major concern from preadolescence through young adulthood in the United States. Results of recent neuroscience research have helped to elucidate neurobiological models of addiction, substantiated the deleterious effects of alcohol on adolescent brain development, and added additional evidence to support the call to prevent and reduce underage drinking. This technical report reviews the relevant literature and supports the accompanying policy statement in this issue of *Pediatrics.* (6/19)

ALLERGY TESTING IN CHILDHOOD: USING ALLERGEN-SPECIFIC IGE TESTS (CLINICAL REPORT)

Scott H. Sicherer, MD; Robert A. Wood, MD; and Section on Allergy and Immunology

ABSTRACT. A variety of triggers can induce common pediatric allergic diseases which include asthma, allergic rhinitis, atopic dermatitis, food allergy, and anaphylaxis. Allergy testing serves to confirm an allergic trigger suspected on the basis of history. Tests for allergen-specific immunoglobulin E (IgE) are performed by in vitro assays or skin tests. The tests are excellent for identifying a sensitized state in which allergen-specific IgE is present, and may identify triggers to be eliminated and help guide immunotherapy treatment. However, a positive test result does not always equate with clinical allergy. Newer enzymatic assays based on anti-IgE antibodies have supplanted the radioallergosorbent test (RAST). This clinical report focuses on allergen-specific IgE testing, emphasizing that the medical history and knowledge of disease characteristics are crucial for rational test selection and interpretation. (12/11)

ALL-TERRAIN VEHICLE INJURY PREVENTION: TWO-, THREE-, AND FOUR-WHEELED UNLICENSED MOTOR VEHICLES

Committee on Injury and Poison Prevention

ABSTRACT. Since 1987, the American Academy of Pediatrics (AAP) has had a policy about the use of motorized cycles and all-terrain vehicles (ATVs) by children. The purpose of this policy statement is to update and strengthen previous policy. This statement describes the various kinds of motorized cycles and ATVs and outlines the epidemiologic characteristics of deaths and injuries related to their use by children in light of the 1987 consent decrees entered into by the US Consumer Product Safety Commission and the manufacturers of ATVs. Recommendations are made for public, patient, and parent education by pediatricians; equipment modifications; the use of safety equipment; and the development and improvement of safer off-road trails and responsive emergency medical systems. In addition, the AAP strengthens its recommendation for passage of legislation in all states prohibiting the use of 2- and 4-wheeled off-road vehicles by children younger than 16 years, as well as a ban on the sale of new and used 3-wheeled ATVs, with a recall of all used 3-wheeled ATVs. (6/00, reaffirmed 5/04, 1/07, 5/13, 11/19)

ALUMINUM EFFECTS IN INFANTS AND CHILDREN

Mark R. Corkins, MD, FAAP, and Committee on Nutrition

ABSTRACT. Aluminum has no known biological function; however, it is a contaminant present in most foods and medications. Aluminum is excreted by the renal system, and patients with renal diseases should avoid aluminum-containing medications. Studies demonstrating long-term toxicity from the aluminum content in parenteral nutrition components led the US Food and Drug Administration to implement rules for these solutions. Large-volume ingredients were required to reduce the aluminum concentration, and small-volume components were required to be labeled with the aluminum concentration. Despite these rules, the total aluminum concentration from some components continues to be above the recommended final concentration. The concerns about toxicity from the aluminum present in infant formulas and antiperspirants have not been substantiated but require more research. Aluminum is one of the most effective adjuvants used in vaccines, and a large number of studies have documented minimal adverse effects from this use. Long-term, high-concentration exposure to aluminum has been linked in meta-analyses with the development of Alzheimer disease. (11/19)

AMBIENT AIR POLLUTION: HEALTH HAZARDS TO CHILDREN

Committee on Environmental Health

ABSTRACT. Ambient (outdoor) air pollution is now recognized as an important problem, both nationally and worldwide. Our scientific understanding of the spectrum of health effects of air pollution has increased, and numerous studies are finding important health effects from air pollution at levels once considered safe. Children and infants are among the most susceptible to many of the air pollutants. In addition to associations between air pollution and respiratory symptoms, asthma exacerbations, and asthma hospitalizations, recent studies have found links between air pollution and preterm birth, infant mortality, deficits in lung growth, and possibly, development of asthma. This policy statement summarizes the recent literature linking ambient air pollution to adverse health outcomes in children and includes a perspective on the current regulatory process. The statement provides advice to pediatricians on how to integrate issues regarding air quality and health into patient education and children's environmental health advocacy and concludes with recommendations to the government on promotion of effective air-pollution policies to ensure protection of children's health. (12/04, reaffirmed 4/09)

ANTENATAL COUNSELING REGARDING RESUSCITATION AND INTENSIVE CARE BEFORE 25 WEEKS OF GESTATION (CLINICAL REPORT)

James Cummings, MD, FAAP, and Committee on Fetus and Newborn

ABSTRACT. The anticipated birth of an extremely low gestational age (<25 weeks) infant presents many difficult questions, and variations in practice continue to exist. Decisions regarding care of periviable infants should ideally be well informed, ethically sound, consistent within medical teams, and consonant with the parents' wishes. Each health care institution should consider having policies and procedures for antenatal counseling in these situations. Family counseling may be aided by the use of visual materials, which should take into consideration the intellectual, cultural, and other characteristics of the family members. Although general recommendations can guide practice, each situation is unique; thus, decision-making should be individualized. In most cases, the approach should be shared decision-making with the family, guided by considering both the likelihood of death or morbidity and the parents' desires for their unborn child. If a decision is made not to resuscitate, providing comfort care, encouraging family bonding, and palliative care support are appropriate. (8/15)

ANTERIOR CRUCIATE LIGAMENT INJURIES: DIAGNOSIS, TREATMENT, AND PREVENTION (CLINICAL REPORT)

Cynthia R. LaBella, MD, FAAP; William Hennrikus, MD, FAAP; Timothy E. Hewett, PhD, FACSM; Council on Sports Medicine and Fitness; and Section on Orthopaedics

ABSTRACT. The number of anterior cruciate ligament (ACL) injuries reported in athletes younger than 18 years has increased over the past 2 decades. Reasons for the increasing ACL injury rate include the growing number of children and adolescents participating in organized sports, intensive sports training at an earlier age, and greater rate of diagnosis because of increased awareness and greater use of advanced medical imaging. ACL injury rates are low in young children and increase sharply during puberty, especially for girls, who have higher rates of noncontact ACL injuries than boys do in similar sports. Intrinsic risk factors for ACL injury include higher BMI, subtalar joint overpronation, generalized ligamentous laxity, and decreased neuromuscular control of knee motion. ACL injuries often require surgery and/or many months of rehabilitation and substantial time lost from school and sports participation. Unfortunately, regardless of treatment, athletes with ACL injuries are up to 10 times more likely to develop degenerative arthritis of the knee. Safe and effective surgical techniques for children and adolescents continue to evolve. Neuromuscular training can reduce risk of ACL injury in adolescent girls. This report outlines the current state of knowledge on epidemiology, diagnosis, treatment, and prevention of ACL injuries in children and adolescents. (4/14, reaffirmed 7/18)

THE APGAR SCORE

Committee on Fetus and Newborn (joint with American College of Obstetricians and Gynecologists Committee on Obstetric Practice)

ABSTRACT. The Apgar score provides an accepted and convenient method for reporting the status of the newborn infant immediately after birth and the response to resuscitation if needed. The Apgar score alone cannot be considered as evidence

of, or a consequence of, asphyxia; does not predict individual neonatal mortality or neurologic outcome; and should not be used for that purpose. An Apgar score assigned during resuscitation is not equivalent to a score assigned to a spontaneously breathing infant. The American Academy of Pediatrics and the American College of Obstetricians and Gynecologists encourage use of an expanded Apgar score reporting form that accounts for concurrent resuscitative interventions. (9/15)
http://pediatrics.aappublications.org/content/136/4/819

APNEA OF PREMATURITY (CLINICAL REPORT)

Eric C. Eichenwald, MD, FAAP, and Committee on Fetus and Newborn

ABSTRACT. Apnea of prematurity is one of the most common diagnoses in the NICU. Despite the frequency of apnea of prematurity, it is unknown whether recurrent apnea, bradycardia, and hypoxemia in preterm infants are harmful. Research into the development of respiratory control in immature animals and preterm infants has facilitated our understanding of the pathogenesis and treatment of apnea of prematurity. However, the lack of consistent definitions, monitoring practices, and consensus about clinical significance leads to significant variation in practice. The purpose of this clinical report is to review the evidence basis for the definition, epidemiology, and treatment of apnea of prematurity as well as discharge recommendations for preterm infants diagnosed with recurrent apneic events. (12/15)
http://pediatrics.aappublications.org/content/137/1/e20153757

ASSESSMENT AND MANAGEMENT OF INGUINAL HERNIA IN INFANTS (CLINICAL REPORT)

Kasper S. Wang, MD; Committee on Fetus and Newborn; and Section on Surgery

ABSTRACT. Inguinal hernia repair in infants is a routine surgical procedure. However, numerous issues, including timing of the repair, the need to explore the contralateral groin, use of laparoscopy, and anesthetic approach, remain unsettled. Given the lack of compelling data, consideration should be given to large, prospective, randomized controlled trials to determine best practices for the management of inguinal hernias in infants. (9/12)
http://pediatrics.aappublications.org/content/130/4/768

ATOPIC DERMATITIS: SKIN-DIRECTED MANAGEMENT (CLINICAL REPORT)

Megha M. Tollefson, MD; Anna L. Bruckner, MD, FAAP; and Section on Dermatology

ABSTRACT. Atopic dermatitis is a common inflammatory skin condition characterized by relapsing eczematous lesions in a typical distribution. It can be frustrating for pediatric patients, parents, and health care providers alike. The pediatrician will treat the majority of children with atopic dermatitis as many patients will not have access to a pediatric medical subspecialist, such as a pediatric dermatologist or pediatric allergist. This report provides up-to-date information regarding the disease and its impact, pathogenesis, treatment options, and potential complications. The goal of this report is to assist pediatricians with accurate and useful information that will improve the care of patients with atopic dermatitis. (11/14)
http://pediatrics.aappublications.org/content/134/6/e1735

ATTENTION-DEFICIT/HYPERACTIVITY DISORDER AND SUBSTANCE ABUSE (CLINICAL REPORT)

Elizabeth Harstad, MD, MPH, FAAP; Sharon Levy, MD, MPH, FAAP; and Committee on Substance Abuse

ABSTRACT. Attention-deficit/hyperactivity disorder (ADHD) and substance use disorders are inextricably intertwined. Children with ADHD are more likely than peers to develop substance use disorders. Treatment with stimulants may reduce the risk of substance use disorders, but stimulants are a class of medication with significant abuse and diversion potential. The objectives of this clinical report were to present practical strategies for reducing the risk of substance use disorders in patients with ADHD and suggestions for safe stimulant prescribing. (6/14, reaffirmed 10/20)

BARRIER PROTECTION USE BY ADOLESCENTS DURING SEXUAL ACTIVITY

Laura K. Grubb, MD, MPH, FAAP, and Committee on Adolescence

ABSTRACT. Rates of sexual activity, pregnancies, and births among adolescents have continued to decline during the past decade to historic lows. Despite these positive trends, many adolescents remain at risk for unintended pregnancy and sexually transmitted infections (STIs). When used consistently and correctly, latex and synthetic barrier methods reduce the risk of many STIs, including HIV, and pregnancy. This update of the 2013 policy statement is intended to assist pediatricians in understanding and supporting the use of barrier methods by their patients to prevent unintended pregnancies and STIs and address obstacles to their use. (7/20)
See full text on page 581.
https://pediatrics.aappublications.org/content/146/2/e2020007237

BARRIER PROTECTION USE BY ADOLESCENTS DURING SEXUAL ACTIVITY (TECHNICAL REPORT)

Laura K. Grubb, MD, MPH, FAAP, and Committee on Adolescence

ABSTRACT. Rates of sexual activity, pregnancies, and births among adolescents have continued to decline during the past decade to historic lows. Despite these positive trends, many adolescents remain at risk for unintended pregnancy and sexually transmitted infections (STIs). This technical report discusses the new data and trends in adolescent sexual behavior and barrier protection use. Since 2017, STI rates have increased and use of barrier methods, specifically external condom use, has declined among adolescents and young adults. Interventions that increase availability of or accessibility to barrier methods are most efficacious when combined with additional individual, small-group, or community-level activities that include messages about safer sex. Continued research informs public health interventions for adolescents that increase the consistent and correct use of barrier methods and promote dual protection of barrier methods for STI prevention together with other effective methods of contraception. (7/20)

BEST PRACTICES FOR IMPROVING FLOW AND CARE OF PEDIATRIC PATIENTS IN THE EMERGENCY DEPARTMENT (TECHNICAL REPORT)

Isabel A. Barata, MD, FACEP; Kathleen M. Brown, MD, FACEP; Laura Fitzmaurice, MD, FACEP, FAAP; Elizabeth Stone Griffin, RN; Sally K. Snow, BSN, RN; and Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee and Emergency Nurses Association Pediatric Committee)

ABSTRACT. This report provides a summary of best practices for improving flow, reducing waiting times, and improving the quality of care of pediatric patients in the emergency department. (12/14, reaffirmed 7/20)
http://pediatrics.aappublications.org/content/135/1/e273

BICYCLE HELMETS

Committee on Injury and Poison Prevention

ABSTRACT. Bicycling remains one of the most popular recreational sports among children in America and is the leading cause of recreational sports injuries treated in emergency departments. An estimated 23 000 children younger than 21 years sus-

tained head injuries (excluding the face) while bicycling in 1998. The bicycle helmet is a very effective device that can prevent the occurrence of up to 88% of serious brain injuries. Despite this, most children do not wear a helmet each time they ride a bicycle, and adolescents are particularly resistant to helmet use. Recently, a group of national experts and government agencies renewed the call for all bicyclists to wear helmets. This policy statement describes the role of the pediatrician in helping attain universal helmet use among children and teens for each bicycle ride. (10/01, reaffirmed 1/05, 2/08, 11/11)
http://pediatrics.aappublications.org/content/108/4/1030

BINGE DRINKING (CLINICAL REPORT)

Lorena Siqueira, MD, MSPH, FAAP; Vincent C. Smith, MD, MPH, FAAP; and Committee on Substance Abuse

ABSTRACT. Alcohol is the substance most frequently abused by children and adolescents in the United States, and its use is associated with the leading causes of death and serious injury at this age (ie, motor vehicle accidents, homicides, and suicides). Among youth who drink, the proportion who drink heavily is higher than among adult drinkers, increasing from approximately 50% in those 12 to 14 years of age to 72% among those 18 to 20 years of age. In this clinical report, the definition, epidemiology, and risk factors for binge drinking; the neurobiology of intoxication, blackouts, and hangovers; genetic considerations; and adverse outcomes are discussed. The report offers guidance for the pediatrician. As with any high-risk behavior, prevention plays a more important role than later intervention and has been shown to be more effective. In the pediatric office setting, it is important to ask every adolescent about alcohol use. (8/15)
http://pediatrics.aappublications.org/content/136/3/e718

BONE DENSITOMETRY IN CHILDREN AND ADOLESCENTS (CLINICAL REPORT)

Laura K. Bachrach, MD; Catherine M. Gordon, MD, MS; and Section on Endocrinology

ABSTRACT. Concerns about bone health and potential fragility in children and adolescents have led to a high interest in bone densitometry. Pediatric patients with genetic and acquired chronic diseases, immobility, and inadequate nutrition may fail to achieve expected gains in bone size, mass, and strength, leaving them vulnerable to fracture. In older adults, bone densitometry has been shown to predict fracture risk and reflect response to therapy. The role of densitometry in the management of children at risk of bone fragility is less clear. This clinical report summarizes current knowledge about bone densitometry in the pediatric population, including indications for its use, interpretation of results, and risks and costs. The report emphasizes updated consensus statements generated at the 2013 Pediatric Position Development Conference of the International Society of Clinical Densitometry by an international panel of bone experts. Some of these recommendations are evidence-based, whereas others reflect expert opinion, because data are sparse on many topics. The statements from this and other expert panels provide general guidance to the pediatrician, but decisions about ordering and interpreting bone densitometry still require clinical judgment. The interpretation of bone densitometry results in children differs from that in older adults. The terms "osteopenia" and "osteoporosis" based on bone densitometry findings alone should not be used in younger patients; instead, bone mineral content or density that falls >2 SDs below expected is labeled "low for age." Pediatric osteoporosis is defined by the Pediatric Position Development Conference by using 1 of the following criteria: ≥1 vertebral fractures occurring in the absence of local disease or high-energy trauma (without or with densitometry measurements) or low bone density for age and a significant fracture history (defined as ≥2 long bone fractures before 10 years of age or ≥3 long bone fractures before 19 years of age). Ongoing research will help define the indications and best methods for assessing bone strength in children and the clinical factors that contribute to fracture risk. The Pediatric Endocrine Society affirms the educational value of this publication. (9/16)

BOXING PARTICIPATION BY CHILDREN AND ADOLESCENTS

Council on Sports Medicine and Fitness (joint with Canadian Paediatric Society Healthy Active Living and Sports Medicine Committee)

ABSTRACT. Thousands of boys and girls younger than 19 years participate in boxing in North America. Although boxing provides benefits for participants, including exercise, self-discipline, and self-confidence, the sport of boxing encourages and rewards deliberate blows to the head and face. Participants in boxing are at risk of head, face, and neck injuries, including chronic and even fatal neurologic injuries. Concussions are one of the most common injuries that occur with boxing. Because of the risk of head and facial injuries, the American Academy of Pediatrics and the Canadian Paediatric Society oppose boxing as a sport for children and adolescents. These organizations recommend that physicians vigorously oppose boxing in youth and encourage patients to participate in alternative sports in which intentional head blows are not central to the sport. (8/11, reaffirmed 2/15, 3/20)
http://pediatrics.aappublications.org/content/128/3/617

BREASTFEEDING AND THE USE OF HUMAN MILK

Section on Breastfeeding

ABSTRACT. Breastfeeding and human milk are the normative standards for infant feeding and nutrition. Given the documented short- and long-term medical and neurodevelopmental advantages of breastfeeding, infant nutrition should be considered a public health issue and not only a lifestyle choice. The American Academy of Pediatrics reaffirms its recommendation of exclusive breastfeeding for about 6 months, followed by continued breastfeeding as complementary foods are introduced, with continuation of breastfeeding for 1 year or longer as mutually desired by mother and infant. Medical contraindications to breastfeeding are rare. Infant growth should be monitored with the World Health Organization (WHO) Growth Curve Standards to avoid mislabeling infants as underweight or failing to thrive. Hospital routines to encourage and support the initiation and sustaining of exclusive breastfeeding should be based on the American Academy of Pediatrics-endorsed WHO/UNICEF "Ten Steps to Successful Breastfeeding." National strategies supported by the US Surgeon General's Call to Action, the Centers for Disease Control and Prevention, and The Joint Commission are involved to facilitate breastfeeding practices in US hospitals and communities. Pediatricians play a critical role in their practices and communities as advocates of breastfeeding and thus should be knowledgeable about the health risks of not breastfeeding, the economic benefits to society of breastfeeding, and the techniques for managing and supporting the breastfeeding dyad. The "Business Case for Breastfeeding" details how mothers can maintain lactation in the workplace and the benefits to employers who facilitate this practice. (2/12)
http://pediatrics.aappublications.org/content/129/3/e827

THE BREASTFEEDING-FRIENDLY PEDIATRIC OFFICE PRACTICE (CLINICAL REPORT)

Joan Younger Meek, MD, MS, RD, FAAP, IBCLC; Amy J. Hatcher, MD, FAAP; and Section on Breastfeeding

ABSTRACT. The landscape of breastfeeding has changed over the past several decades as more women initiate breastfeeding in the postpartum period and more hospitals are designated as Baby-Friendly Hospitals by following the evidence-based Ten

Steps to Successful Breastfeeding. The number of births in such facilities has increased more than sixfold over the past decade. With more women breastfeeding and stays in the maternity facilities lasting only a few days, the vast majority of continued breastfeeding support occurs in the community. Pediatric care providers evaluate breastfeeding infants and their mothers in the office setting frequently during the first year of life. The office setting should be conducive to providing ongoing breastfeeding support. Likewise, the office practice should avoid creating barriers for breastfeeding mothers and families or unduly promoting infant formula. This clinical report aims to review practices shown to support breastfeeding that can be implemented in the outpatient setting, with the ultimate goal of increasing the duration of exclusive breastfeeding and the continuation of any breastfeeding. (4/17)

THE BUILT ENVIRONMENT: DESIGNING COMMUNITIES TO PROMOTE PHYSICAL ACTIVITY IN CHILDREN

Committee on Environmental Health

ABSTRACT. An estimated 32% of American children are overweight, and physical inactivity contributes to this high prevalence of overweight. This policy statement highlights how the built environment of a community affects children's opportunities for physical activity. Neighborhoods and communities can provide opportunities for recreational physical activity with parks and open spaces, and policies must support this capacity. Children can engage in physical activity as a part of their daily lives, such as on their travel to school. Factors such as school location have played a significant role in the decreased rates of walking to school, and changes in policy may help to increase the number of children who are able to walk to school. Environment modification that addresses risks associated with automobile traffic is likely to be conducive to more walking and biking among children. Actions that reduce parental perception and fear of crime may promote outdoor physical activity. Policies that promote more active lifestyles among children and adolescents will enable them to achieve the recommended 60 minutes of daily physical activity. By working with community partners, pediatricians can participate in establishing communities designed for activity and health. (5/09, reaffirmed 1/13)
http://pediatrics.aappublications.org/content/123/6/1591

CALCIUM AND VITAMIN D REQUIREMENTS OF ENTERALLY FED PRETERM INFANTS (CLINICAL REPORT)

Steven A. Abrams, MD, and Committee on Nutrition

ABSTRACT. Bone health is a critical concern in managing preterm infants. Key nutrients of importance are calcium, vitamin D, and phosphorus. Although human milk is critical for the health of preterm infants, it is low in these nutrients relative to the needs of the infants during growth. Strategies should be in place to fortify human milk for preterm infants with birth weight <1800 to 2000 g and to ensure adequate mineral intake during hospitalization and after hospital discharge. Biochemical monitoring of very low birth weight infants should be performed during their hospitalization. Vitamin D should be provided at 200 to 400 IU/day both during hospitalization and after discharge from the hospital. Infants with radiologic evidence of rickets should have efforts made to maximize calcium and phosphorus intake by using available commercial products and, if needed, direct supplementation with these minerals. CARDIOVASCULAR MONITORING AND STIMULANT DRUGS FOR ATTENTION-DEFICIT/HYPERACTIVITY DISORDER

James M. Perrin, MD; Richard A. Friedman, MD; Timothy K. Knilans, MD; Black Box Working Group; and Section on Cardiology and Cardiac Surgery

ABSTRACT. A recent American Heart Association (AHA) statement recommended electrocardiograms (ECGs) routinely for children before they start medications to treat attention-deficit/hyperactivity disorder (ADHD). The AHA statement reflected the thoughtful work of a group committed to improving the health of children with heart disease. However, the recommendation to obtain an ECG before starting medications for treating ADHD contradicts the carefully considered and evidence-based recommendations of the American Academy of Child and Adolescent Psychiatry and the American Academy of Pediatrics (AAP). These organizations have concluded that sudden cardiac death (SCD) in persons taking medications for ADHD is a very rare event, occurring at rates no higher than those in the general population of children and adolescents. Both of these groups also noted the lack of any evidence that the routine use of ECG screening before beginning medication for ADHD treatment would prevent sudden death. The AHA statement pointed out the importance of detecting silent but clinically important cardiac conditions in children and adolescents, which is a goal that the AAP shares. The primary purpose of the AHA statement is to prevent cases of SCD that may be related to stimulant medications. The recommendations of the AAP and the rationale for these recommendations are the subject of this statement. (8/08)

CARE OF ADOLESCENT PARENTS AND THEIR CHILDREN (CLINICAL REPORT)

Jorge L. Pinzon, MD; Veronnie F. Jones, MD; Committee on Adolescence; and Committee on Early Childhood

ABSTRACT. Teen pregnancy and parenting remain an important public health issue in the United States and the world, and many children live with their adolescent parents alone or as part of an extended family. A significant proportion of teen parents reside with their family of origin, significantly affecting the multigenerational family structure. Repeated births to teen parents are also common. This clinical report updates a previous policy statement on care of the adolescent parent and their children and addresses medical and psychosocial risks specific to this population. Challenges unique to teen parents and their children are reviewed, along with suggestions for the pediatrician on models for intervention and care. (11/12, reaffirmed 7/16)

THE CARE OF CHILDREN WITH CONGENITAL HEART DISEASE IN THEIR PRIMARY MEDICAL HOME

M. Regina Lantin-Hermoso, MD, FAAP, FACC; Stuart Berger, MD, FAAP; Ami B. Bhatt, MD, FACC; Julia E. Richerson, MD, FAAP; Robert Morrow, MD, FAAP; Michael D. Freed, MD, FAAP, FACC; Robert H. Beekman III, MD, FAAP, FACC; and Section on Cardiology and Cardiac Surgery

ABSTRACT. Congenital heart disease (CHD) is the most common birth anomaly. With advances in repair and palliation of these complex lesions, more and more patients are surviving and are discharged from the hospital to return to their families. Patients with CHD have complex health care needs that often must be provided for or coordinated for by the primary care provider (PCP) and medical home. This policy statement aims to provide the PCP with general guidelines for the care of the child with congenital heart defects and outlines anticipated problems, serving as a repository of current knowledge in a practical, read-

ily accessible format. A timeline approach is used, emphasizing the role of the PCP and medical home in the management of patients with CHD in their various life stages. (10/17)
http://pediatrics.aappublications.org/content/140/5/e20172607

CARE OF THE ADOLESCENT AFTER AN ACUTE SEXUAL ASSAULT (CLINICAL REPORT)

James E. Crawford-Jakubiak, MD, FAAP; Elizabeth M. Alderman, MD, FAAP, SAHM; John M. Leventhal, MD, FAAP; Committee on Child Abuse and Neglect; and Committee on Adolescence

ABSTRACT. Sexual violence is a broad term that encompasses a wide range of sexual victimizations. Since the American Academy of Pediatrics published its last policy statement on sexual assault in 2008, additional information and data have emerged about sexual violence affecting adolescents and the treatment and management of the adolescent who has been a victim of sexual assault. This report provides new information to update physicians and focuses on the acute assessment and care of adolescent victims who have experienced a recent sexual assault. Follow-up of the acute assault, as well as prevention of sexual assault, are also discussed. (2/17)

CAREGIVER-FABRICATED ILLNESS IN A CHILD: A MANIFESTATION OF CHILD MALTREATMENT (CLINICAL REPORT)

Emalee G. Flaherty, MD, FAAP; Harriet L. MacMillan, MD; and Committee on Child Abuse and Neglect

ABSTRACT. Caregiver-fabricated illness in a child is a form of child maltreatment caused by a caregiver who falsifies and/or induces a child's illness, leading to unnecessary and potentially harmful medical investigations and/or treatment. This condition can result in significant morbidity and mortality. Although caregiver-fabricated illness in a child has been widely known as Munchausen syndrome by proxy, there is ongoing discussion about alternative names, including pediatric condition falsification, factitious disorder (illness) by proxy, child abuse in the medical setting, and medical child abuse. Because it is a relatively uncommon form of maltreatment, pediatricians need to have a high index of suspicion when faced with a persistent or recurrent illness that cannot be explained and that results in multiple medical procedures or when there are discrepancies between the history, physical examination, and health of a child. This report updates the previous clinical report "Beyond Munchausen Syndrome by Proxy: Identification and Treatment of Child Abuse in the Medical Setting." The authors discuss the need to agree on appropriate terminology, provide an update on published reports of new manifestations of fabricated medical conditions, and discuss approaches to assessment, diagnosis, and management, including how best to protect the child from further harm. (8/13, reaffirmed 8/18)

CHEERLEADING INJURIES: EPIDEMIOLOGY AND RECOMMENDATIONS FOR PREVENTION

Council on Sports Medicine and Fitness

ABSTRACT. Over the last 30 years, cheerleading has increased dramatically in popularity and has evolved from leading the crowd in cheers at sporting events into a competitive, year-round sport involving complex acrobatic stunts and tumbling. Consequently, cheerleading injuries have steadily increased over the years in both number and severity. Sprains and strains to the lower extremities are the most common injuries. Although the overall injury rate remains relatively low, cheerleading has accounted for approximately 66% of all catastrophic injuries in high school girl athletes over the past 25 years. Risk factors for injuries in cheerleading include higher BMI, previous injury, cheering on harder surfaces, performing stunts, and supervision by a coach with low level of training and experience. This policy statement describes the epidemiology of cheerleading injuries and provides recommendations for injury prevention. (10/12, reaffirmed 7/15)

CHEMICAL-BIOLOGICAL TERRORISM AND ITS IMPACT ON CHILDREN

Sarita Chung, MD, FAAP; Carl R. Baum, MD, FACMT, FAAP; Ann-Christine Nyquist, MD, MSPH, FAAP; Disaster Preparedness Advisory Council; Council on Environmental Health; and Committee on Infectious Diseases

ABSTRACT. Chemical and biological events (including infectious disease outbreaks) may affect children disproportionately, and the threat of a chemical or biological attack remains in the United States and worldwide. Although federal programs and funding support a broad range of federal initiatives for public health preparedness and response, funding at the state and local levels has been flat or is decreasing, potentially leaving communities vulnerable. Consequently, pediatricians need to prepare and be ready to care for children in their communities before, during, and after a chemical or biological event, including during long-term recovery. Some medical countermeasures for particular chemical and biological agents have not been adequately studied or approved for children. The American Academy of Pediatrics provides resources and education on disaster preparedness and response, including information on the pediatrician's role in disasters, pediatric medical countermeasures, and mental health after an event as well as individual and family preparedness. This policy statement addresses the steps that clinicians and policy makers can take to protect children and mitigate the effects of a chemical or biological attack. (1/20)

CHEMICAL-BIOLOGICAL TERRORISM AND ITS IMPACT ON CHILDREN (TECHNICAL REPORT)

Sarita Chung, MD, FAAP; Carl R. Baum, MD, FACMT, FAAP; Ann-Christine Nyquist, MD, MSPH, FAAP; Disaster Preparedness Advisory Council; Council on Environmental Health; and Committee on Infectious Diseases

ABSTRACT. Children are potential victims of chemical or biological terrorism. In recent years, children have been victims of terrorist acts such as the chemical attacks (2017–2018) in Syria. Consequently, it is necessary to prepare for and respond to the needs of children after a chemical or biological attack. A broad range of public health initiatives have occurred since the terrorist attacks of September 11, 2001. However, in many cases, these initiatives have not ensured the protection of children. Since 2001, public health preparedness has broadened to an all-hazards approach, in which response plans for terrorism are blended with those for unintentional disasters or outbreaks (eg, natural events such as earthquakes or pandemic influenza or man-made catastrophes such as a hazardous-materials spill). In response to new principles and programs that have evolved over the last decade, this technical report supports the accompanying update of the American Academy of Pediatrics 2006 policy statement "Chemical-Biological Terrorism and its Impact on Children." The roles of the pediatrician and public health agencies continue to evolve, and only their coordinated readiness and response efforts will ensure that the medical and mental health needs of children will be met successfully. In this document, we will address chemical and biological incidents. Radiation disasters are addressed separately. (1/20)

CHEMICAL-MANAGEMENT POLICY: PRIORITIZING CHILDREN'S HEALTH

Council on Environmental Health

ABSTRACT. The American Academy of Pediatrics recommends that chemical-management policy in the United States be revised to protect children and pregnant women and to better protect other populations. The Toxic Substance Control Act (TSCA) was passed in 1976. It is widely recognized to have been ineffective in protecting children, pregnant women, and the general population from hazardous chemicals in the marketplace. It does not take into account the special vulnerabilities of children in attempting to protect the population from chemical hazards. Its processes are so cumbersome that in its more than 30 years of existence, the TSCA has been used to regulate only 5 chemicals or chemical classes of the tens of thousands of chemicals that are in commerce. Under the TSCA, chemical companies have no responsibility to perform premarket testing or postmarket follow-up of the products that they produce; in fact, the TSCA contains disincentives for the companies to produce such data. Voluntary programs have been inadequate in resolving problems. Therefore, chemical-management policy needs to be rewritten in the United States. Manufacturers must be responsible for developing information about chemicals before marketing. The US Environmental Protection Agency must have the authority to demand additional safety data about a chemical and to limit or stop the marketing of a chemical when there is a high degree of suspicion that the chemical might be harmful to children, pregnant women, or other populations. (4/11, reaffirmed 9/16)

CHILD ABUSE, CONFIDENTIALITY, AND THE HEALTH INSURANCE PORTABILITY AND ACCOUNTABILITY ACT

Committee on Child Abuse and Neglect

ABSTRACT. The federal Health Insurance Portability and Accountability Act (HIPAA) of 1996 has significantly affected clinical practice, particularly with regard to how patient information is shared. HIPAA addresses the security and privacy of patient health data, ensuring that information is released appropriately with patient or guardian consent and knowledge. However, when child abuse or neglect is suspected in a clinical setting, the physician may determine that release of information without consent is necessary to ensure the health and safety of the child. This policy statement provides an overview of HIPAA regulations with regard to the role of the pediatrician in releasing or reviewing patient health information when the patient is a child who is a suspected victim of abuse or neglect. This statement is based on the most current regulations provided by the US Department of Health and Human Services and is subject to future changes and clarifications as updates are provided. (12/09, reaffirmed 1/14)

CHILD FATALITY REVIEW

Cindy W. Christian, MD; Robert D. Sege, MD, PhD; Committee on Child Abuse and Neglect; Committee on Injury, Violence, and Poison Prevention; and Council on Community Pediatrics

ABSTRACT. Injury remains the leading cause of pediatric mortality and requires public health approaches to reduce preventable deaths. Child fatality review teams, first established to review suspicious child deaths involving abuse or neglect, have expanded toward a public health model of prevention of child fatality through systematic review of child deaths from birth through adolescence. Approximately half of all states report reviewing child deaths from all causes, and the process of fatality review has identified effective local and state prevention strategies for reducing child deaths. This expanded approach can be a powerful tool in understanding the epidemiology and preventability of child death locally, regionally, and nationally; improving accuracy of vital statistics data; and identifying public health and legislative strategies for reducing preventable child fatalities. The American Academy of Pediatrics supports the development of federal and state legislation to enhance the child fatality review process and recommends that pediatricians become involved in local and state child death reviews. CHILD LIFE SERVICES

Committee on Hospital Care and Child Life Council

ABSTRACT. Child life programs are an important component of pediatric hospital–based care to address the psychosocial concerns that accompany hospitalization and other health care experiences. Child life specialists focus on the optimal development and well-being of infants, children, adolescents, and young adults while promoting coping skills and minimizing the adverse effects of hospitalization, health care, and/or other potentially stressful experiences. Using therapeutic play, expressive modalities, and psychological preparation as primary tools, in collaboration with the entire health care team and family, child life interventions facilitate coping and adjustment at times and under circumstances that might otherwise prove overwhelming for the child. Play and developmentally appropriate communication are used to: (1) promote optimal development; (2) educate children and families about health conditions; (3) prepare children and families for medical events or procedures; (4) plan and rehearse useful coping and pain management strategies; (5) help children work through feelings about past or impending experiences; and (6) establish therapeutic relationships with patients, siblings, and parents to support family involvement in each child's care. (4/14, reaffirmed 2/18)

CHILD PASSENGER SAFETY

Dennis R. Durbin, MD, MSCE, FAAP; Benjamin D. Hoffman, MD, FAAP; and Council on Injury, Violence, and Poison Prevention

ABSTRACT. Child passenger safety has dramatically evolved over the past decade; however, motor vehicle crashes continue to be the leading cause of death for children 4 years and older. This policy statement provides 4 evidence-based recommendations for best practices in the choice of a child restraint system to optimize safety in passenger vehicles for children from birth through adolescence: (1) rear-facing car safety seats as long as possible; (2) forward-facing car safety seats from the time they outgrow rear-facing seats for most children through at least 4 years of age; (3) belt-positioning booster seats from the time they outgrow forward-facing seats for most children through at least 8 years of age; and (4) lap and shoulder seat belts for all who have outgrown booster seats. In addition, a fifth evidence-based recommendation is for all children younger than 13 years to ride in the rear seats of vehicles. It is important to note that every transition is associated with some decrease in protection; therefore, parents should be encouraged to delay these transitions for as long as possible. These recommendations are presented in the form of an algorithm that is intended to facilitate implementation of the recommendations by pediatricians to their patients and families and should cover most situations that pediatricians will encounter in practice. The American Academy of Pediatrics urges all pediatricians to know and promote these recommendations as part of child passenger safety anticipatory guidance at every health supervision visit. (10/18)

http://pediatrics.aappublications.org/content/142/5/e20182460

CHILD PASSENGER SAFETY (TECHNICAL REPORT)

Dennis R. Durbin, MD, MSCE, FAAP; Benjamin D. Hoffman, MD, FAAP; and Council on Injury, Violence, and Poison Prevention

ABSTRACT. Despite significant reductions in the number of children killed in motor vehicle crashes over the past decade, crashes continue to be the leading cause of death to children 4 years and older. Therefore, the American Academy of Pediatrics continues to recommend the inclusion of child passenger safety anticipatory guidance at every health supervision visit. This technical report provides a summary of the evidence in support of 5 recommendations for best practices to optimize safety in passenger vehicles for children from birth through adolescence that all pediatricians should know and promote in their routine practice. These recommendations are presented in the revised policy statement on child passenger safety in the form of an algorithm that is intended to facilitate their implementation by pediatricians with their patients and families. The algorithm is designed to cover the majority of situations that pediatricians will encounter in practice. In addition, a summary of evidence on a number of additional issues affecting the safety of children in motor vehicles, including the proper use and installation of child restraints, exposure to air bags, travel in pickup trucks, children left in or around vehicles, and the importance of restraint laws, is provided. Finally, this technical report provides pediatricians with a number of resources for additional information to use when providing anticipatory guidance to families. (10/18)

CHILD SEX TRAFFICKING AND COMMERCIAL SEXUAL EXPLOITATION: HEALTH CARE NEEDS OF VICTIMS (CLINICAL REPORT)

Jordan Greenbaum, MD; James E. Crawford-Jakubiak, MD, FAAP; and Committee on Child Abuse and Neglect

ABSTRACT. Child sex trafficking and commercial sexual exploitation of children (CSEC) are major public health problems in the United States and throughout the world. Despite large numbers of American and foreign youth affected and a plethora of serious physical and mental health problems associated with CSEC, there is limited information available to pediatricians regarding the nature and scope of human trafficking and how pediatricians and other health care providers may help protect children. Knowledge of risk factors, recruitment practices, possible indicators of CSEC, and common medical and behavioral health problems experienced by victims will help pediatricians recognize potential victims and respond appropriately. As health care providers, educators, and leaders in child advocacy, pediatricians play an essential role in addressing the public health issues faced by child victims of CSEC. Their roles can include working to increase recognition of CSEC, providing direct care and anticipatory guidance related to CSEC, engaging in collaborative efforts with medical and nonmedical colleagues to provide for the complex needs of youth, and educating child-serving professionals and the public. (2/15, reaffirmed 10/20)

THE CHILD WITNESS IN THE COURTROOM

Robert H. Pantell, MD, FAAP, and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Beginning in the 1980s, children have increasingly served as witnesses in the criminal, civil, and family courts; currently, >100 000 children appear in court each year. This statement updates the 1992 American Academy of Pediatrics (AAP) policy statement "The Child as a Witness" and the subsequent 1999 "The Child in Court: A Subject Review." It also builds on existing AAP policy on adverse life events affecting children and resources developed to understand and address childhood trauma. The purpose of this policy statement is to provide background information on some of the legal issues involving children testifying in court, including the accuracy and psychological impact of child testimony; to provide suggestions for how pediatricians can support patients who will testify in court; and to make recommendations for policy improvements to minimize the adverse psychological consequences for child witnesses. These recommendations are, for the most part, based on studies on the psychological and physiologic consequences of children witnessing and experiencing violence, as well as appearing in court, that have emerged since the previous AAP publications on the subject. The goal is to reduce the secondary traumatization of and long-term consequences for children providing testimony about violence they have experienced or witnessed. This statement primarily addresses children appearing in court as victims of physical or sexual abuse or as witnesses of violent acts; most of the scientific literature addresses these specific situations. It may apply, in certain situations, to children required to provide testimony in custody disputes, child welfare proceedings, or immigration court. It does not address children appearing in court as offenders or as part of juvenile justice proceedings. (2/17)

http://pediatrics.aappublications.org/content/139/3/e20164008

CHILDREN, ADOLESCENTS, AND THE MEDIA

Council on Communications and Media

ABSTRACT. Media, from television to the "new media" (including cell phones, iPads, and social media), are a dominant force in children's lives. Although television is still the predominant medium for children and adolescents, new technologies are increasingly popular. The American Academy of Pediatrics continues to be concerned by evidence about the potential harmful effects of media messages and images; however, important positive and prosocial effects of media use should also be recognized. Pediatricians are encouraged to take a media history and ask 2 media questions at every well-child visit: How much recreational screen time does your child or teenager consume daily? Is there a television set or Internet-connected device in the child's bedroom? Parents are encouraged to establish a family home use plan for all media. Media influences on children and teenagers should be recognized by schools, policymakers, product advertisers, and entertainment producers. (10/13)

http://pediatrics.aappublications.org/content/132/5/958

CHILDREN AND ADOLESCENTS AND DIGITAL MEDIA (TECHNICAL REPORT)

Yolanda (Linda) Reid Chassiakos, MD, FAAP; Jenny Radesky, MD, FAAP; Dimitri Christakis, MD, FAAP; Megan A. Moreno, MD, MSEd, MPH, FAAP; Corinn Cross, MD, FAAP; and Council on Communications and Media

ABSTRACT. Today's children and adolescents are immersed in both traditional and new forms of digital media. Research on traditional media, such as television, has identified health concerns and negative outcomes that correlate with the duration and content of viewing. Over the past decade, the use of digital media, including interactive and social media, has grown, and research evidence suggests that these newer media offer both benefits and risks to the health of children and teenagers. Evidence-based benefits identified from the use of digital and social media include early learning, exposure to new ideas and knowledge, increased opportunities for social contact and support, and new opportunities to access health promotion messages and information. Risks of such media include negative health effects on sleep, attention, and learning; a higher incidence of obesity and depression; exposure to inaccurate, inappropriate, or unsafe content and contacts; and compromised privacy and confidentiality. This technical report reviews the literature regarding these opportunities and risks, framed around clinical questions, for

children from birth to adulthood. To promote health and wellness in children and adolescents, it is important to maintain adequate physical activity, healthy nutrition, good sleep hygiene, and a nurturing social environment. A healthy Family Media Use Plan (www.healthychildren.org/MediaUsePlan) that is individualized for a specific child, teenager, or family can identify an appropriate balance between screen time/online time and other activities, set boundaries for accessing content, guide displays of personal information, encourage age-appropriate critical thinking and digital literacy, and support open family communication and implementation of consistent rules about media use. (10/16)

CHILDREN EXPOSED TO MALTREATMENT: ASSESSMENT AND THE ROLE OF PSYCHOTROPIC MEDICATION (CLINICAL REPORT)

Brooks Keeshin, MD, FAAP; Heather C. Forkey, MD, FAAP; George Fouras, MD, DFAACAP; Harriet L. MacMillan, CM, MD, MSc, FRCPC; Council on Child Abuse and Neglect; and Council on Foster Care, Adoption, and Kinship Care (joint with American Academy of Child and Adolescent Psychiatry Committee on Child Maltreatment and Violence and Committee on Adoption and Foster Care)

ABSTRACT. Pediatricians regularly care for children who have experienced child maltreatment. Child maltreatment is a risk factor for a broad range of mental health problems. Issues specific to child maltreatment make addressing emotional and behavioral challenges among maltreated children difficult. This clinical report focuses on 2 key issues necessary for the care of maltreated children and adolescents in pediatric settings: trauma-informed assessments and the role of pharmacotherapy in maltreated children and adolescents. Specific to assessment, current or past involvement of the child in the child welfare system can hinder obtaining necessary information or access to appropriate treatments. Furthermore, trauma-informed assessments can help identify the need for specific interventions. Finally, it is important to take both child welfare system and trauma-informed assessment approaches into account when considering the use of psychotropic agents because there are critical diagnostic and systemic issues that affect the prescribing and discontinuing of psychiatric medications among children with a history of child maltreatment. (1/20)

CHILDREN WITH INTELLECTUAL AND DEVELOPMENTAL DISABILITIES AS ORGAN TRANSPLANTATION RECIPIENTS

Mindy B. Statter, MD, MBE; Garey Noritz, MD; Committee on Bioethics; and Council on Children With Disabilities

ABSTRACT. The demand for transplantable solid organs far exceeds the supply of deceased donor organs. Patient selection criteria are determined by individual transplant programs; given the scarcity of solid organs for transplant, allocation to those most likely to benefit takes into consideration both medical and psychosocial factors. Children with intellectual and developmental disabilities have historically been excluded as potential recipients of organ transplants. When a transplant is likely to provide significant health benefits, denying a transplant to otherwise eligible children with disabilities may constitute illegal and unjustified discrimination. Children with intellectual and developmental disabilities should not be excluded from the potential pool of recipients and should be referred for evaluation as recipients of solid organ transplants. (4/20)

CHILDREN'S HEALTH INSURANCE PROGRAM (CHIP): ACCOMPLISHMENTS, CHALLENGES, AND POLICY RECOMMENDATIONS

Committee on Child Health Financing

ABSTRACT. Sixteen years ago, the 105th Congress, responding to the needs of 10 million children in the United States who lacked health insurance, created the State Children's Health Insurance Program (SCHIP) as part of the Balanced Budget Act of 1997. Enacted as Title XXI of the Social Security Act, the Children's Health Insurance Program (CHIP; or SCHIP as it has been known at some points) provided states with federal assistance to create programs specifically designed for children from families with incomes that exceeded Medicaid thresholds but that were insufficient to enable them to afford private health insurance. Congress provided $40 billion in block grants over 10 years for states to expand their existing Medicaid programs to cover the intended populations, to erect new stand-alone SCHIP programs for these children, or to effect some combination of both options. Congress reauthorized CHIP once in 2009 under the Children's Health Insurance Program Reauthorization Act and extended its life further within provisions of the Patient Protection and Affordable Care Act of 2010. The purpose of this statement is to review the features of CHIP as it has evolved over the 16 years of its existence; to summarize what is known about the effects that the program has had on coverage, access, health status, and disparities among participants; to identify challenges that remain with respect to insuring this group of vulnerable children, including the impact that provisions of the new Affordable Care Act will have on the issue of health insurance coverage for near-poor children after 2015; and to offer recommendations on how to expand and strengthen the national commitment to provide health insurance to all children regardless of means. (2/14, reaffirmed 8/20)
http://pediatrics.aappublications.org/content/133/3/e784

CIRCUMCISION POLICY STATEMENT

Task Force on Circumcision

ABSTRACT. Male circumcision is a common procedure, generally performed during the newborn period in the United States. In 2007, the American Academy of Pediatrics (AAP) formed a multidisciplinary task force of AAP members and other stakeholders to evaluate the recent evidence on male circumcision and update the Academy's 1999 recommendations in this area. Evaluation of current evidence indicates that the health benefits of newborn male circumcision outweigh the risks and that the procedure's benefits justify access to this procedure for families who choose it. Specific benefits identified included prevention of urinary tract infections, penile cancer, and transmission of some sexually transmitted infections, including HIV. The American College of Obstetricians and Gynecologists has endorsed this statement. (8/12)
http://pediatrics.aappublications.org/content/130/3/585

CLIMATIC HEAT STRESS AND EXERCISING CHILDREN AND ADOLESCENTS

Council on Sports Medicine and Fitness and Council on School Health

ABSTRACT. Results of new research indicate that, contrary to previous thinking, youth do not have less effective thermoregulatory ability, insufficient cardiovascular capacity, or lower physical exertion tolerance compared with adults during exercise in the heat when adequate hydration is maintained. Accordingly, besides poor hydration status, the primary determinants of reduced performance and exertional heat-illness risk in youth during sports and other physical activities in a hot environment include undue physical exertion, insufficient recovery between repeated exercise bouts or closely scheduled same-day training sessions or rounds of sports competition, and inappropriately

wearing clothing, uniforms, and protective equipment that play a role in excessive heat retention. Because these known contributing risk factors are modifiable, exertional heat illness is usually preventable. With appropriate preparation, modifications, and monitoring, most healthy children and adolescents can safely participate in outdoor sports and other physical activities through a wide range of challenging warm to hot climatic conditions. (8/11, reaffirmed 2/15)
http://pediatrics.aappublications.org/content/128/3/e741

CLINICAL CONSIDERATIONS RELATED TO THE BEHAVIORAL MANIFESTATIONS OF CHILD MALTREATMENT (CLINICAL REPORT)

Robert D. Sege, MD, PhD, FAAP; Lisa Amaya-Jackson, MD, MPH, FAACAP; Committee on Child Abuse and Neglect; and Council on Foster Care, Adoption, and Kinship Care (joint with American Academy of Child and Adolescent Psychiatry Committee on Child Maltreatment and Violence and National Center for Child Traumatic Stress)

ABSTRACT. Children who have suffered early abuse or neglect may later present with significant health and behavior problems that may persist long after the abusive or neglectful environment has been remediated. Neurobiological research suggests that early maltreatment may result in an altered psychological and physiologic response to stressful stimuli, a response that deleteriously affects the child's subsequent development. Pediatricians can assist caregivers by helping them recognize the abused or neglected child's emotional and behavioral responses associated with child maltreatment and guide them in the use of positive parenting strategies, referring the children and families to evidence-based therapeutic treatment and mobilizing available community resources. (3/17)
http://pediatrics.aappublications.org/content/139/4/e20170100

CLINICAL GENETIC EVALUATION OF THE CHILD WITH MENTAL RETARDATION OR DEVELOPMENTAL DELAYS (CLINICAL REPORT)

John B. Moeschler, MD; Michael Shevell, MD; and Committee on Genetics

ABSTRACT. This clinical report describes the clinical genetic evaluation of the child with developmental delays or mental retardation. The purpose of this report is to describe the optimal clinical genetics diagnostic evaluation to assist pediatricians in providing a medical home for children with developmental delays or mental retardation and their families. The literature supports the benefit of expert clinical judgment by a consulting clinical geneticist in the diagnostic evaluation. However, it is recognized that local factors may preclude this particular option. No single approach to the diagnostic process is supported by the literature. This report addresses the diagnostic importance of clinical history, 3-generation family history, dysmorphologic examination, neurologic examination, chromosome analysis (≥650 bands), fragile X molecular genetic testing, fluorescence in situ hybridization studies for subtelomere chromosome rearrangements, molecular genetic testing for typical and atypical presentations of known syndromes, computed tomography and/or magnetic resonance brain imaging, and targeted studies for metabolic disorders. (6/06, reaffirmed 5/12)
http://pediatrics.aappublications.org/content/117/6/2304

CLINICAL PRACTICE POLICY TO PROTECT CHILDREN FROM TOBACCO, NICOTINE, AND TOBACCO SMOKE

Section on Tobacco Control

ABSTRACT. Tobacco dependence starts in childhood. Tobacco exposure of children is common and causes illness and premature death in children and adults, with adverse effects starting in the womb. There is no safe level of tobacco smoke exposure. Pediatricians should screen for use of tobacco and other nicotine delivery devices and provide anticipatory guidance to prevent smoking initiation and reduce tobacco smoke exposure. Pediatricians need to be aware of the different nicotine delivery systems marketed and available.

Parents and caregivers are important sources of children's tobacco smoke exposure. Because tobacco dependence is a severe addiction, to protect children's health, caregiver tobacco dependence treatment should be offered or referral for treatment should be provided (such as referral to the national smoker's quitline at 1-800-QUIT-NOW). If the source of tobacco exposure cannot be eliminated, counseling about reducing exposure to children should be provided.

Health care delivery systems should facilitate the effective prevention, identification, and treatment of tobacco dependence in children and adolescents, their parents, and other caregivers. Health care facilities should protect children from tobacco smoke exposure and tobacco promotion. Tobacco dependence prevention and treatment should be part of medical education, with knowledge assessed as part of board certification examinations. (10/15, reaffirmed 6/20)

CLINICAL TOOLS TO ASSESS ASTHMA CONTROL IN CHILDREN (CLINICAL REPORT)

Chitra Dinakar, MD, FAAP; Bradley E. Chipps, MD, FAAP; Section on Allergy and Immunology; and Section on Pediatric Pulmonology and Sleep Medicine

ABSTRACT. Asthma affects an estimated 7 million children and causes significant health care and disease burden. The most recent iteration of the National Heart, Lung and Blood Institute asthma guidelines, the Expert Panel Report 3, emphasizes the assessment and monitoring of asthma control in the management of asthma. Asthma control refers to the degree to which the manifestations of asthma are minimized by therapeutic interventions and the goals of therapy are met. Although assessment of asthma severity is used to guide initiation of therapy, monitoring of asthma control helps determine whether therapy should be maintained or adjusted. The nuances of estimation of asthma control include understanding concepts of current impairment and future risk and incorporating their measurement into clinical practice. Impairment is assessed on the basis of frequency and intensity of symptoms, variations in lung function, and limitations of daily activities. "Risk" refers to the likelihood of exacerbations, progressive loss of lung function, or adverse effects from medications. Currently available ambulatory tools to measure asthma control range are subjective measures, such as patient-reported composite asthma control score instruments or objective measures of lung function, airway hyperreactivity, and biomarkers. Because asthma control exhibits short- and long-term variability, health care providers need to be vigilant regarding the fluctuations in the factors that can create discordance between subjective and objective assessment of asthma control. Familiarity with the properties, application, and relative value of these measures will enable health care providers to choose the optimal set of measures that will adhere to national standards of care and ensure delivery of high-quality care customized to their patients. COCHLEAR IMPLANTS IN CHILDREN: SURGICAL SITE INFECTIONS AND PREVENTION AND TREATMENT OF ACUTE OTITIS MEDIA AND MENINGITIS

Lorry G. Rubin, MD; Blake Papsin, MD; Committee on Infectious Diseases; and Section on Otolaryngology—Head and Neck Surgery

ABSTRACT. The use of cochlear implants is increasingly common, particularly in children younger than 3 years. Bacterial meningitis, often with associated acute otitis media, is more

common in children with cochlear implants than in groups of control children. Children with profound deafness who are candidates for cochlear implants should receive all age-appropriate doses of pneumococcal conjugate and Haemophilus influenzae type b conjugate vaccines and appropriate annual immunization against influenza. In addition, starting at 24 months of age, a single dose of 23-valent pneumococcal polysaccharide vaccine should be administered. Before implant surgery, primary care providers and cochlear implant teams should ensure that immunizations are up-to-date, preferably with completion of indicated vaccines at least 2 weeks before implant surgery. Imaging of the temporal bone/inner ear should be performed before cochlear implantation in all children with congenital deafness and all patients with profound hearing impairment and a history of bacterial meningitis to identify those with inner-ear malformations/cerebrospinal fluid fistulas or ossification of the cochlea. During the initial months after cochlear implantation, the risk of complications of acute otitis media may be higher than during subsequent time periods. Therefore, it is recommended that acute otitis media diagnosed during the first 2 months after implantation be initially treated with a parenteral antibiotic (eg, ceftriaxone or cefotaxime). Episodes occurring 2 months or longer after implantation can be treated with a trial of an oral antimicrobial agent (eg, amoxicillin or amoxicillin/clavulanate at a dose of approximately 90 mg/kg per day of amoxicillin component), provided the child does not appear toxic and the implant does not have a spacer/positioner, a wedge that rests in the cochlea next to the electrodes present in certain implant models available between 1999 and 2002. "Watchful waiting" without antimicrobial therapy is inappropriate for children with implants with acute otitis media. If feasible, tympanocentesis should be performed for acute otitis media, and the material should be sent for culture, but performance of this procedure should not result in an undue delay in initiating antimicrobial therapy. For patients with suspected meningitis, cerebrospinal fluid as well as middle-ear fluid, if present, should be sent for culture. Empiric antimicrobial therapy for meningitis occurring within 2 months of implantation should include an agent with broad activity against Gram-negative bacilli (eg, meropenem) plus vancomycin. For meningitis occurring 2 months or longer after implantation, standard empiric antimicrobial therapy for meningitis (eg, ceftriaxone plus vancomycin) is indicated. For patients with meningitis, urgent evaluation by an otolaryngologist is indicated for consideration of imaging and surgical exploration. (7/10, reaffirmed 1/18)

CODEINE: TIME TO SAY "NO" (CLINICAL REPORT)

Joseph D. Tobias, MD, FAAP; Thomas P. Green, MD, FAAP; Charles J. Coté, MD, FAAP; Section on Anesthesiology and Pain Medicine; and Committee on Drugs

ABSTRACT. Codeine has been prescribed to pediatric patients for many decades as both an analgesic and an antitussive agent. Codeine is a prodrug with little inherent pharmacologic activity and must be metabolized in the liver into morphine, which is responsible for codeine's analgesic effects. However, there is substantial genetic variability in the activity of the responsible hepatic enzyme, *CYP2D6,* and, as a consequence, individual patient response to codeine varies from no effect to high sensitivity. Drug surveillance has documented the occurrence of unanticipated respiratory depression and death after receiving codeine in children, many of whom have been shown to be ultrarapid metabolizers. Patients with documented or suspected obstructive sleep apnea appear to be at particular risk because of opioid sensitivity, compounding the danger among rapid metabolizers in this group. Recently, various organizations and regulatory bodies, including the World Health Organization, the US Food and Drug Administration, and the European Medicines Agency, have promulgated stern warnings regarding the occurrence of adverse effects of codeine in children. These and other groups have or are considering a declaration of a contraindication for the use of codeine for children as either an analgesic or an antitussive. Additional clinical research must extend the understanding of the risks and benefits of both opioid and nonopioid alternatives for orally administered, effective agents for acute and chronic pain. COLLABORATIVE ROLE OF THE PEDIATRICIAN IN THE DIAGNOSIS AND MANAGEMENT OF BIPOLAR DISORDER IN ADOLESCENTS (CLINICAL REPORT)

Benjamin N. Shain, MD, PhD, and Committee on Adolescence

ABSTRACT. Despite the complexity of diagnosis and management, pediatricians have an important collaborative role in referring and partnering in the management of adolescents with bipolar disorder. This report presents the classification of bipolar disorder as well as interviewing and diagnostic guidelines. Treatment options are described, particularly focusing on medication management and rationale for the common practice of multiple, simultaneous medications. Medication adverse effects may be problematic and better managed with collaboration between mental health professionals and pediatricians. Case examples illustrate a number of common diagnostic and management issues. (11/12)

COMMUNICATING WITH CHILDREN AND FAMILIES: FROM EVERYDAY INTERACTIONS TO SKILL IN CONVEYING DISTRESSING INFORMATION (TECHNICAL REPORT)

Marcia Levetown, MD, and Committee on Bioethics

ABSTRACT. Health care communication is a skill that is critical to safe and effective medical practice; it can and must be taught. Communication skill influences patient disclosure, treatment adherence and outcome, adaptation to illness, and bereavement. This article provides a review of the evidence regarding clinical communication in the pediatric setting, covering the spectrum from outpatient primary care consultation to death notification, and provides practical suggestions to improve communication with patients and families, enabling more effective, efficient, and empathic pediatric health care. COMMUNITY PEDIATRICS: NAVIGATING THE INTERSECTION OF MEDICINE, PUBLIC HEALTH, AND SOCIAL DETERMINANTS OF CHILDREN'S HEALTH

Council on Community Pediatrics

ABSTRACT. This policy statement provides a framework for the pediatrician's role in promoting the health and well-being of all children in the context of their families and communities. It offers pediatricians a definition of community pediatrics, emphasizes the importance of recognizing social determinants of health, and delineates the need to partner with public health to address population-based child health issues. It also recognizes the importance of pediatric involvement in child advocacy at local, state, and federal levels to ensure all children have access to a high-quality medical home and to eliminate child health disparities. This statement provides a set of specific recommendations that underscore the critical nature of this dimension of pediatric practice, teaching, and research. (2/13, reaffirmed 10/16)

COMPREHENSIVE EVALUATION OF THE CHILD WITH INTELLECTUAL DISABILITY OR GLOBAL DEVELOPMENTAL DELAYS (CLINICAL REPORT)

John B. Moeschler, MD, MS, FAAP, FACMG; Michael Shevell, MDCM, FRCP; and Committee on Genetics

ABSTRACT. Global developmental delay and intellectual disability are relatively common pediatric conditions. This report describes the recommended clinical genetics diagnostic approach. The report is based on a review of published reports, most consisting of medium to large case series of diagnostic tests used, and the proportion of those that led to a diagnosis in such patients. Chromosome microarray is designated as a first-line test and replaces the standard karyotype and fluorescent in situ hybridization subtelomere tests for the child with intellectual disability of unknown etiology. Fragile X testing remains an important first-line test. The importance of considering testing for inborn errors of metabolism in this population is supported by a recent systematic review of the literature and several case series recently published. The role of brain MRI remains important in certain patients. There is also a discussion of the emerging literature on the use of whole-exome sequencing as a diagnostic test in this population. Finally, the importance of intentional comanagement among families, the medical home, and the clinical genetics specialty clinic is discussed. (8/14, reaffirmed 10/19)

COMPREHENSIVE HEALTH EVALUATION OF THE NEWLY ADOPTED CHILD (CLINICAL REPORT)

Veronnie Faye Jones, MD, PhD, MSPH, FAAP; Elaine E. Schulte, MD, MPH, FAAP; and Council on Foster Care, Adoption, and Kinship Care

ABSTRACT. Children who join families through the process of adoption, whether through a domestic or international route, often have multiple health care needs. Pediatricians and other health care personnel are in a unique position to guide families in achieving optimal health for the adopted children as families establish a medical home. Shortly after placement in an adoptive home, it is recommended that children have a timely comprehensive health evaluation to provide care for known medical needs and identify health issues that are unknown. It is important to begin this evaluation with a review of all available medical records and pertinent verbal history. A complete physical examination then follows. The evaluation should also include diagnostic testing based on findings from the history and physical examination as well as the risks presented by the child's previous living conditions. Age-appropriate screenings may include, but are not limited to, newborn screening panels and hearing, vision, dental, and formal behavioral and/or developmental screenings. The comprehensive assessment may occur at the time of the initial visit to the physician after adoptive placement or can take place over several visits. Adopted children can be referred to other medical specialists as deemed appropriate. The Council on Adoption, Foster Care, and Kinship Care is a resource within the American Academy of Pediatrics for physicians providing care for children who are being adopted. (4/19)

CONFLICTS BETWEEN RELIGIOUS OR SPIRITUAL BELIEFS AND PEDIATRIC CARE: INFORMED REFUSAL, EXEMPTIONS, AND PUBLIC FUNDING

Committee on Bioethics

ABSTRACT. Although respect for parents' decision-making authority is an important principle, pediatricians should report suspected cases of medical neglect, and the state should, at times, intervene to require medical treatment of children. Some parents' reasons for refusing medical treatment are based on their religious or spiritual beliefs. In cases in which treatment is likely to prevent death or serious disability or relieve severe pain, children's health and future autonomy should be protected. Because religious exemptions to child abuse and neglect laws do not equally protect all children and may harm some children by causing confusion about the duty to provide medical treatment, these exemptions should be repealed. Furthermore, public health care funds should not cover alternative unproven religious or spiritual healing practices. Such payments may inappropriately legitimize these practices as appropriate medical treatment. (10/13, reaffirmed 12/16, 11/17)

CONGENITAL BRAIN AND SPINAL CORD MALFORMATIONS AND THEIR ASSOCIATED CUTANEOUS MARKERS (CLINICAL REPORT)

Mark Dias, MD, FAANS, FAAP; Michael Partington, MD, FAANS, FAAP; and Section on Neurologic Surgery

ABSTRACT. The brain, spinal cord, and skin are all derived from the embryonic ectoderm; this common derivation leads to a high association between central nervous system dysraphic malformations and abnormalities of the overlying skin. A myelomeningocele is an obvious open malformation, the identification of which is not usually difficult. However, the relationship between congenital spinal cord malformations and other cutaneous malformations, such as dimples, vascular anomalies (including infantile hemangiomata and other vascular malformations), congenital pigmented nevi or other hamartomata, or midline hairy patches may be less obvious but no less important. Pediatricians should be aware of these associations, recognize the cutaneous markers associated with congenital central nervous system malformations, and refer children with such markers to the appropriate specialist in a timely fashion for further evaluation and treatment. (9/15)

http://pediatrics.aappublications.org/content/136/4/e1105

CONSENT BY PROXY FOR NONURGENT PEDIATRIC CARE (CLINICAL REPORT)

Jonathan M. Fanaroff, MD, JD, FAAP, FCLM, and Committee on Medical Liability and Risk Management

ABSTRACT. Minor-aged patients are often brought to the pediatrician for nonurgent acute medical care, physical examinations, or health supervision visits by someone other than their legally authorized representative, which, in most situations, is a parent. These surrogates or proxies can be members of the child's extended family, such as a grandparent, adult sibling, or aunt/uncle; a noncustodial parent or stepparent in cases of divorce and remarriage; an adult who lives in the home but is not biologically or legally related to the child; or even a child care provider (eg, au pair, nanny, private-duty nurse/nurse's aide, group home supervisor). This report identifies common situations in which pediatricians may encounter "consent by proxy" for nonurgent medical care for minors, including physical examinations, and explains the potential for liability exposure associated with these circumstances. The report suggests practical steps that balance the need to minimize the physician's liability exposure with the patient's access to health care. Key issues to be considered when creating or updating office policies for obtaining and documenting consent by proxy are offered. (1/17)

http://pediatrics.aappublications.org/content/139/2/e20163911

CONSENT FOR EMERGENCY MEDICAL SERVICES FOR CHILDREN AND ADOLESCENTS

Committee on Pediatric Emergency Medicine and Committee on Bioethics

ABSTRACT. Parental consent generally is required for the medical evaluation and treatment of minor children. However, children and adolescents might require evaluation of and treatment for emergency medical conditions in situations in which a parent or legal guardian is not available to provide consent or

conditions under which an adolescent patient might possess the legal authority to provide consent. In general, a medical screening examination and any medical care necessary and likely to prevent imminent and significant harm to the pediatric patient with an emergency medical condition should not be withheld or delayed because of problems obtaining consent. The purpose of this policy statement is to provide guidance in those situations in which parental consent is not readily available, in which parental consent is not necessary, or in which parental refusal of consent places a child at risk of significant harm. (7/11, reaffirmed 9/15)

CONSUMPTION OF RAW OR UNPASTEURIZED MILK AND MILK PRODUCTS BY PREGNANT WOMEN AND CHILDREN

Committee on Infectious Diseases and Committee on Nutrition

ABSTRACT. Sales of raw or unpasteurized milk and milk products are still legal in at least 30 states in the United States. Raw milk and milk products from cows, goats, and sheep continue to be a source of bacterial infections attributable to a number of virulent pathogens, including *Listeria monocytogenes, Campylobacter jejuni, Salmonella* species, *Brucella* species, and *Escherichia coli* O157. These infections can occur in both healthy and immunocompromised individuals, including older adults, infants, young children, and pregnant women and their unborn fetuses, in whom life-threatening infections and fetal miscarriage can occur. Efforts to limit the sale of raw milk products have met with opposition from those who are proponents of the purported health benefits of consuming raw milk products, which contain natural or unprocessed factors not inactivated by pasteurization. However, the benefits of these natural factors have not been clearly demonstrated in evidence-based studies and, therefore, do not outweigh the risks of raw milk consumption. Substantial data suggest that pasteurized milk confers equivalent health benefits compared with raw milk, without the additional risk of bacterial infections. The purpose of this policy statement was to review the risks of raw milk consumption in the United States and to provide evidence of the risks of infectious complications associated with consumption of unpasteurized milk and milk products, especially among pregnant women, infants, and children. (12/13, reaffirmed 11/19)

CONTRACEPTION FOR ADOLESCENTS

Committee on Adolescence

ABSTRACT. Contraception is a pillar in reducing adolescent pregnancy rates. The American Academy of Pediatrics recommends that pediatricians develop a working knowledge of contraception to help adolescents reduce risks of and negative health consequences related to unintended pregnancy. Over the past 10 years, a number of new contraceptive methods have become available to adolescents, newer guidance has been issued on existing contraceptive methods, and the evidence base for contraception for special populations (adolescents who have disabilities, are obese, are recipients of solid organ transplants, or are HIV infected) has expanded. The Academy has addressed contraception since 1980, and this policy statement updates the 2007 statement on contraception and adolescents. It provides the pediatrician with a description and rationale for best practices in counseling and prescribing contraception for adolescents. It is supported by an accompanying technical report. (9/14)
http://pediatrics.aappublications.org/content/134/4/e1244

CONTRACEPTION FOR ADOLESCENTS (TECHNICAL REPORT)

Mary A. Ott, MD, MA, FAAP; Gina S. Sucato, MD, MPH, FAAP; and Committee on Adolescence

ABSTRACT. A working knowledge of contraception will assist the pediatrician in both sexual health promotion as well as treatment of common adolescent gynecologic problems. Best practices in adolescent anticipatory guidance and screening include a sexual health history, screening for pregnancy and sexually transmitted infections, counseling, and if indicated, providing access to contraceptives. Pediatricians' long-term relationships with adolescents and families allow them to help promote healthy sexual decision-making, including abstinence and contraceptive use. Additionally, medical indications for contraception, such as acne, dysmenorrhea, and heavy menstrual bleeding, are frequently uncovered during adolescent visits. This technical report provides an evidence base for the accompanying policy statement and addresses key aspects of adolescent contraceptive use, including the following: (1) sexual history taking, confidentiality, and counseling; (2) adolescent data on the use and side effects of newer contraceptive methods; (3) new data on older contraceptive methods; and (4) evidence supporting the use of contraceptives in adolescent patients with complex medical conditions. (9/14)
http://pediatrics.aappublications.org/content/134/4/e1257

CONTRACEPTION FOR HIV-INFECTED ADOLESCENTS (CLINICAL REPORT)

Athena P. Kourtis, MD, PhD, MPH, FAAP; Ayesha Mirza, MD, FAAP; and Committee on Pediatric AIDS

ABSTRACT. Access to high-quality reproductive health care is important for adolescents and young adults with HIV infection to prevent unintended pregnancies, sexually transmitted infections, and secondary transmission of HIV to partners and children. As perinatally HIV-infected children mature into adolescence and adulthood and new HIV infections among adolescents and young adults continue to occur in the United States, medical providers taking care of such individuals often face issues related to sexual and reproductive health. Challenges including drug interactions between several hormonal methods and antiretroviral agents make decisions regarding contraceptive options more complex for these adolescents. Dual protection, defined as the use of an effective contraceptive along with condoms, should be central to ongoing discussions with HIV-infected young women and couples wishing to avoid pregnancy. Last, reproductive health discussions need to be integrated with discussions on HIV care, because a reduction in plasma HIV viral load below the level of detection (an "undetectable viral load") is essential for the individual's health as well as for a reduction in HIV transmission to partners and children. (8/16)
http://pediatrics.aappublications.org/content/138/3/e20161892

CONTROVERSIES CONCERNING VITAMIN K AND THE NEWBORN

Committee on Fetus and Newborn

ABSTRACT. Prevention of early vitamin K deficiency bleeding (VKDB) of the newborn, with onset at birth to 2 weeks of age (formerly known as classic hemorrhagic disease of the newborn), by oral or parenteral administration of vitamin K is accepted practice. In contrast, late VKDB, with onset from 2 to 12 weeks of age, is most effectively prevented by parenteral administration of vitamin K. Earlier concern regarding a possible causal association between parenteral vitamin K and childhood cancer has not been substantiated. This revised statement presents updated recommendations for the use of vitamin K in the prevention of early and late VKDB. (7/03, reaffirmed 5/06, 5/09, 9/14, 2/20)

CORD BLOOD BANKING FOR POTENTIAL FUTURE TRANSPLANTATION

William T. Shearer, MD, PhD, FAAP; Bertram H. Lubin, MD, FAAP; Mitchell S. Cairo, MD, FAAP; Luigi D. Notarangelo, MD; Section on Hematology/Oncology; and Section on Allergy and Immunology

ABSTRACT. This policy statement is intended to provide information to guide pediatricians, obstetricians, and other medical specialists and health care providers in responding to parents' questions about cord blood donation and banking as well as the types (public versus private) and quality of cord blood banks. Cord blood is an excellent source of stem cells for hematopoietic stem cell transplantation in children with some fatal diseases. Cord blood transplantation offers another method of definitive therapy for infants, children, and adults with certain hematologic malignancies, hemoglobinopathies, severe forms of T-lymphocyte and other immunodeficiencies, and metabolic diseases. The development of universal screening for severe immunodeficiency assay in a growing number of states is likely to increase the number of cord blood transplants. Both public and private cord blood banks worldwide hold hundreds of thousands of cord blood units designated for the treatment of fatal or debilitating illnesses. The procurement, characterization, and cryopreservation of cord blood is free for families who choose public banking. However, the family cost for private banking is significant and not covered by insurance, and the unit may never be used. Quality-assessment reviews by several national and international accrediting bodies show private cord blood banks to be underused for treatment, less regulated for quality control, and more expensive for the family than public cord blood banks. There is an unquestionable need to study the use of cord blood banking to make new and important alternative means of reconstituting the hematopoietic blood system in patients with malignancies and blood disorders and possibly regenerating tissue systems in the future. Recommendations regarding appropriate ethical and operational standards (including informed consent policies, financial disclosures, and conflict-of-interest policies) are provided for physicians, institutions, and organizations that operate or have a relationship with cord blood banking programs. The information on all aspects of cord blood banking gathered in this policy statement will facilitate parental choice for public or private cord blood banking. (10/17)

CORPORAL PUNISHMENT IN SCHOOLS

Committee on School Health

ABSTRACT. The American Academy of Pediatrics recommends that corporal punishment in schools be abolished in all states by law and that alternative forms of student behavior management be used. (8/00, reaffirmed 6/03, 5/06, 2/12, 12/18)
http://pediatrics.aappublications.org/content/106/2/343

COUNSELING IN PEDIATRIC POPULATIONS AT RISK FOR INFERTILITY AND/OR SEXUAL FUNCTION CONCERNS (CLINICAL REPORT)

Leena Nahata, MD, FAAP; Gwendolyn P. Quinn, PhD; Amy C. Tishelman, PhD; and Section on Endocrinology

ABSTRACT. Reproductive health is an important yet often overlooked topic in pediatric health care; when addressed, the focus is generally on prevention of sexually transmitted infections and unwanted pregnancy. Two aspects of reproductive health counseling that have received minimal attention in pediatrics are fertility and sexual function for at-risk pediatric populations, and youth across many disciplines are affected. Although professional organizations, such as the American Academy of Pediatrics and the American Society of Clinical Oncology, have published recommendations about fertility preservation discussions, none of these guidelines address how to have ongoing conversations with at-risk youth and their families about the potential for future infertility and sexual dysfunction in developmentally appropriate ways. Researchers suggest many pediatric patients at risk for reproductive problems remain uncertain and confused about their fertility or sexual function status well into young adulthood. Potential infertility may cause distress and anxiety, has been shown to affect formation of romantic relationships, and may lead to unplanned pregnancy in those who incorrectly assumed they were infertile. Sexual dysfunction is also common and may lead to problems with intimacy and self-esteem; survivors of pediatric conditions consistently report inadequate guidance from clinicians in this area. Health care providers and parents report challenges in knowing how and when to discuss these issues. In this context, the goal of this clinical report is to review evidence and considerations for providers related to information sharing about impaired fertility and sexual function in pediatric patients attributable to congenital and acquired conditions or treatments. (7/18)

COUNSELING PARENTS AND TEENS ABOUT MARIJUANA USE IN THE ERA OF LEGALIZATION OF MARIJUANA (CLINICAL REPORT)

Sheryl A. Ryan, MD, FAAP; Seth D. Ammerman, MD, FAAP; and Committee on Substance Use and Prevention

ABSTRACT. Many states have recently made significant changes to their legislation making recreational and/or medical marijuana use by adults legal. Although these laws, for the most part, have not targeted the adolescent population, they have created an environment in which marijuana increasingly is seen as acceptable, safe, and therapeutic. This clinical report offers guidance to the practicing pediatrician based on existing evidence and expert opinion/consensus of the American Academy of Pediatrics regarding anticipatory guidance and counseling to teenagers and their parents about marijuana and its use. The recently published technical report provides the detailed evidence and references regarding the research on which the information in this clinical report is based. (2/17)
http://pediatrics.aappublications.org/content/139/3/e20164069

COUNTERING VACCINE HESITANCY (CLINICAL REPORT)

Kathryn M. Edwards, MD, FAAP; Jesse M. Hackell, MD, FAAP; Committee on Infectious Diseases; and Committee on Practice and Ambulatory Medicine

ABSTRACT. Immunizations have led to a significant decrease in rates of vaccine-preventable diseases and have made a significant impact on the health of children. However, some parents express concerns about vaccine safety and the necessity of vaccines. The concerns of parents range from hesitancy about some immunizations to refusal of all vaccines. This clinical report provides information about addressing parental concerns about vaccination. (8/16)

THE CRUCIAL ROLE OF RECESS IN SCHOOL

Council on School Health

ABSTRACT. Recess is at the heart of a vigorous debate over the role of schools in promoting the optimal development of the whole child. A growing trend toward reallocating time in school to accentuate the more academic subjects has put this important facet of a child's school day at risk. Recess serves as a necessary break from the rigors of concentrated, academic challenges in the

classroom. But equally important is the fact that safe and well-supervised recess offers cognitive, social, emotional, and physical benefits that may not be fully appreciated when a decision is made to diminish it. Recess is unique from, and a complement to, physical education—not a substitute for it. The American Academy of Pediatrics believes that recess is a crucial and necessary component of a child's development and, as such, it should not be withheld for punitive or academic reasons. (12/12, reaffirmed 8/16)

DEALING WITH THE CARETAKER WHOSE JUDGMENT IS IMPAIRED BY ALCOHOL OR DRUGS: LEGAL AND ETHICAL CONSIDERATIONS (CLINICAL REPORT)

Steven A. Bondi, JD, MD, FAAP; James Scibilia, MD, FAAP; and Committee on Medical Liability and Risk Management

ABSTRACT. An estimated 8.7 million children live in a household with a substance-using parent or guardian. Substance-using caretakers may have impaired judgment that can negatively affect their child's well-being, including his or her ability to receive appropriate medical care. Although the physician-patient relationship exists between the pediatrician and the child, obligations related to safety and confidentiality should be considered as well. In managing encounters with impaired caretakers who may become disruptive or dangerous, pediatricians should be aware of their responsibilities before acting. In addition to fulfilling the duty involved with an established physician-patient relationship, the pediatrician should take reasonable care to safeguard patient confidentiality; protect the safety of their patient, other patients in the facility, visitors, and employees; and comply with reporting mandates. This clinical report identifies and discusses the legal and ethical concepts related to these circumstances. The report offers implementation suggestions when establishing anticipatory procedures and training programs for staff in such situations to maximize the patient's well-being and safety and minimize the liability of the pediatrician. DEATH OF A CHILD IN THE EMERGENCY DEPARTMENT

Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee and Emergency Nurses Association Pediatric Committee)

ABSTRACT. The American Academy of Pediatrics, American College of Emergency Physicians, and Emergency Nurses Association have collaborated to identify practices and principles to guide the care of children, families, and staff in the challenging and uncommon event of the death of a child in the emergency department in this policy statement and in an accompanying technical report. (6/14, reaffirmed 9/19)
http://pediatrics.aappublications.org/content/134/1/198

DEATH OF A CHILD IN THE EMERGENCY DEPARTMENT (TECHNICAL REPORT)

Patricia J. O'Malley, MD, FAAP; Isabel A. Barata, MD, FACEP, FAAP; Sally K. Snow, RN, BSN, CPEN, FAEN; and Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee and Emergency Nurses Association Pediatric Committee)

ABSTRACT. The death of a child in the emergency department (ED) is one of the most challenging problems facing ED clinicians. This revised technical report and accompanying policy statement reaffirm principles of patient- and family-centered care. Recent literature is examined regarding family presence, termination of resuscitation, bereavement responsibilities of ED clinicians, support of child fatality review efforts, and other issues inherent in caring for the patient, family, and staff when a child dies in the ED. Appendices are provided that offer an approach to bereavement activities in the ED, carrying out forensic responsibilities while providing compassionate care, communicating the news of the death of a child in the acute setting, providing a closing ritual at the time of terminating resuscitation efforts, and managing the child with a terminal condition who presents near death in the ED. (6/14, reaffirmed 9/19)
http://pediatrics.aappublications.org/content/134/1/e313

DEFINITION OF A PEDIATRICIAN

Committee on Pediatric Workforce

POLICY. The American Academy of Pediatrics (AAP) has developed the following definition of pediatrics and a pediatrician:

Pediatrics is the specialty of medical science concerned with the physical, mental, and social health of children from birth to young adulthood. Pediatric care encompasses a broad spectrum of health services ranging from preventive health care to the diagnosis and treatment of acute and chronic diseases.

Pediatrics is a discipline that deals with biological, social, and environmental influences on the developing child and with the impact of disease and dysfunction on development. Children differ from adults anatomically, physiologically, immunologically, psychologically, developmentally, and metabolically.

The pediatrician, a term that includes primary care pediatricians, pediatric medical subspecialists, and pediatric surgical specialists, understands this constantly changing functional status of his or her patients' incident to growth and development and the consequent changing standards of "normal" for age. A pediatrician is a physician who is concerned primarily with the health, welfare, and development of children and is uniquely qualified for these endeavors by virtue of interest and initial training. This training includes 4 years of medical school education, plus an additional year or years (usually at least 3) of intensive training devoted solely to all aspects of medical care for children, adolescents, and young adults. Maintenance of these competencies is achieved by experience, training, continuous education, self-assessment, and practice improvement.

A pediatrician is able to define accurately the child's health status and to serve as a consultant and make use of other specialists as consultants as needed, ideally in the context of, or in conjunction with, the physician-led medical home. Because the child's welfare is heavily dependent on the home and family, the pediatrician supports efforts to create a nurturing environment. Such support includes education about healthful living and anticipatory guidance for both patients and parents.

A pediatrician participates at the community level in preventing or solving problems in child health care and publicly advocates the causes of children. (3/15, reaffirmed 12/19)

DETENTION OF IMMIGRANT CHILDREN

Julie M. Linton, MD, FAAP; Marsha Griffin, MD, FAAP; Alan J. Shapiro, MD, FAAP; and Council on Community Pediatrics

ABSTRACT. Immigrant children seeking safe haven in the United States, whether arriving unaccompanied or in family units, face a complicated evaluation and legal process from the point of arrival through permanent resettlement in communities. The conditions in which children are detained and the support services that are available to them are of great concern to pediatricians and other advocates for children. In accordance with internationally accepted rights of the child, immigrant and refugee children should be treated with dignity and respect and should not be exposed to conditions that may harm or traumatize them. The Department of Homeland Security facilities do not meet the basic standards for the care of children in residential settings. The recommendations in this statement call for limited exposure of any child to current Department of Homeland Security facilities (ie, Customs and Border Protection and Immigration and Customs Enforcement facilities) and for

longitudinal evaluation of the health consequences of detention of immigrant children in the United States. From the moment children are in the custody of the United States, they deserve health care that meets guideline-based standards, treatment that mitigates harm or traumatization, and services that support their health and well-being. This policy statement also provides specific recommendations regarding postrelease services once a child is released into communities across the country, including a coordinated system that facilitates access to a medical home and consistent access to education, child care, interpretation services, and legal services. DEVELOPMENTAL DYSPLASIA OF THE HIP PRACTICE GUIDELINE (TECHNICAL REPORT)

Harold P. Lehmann, MD, PhD; Richard Hinton, MD, MPH; Paola Morello, MD; Jeanne Santoli, MD; in conjunction with Steering Committee on Quality Improvement and Subcommittee on Developmental Dysplasia of the Hip

ABSTRACT. *Objective.* To create a recommendation for pediatricians and other primary care providers about their role as screeners for detecting developmental dysplasia of the hip (DDH) in children.

Patients. Theoretical cohorts of newborns.

Method. Model-based approach using decision analysis as the foundation. Components of the approach include the following:

Perspective: Primary care provider.

Outcomes: DDH, avascular necrosis of the hip (AVN).

Options: Newborn screening by pediatric examination; orthopaedic examination; ultrasonographic examination; orthopaedic or ultrasonographic examination by risk factors. Intercurrent health supervision-based screening.

Preferences: 0 for bad outcomes, 1 for best outcomes.

Model: Influence diagram assessed by the Subcommittee and by the methodology team, with critical feedback from the Subcommittee.

Evidence Sources: Medline and EMBASE search of the research literature through June 1996. Hand search of sentinel journals from June 1996 through March 1997. Ancestor search of accepted articles.

Evidence Quality: Assessed on a custom subjective scale, based primarily on the fit of the evidence to the decision model.

Results. After discussion, explicit modeling, and critique, an influence diagram of 31 nodes was created. The computer-based and the hand literature searches found 534 articles, 101 of which were reviewed by 2 or more readers. Ancestor searches of these yielded a further 17 articles for evidence abstraction. Articles came from around the globe, although primarily Europe, British Isles, Scandinavia, and their descendants. There were 5 controlled trials, each with a sample size less than 40. The remainder were case series. Evidence was available for 17 of the desired 30 probabilities. Evidence quality ranged primarily between one third and two thirds of the maximum attainable score (median: 10–21; interquartile range: 8–14).

Based on the raw evidence and Bayesian hierarchical meta-analyses, our estimate for the incidence of DDH revealed by physical examination performed by pediatricians is 8.6 per 1000; for orthopaedic screening, 11.5; for ultrasonography, 25. The odds ratio for DDH, given breech delivery, is 5.5; for female sex, 4.1; for positive family history, 1.7, although this last factor is not statistically significant. Postneonatal cases of DDH were divided into mid-term (younger than 6 months of age) and late-term (older than 6 months of age). Our estimates for the mid-term rate for screening by pediatricians is 0.34/1000 children screened; for orthopaedists, 0.1; and for ultrasonography, 0.28. Our estimates for late-term DDH rates are 0.21/1000 newborns screened by pediatricians; 0.08, by orthopaedists; and 0.2 for ultrasonography. The rates of AVN for children referred before 6 months of age is estimated at 2.5/1000 infants referred. For those referred after 6 months of age, our estimate is 109/1000 referred infants.

The decision model (reduced, based on available evidence) suggests that orthopaedic screening is optimal, but because orthopaedists in the published studies and in practice would differ, the supply of orthopaedists is relatively limited, and the difference between orthopaedists and pediatricians is statistically insignificant, we conclude that pediatric screening is to be recommended. The place of ultrasonography in the screening process remains to be defined because there are too few data about postneonatal diagnosis by ultrasonographic screening to permit definitive recommendations. These data could be used by others to refine the conclusions based on costs, parental preferences, or physician style. Areas for research are well defined by our model-based approach. (4/00)

DIAGNOSIS, EVALUATION, AND MANAGEMENT OF HIGH BLOOD PRESSURE IN CHILDREN AND ADOLESCENTS (TECHNICAL REPORT)

Carissa M. Baker-Smith, MD, MS, MPH, FAAP, FAHA; Susan K. Flinn, MA; Joseph T. Flynn, MD, MS, FAAP; David C. Kaelber, MD, PhD, MPH, FAAP, FACP, FACMI; Douglas Blowey, MD; Aaron E. Carroll, MD, MS, FAAP; Stephen R. Daniels, MD, PhD, FAAP; Sarah D. de Ferranti, MD, MPH, FAAP; Janis M. Dionne, MD, FRCPC; Bonita Falkner, MD; Samuel S. Gidding, MD; Celeste Goodwin; Michael G. Leu, MD, MS, MHS, FAAP; Makia E. Powers, MD, MPH, FAAP; Corinna Rea, MD, MPH, FAAP; Joshua Samuels, MD, MPH, FAAP; Madeline Simasek, MD, MSCP, FAAP; Vidhu V. Thaker, MD, FAAP; Elaine M. Urbina, MD, MS, FAAP; and Subcommittee on Screening and Management of High Blood Pressure in Children

ABSTRACT. Systemic hypertension is a major cause of morbidity and mortality in adulthood. High blood pressure (HBP) and repeated measures of HBP, hypertension (HTN), begin in youth. Knowledge of how best to diagnose, manage, and treat systemic HTN in children and adolescents is important for primary and subspecialty care providers.

Objectives: To provide a technical summary of the methodology used to generate the 2017 "Clinical Practice Guideline for Screening and Management of High Blood Pressure in Children and Adolescents," an update to the 2004 "Fourth Report on the Diagnosis, Evaluation, and Treatment of High Blood Pressure in Children and Adolescents."

Data Sources: Medline, Cochrane Central Register of Controlled Trials, and Excerpta Medica Database references published between January 2003 and July 2015 followed by an additional search between August 2015 and July 2016.

Study Selection: English-language observational studies and randomized trials.

Methods: Key action statements (KASs) and additional recommendations regarding the diagnosis, management, and treatment of HBP in youth were the product of a detailed systematic review of the literature. A content outline establishing the breadth and depth was followed by the generation of 4 patient, intervention, comparison, outcome, time questions. Key questions addressed: (1) diagnosis of systemic HTN, (2) recommended work-up of systemic HTN, (3) optimal blood pressure (BP) goals, and (4) impact of high BP on indirect markers of cardiovascular disease in youth. Once selected, references were subjected to a 2-person review of the abstract and title followed by a separate 2-person full-text review. Full citation information, population data, findings, benefits and harms of the findings, as well as other key reference information were archived. Selected primary references were then used for KAS generation. Level of

evidence (LOE) scoring was assigned for each reference and then in aggregate. Appropriate language was used to generate each KAS based on the LOE and the balance of benefit versus harm of the findings. Topics that could not be researched via the stated approach were (1) definition of HTN in youth, and (2) definition of left ventricular hypertrophy. KASs related to these stated topics were generated via expert opinion.

Results: Nearly 15 000 references were identified during an initial literature search. After a deduplication process, 14 382 references were available for title and abstract review, and 1379 underwent full text review. One hundred twenty-four experimental and observational studies published between 2003 and 2016 were selected as primary references for KAS generation, followed by an additional 269 primary references selected between August 2015 and July 2016. The LOE for the majority of references was C. In total, 30 KASs and 27 additional recommendations were generated; 12 were related to the diagnosis of HTN, 13 were related to management and additional diagnostic testing, 3 to treatment goals, and 2 to treatment options. Finally, special additions to the clinical practice guideline included creation of new BP tables based on BP values obtained solely from children with normal weight, creation of a simplified table to enhance screening and recognition of abnormal BP, and a revision of the criteria for diagnosing left ventricular hypertrophy.

Conclusions: An extensive and detailed systematic approach was used to generate evidence-based guidelines for the diagnosis, management, and treatment of youth with systemic HTN. (8/18)

DIAGNOSIS, MANAGEMENT, AND TREATMENT OF FEMALE GENITAL MUTILATION OR CUTTING IN GIRLS (CLINICAL REPORT)

Janine Young, MD, FAAP; Nawal M. Nour, MD, MPH, FACOG; Robert C. Macauley, MD, FAAP; Sandeep K. Narang, MD, JD, FAAP; Crista Johnson-Agbakwu, MD, MSc, FACOG; Section on Global Health; Committee on Medical Liability and Risk Management; and Committee on Bioethics

ABSTRACT. Female genital mutilation or cutting (FGM/C) involves medically unnecessary cutting of parts or all of the external female genitalia. It is outlawed in the United States and much of the world but is still known to occur in more than 30 countries. FGM/C most often is performed on children, from infancy to adolescence, and has significant morbidity and mortality. In 2018, an estimated 200 million girls and women alive at that time had undergone FGM/C worldwide. Some estimate that more than 500 000 girls and women in the United States have had or are at risk for having FGM/C. However, pediatric prevalence of FGM/C is only estimated given that most pediatric cases remain undiagnosed both in countries of origin and in the Western world, including in the United States. It is a cultural practice not directly tied to any specific religion, ethnicity, or race and has occurred in the United States. Although it is mostly a pediatric practice, currently there is no standard FGM/C teaching required for health care providers who care for children, including pediatricians, family physicians, child abuse pediatricians, pediatric urologists, and pediatric urogynecologists. This clinical report is the first comprehensive summary of FGM/C in children and includes education regarding a standard-of-care approach for examination of external female genitalia at all health supervision examinations, diagnosis, complications, management, treatment, culturally sensitive discussion and counseling approaches, and legal and ethical considerations. (7/20)

DIAGNOSIS, TREATMENT, AND PREVENTION OF CONGENITAL TOXOPLASMOSIS IN THE UNITED STATES (TECHNICAL REPORT)

Yvonne A. Maldonado, MD, FAAP; Jennifer S. Read, MD, MS, MPH, DTM&H, FAAP; and Committee on Infectious Diseases

ABSTRACT. Congenital toxoplasmosis (CT) is a parasitic disease that can cause significant fetal and neonatal harm. Coordinated efforts by pregnant women, researchers, physicians, and health policy makers regarding potential primary and secondary preventive measures for CT and their implementation may lead to a lower incidence of CT as well as lower morbidity and mortality rates associated with CT. The purpose of this technical report is to summarize available information regarding the diagnosis, treatment, and prevention of CT. (1/17)

DIAGNOSIS AND MANAGEMENT OF AN INITIAL UTI IN FEBRILE INFANTS AND YOUNG CHILDREN (TECHNICAL REPORT)

S. Maria E. Finnell, MD, MS; Aaron E. Carroll, MD, MS; Stephen M. Downs, MD, MS; Steering Committee on Quality Improvement and Management; and Subcommittee on Urinary Tract Infection

ABSTRACT. *Objectives.* The diagnosis and management of urinary tract infections (UTIs) in young children are clinically challenging. This report was developed to inform the revised, evidence-based, clinical guideline regarding the diagnosis and management of initial UTIs in febrile infants and young children, 2 to 24 months of age, from the American Academy of Pediatrics Subcommittee on Urinary Tract Infection.

Methods. The conceptual model presented in the 1999 technical report was updated after a comprehensive review of published literature. Studies with potentially new information or with evidence that reinforced the 1999 technical report were retained. Meta-analyses on the effectiveness of antimicrobial prophylaxis to prevent recurrent UTI were performed.

Results. Review of recent literature revealed new evidence in the following areas. Certain clinical findings and new urinalysis methods can help clinicians identify febrile children at very low risk of UTI. Oral antimicrobial therapy is as effective as parenteral therapy in treating UTI. Data from published, randomized controlled trials do not support antimicrobial prophylaxis to prevent febrile UTI when vesicoureteral reflux is found through voiding cystourethrography. Ultrasonography of the urinary tract after the first UTI has poor sensitivity. Early antimicrobial treatment may decrease the risk of renal damage from UTI.

Conclusions. Recent literature agrees with most of the evidence presented in the 1999 technical report, but meta-analyses of data from recent, randomized controlled trials do not support antimicrobial prophylaxis to prevent febrile UTI. This finding argues against voiding cystourethrography after the first UTI. (8/11)

DIAGNOSIS AND MANAGEMENT OF CHILDHOOD OBSTRUCTIVE SLEEP APNEA SYNDROME (TECHNICAL REPORT)

Carole L. Marcus, MBBCh; Lee J. Brooks, MD; Sally Davidson Ward, MD; Kari A. Draper, MD; David Gozal, MD; Ann C. Halbower, MD; Jacqueline Jones, MD; Christopher Lehmann, MD; Michael S. Schechter, MD, MPH; Stephen Sheldon, MD; Richard N. Shiffman, MD, MCIS; Karen Spruyt, PhD; Steering Committee on Quality Improvement and Management; and Subcommittee on Obstructive Sleep Apnea Syndrome

ABSTRACT. *Objective.* This technical report describes the procedures involved in developing recommendations on the management of childhood obstructive sleep apnea syndrome (OSAS).

Methods. The literature from 1999 through 2011 was evaluated.

Results and Conclusions. A total of 3166 titles were reviewed, of which 350 provided relevant data. Most articles were level II through IV. The prevalence of OSAS ranged from 0% to 5.7%, with obesity being an independent risk factor. OSAS was associated with cardiovascular, growth, and neurobehavioral abnormalities and possibly inflammation. Most diagnostic screening tests had low sensitivity and specificity. Treatment of OSAS resulted in improvements in behavior and attention and likely improvement in cognitive abilities. Primary treatment is adenotonsillectomy (AT). Data were insufficient to recommend specific surgical techniques; however, children undergoing partial tonsillectomy should be monitored for possible recurrence of OSAS. Although OSAS improved postoperatively, the proportion of patients who had residual OSAS ranged from 13% to 29% in low-risk populations to 73% when obese children were included and stricter polysomnographic criteria were used. Nevertheless, OSAS may improve after AT even in obese children, thus supporting surgery as a reasonable initial treatment. A significant number of obese patients required intubation or continuous positive airway pressure (CPAP) postoperatively, which reinforces the need for inpatient observation. CPAP was effective in the treatment of OSAS, but adherence is a major barrier. For this reason, CPAP is not recommended as first-line therapy for OSAS when AT is an option. Intranasal steroids may ameliorate mild OSAS, but follow-up is needed. Data were insufficient to recommend rapid maxillary expansion. (8/12)

DIAGNOSIS AND MANAGEMENT OF GASTROESOPHAGEAL REFLUX IN PRETERM INFANTS (CLINICAL REPORT)

Eric C. Eichenwald, MD, FAAP, and Committee on Fetus and Newborn

ABSTRACT. Gastroesophageal reflux (GER), generally defined as the passage of gastric contents into the esophagus, is an almost universal phenomenon in preterm infants. It is a common diagnosis in the NICU; however, there is large variation in its treatment across NICU sites. In this clinical report, the physiology, diagnosis, and symptomatology in preterm infants as well as currently used treatment strategies in the NICU are examined. Conservative measures to control reflux, such as left lateral body position, head elevation, and feeding regimen manipulation, have not been shown to reduce clinically assessed signs of GER in the preterm infant. In addition, preterm infants with clinically diagnosed GER are often treated with pharmacologic agents; however, a lack of evidence of efficacy together with emerging evidence of significant harm (particularly with gastric acid blockade) strongly suggest that these agents should be used sparingly, if at all, in preterm infants. (6/18)

DIAGNOSIS AND MANAGEMENT OF INFANTILE HEMANGIOMA (CLINICAL REPORT)

David H. Darrow, MD, DDS; Arin K. Greene, MD; Anthony J. Mancini, MD; Amy J. Nopper, MD; Section on Dermatology; Section on Otolaryngology—Head & Neck Surgery; and Section on Plastic Surgery

ABSTRACT. Infantile hemangiomas (IHs) are the most common tumors of childhood. Unlike other tumors, they have the unique ability to involute after proliferation, often leading primary care providers to assume they will resolve without intervention or consequence. Unfortunately, a subset of IHs rapidly develop complications, resulting in pain, functional impairment, or permanent disfigurement. As a result, the primary clinician has the task of determining which lesions require early consultation with a specialist. Although several recent reviews have been published, this clinical report is the first based on input from individuals representing the many specialties involved in the treatment of IH. Its purpose is to update the pediatric community regarding recent discoveries in IH pathogenesis, treatment, and clinical associations and to provide a basis for clinical decision-making in the management of IH. (9/15)
http://pediatrics.aappublications.org/content/136/4/e1060

DIAGNOSIS AND MANAGEMENT OF INFANTILE HEMANGIOMA: EXECUTIVE SUMMARY

David H. Darrow, MD, DDS, FAAP; Arin K. Greene, MD, FAAP; Anthony J. Mancini, MD, FAAP; Amy J. Nopper, MD, FAAP; Section on Dermatology; Section on Otolaryngology—Head & Neck Surgery; and Section on Plastic Surgery

ABSTRACT. Infantile hemangiomas (IHs) are the most common tumors of childhood. Unlike other tumors, they have the capacity to involute after proliferation, often leading primary care providers to assume they will resolve without intervention or consequence. However, a subset of IHs may be associated with complications, resulting in pain, functional impairment, or permanent disfigurement. As a result, the primary care provider is often called on to decide which lesions should be referred for early consultation with a specialist.

This document provides a summary of the guidance contained in the clinical report "Diagnosis and Management of Infantile Hemangioma," published concurrently in the online version of *Pediatrics* (*Pediatrics.* 2015;136[4]:e1060–e1104, available at: www.pediatrics.org/content/136/4/e1060). The report is uniquely based on input from the many specialties involved in the treatment of IH. Its purpose is to update the pediatric community about recent discoveries in IH pathogenesis, clinical associations, and treatment and to provide a knowledge base and framework for clinical decision-making in the management of IH. (9/15)

DIAGNOSIS AND PREVENTION OF IRON DEFICIENCY AND IRON-DEFICIENCY ANEMIA IN INFANTS AND YOUNG CHILDREN (0–3 YEARS OF AGE) (CLINICAL REPORT)

Robert D. Baker, MD, PhD; Frank R. Greer, MD; and Committee on Nutrition

ABSTRACT. This clinical report covers diagnosis and prevention of iron deficiency and iron-deficiency anemia in infants (both breastfed and formula fed) and toddlers from birth through 3 years of age. Results of recent basic research support the concerns that iron-deficiency anemia and iron deficiency without anemia during infancy and childhood can have long-lasting detrimental effects on neurodevelopment. Therefore, pediatricians and other health care providers should strive to eliminate iron deficiency and iron-deficiency anemia. Appropriate iron intakes for infants and toddlers as well as methods for screening for iron deficiency and iron-deficiency anemia are presented. (10/10)
http://pediatrics.aappublications.org/content/126/5/1040

DIAGNOSIS OF HIV-1 INFECTION IN CHILDREN YOUNGER THAN 18 MONTHS IN THE UNITED STATES (TECHNICAL REPORT)

Jennifer S. Read, MD, MS, MPH, DTM&H, and Committee on Pediatric AIDS

ABSTRACT. The objectives of this technical report are to describe methods of diagnosis of HIV-1 infection in children younger than 18 months in the United States and to review important issues that must be considered by clinicians who care for infants and young children born to HIV-1–infected women. Appropriate HIV-1 diagnostic testing for infants and children younger than 18 months differs from that for older children, adolescents, and adults because of passively transferred maternal HIV-1 antibodies, which may be detectable in the child's bloodstream until 18 months of age. Therefore, routine serologic testing of these infants and young children is generally only informative before the age of 18 months if the test result is negative. Virologic assays, including HIV-1 DNA or RNA assays, represent the gold

standard for diagnostic testing of infants and children younger than 18 months. With such testing, the diagnosis of HIV-1 infection (as well as the presumptive exclusion of HIV-1 infection) can be established within the first several weeks of life among nonbreastfed infants. Important factors that must be considered when selecting HIV-1 diagnostic assays for pediatric patients and when choosing the timing of such assays include the age of the child, potential timing of infection of the child, whether the infection status of the child's mother is known or unknown, the antiretroviral exposure history of the mother and of the child, and characteristics of the virus. If the mother's HIV-1 serostatus is unknown, rapid HIV-1 antibody testing of the newborn infant to identify HIV-1 exposure is essential so that antiretroviral prophylaxis can be initiated within the first 12 hours of life if test results are positive. For HIV-1–exposed infants (identified by positive maternal test results or positive antibody results for the infant shortly after birth), it has been recommended that diagnostic testing with HIV-1 DNA or RNA assays be performed within the first 14 days of life, at 1 to 2 months of age, and at 3 to 6 months of age. If any of these test results are positive, repeat testing is recommended to confirm the diagnosis of HIV-1 infection. A diagnosis of HIV-1 infection can be made on the basis of 2 positive HIV-1 DNA or RNA assay results. In nonbreastfeeding children younger than 18 months with no positive HIV-1 virologic test results, presumptive exclusion of HIV-1 infection can be based on 2 negative virologic test results (1 obtained at ≥2 weeks and 1 obtained at ≥4 weeks of age); 1 negative virologic test result obtained at ≥8 weeks of age; or 1 negative HIV-1 antibody test result obtained at ≥6 months of age. Alternatively, presumptive exclusion of HIV-1 infection can be based on 1 positive HIV-1 virologic test with at least 2 subsequent negative virologic test results (at least 1 of which is performed at ≥8 weeks of age) or negative HIV-1 antibody test results (at least 1 of which is performed at ≥6 months of age). Definitive exclusion of HIV-1 infection is based on 2 negative virologic test results, 1 obtained at ≥1 month of age and 1 obtained at ≥4 months of age, or 2 negative HIV-1 antibody test results from separate specimens obtained at ≥6 months of age. For both presumptive and definitive exclusion of infection, the child should have no other laboratory (eg, no positive virologic test results) or clinical (eg, no AIDS-defining conditions) evidence of HIV-1 infection. Many clinicians confirm the absence of HIV-1 infection with a negative HIV-1 antibody assay result at 12 to 18 months of age. For breastfeeding infants, a similar testing algorithm can be followed, with timing of testing starting from the date of complete cessation of breastfeeding instead of the date of birth. (12/07, reaffirmed 4/10, 2/15)

DIAGNOSIS OF PREGNANCY AND PROVIDING OPTIONS COUNSELING FOR THE ADOLESCENT PATIENT (CLINICAL REPORT)

Laurie L. Hornberger, MD, MPH, FAAP, and Committee on Adolescence

ABSTRACT. The American Academy of Pediatrics policy statement "Options Counseling for the Pregnant Adolescent Patient" recommends the basic content of the pediatrician's counseling for an adolescent facing a new diagnosis of pregnancy. However, options counseling is just one aspect of what may be one of the more challenging scenarios in the pediatric office. Pediatricians must remain alert to the possibility of pregnancy among their adolescent female patients. When discovering symptoms suggestive of pregnancy, pediatricians must obtain a relevant history, perform diagnostic testing and properly interpret the results, and understand the significance of the results from the patient perspective and reveal them to the patient in a sensitive manner. If the patient is indeed pregnant, the pediatrician, in addition to providing comprehensive options counseling, may need to help recruit adult support for the patient and should offer continued assistance to the adolescent and her family after the office visit. All pediatricians should be aware of the legal aspects of adolescent reproductive care and the resources for pregnant adolescents in their communities. This clinical report presents a more comprehensive view of the evaluation and management of pregnancy in the adolescent patient and a context for options counseling. (8/17)

DIAGNOSTIC IMAGING OF CHILD ABUSE

Section on Radiology

ABSTRACT. The role of imaging in cases of child abuse is to identify the extent of physical injury when abuse is present and to elucidate all imaging findings that point to alternative diagnoses. Effective diagnostic imaging of child abuse rests on high-quality technology as well as a full appreciation of the clinical and pathologic alterations occurring in abused children. This statement is a revision of the previous policy published in 2000. (4/09)

http://pediatrics.aappublications.org/content/123/5/1430

DIGITAL ADVERTISING TO CHILDREN

Jenny Radesky, MD, FAAP; Yolanda (Linda) Reid Chassiakos, MD, FAAP, FACP; Nusheen Ameenuddin, MD, MPH, MPA, FAAP; Dipesh Navsaria, MPH, MSLIS, MD, FAAP; and Council on Communication and Media

ABSTRACT. Advertising to children and teenagers is a multibillion-dollar industry. This policy statement reviews the forms of advertising that children and teenagers encounter, including newer forms of digital marketing, such as sponsored content, influencers, data collection, persuasive design, and personalized behavioral marketing driven by machine learning. Parents and pediatric health care providers need to be aware of the ways different marketing messages reach children and teenagers, including Internet sites, social media, and mobile apps. Evidence suggests that exposure to advertising is associated with unhealthy behaviors, such as intake of high-calorie, low-nutrient food and beverages; use of tobacco products and electronic cigarettes; use of alcohol and marijuana; and indoor tanning. Children are uniquely vulnerable to the persuasive effects of advertising because of immature critical thinking skills and impulse inhibition. School-aged children and teenagers may be able to recognize advertising but often are not able to resist it when it is embedded within trusted social networks, encouraged by celebrity influencers, or delivered next to personalized content. This policy statement expresses concern about the practice of tracking and using children's digital behavior to inform targeted marketing campaigns, which may contribute to health disparities among vulnerable children or populations. Pediatricians should guide parents and children to develop digital literacy skills to prevent or mitigate negative outcomes, but it is equally important that policy makers and technology companies embrace digital design, data collection, and marketing practices within today's broad digital environment that support healthier decision-making and outcomes. (6/20)

DISASTER PREPAREDNESS IN NEONATAL INTENSIVE CARE UNITS (CLINICAL REPORT)

Wanda D. Barfield, MD, MPH, FAAP, RADM USPHS; Steven E. Krug, MD, FAAP; Committee on Fetus and Newborn; and Disaster Preparedness Council

ABSTRACT. Disasters disproportionally affect vulnerable, technology-dependent people, including preterm and critically ill newborn infants. It is important for health care providers to be aware of and prepared for the potential consequences of disasters for the NICU. Neonatal intensive care personnel can

provide specialized expertise for their hospital, community, and regional emergency preparedness plans and can help develop institutional surge capacity for mass critical care, including equipment, medications, personnel, and facility resources. (4/17)
http://pediatrics.aappublications.org/content/139/5/e20170507

DISCLOSURE OF ADVERSE EVENTS IN PEDIATRICS

Committee on Medical Liability and Risk Management and Council on Quality Improvement and Patient Safety

ABSTRACT. Despite increasing attention to issues of patient safety, preventable adverse events (AEs) continue to occur, causing direct and consequential injuries to patients, families, and health care providers. Pediatricians generally agree that there is an ethical obligation to inform patients and families about preventable AEs and medical errors. Nonetheless, barriers, such as fear of liability, interfere with disclosure regarding preventable AEs. Changes to the legal system, improved communications skills, and carefully developed disclosure policies and programs can improve the quality and frequency of appropriate AE disclosure communications. (11/16)

DISPENSING MEDICATIONS AT THE HOSPITAL UPON DISCHARGE FROM AN EMERGENCY DEPARTMENT (TECHNICAL REPORT)

Loren G. Yamamoto, MD, MPH, MBA; Shannon Manzi, PharmD; and Committee on Pediatric Emergency Medicine

ABSTRACT. Although most health care services can and should be provided by their medical home, children will be referred or require visits to the emergency department (ED) for emergent clinical conditions or injuries. Continuation of medical care after discharge from an ED is dependent on parents or caregivers' understanding of and compliance with follow-up instructions and on adherence to medication recommendations. ED visits often occur at times when the majority of pharmacies are not open and caregivers are concerned with getting their ill or injured child directly home. Approximately one-third of patients fail to obtain priority medications from a pharmacy after discharge from an ED. The option of judiciously dispensing ED discharge medications from the ED's outpatient pharmacy within the facility is a major convenience that overcomes this obstacle, improving the likelihood of medication adherence. Emergency care encounters should be routinely followed up with primary care provider medical homes to ensure complete and comprehensive care. (1/12, reaffirmed 9/15, 7/19)

DISTINGUISHING SUDDEN INFANT DEATH SYNDROME FROM CHILD ABUSE FATALITIES (CLINICAL REPORT)

Kent P. Hymel, MD, and Committee on Child Abuse and Neglect (joint with National Association of Medical Examiners)

ABSTRACT. Fatal child abuse has been mistaken for sudden infant death syndrome. When a healthy infant younger than 1 year dies suddenly and unexpectedly, the cause of death may be certified as sudden infant death syndrome. Sudden infant death syndrome is more common than infanticide. Parents of sudden infant death syndrome victims typically are anxious to provide unlimited information to professionals involved in death investigation or research. They also want and deserve to be approached in a nonaccusatory manner. This clinical report provides professionals with information and suggestions for procedures to help avoid stigmatizing families of sudden infant death syndrome victims while allowing accumulation of appropriate evidence in potential cases of infanticide. This clinical report addresses deficiencies and updates recommendations in the 2001 American Academy of Pediatrics policy statement of the same name. (7/06, reaffirmed 4/09, 3/13, 7/17)

DONOR HUMAN MILK FOR THE HIGH-RISK INFANT: PREPARATION, SAFETY, AND USAGE OPTIONS IN THE UNITED STATES

Committee on Nutrition, Section on Breastfeeding, and Committee on Fetus and Newborn

ABSTRACT. The use of donor human milk is increasing for high-risk infants, primarily for infants born weighing <1500 g or those who have severe intestinal disorders. Pasteurized donor milk may be considered in situations in which the supply of maternal milk is insufficient. The use of pasteurized donor milk is safe when appropriate measures are used to screen donors and collect, store, and pasteurize the milk and then distribute it through established human milk banks. The use of nonpasteurized donor milk and other forms of direct, Internet-based, or informal human milk sharing does not involve this level of safety and is not recommended. It is important that health care providers counsel families considering milk sharing about the risks of bacterial or viral contamination of nonpasteurized human milk and about the possibilities of exposure to medications, drugs, or herbs in human milk. Currently, the use of pasteurized donor milk is limited by its availability and affordability. The development of public policy to improve and expand access to pasteurized donor milk, including policies that support improved governmental and private financial support for donor milk banks and the use of donor milk, is important. DRINKING WATER FROM PRIVATE WELLS AND RISKS TO CHILDREN

Committee on Environmental Health and Committee on Infectious Diseases

ABSTRACT. Drinking water for approximately one sixth of US households is obtained from private wells. These wells can become contaminated by pollutant chemicals or pathogenic organisms and cause illness. Although the US Environmental Protection Agency and all states offer guidance for construction, maintenance, and testing of private wells, there is little regulation. With few exceptions, well owners are responsible for their own wells. Children may also drink well water at child care or when traveling. Illness resulting from children's ingestion of contaminated water can be severe. This policy statement provides recommendations for inspection, testing, and remediation for wells providing drinking water for children. (5/09, reaffirmed 1/13, 9/19)
http://pediatrics.aappublications.org/content/123/6/1599

DRINKING WATER FROM PRIVATE WELLS AND RISKS TO CHILDREN (TECHNICAL REPORT)

Walter J. Rogan, MD; Michael T. Brady, MD; Committee on Environmental Health; and Committee on Infectious Diseases

ABSTRACT. Drinking water for approximately one sixth of US households is obtained from private wells. These wells can become contaminated by pollutant chemicals or pathogenic organisms, leading to significant illness. Although the US Environmental Protection Agency and all states offer guidance for construction, maintenance, and testing of private wells, there is little regulation, and with few exceptions, well owners are responsible for their own wells. Children may also drink well water at child care or when traveling. Illness resulting from children's ingestion of contaminated water can be severe. This report reviews relevant aspects of groundwater and wells; describes the common chemical and microbiologic contaminants; gives an algorithm with recommendations for inspection, testing, and remediation for wells providing drinking water for children; reviews the definitions and uses of various bottled waters; provides current estimates of costs for well testing; and provides

federal, national, state, and, where appropriate, tribal contacts for more information. (5/09, reaffirmed 1/13, 9/19)

DRUGS USED TO TREAT PEDIATRIC EMERGENCIES (CLINICAL REPORT)

Rohit P. Shenoi, MD, FAAP; Nathan Timm, MD, FAAP; Committee on Drugs; and Committee on Pediatric Emergency Medicine

ABSTRACT. This clinical report is a revision of "Preparing for Pediatric Emergencies: Drugs to Consider." It updates the list, indications, and dosages of medications used to treat pediatric emergencies in the prehospital, pediatric clinic, and emergency department settings. Although it is not an all-inclusive list of medications that may be used in all emergencies, this resource will be helpful when treating a vast majority of pediatric medical emergencies. Dosage recommendations are consistent with current emergency references such as the Advanced Pediatric Life Support and Pediatric Advanced Life Support textbooks and American Heart Association resuscitation guidelines. (12/19)

E-CIGARETTES AND SIMILAR DEVICES

Brian P. Jenssen, MD, MSHP, FAAP; Susan C. Walley, MD, FAAP; and Section on Tobacco Control

ABSTRACT. Electronic cigarettes (e-cigarettes) are the most commonly used tobacco product among youth. The 2016 US Surgeon General's Report on e-cigarette use among youth and young adults concluded that e-cigarettes are unsafe for children and adolescents. Furthermore, strong and consistent evidence finds that children and adolescents who use e-cigarettes are significantly more likely to go on to use traditional cigarettes—a product that kills half its long-term users. E-cigarette manufacturers target children with enticing candy and fruit flavors and use marketing strategies that have been previously successful with traditional cigarettes to attract youth to these products. Numerous toxicants and carcinogens have been found in e-cigarette solutions. Nonusers are involuntarily exposed to the emissions of these devices with secondhand and thirdhand aerosol. To prevent children, adolescents, and young adults from transitioning from e-cigarettes to traditional cigarettes and minimize the potential public health harm from e-cigarette use, there is a critical need for e-cigarette regulation, legislative action, and counterpromotion to protect youth. EARLY CHILDHOOD ADVERSITY, TOXIC STRESS, AND THE ROLE OF THE PEDIATRICIAN: TRANSLATING DEVELOPMENTAL SCIENCE INTO LIFELONG HEALTH

Committee on Psychosocial Aspects of Child and Family Health; Committee on Early Childhood, Adoption, and Dependent Care; and Section on Developmental and Behavioral Pediatrics

ABSTRACT. Advances in a wide range of biological, behavioral, and social sciences are expanding our understanding of how early environmental influences (the ecology) and genetic predispositions (the biologic program) affect learning capacities, adaptive behaviors, lifelong physical and mental health, and adult productivity. A supporting technical report from the American Academy of Pediatrics (AAP) presents an integrated ecobiodevelopmental framework to assist in translating these dramatic advances in developmental science into improved health across the life span. Pediatricians are now armed with new information about the adverse effects of toxic stress on brain development, as well as a deeper understanding of the early life origins of many adult diseases. As trusted authorities in child health and development, pediatric providers must now complement the early identification of developmental concerns with a greater focus on those interventions and community investments that reduce external threats to healthy brain growth. To this end, AAP endorses a developing leadership role for the entire pediatric community—one that mobilizes the scientific expertise of both basic and clinical researchers, the family-centered care of the pediatric medical home, and the public influence of AAP and its state chapters—to catalyze fundamental change in early childhood policy and services. AAP is committed to leveraging science to inform the development of innovative strategies to reduce the precipitants of toxic stress in young children and to mitigate their negative effects on the course of development and health across the life span. (12/11, reaffirmed 7/16)

EARLY CHILDHOOD CARIES IN INDIGENOUS COMMUNITIES

Committee on Native American Child Health (joint with Canadian Paediatric Society First Nations, Inuit, and Métis Committee)

ABSTRACT. The oral health of Indigenous children of Canada (First Nations, Inuit, and Métis) and the United States (American Indian, Alaska Native) is a major child health issue: there is a high prevalence of early childhood caries (ECC) and resulting adverse health effects in this community, as well as high rates and costs of restorative and surgical treatments under general anesthesia. ECC is an infectious disease that is influenced by multiple factors, including socioeconomic determinants, and requires a combination of approaches for improvement. This statement includes recommendations for preventive oral health and clinical care for young infants and pregnant women by primary health care providers, community-based health-promotion initiatives, oral health workforce and access issues, and advocacy for community water fluoridation and fluoride-varnish program access. Further community-based research on the epidemiology, prevention, management, and microbiology of ECC in Indigenous communities would be beneficial. (5/11, reaffirmed 10/16)
http://pediatrics.aappublications.org/content/127/6/1190

EARLY CHILDHOOD HOME VISITING

James H. Duffee, MD, MPH, FAAP; Alan L. Mendelsohn, MD, FAAP; Alice A. Kuo, MD, PhD, FAAP; Lori A. Legano, MD, FAAP; Marian F. Earls, MD, MTS, FAAP; Council on Community Pediatrics; Council on Early Childhood; and Committee on Child Abuse and Neglect

ABSTRACT. High-quality home-visiting services for infants and young children can improve family relationships, advance school readiness, reduce child maltreatment, improve maternal-infant health outcomes, and increase family economic self-sufficiency. The American Academy of Pediatrics supports unwavering federal funding of state home-visiting initiatives, the expansion of evidence-based programs, and a robust, coordinated national evaluation designed to confirm best practices and cost-efficiency. Community home visiting is most effective as a component of a comprehensive early childhood system that actively includes and enhances a family-centered medical home. (8/17)
http://pediatrics.aappublications.org/content/140/3/e20172150

EARLY INTERVENTION, IDEA PART C SERVICES, AND THE MEDICAL HOME: COLLABORATION FOR BEST PRACTICE AND BEST OUTCOMES (CLINICAL REPORT)

Richard C. Adams, MD; Carl Tapia, MD; and Council on Children With Disabilities

ABSTRACT. The medical home and the Individuals With Disabilities Education Act Part C Early Intervention Program share many common purposes for infants and children ages 0 to 3 years, not the least of which is a family-centered focus. Professionals in pediatric medical home practices see substantial numbers of infants and toddlers with developmental delays

and/or complex chronic conditions. Economic, health, and family-focused data each underscore the critical role of timely referral for relationship-based, individualized, accessible early intervention services and the need for collaborative partnerships in care. The medical home process and Individuals With Disabilities Education Act Part C policy both support nurturing relationships and family-centered care; both offer clear value in terms of economic and health outcomes. Best practice models for early intervention services incorporate learning in the natural environment and coaching models. Proactive medical homes provide strategies for effective developmental surveillance, family-centered resources, and tools to support high-risk groups, and comanagement of infants with special health care needs, including the monitoring of services provided and outcomes achieved. (9/13, reaffirmed 5/17)

ECHOCARDIOGRAPHY IN INFANTS AND CHILDREN

Section on Cardiology

ABSTRACT. It is the intent of this statement to inform pediatric providers on the appropriate use of echocardiography. Although on-site consultation may be impossible, methods should be established to ensure timely review of echocardiograms by a pediatric cardiologist. With advances in data transmission, echocardiography information can be exchanged, in some cases eliminating the need for a costly patient transfer. By cooperating through training, education, and referral, complete and cost-effective echocardiographic services can be provided to all children. (6/97, reaffirmed 3/03, 3/07)
http://pediatrics.aappublications.org/content/99/6/921

EFFECTIVE DISCIPLINE TO RAISE HEALTHY CHILDREN

Robert D. Sege, MD, PhD, FAAP; Benjamin S. Siegel, MD, FAAP; Council on Child Abuse and Neglect; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Pediatricians are a source of advice for parents and guardians concerning the management of child behavior, including discipline strategies that are used to teach appropriate behavior and protect their children and others from the adverse effects of challenging behavior. Aversive disciplinary strategies, including all forms of corporal punishment and yelling at or shaming children, are minimally effective in the short-term and not effective in the long-term. With new evidence, researchers link corporal punishment to an increased risk of negative behavioral, cognitive, psychosocial, and emotional outcomes for children. In this Policy Statement, the American Academy of Pediatrics provides guidance for pediatricians and other child health care providers on educating parents about positive and effective parenting strategies of discipline for children at each stage of development as well as references to educational materials. This statement supports the need for adults to avoid physical punishment and verbal abuse of children. (11/18)

THE EFFECTS OF ARMED CONFLICT ON CHILDREN

Sherry Shenoda, MD, FAAP; Ayesha Kadir, MD, MSc, FAAP; Shelly Pitterman, PhD; Jeffrey Goldhagen, MD, MPH, FAAP; and Section on International Child Health

ABSTRACT. Children are increasingly exposed to armed conflict and targeted by governmental and nongovernmental combatants. Armed conflict directly and indirectly affects children's physical, mental, and behavioral health. It can affect every organ system, and its impact can persist throughout the life course. In addition, children are disproportionately impacted by morbidity and mortality associated with armed conflict. A children's rights–based approach provides a framework for collaboration by the American Academy of Pediatrics, child health professionals, and national and international partners to respond in the domains of clinical care, systems development, and policy formulation. The American Academy of Pediatrics and child health professionals have critical and synergistic roles to play in the global response to the impact of armed conflict on children. (11/18)
http://pediatrics.aappublications.org/content/142/6/e20182585

THE EFFECTS OF ARMED CONFLICT ON CHILDREN (TECHNICAL REPORT)

Ayesha Kadir, MD, MSc, FAAP; Sherry Shenoda, MD, FAAP; Jeffrey Goldhagen, MD, MPH, FAAP; Shelly Pitterman, PhD; and Section on International Child Health

ABSTRACT. More than 1 in 10 children worldwide are affected by armed conflict. The effects are both direct and indirect and are associated with immediate and long-term harm. The direct effects of conflict include death, physical and psychological trauma, and displacement. Indirect effects are related to a large number of factors, including inadequate and unsafe living conditions, environmental hazards, caregiver mental health, separation from family, displacement-related health risks, and the destruction of health, public health, education, and economic infrastructure. Children and health workers are targeted by combatants during attacks, and children are recruited or forced to take part in combat in a variety of ways. Armed conflict is both a toxic stress and a significant social determinant of child health. In this Technical Report, we review the available knowledge on the effects of armed conflict on children and support the recommendations in the accompanying Policy Statement on children and armed conflict. (11/18)

THE EFFECTS OF EARLY NUTRITIONAL INTERVENTIONS ON THE DEVELOPMENT OF ATOPIC DISEASE IN INFANTS AND CHILDREN: THE ROLE OF MATERNAL DIETARY RESTRICTION, BREASTFEEDING, HYDROLYZED FORMULAS, AND TIMING OF INTRODUCTION OF ALLERGENIC COMPLEMENTARY FOODS (CLINICAL REPORT)

Frank R. Greer, MD, FAAP; Scott H. Sicherer, MD, FAAP; A. Wesley Burks, MD, FAAP; Committee on Nutrition; and Section on Allergy and Immunology

ABSTRACT. This clinical report updates and replaces a 2008 clinical report from the American Academy of Pediatrics, which addressed the roles of maternal and early infant diet on the prevention of atopic disease, including atopic dermatitis, asthma, and food allergy. As with the previous report, the available data still limit the ability to draw firm conclusions about various aspects of atopy prevention through early dietary interventions. Current evidence does not support a role for maternal dietary restrictions during pregnancy or lactation. Although there is evidence that exclusive breastfeeding for 3 to 4 months decreases the incidence of eczema in the first 2 years of life, there are no short- or long-term advantages for exclusive breastfeeding beyond 3 to 4 months for prevention of atopic disease. The evidence now suggests that any duration of breastfeeding ≥3 to 4 months is protective against wheezing in the first 2 years of life, and some evidence suggests that longer duration of any breastfeeding protects against asthma even after 5 years of age. No conclusions can be made about the role of breastfeeding in either preventing or delaying the onset of specific food allergies. There is a lack of evidence that partially or extensively hydrolyzed formula prevents atopic disease. There is no evidence that delaying the introduction of allergenic foods, including peanuts, eggs, and fish, beyond 4 to 6 months prevents atopic disease. There is now evidence that early introduction of peanuts may prevent peanut allergy. (3/19)

ELECTRONIC COMMUNICATION OF THE HEALTH RECORD AND INFORMATION WITH PEDIATRIC PATIENTS AND THEIR GUARDIANS

Emily C. Webber, MD, FAAP, FAMIA; David Brick, MD, FAAP; James P. Scibilia, MD, FAAP; Peter Dehnel, MD, FAAP; Council on Clinical Information Technology; Committee on Medical Liability and Risk Management; and Section on Telehealth Care

ABSTRACT. Communication of health data has evolved rapidly with the widespread adoption of electronic health records (EHRs) and communication technology. What used to be sent to patients via paper mail, fax, or e-mail may now be accessed by patients via their EHRs, and patients may also communicate securely with their medical team via certified technology. Although EHR technologies have great potential, their most effective applications and uses for communication between pediatric and adolescent patients, guardians, and medical teams has not been realized. There are wide variations in available technologies, guiding policies, and practices; some physicians and patients are successful in using certified tools but others are forced to limit their patients' access to e-health data and associated communication altogether. In general, pediatric and adolescent patients are less likely than adult patients to have electronic access and the ability to exchange health data. There are several reasons for these limitations, including inconsistent standards and recommendations regarding the recommended age for independent access, lack of routine EHR support for the ability to filter or proxy such access, and conflicting laws about patients' and physicians' rights to access EHRs and ability to communicate electronically. Effective, safe electronic exchange of health data requires active collaboration between physicians, patients, policy makers, and health information technology vendors. This policy statement addresses current best practices for these stakeholders and delineates the continued gaps and how to address them. (6/19)

ELECTRONIC DOCUMENTATION IN PEDIATRICS: THE RATIONALE AND FUNCTIONALITY REQUIREMENTS

Heather C. O'Donnell, MD, MSc, FAAP; Srinivasan Suresh, MD, MBA, FAAP; and Council on Clinical Information Technology

ABSTRACT. Clinical documentation is a fundamental component of the practice of medicine. It has significantly evolved over the past decade, largely because of the growth of health information technology and electronic health records. Although government agencies and other professional organizations have published position statements on the structure and use of electronic documentation, few have specifically addressed the documentation needs for the care of children. A policy statement on electronic documentation of clinical care by general pediatric and subspecialist providers by the American Academy of Pediatrics is needed. This statement provides insight on the unmet needs of key stakeholders to direct future research and development of the electronic media necessary to enhance the wellness of children and improve health care delivery. It also addresses the challenges and opportunities for efficient and effective clinical documentation in pediatrics. (6/20)

ELECTRONIC DOCUMENTATION IN PEDIATRICS: THE RATIONALE AND FUNCTIONALITY REQUIREMENTS (TECHNICAL REPORT)

Heather C. O'Donnell, MD, MSc, FAAP; Srinivasan Suresh, MD, MBA, FAAP; and Council on Clinical Information Technology

ABSTRACT. Clinical documentation has dramatically changed since the implementation and use of electronic health records and electronic provider documentation. The purpose of this report is to review these changes and promote the development of standards and best practices for electronic documentation for pediatric patients. In this report, we evaluate the unique aspects of clinical documentation for pediatric care, including specialized information needs and stakeholders specific to the care of children. Additionally, we explore new models of documentation, such as shared documentation, in which patients may be both authors and consumers, and among care teams while still maintaining the ability to clearly define care and services provided to patients in a given day or encounter. Finally, we describe alternative documentation techniques and newer technologies that could improve provider efficiency and the reuse of clinical data. (6/20)

https://pediatrics.aappublications.org/content/146/1/00

ELECTRONIC PRESCRIBING IN PEDIATRICS: TOWARD SAFER AND MORE EFFECTIVE MEDICATION MANAGEMENT

Council on Clinical Information Technology

ABSTRACT. This policy statement identifies the potential value of electronic prescribing (e-prescribing) systems in improving quality and reducing harm in pediatric health care. On the basis of limited but positive pediatric data and on the basis of federal statutes that provide incentives for the use of e-prescribing systems, the American Academy of Pediatrics recommends the adoption of e-prescribing systems with pediatric functionality. The American Academy of Pediatrics also recommends a set of functions that technology vendors should provide when e-prescribing systems are used in environments in which children receive care. (3/13, reaffirmed 12/18)

http://pediatrics.aappublications.org/content/131/4/824

ELECTRONIC PRESCRIBING IN PEDIATRICS: TOWARD SAFER AND MORE EFFECTIVE MEDICATION MANAGEMENT (TECHNICAL REPORT)

Kevin B. Johnson, MD, MS; Christoph U. Lehmann, MD; and Council on Clinical Information Technology

ABSRACT. This technical report discusses recent advances in electronic prescribing (e-prescribing) systems, including the evidence base supporting their limitations and potential benefits. Specifically, this report acknowledges that there are limited but positive pediatric data supporting the role of e-prescribing in mitigating medication errors, improving communication with dispensing pharmacists, and improving medication adherence. On the basis of these data and on the basis of federal statutes that provide incentives for the use of e-prescribing systems, the American Academy of Pediatrics recommends the adoption of e-prescribing systems with pediatric functionality. This report supports the accompanying policy statement from the American Academy of Pediatrics recommending the adoption of e-prescribing by pediatric health care providers. (3/13, reaffirmed 12/18)

ELIMINATION OF PERINATAL HEPATITIS B: PROVIDING THE FIRST VACCINE DOSE WITHIN 24 HOURS OF BIRTH

Committee on Infectious Diseases and Committee on Fetus and Newborn

ABSTRACT. After the introduction of the hepatitis B vaccine in the United States in 1982, a greater than 90% reduction in new infections was achieved. However, approximately 1000 new cases of perinatal hepatitis B infection are still identified annually in the United States. Prevention of perinatal hepatitis B relies on the proper and timely identification of infants born to mothers who are hepatitis B surface antigen positive and to mothers with unknown status to ensure administration of appropriate postexposure immunoprophylaxis with hepatitis B vaccine and immune globulin. To reduce the incidence of perinatal hepatitis

B transmission further, the American Academy of Pediatrics endorses the recommendation of the Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention that all newborn infants with a birth weight of greater than or equal to 2000 g receive hepatitis B vaccine by 24 hours of age. (8/17)

EMERGENCY CONTRACEPTION

Krishna K. Upadhya, MD, MPH, FAAP, and Committee on Adolescence

ABSTRACT. Despite significant declines over the past 2 decades, the United States continues to experience birth rates among teenagers that are significantly higher than other high-income nations. Use of emergency contraception (EC) within 120 hours after unprotected or underprotected intercourse can reduce the risk of pregnancy. Emergency contraceptive methods include oral medications labeled and dedicated for use as EC by the US Food and Drug Administration (ulipristal and levonorgestrel), the "off-label" use of combined oral contraceptives, and insertion of a copper intrauterine device. Indications for the use of EC include intercourse without use of contraception; condom breakage or slippage; missed or late doses of contraceptives, including the oral contraceptive pill, contraceptive patch, contraceptive ring, and injectable contraception; vomiting after use of oral contraceptives; and sexual assault. Our aim in this updated policy statement is to (1) educate pediatricians and other physicians on available emergency contraceptive methods; (2) provide current data on the safety, efficacy, and use of EC in teenagers; and (3) encourage routine counseling and advance EC prescription as 1 public health strategy to reduce teenaged pregnancy. (11/19)

EMERGENCY INFORMATION FORMS AND EMERGENCY PREPAREDNESS FOR CHILDREN WITH SPECIAL HEALTH CARE NEEDS

Committee on Pediatric Emergency Medicine and Council on Clinical Information Technology (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee)

ABSTRACT. Children with chronic medical conditions rely on complex management plans for problems that cause them to be at increased risk for suboptimal outcomes in emergency situations. The emergency information form (EIF) is a medical summary that describes medical condition(s), medications, and special health care needs to inform health care providers of a child's special health conditions and needs so that optimal emergency medical care can be provided. This statement describes updates to EIFs, including computerization of the EIF, expanding the potential benefits of the EIF, quality-improvement programs using the EIF, the EIF as a central repository, and facilitating emergency preparedness in disaster management and drills by using the EIF. (3/10, reaffirmed 7/14, 10/14)

EMERGING ISSUES IN MALE ADOLESCENT SEXUAL AND REPRODUCTIVE HEALTH CARE (CLINICAL REPORT)

Laura K. Grubb, MD, MPH, FAAP; Makia Powers, MD, MPH, MSc, FAAP; and Committee on Adolescence

ABSTRACT. Pediatricians are encouraged to address male adolescent sexual and reproductive health on a regular basis, including taking a sexual history, discussing healthy sexuality, performing an appropriate physical examination, providing patient-centered and age-appropriate anticipatory guidance, and administering appropriate vaccinations. These services can be provided to male adolescent patients in a confidential and culturally appropriate manner, can promote healthy sexual relationships and responsibility, can and involve parents in age-appropriate discussions about sexual health. (4/20)

ENDORSEMENT OF HEALTH AND HUMAN SERVICES RECOMMENDATION FOR PULSE OXIMETRY SCREENING FOR CRITICAL CONGENITAL HEART DISEASE

Section on Cardiology and Cardiac Surgery Executive Committee

ABSTRACT. Incorporation of pulse oximetry to the assessment of the newborn infant can enhance detection of critical congenital heart disease (CCHD). Recently, the Secretary of Health and Human Services (HHS) recommended that screening for CCHD be added to the uniform screening panel. The American Academy of Pediatrics (AAP) has been a strong advocate of early detection of CCHD and fully supports the decision of the Secretary of HHS.

The AAP has published strategies for the implementation of pulse oximetry screening, which addressed critical issues such as necessary equipment, personnel, and training, and also provided specific recommendations for assessment of saturation by using pulse oximetry as well as appropriate management of a positive screening result. The AAP is committed to the safe and effective implementation of pulse oximetry screening and is working with other advocacy groups and governmental agencies to promote pulse oximetry and to support widespread surveillance for CCHD.

Going forward, AAP chapters will partner with state health departments to implement the new screening strategy for CCHD and will work to ensure that there is an adequate system for referral for echocardiographic/pediatric cardiac evaluation after a positive screening result. It is imperative that AAP members engage their respective policy makers in adopting and funding the recommendations made by the Secretary of HHS. (12/11)
http://pediatrics.aappublications.org/content/129/1/190

ENHANCING PEDIATRIC WORKFORCE DIVERSITY AND PROVIDING CULTURALLY EFFECTIVE PEDIATRIC CARE: IMPLICATIONS FOR PRACTICE, EDUCATION, AND POLICY MAKING

Committee on Pediatric Workforce

ABSTRACT. This policy statement serves to combine and update 2 previously independent but overlapping statements from the American Academy of Pediatrics (AAP) on culturally effective health care (CEHC) and workforce diversity. The AAP has long recognized that with the ever-increasing diversity of the pediatric population in the United States, the health of all children depends on the ability of all pediatricians to practice culturally effective care. CEHC can be defined as the delivery of care within the context of appropriate physician knowledge, understanding, and appreciation of all cultural distinctions, leading to optimal health outcomes. The AAP believes that CEHC is a critical social value and that the knowledge and skills necessary for providing CEHC can be taught and acquired through focused curricula across the spectrum of lifelong learning.

This statement also addresses workforce diversity, health disparities, and affirmative action. The discussion of diversity is broadened to include not only race, ethnicity, and language but also cultural attributes such as gender, religious beliefs, sexual orientation, and disability, which may affect the quality of health care. The AAP believes that efforts must be supported through health policy and advocacy initiatives to promote the delivery of CEHC and to overcome educational, organizational, and other barriers to improving workforce diversity. (9/13, reaffirmed 10/15)

ENSURING COMPREHENSIVE CARE AND SUPPORT FOR TRANSGENDER AND GENDER-DIVERSE CHILDREN AND ADOLESCENTS

Jason Rafferty, MD, MPH, EdM, FAAP; Committee on Psychosocial Aspects of Child and Family Health; Committee on Adolescence; and Section on Lesbian, Gay, Bisexual, and Transgender Health and Wellness

ABSTRACT. As a traditionally underserved population that faces numerous health disparities, youth who identify as transgender and gender diverse (TGD) and their families are increasingly presenting to pediatric providers for education, care, and referrals. The need for more formal training, standardized treatment, and research on safety and medical outcomes often leaves providers feeling ill equipped to support and care for patients that identify as TGD and families. In this policy statement, we review relevant concepts and challenges and provide suggestions for pediatric providers that are focused on promoting the health and positive development of youth that identify as TGD while eliminating discrimination and stigma. (9/18)

http://pediatrics.aappublications.org/content/142/4/e20182162

ENSURING THE HEALTH OF CHILDREN IN DISASTERS

Disaster Preparedness Advisory Council and Committee on Pediatric Emergency Medicine

ABSTRACT. Infants, children, adolescents, and young adults have unique physical, mental, behavioral, developmental, communication, therapeutic, and social needs that must be addressed and met in all aspects of disaster preparedness, response, and recovery. Pediatricians, including primary care pediatricians, pediatric medical subspecialists, and pediatric surgical specialists, have key roles to play in preparing and treating families in cases of disasters. Pediatricians should attend to the continuity of practice operations to provide services in time of need and stay abreast of disaster and public health developments to be active participants in community planning efforts. Federal, state, tribal, local, and regional institutions and agencies that serve children should collaborate with pediatricians to ensure the health and well-being of children in disasters. (10/15)

http://pediatrics.aappublications.org/content/136/5/e1407

EPIDEMIOLOGY AND DIAGNOSIS OF HEALTH CARE–ASSOCIATED INFECTIONS IN THE NICU (TECHNICAL REPORT)

Committee on Fetus and Newborn and Committee on Infectious Diseases

ABSTRACT. Health care–associated infections in the NICU are a major clinical problem resulting in increased morbidity and mortality, prolonged length of hospital stays, and increased medical costs. Neonates are at high risk for health care–associated infections because of impaired host defense mechanisms, limited amounts of protective endogenous flora on skin and mucosal surfaces at time of birth, reduced barrier function of neonatal skin, the use of invasive procedures and devices, and frequent exposure to broad-spectrum antibiotics. This statement will review the epidemiology and diagnosis of health care–associated infections in newborn infants. (3/12, reaffirmed 2/16)

http://pediatrics.aappublications.org/content/129/4/e1104

EPINEPHRINE FOR FIRST-AID MANAGEMENT OF ANAPHYLAXIS (CLINICAL REPORT)

Scott H. Sicherer, MD, FAAP; F. Estelle R. Simons, MD, FAAP; and Section on Allergy and Immunology

ABSTRACT. Anaphylaxis is a severe, generalized allergic or hypersensitivity reaction that is rapid in onset and may cause death. Epinephrine (adrenaline) can be life-saving when administered as rapidly as possible once anaphylaxis is recognized. This clinical report from the American Academy of Pediatrics is an update of the 2007 clinical report on this topic. It provides information to help clinicians identify patients at risk of anaphylaxis and new information about epinephrine and epinephrine autoinjectors (EAs). The report also highlights the importance of patient and family education about the recognition and management of anaphylaxis in the community. Key points emphasized include the following: (1) validated clinical criteria are available to facilitate prompt diagnosis of anaphylaxis; (2) prompt intramuscular epinephrine injection in the mid-outer thigh reduces hospitalizations, morbidity, and mortality; (3) prescribing EAs facilitates timely epinephrine injection in community settings for patients with a history of anaphylaxis and, if specific circumstances warrant, for some high-risk patients who have not previously experienced anaphylaxis; (4) prescribing epinephrine for infants and young children weighing <15 kg, especially those who weigh 7.5 kg and under, currently presents a dilemma, because the lowest dose available in EAs, 0.15 mg, is a high dose for many infants and some young children; (5) effective management of anaphylaxis in the community requires a comprehensive approach involving children, families, preschools, schools, camps, and sports organizations; and (6) prevention of anaphylaxis recurrences involves confirmation of the trigger, discussion of specific allergen avoidance, allergen immunotherapy (eg, with stinging insect venom, if relevant), and a written, personalized anaphylaxis emergency action plan; and (7) the management of anaphylaxis also involves education of children and supervising adults about anaphylaxis recognition and first-aid treatment. EQUIPMENT FOR GROUND AMBULANCES

American Academy of Pediatrics (joint with American College of Emergency Physicians, American College of Surgeons Committee on Trauma, Emergency Medical Services for Children, Emergency Nurses Association, National Association of EMS Physicians, and National Association of State EMS Officials)

On January 1, 2014, the American Academy of Pediatrics, American College of Emergency Physicians, American College of Surgeons Committee on Trauma, Emergency Medical Services for Children, Emergency Nurses Association, National Association of EMS Physicians, and National Association of State EMS Officials coauthored a joint policy statement, "Equipment for Ground Ambulances" (*Prehosp Emerg Care.* 2014;19[1]:92–97). The full text of the joint policy statement is available at: http://informahealthcare.com/doi/full/10.3109/10903127.2013.851312. (8/14, reaffirmed 1/20)

ERADICATING POLIO: HOW THE WORLD'S PEDIATRICIANS CAN HELP STOP THIS CRIPPLING ILLNESS FOREVER (CLINICAL REPORT)

Walter A. Orenstein, MD, FAAP, and Committee on Infectious Diseases

ABSTRACT. The American Academy of Pediatrics strongly supports the Polio Eradication and Endgame Strategic Plan of the Global Polio Eradication Initiative. This plan was endorsed in November 2012 by the Strategic Advisory Group of Experts on Immunization of the World Health Organization and published by the World Health Organization in April 2013. As a key component of the plan, it will be necessary to stop oral polio vaccine (OPV) use globally to achieve eradication, because the attenuated viruses in the vaccine rarely can cause polio. The plan includes procedures for elimination of vaccine-associated paralytic polio and circulating vaccine-derived polioviruses (cVDPVs). cVDPVs can proliferate when vaccine viruses are transmitted among susceptible people, resulting in mutations conferring both the neurovirulence and transmissibility characteristics of wild polioviruses. Although there are 3 different types of wild poliovirus strains, the polio eradication effort has already

resulted in the global elimination of type 2 poliovirus for more than a decade. Type 3 poliovirus may be eliminated because the wild type 3 poliovirus was last detected in 2012. Thus, of the 3 wild types, only wild type 1 poliovirus is still known to be circulating and causing disease. OPV remains the key vaccine for eradicating wild polioviruses in polio-infected countries because it induces high levels of systemic immunity to prevent paralysis and intestinal immunity to reduce transmission. However, OPV is a rare cause of paralysis and the substantial decrease in wild-type disease has resulted in estimates that the vaccine is causing more polio-related paralysis annually in recent years than the wild virus. The new endgame strategic plan calls for stepwise removal of the type 2 poliovirus component from trivalent oral vaccines, because type 2 wild poliovirus appears to have been eradicated (since 1999) and yet is the main cause of cVDPV outbreaks and approximately 40% of vaccine-associated paralytic polio cases. The Endgame and Strategic Plan will be accomplished by shifting from trivalent OPV to bivalent OPV (containing types 1 and 3 poliovirus only). It will be necessary to introduce trivalent inactivated poliovirus vaccine (IPV) into routine immunization programs in all countries using OPV to provide population immunity to type 2 before the switch from trivalent OPV to bivalent OPV. The Global Polio Eradication Initiative hopes to achieve global eradication of polio by 2018 with this strategy, after which all OPV use will be stopped. Challenges expected for adding IPV into routine immunization schedules include higher cost of IPV compared with OPV, cold-chain capacity limits, more complex administration of vaccine because IPV requires injections as opposed to oral administration, and inferior intestinal immunity conferred by IPV. The goal of this report is to help pediatricians understand the change in strategy and outline ways that pediatricians can help global polio eradication efforts, including advocating for the resources needed to accomplish polio eradication and for incorporation of IPV into routine immunization programs in all countries. ESSENTIAL CONTRACTUAL LANGUAGE FOR MEDICAL NECESSITY IN CHILDREN

Committee on Child Health Financing

ABSTRACT. The previous policy statement from the American Academy of Pediatrics, "Model Language for Medical Necessity in Children," was published in July 2005. Since that time, there have been new and emerging delivery and payment models. The relationship established between health care providers and health plans should promote arrangements that are beneficial to all who are affected by these contractual arrangements. Pediatricians play an important role in ensuring that the needs of children are addressed in these emerging systems. It is important to recognize that health care plans designed for adults may not meet the needs of children. Language in health care contracts should reflect the health care needs of children and families. Informed pediatricians can make a difference in the care of children and influence the role of primary care physicians in the new paradigms. This policy highlights many of the important elements pediatricians should assess as providers develop a role in emerging care models. (7/13, reaffirmed 9/17)

ESTABLISHING A STANDARD PROTOCOL FOR THE VOIDING CYSTOURETHROGRAPHY (CLINICAL REPORT)

Dominic Frimberger, MD; Maria-Gisela Mercado-Deane, MD, FAAP; Section on Urology; and Section on Radiology

ABSTRACT. The voiding cystourethrogram (VCUG) is a frequently performed test to diagnose a variety of urologic conditions, such as vesicoureteral reflux. The test results determine whether continued observation or an interventional procedure is indicated. VCUGs are ordered by many specialists and primary care providers, including pediatricians, family practitioners, nephrologists, hospitalists, emergency department physicians, and urologists. Current protocols for performing and interpreting a VCUG are based on the International Reflux Study in 1985. However, more recent information provided by many national and international institutions suggests a need to refine those recommendations. The lead author of the 1985 study, R.L. Lebowitz, agreed to and participated in the current protocol. In addition, a recent survey directed to the chairpersons of pediatric radiology of 65 children's hospitals throughout the United States and Canada showed that VCUG protocols vary substantially. Recent guidelines from the American Academy of Pediatrics (AAP) recommend a VCUG for children between 2 and 24 months of age with urinary tract infections but did not specify how this test should be performed. To improve patient safety and to standardize the data obtained when a VCUG is performed, the AAP Section on Radiology and the AAP Section on Urology initiated the current VCUG protocol to create a consensus on how to perform this test. ETHICAL AND POLICY ISSUES IN GENETIC TESTING AND SCREENING OF CHILDREN

Committee on Bioethics and Committee on Genetics (joint with American College of Medical Genetics and Genomics)

ABSTRACT. The genetic testing and genetic screening of children are commonplace. Decisions about whether to offer genetic testing and screening should be driven by the best interest of the child. The growing literature on the psychosocial and clinical effects of such testing and screening can help inform best practices. This policy statement represents recommendations developed collaboratively by the American Academy of Pediatrics and the American College of Medical Genetics and Genomics with respect to many of the scenarios in which genetic testing and screening can occur. ETHICAL CONSIDERATIONS IN RESEARCH WITH SOCIALLY IDENTIFIABLE POPULATIONS

Committee on Native American Child Health and Committee on Community Health Services

ABSTRACT. Community-based research raises ethical issues not normally encountered in research conducted in academic settings. In particular, conventional risk-benefits assessments frequently fail to recognize harms that can occur in socially identifiable populations as a result of research participation. Furthermore, many such communities require more stringent measures of beneficence that must be applied directly to the participating communities. In this statement, the American Academy of Pediatrics sets forth recommendations for minimizing harms that may result from community-based research by emphasizing community involvement in the research process. (1/04, reaffirmed 10/07, 1/13)

ETHICAL CONTROVERSIES IN ORGAN DONATION AFTER CIRCULATORY DEATH

Committee on Bioethics

ABSTRACT. The persistent mismatch between the supply of and need for transplantable organs has led to efforts to increase the supply, including controlled donation after circulatory death (DCD). Controlled DCD involves organ recovery after the planned withdrawal of life-sustaining treatment and the declaration of death according to the cardiorespiratory criteria. Two central ethical issues in DCD are when organ recovery can begin and how to manage conflicts of interests. The "dead donor rule" should be maintained, and donors in cases of DCD should

only be declared dead after the permanent cessation of circulatory function. Permanence is generally established by a 2- to 5-minute waiting period. Given ongoing controversy over whether the cessation must also be irreversible, physicians should not be required to participate in DCD. Because the preparation for organ recovery in DCD begins before the declaration of death, there are potential conflicts between the donor's and recipient's interests. These conflicts can be managed in a variety of ways, including informed consent and separating the various participants' roles. For example, informed consent should be sought for premortem interventions to improve organ viability, and organ procurement organization personnel and members of the transplant team should not be involved in the discontinuation of life-sustaining treatment or the declaration of death. It is also important to emphasize that potential donors in cases of DCD should receive integrated interdisciplinary palliative care, including sedation and analgesia. (4/13, reaffirmed 12/16)

EVALUATING CHILDREN WITH FRACTURES FOR CHILD PHYSICAL ABUSE (CLINICAL REPORT)

Emalee G. Flaherty, MD, FAAP; Jeannette M. Perez-Rossello, MD; Michael A. Levine, MD; William L. Hennrikus, MD; Committee on Child Abuse and Neglect; Section on Radiology; Section on Endocrinology; and Section on Orthopaedics (joint with Society for Pediatric Radiology)

ABSTRACT. Fractures are common injuries caused by child abuse. Although the consequences of failing to diagnose an abusive injury in a child can be grave, incorrectly diagnosing child abuse in a child whose fractures have another etiology can be distressing for a family. The aim of this report is to review recent advances in the understanding of fracture specificity, the mechanism of fractures, and other medical diseases that predispose to fractures in infants and children. This clinical report will aid physicians in developing an evidence-based differential diagnosis and performing the appropriate evaluation when assessing a child with fractures. (1/14)

EVALUATING FOR SUSPECTED CHILD ABUSE: CONDITIONS THAT PREDISPOSE TO BLEEDING (TECHNICAL REPORT)

Shannon L. Carpenter, MD, MS; Thomas C. Abshire, MD; James D. Anderst, MD, MS; Section on Hematology/Oncology; and Committee on Child Abuse and Neglect

ABSTRACT. Child abuse might be suspected when children present with cutaneous bruising, intracranial hemorrhage, or other manifestations of bleeding. In these cases, it is necessary to consider medical conditions that predispose to easy bleeding/bruising. When evaluating for the possibility of bleeding disorders and other conditions that predispose to hemorrhage, the pediatrician must consider the child's presenting history, medical history, and physical examination findings before initiating a laboratory investigation. Many medical conditions can predispose to easy bleeding. Before ordering laboratory tests for a disease, it is useful to understand the biochemical basis and clinical presentation of the disorder, condition prevalence, and test characteristics. This technical report reviews the major medical conditions that predispose to bruising/bleeding and should be considered when evaluating for abusive injury. (3/13, reaffirmed 7/16)

EVALUATION AND MANAGEMENT OF CHILDREN AND ADOLESCENTS WITH ACUTE MENTAL HEALTH OR BEHAVIORAL PROBLEMS. PART I: COMMON CLINICAL CHALLENGES OF PATIENTS WITH MENTAL HEALTH AND/OR BEHAVIORAL EMERGENCIES (CLINICAL REPORT)

Thomas H. Chun, MD, MPH, FAAP; Sharon E. Mace, MD, FAAP, FACEP; Emily R. Katz, MD, FAAP; and Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee)

INTRODUCTION. Mental health problems are among the leading contributors to the global burden of disease. Unfortunately, pediatric populations are not spared of mental health problems. In the United States, 21% to 23% of children and adolescents have a diagnosable mental health or substance use disorder. Among patients of emergency departments (EDs), 70% screen positive for at least 1 mental health disorder, 23% meet criteria for 2 or more mental health concerns, 45% have a mental health problem resulting in impaired psychosocial functioning, and 10% of adolescents endorse significant levels of psychiatric distress at the time of their ED visit. In pediatric primary care settings, the reported prevalence of mental health and behavioral disorders is between 12% to 22% of children and adolescents.

Although the American Academy of Pediatrics (AAP) has published a policy statement on mental health competencies and a Mental Health Toolkit for pediatric primary care providers, no such guidelines or resources exist for clinicians who care for pediatric mental health emergencies. This clinical report supports the 2006 joint policy statement of the AAP and American College of Emergency Physicians (ACEP) on pediatric mental health emergencies, with the goal of addressing the knowledge gaps in this area. The report is written primarily from the perspective of ED clinicians, but it is intended for all clinicians who care for children and adolescents with acute mental health and behavioral problems.

Recent epidemiologic studies of mental health visits have revealed a rapid burgeoning of both ED and primary care visits. An especially problematic trend is the increase in "boarding" of psychiatric patients in the ED and inpatient pediatric beds (ie, extended stays lasting days or even weeks). Although investigation of boarding practices is still in its infancy, the ACEP and the American Medical Association have both expressed concern about it, because it significantly taxes the functioning and efficiency of both the ED and hospital, and mental health services may not be available in the ED.

In addition, compared with other pediatric care settings, ED patients are known to be at higher risk of mental health disorders, including depression, anxiety, posttraumatic stress disorder, and substance abuse. These mental health conditions may be unrecognized not only by treating clinicians but also by the child/adolescent and his or her parents. A similar phenomenon has been described with suicidal patients. Individuals who have committed suicide frequently visited a health care provider in the months preceding their death. Although a minority of suicidal patients present with some form of self-harm, many have vague somatic complaints (eg, headache, gastrointestinal tract distress, back pain, concern for a sexually transmitted infection) masking their underlying mental health condition.

Despite studies demonstrating moderate agreement between emergency physicians and psychiatrists in the assessment and management of patients with mental health problems, ED clinicians frequently cite lack of training and confidence in their abilities as barriers to caring for patients with mental health emergencies. Another study of emergency medicine and pediatric emergency medicine training programs found that formal training in psychiatric problems is not required nor offered by most programs. Pediatric primary care providers report similar barriers to caring for their patients with mental health problems.

Part I of this clinical report focuses on the issues relevant to patients presenting to the ED with a mental health chief complaint and covers the following topics:

- Medical clearance of pediatric psychiatric patients
- Suicidal ideation and suicide attempts
- Involuntary hospitalization
- Restraint of the agitated patient
  - — Verbal restraint
  - — Chemical restraint
  - — Physical restraint
- Coordination with the medical home

Part II discusses challenging patients with primarily medical or indeterminate presentations, in which the contribution of an underlying mental health condition may be unclear or a complicating factor, including:

- Somatic symptom and related disorders
- Adverse effects to psychiatric medications
  - — Antipsychotic adverse effects
  - — Neuroleptic malignant syndrome
  - — Serotonin syndrome
- Children with special needs in the ED (autism spectrum and developmental disorders)
- Mental health screening in the ED

An executive summary of this clinical report can be found at www.pediatrics.org/cgi/doi/10.1542/peds.2016-1571. (8/16)

EVALUATION AND MANAGEMENT OF CHILDREN AND ADOLESCENTS WITH ACUTE MENTAL HEALTH OR BEHAVIORAL PROBLEMS. PART I: COMMON CLINICAL CHALLENGES OF PATIENTS WITH MENTAL HEALTH AND/OR BEHAVIORAL EMERGENCIES—EXECUTIVE SUMMARY (CLINICAL REPORT)

Thomas H. Chun, MD, MPH, FAAP; Sharon E. Mace, MD, FAAP, FACEP; Emily R. Katz, MD, FAAP; and Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee)

ABSTRACT. The number of children and adolescents seen in emergency departments (EDs) and primary care settings for mental health problems has skyrocketed in recent years, with up to 23% of patients in both settings having diagnosable mental health conditions. Even when a mental health problem is not the focus of an ED or primary care visit, mental health conditions, both known and occult, may challenge the treating clinician and complicate the patient's care.

Although the American Academy of Pediatrics has published a policy statement on mental health competencies and a Mental Health Toolkit for pediatric primary care providers, no such guidelines or resources exist for clinicians who care for pediatric mental health emergencies. Many ED and primary care physicians report a paucity of training and lack of confidence in caring for pediatric psychiatry patients. The 2 clinical reports (www.pediatrics.org/cgi/doi/10.1542/peds.2016-1570 and www.pediatrics.org/cgi/doi/10.1542/peds.2016-1573) support the 2006 joint policy statement of the American Academy of Pediatrics and the American College of Emergency Physicians on pediatric mental health emergencies, with the goal of addressing the knowledge gaps in this area. Although written primarily from the perspective of ED clinicians, they are intended for all clinicians who care for children and adolescents with acute mental health and behavioral problems.

The clinical reports are organized around the common clinical challenges pediatric caregivers face, both when a child or adolescent presents with a psychiatric chief complaint or emergency (part I) and also when a mental health condition may be an unclear or complicating factor in a non–mental health clinical presentation (part II). Part II of the clinical reports (www.pediatrics.org/cgi/doi/10.1542/peds.2016-1573) includes discussions of somatic symptom and related disorders, adverse effects of psychiatric medications including neuroleptic malignant syndrome and serotonin syndrome, caring for children with special needs such as autism and developmental disorders, and mental health screening. This executive summary is an overview of part I of the clinical reports. The full text of the below topics can be accessed online at (www.pediatrics.org/cgi/doi/10.1542/peds.2016-1570). (8/16)

http://pediatrics.aappublications.org/content/138/3/e20161571

EVALUATION AND MANAGEMENT OF CHILDREN WITH ACUTE MENTAL HEALTH OR BEHAVIORAL PROBLEMS. PART II: RECOGNITION OF CLINICALLY CHALLENGING MENTAL HEALTH RELATED CONDITIONS PRESENTING WITH MEDICAL OR UNCERTAIN SYMPTOMS (CLINICAL REPORT)

Thomas H. Chun, MD, MPH, FAAP; Sharon E. Mace, MD, FAAP, FACEP; Emily R. Katz, MD, FAAP; and Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee)

INTRODUCTION. Part I of this clinical report (http://www.pediatrics.org/cgi/doi/10.1542/peds.2016-1570) discusses the common clinical issues that may be encountered in caring for children and adolescents presenting to the emergency department (ED) or primary care setting with a mental health condition or emergency and includes the following:

- Medical clearance of pediatric psychiatric patients
- Suicidal ideation and suicide attempts
- Involuntary hospitalization
- Restraint of the agitated patient
  - — Verbal restraint
  - — Chemical restraint
  - — Physical restraint
- Coordination with the medical home

Part II discusses the challenges a pediatric clinician may face when evaluating patients with a mental health condition, which may be contributing to or a complicating factor for a medical or indeterminate clinical presentation. Topics covered include the following:

- Somatic symptom and related disorders
- Adverse effects of psychiatric medications
  - — Antipsychotic adverse effects
  - — Neuroleptic malignant syndrome
  - — Serotonin syndrome
- Children with special needs (autism spectrum disorders [ASDs] and developmental disorders [DDs])
- Mental health screening

The report is written primarily from the perspective of ED clinicians, but it is intended for all clinicians who care for children and adolescents with acute mental health and behavioral problems. An executive summary of this clinical report can be found at http://www.pediatrics.org/cgi/doi/10.1542/peds.2016-1574. (8/16)

http://pediatrics.aappublications.org/content/138/3/e20161573

EVALUATION AND MANAGEMENT OF CHILDREN WITH ACUTE MENTAL HEALTH OR BEHAVIORAL PROBLEMS. PART II: RECOGNITION OF CLINICALLY CHALLENGING MENTAL HEALTH RELATED CONDITIONS PRESENTING WITH MEDICAL OR UNCERTAIN SYMPTOMS—EXECUTIVE SUMMARY (CLINICAL REPORT)

Thomas H. Chun, MD, MPH, FAAP; Sharon E. Mace, MD, FAAP, FACEP; Emily R. Katz, MD, FAAP; and Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee)

ABSTRACT. The number of children and adolescents seen in emergency departments (EDs) and primary care settings for mental health problems has skyrocketed in recent years, with up to 23% of patients in both settings having diagnosable mental health conditions. Even when a mental health problem is not the focus of an ED or primary care visit, mental health conditions, both known and occult, may challenge the treating clinician and complicate the patient's care.

Although the American Academy of Pediatrics (AAP) has published a policy statement on mental health competencies and a Mental Health Toolkit for pediatric primary care providers, no such guidelines or resources exist for clinicians who care for pediatric mental health emergencies. Many ED and primary care physicians report paucity of training and lack of confidence in caring for pediatric psychiatry patients. The 2 clinical reports support the 2006 joint policy statement of the AAP and the American College of Emergency Physicians on pediatric mental health emergencies, with the goal of addressing the knowledge gaps in this area. EVALUATION AND MANAGEMENT OF THE INFANT EXPOSED TO HIV IN THE UNITED STATES (CLINICAL REPORT)

Ellen Gould Chadwick, MD, FAAP; Echezona Edozie Ezeanolue, MD, MPH, FAAP; and Committee on Pediatric AIDS

ABSTRACT. Pediatricians play a crucial role in optimizing the prevention of perinatal transmission of HIV infection. Pediatricians provide antiretroviral prophylaxis to infants born to women with HIV type 1 (HIV) infection during pregnancy and to those whose mother's status was first identified during labor or delivery. Infants whose mothers have an undetermined HIV status should be tested for HIV infection within the boundaries of state laws and receive presumptive HIV therapy if the results are positive. Pediatricians promote avoidance of postnatal HIV transmission by advising mothers with HIV not to breastfeed. Pediatricians test the infant exposed to HIV for determination of HIV infection and monitor possible short- and long-term toxicity from antiretroviral exposure. Finally, pediatricians support families living with HIV by providing counseling to parents or caregivers as an important component of care. (10/20)

EVALUATION AND REFERRAL FOR DEVELOPMENTAL DYSPLASIA OF THE HIP IN INFANTS (CLINICAL REPORT)

Brian A. Shaw, MD, FAAOS, FAAP; Lee S. Segal, MD, FAAOS, FAAP; and Section on Orthopaedics

ABSTRACT. Developmental dysplasia of the hip (DDH) encompasses a wide spectrum of clinical severity, from mild developmental abnormalities to frank dislocation. Clinical hip instability occurs in 1% to 2% of full-term infants, and up to 15% have hip instability or hip immaturity detectable by imaging studies. Hip dysplasia is the most common cause of hip arthritis in women younger than 40 years and accounts for 5% to 10% of all total hip replacements in the United States. Newborn and periodic screening have been practiced for decades, because DDH is clinically silent during the first year of life, can be treated more effectively if detected early, and can have severe consequences if left untreated. However, screening programs and techniques are not uniform, and there is little evidence-based literature to support current practice, leading to controversy. Recent literature shows that many mild forms of DDH resolve without treatment, and there is a lack of agreement on ultrasonographic diagnostic criteria for DDH as a disease versus developmental variations. The American Academy of Pediatrics has not published any policy statements on DDH since its 2000 clinical practice guideline and accompanying technical report. Developments since then include a controversial US Preventive Services Task Force "inconclusive" determination regarding usefulness of DDH screening, several prospective studies supporting observation over treatment of minor ultrasonographic hip variations, and a recent evidence-based clinical practice guideline from the American Academy of Orthopaedic Surgeons on the detection and management of DDH in infants 0 to 6 months of age. The purpose of this clinical report was to provide literature-based updated direction for the clinician in screening and referral for DDH, with the primary goal of preventing and/or detecting a dislocated hip by 6 to 12 months of age in an otherwise healthy child, understanding that no screening program has eliminated late development or presentation of a dislocated hip and that the diagnosis and treatment of milder forms of hip dysplasia remain controversial. (11/16)

EVALUATION AND REFERRAL OF CHILDREN WITH SIGNS OF EARLY PUBERTY (CLINICAL REPORT)

Paul Kaplowitz, MD, PhD, FAAP; Clifford Bloch, MD, FAAP; and Section on Endocrinology

ABSTRACT. Concerns about possible early pubertal development are a common cause for referral to pediatric medical subspecialists. Several recent studies have suggested that onset of breast and/or pubic hair development may be occurring earlier than in the past. Although there is a chance of finding pathology in girls with signs of puberty before 8 years of age and in boys before 9 years of age, the vast majority of these children with signs of apparent puberty have variations of normal growth and physical development and do not require laboratory testing, bone age radiographs, or intervention. The most common of these signs of early puberty are premature adrenarche (early onset of pubic hair and/or body odor), premature thelarche (nonprogressive breast development, usually occurring before 2 years of age), and lipomastia, in which girls have apparent breast development which, on careful palpation, is determined to be adipose tissue. Indicators that the signs of sexual maturation may represent true, central precocious puberty include progressive breast development over a 4- to 6-month period of observation or progressive penis and testicular enlargement, especially if accompanied by rapid linear growth. Children exhibiting these true indicators of early puberty need prompt evaluation by the appropriate pediatric medical subspecialist. Therapy with a

gonadotropin-releasing hormone agonist may be indicated, as discussed in this report. (12/15)

EVALUATION FOR BLEEDING DISORDERS IN SUSPECTED CHILD ABUSE (CLINICAL REPORT)

James D. Anderst, MD, MS; Shannon L. Carpenter, MD, MS; Thomas C. Abshire, MD; Section on Hematology/Oncology; and Committee on Child Abuse and Neglect

ABSTRACT. Bruising or bleeding in a child can raise the concern for child abuse. Assessing whether the findings are the result of trauma and/or whether the child has a bleeding disorder is critical. Many bleeding disorders are rare, and not every child with bruising/bleeding concerning for abuse requires an evaluation for bleeding disorders. In some instances, however, bleeding disorders can present in a manner similar to child abuse. The history and clinical evaluation can be used to determine the necessity of an evaluation for a possible bleeding disorder, and prevalence and known clinical presentations of individual bleeding disorders can be used to guide the extent of the laboratory testing. This clinical report provides guidance to pediatricians and other clinicians regarding the evaluation for bleeding disorders when child abuse is suspected. (3/13, reaffirmed 7/16)

THE EVALUATION OF CHILDREN IN THE PRIMARY CARE SETTING WHEN SEXUAL ABUSE IS SUSPECTED (CLINICAL REPORT)

Carole Jenny, MD, MBA, FAAP; James E. Crawford-Jakubiak, MD, FAAP; and Committee on Child Abuse and Neglect

ABSTRACT. This clinical report updates a 2005 report from the American Academy of Pediatrics on the evaluation of sexual abuse in children. The medical assessment of suspected child sexual abuse should include obtaining a history, performing a physical examination, and obtaining appropriate laboratory tests. The role of the physician includes determining the need to report suspected sexual abuse; assessing the physical, emotional, and behavioral consequences of sexual abuse; providing information to parents about how to support their child; and coordinating with other professionals to provide comprehensive treatment and follow-up of children exposed to child sexual abuse. (7/13, reaffirmed 8/18)
http://pediatrics.aappublications.org/content/132/2/e558

THE EVALUATION OF SEXUAL BEHAVIORS IN CHILDREN (CLINICAL REPORT)

Nancy D. Kellogg, MD, and Committee on Child Abuse and Neglect

ABSTRACT. Most children will engage in sexual behaviors at some time during childhood. These behaviors may be normal but can be confusing and concerning to parents or disruptive or intrusive to others. Knowledge of age-appropriate sexual behaviors that vary with situational and environmental factors can assist the clinician in differentiating normal sexual behaviors from sexual behavior problems. Most situations that involve sexual behaviors in young children do not require child protective services intervention; for behaviors that are age-appropriate and transient, the pediatrician may provide guidance in supervision and monitoring of the behavior. If the behavior is intrusive, hurtful, and/or age-inappropriate, a more comprehensive assessment is warranted. Some children with sexual behavior problems may reside or have resided in homes characterized by inconsistent parenting, violence, abuse, or neglect and may require more immediate intervention and referrals. (8/09, reaffirmed 3/13, 10/18)
http://pediatrics.aappublications.org/content/124/3/992

THE EVALUATION OF SUSPECTED CHILD PHYSICAL ABUSE (CLINICAL REPORT)

Cindy W. Christian, MD, FAAP, and Committee on Child Abuse and Neglect

ABSTRACT. Child physical abuse is an important cause of pediatric morbidity and mortality and is associated with major physical and mental health problems that can extend into adulthood. Pediatricians are in a unique position to identify and prevent child abuse, and this clinical report provides guidance to the practitioner regarding indicators and evaluation of suspected physical abuse of children. The role of the physician may include identifying abused children with suspicious injuries who present for care, reporting suspected abuse to the child protection agency for investigation, supporting families who are affected by child abuse, coordinating with other professionals and community agencies to provide immediate and long-term treatment to victimized children, providing court testimony when necessary, providing preventive care and anticipatory guidance in the office, and advocating for policies and programs that support families and protect vulnerable children. (4/15)

EVIDENCE FOR THE DIAGNOSIS AND TREATMENT OF ACUTE UNCOMPLICATED SINUSITIS IN CHILDREN: A SYSTEMATIC REVIEW (TECHNICAL REPORT)

Michael J. Smith, MD, MSCE

ABSTRACT. In 2001, the American Academy of Pediatrics published clinical practice guidelines for the management of acute bacterial sinusitis (ABS) in children. The technical report accompanying those guidelines included 21 studies that assessed the diagnosis and management of ABS in children. This update to that report incorporates studies of pediatric ABS that have been performed since 2001. Overall, 17 randomized controlled trials of the treatment of sinusitis in children were identified and analyzed. Four randomized, double-blind, placebo-controlled trials of antimicrobial therapy have been published. The results of these studies varied, likely due to differences in inclusion and exclusion criteria. Because of this heterogeneity, formal meta-analyses were not performed. However, qualitative analysis of these studies suggests that children with greater severity of illness at presentation are more likely to benefit from antimicrobial therapy. An additional 5 trials compared different antimicrobial therapies but did not include placebo groups. Six trials assessed a variety of ancillary treatments for ABS in children, and 3 focused on subacute sinusitis. Although the number of pediatric trials has increased since 2001, there are still limited data to guide the diagnosis and management of ABS in children. Diagnostic and treatment guidelines focusing on severity of illness at the time of presentation have the potential to identify those children most likely to benefit from antimicrobial therapy and at the same time minimize unnecessary use of antibiotics. EXECUTIVE SUMMARY: CRITERIA FOR CRITICAL CARE OF INFANTS AND CHILDREN: PICU ADMISSION, DISCHARGE, AND TRIAGE PRACTICE STATEMENT AND LEVELS OF CARE GUIDANCE

Benson S. Hsu, MD, MBA, FAAP; Vanessa Hill, MD, FAAP; Lorry R. Frankel, MD, FCCM; Timothy S. Yeh, MD, MCCM; Shari Simone, CRNP, DNP, FCCM, FAANP, FAAN; Marjorie J. Arca, MD, FACS, FAAP; Jorge A. Coss-Bu, MD; Mary E. Fallat, MD, FACS, FAAP; Jason Foland, MD; Samir Gadepalli, MD, MBA; Michael O. Gayle, BS, MD, FCCM; Lori A. Harmon, RRT, MBA, CPHQ; Christa A. Joseph, RN, MSN; Aaron D. Kessel, BS, MD; Niranjan Kissoon, MD, MCCM; Michele Moss, MD, FCCM; Mohan R. Mysore, MD, FAAP, FCCM; Michele C. Papo, MD, MPH, FCCM; Kari L. Rajzer-Wakeham, CCRN, MSN, PCCNP, RN; Tom B. Rice, MD; David L. Rosenberg, MD, FAAP, FCCM;

Martin K. Wakeham, MD; Edward E. Conway, Jr, MD, FCCM, MS; Michael S.D. Agus, MD, FAAP, FCCM

ABSTRACT. This is an executive summary of the 2019 update of the 2004 guidelines and levels of care for PICU. Since previous guidelines, there has been a tremendous transformation of Pediatric Critical Care Medicine with advancements in pediatric cardiovascular medicine, transplant, neurology, trauma, and oncology as well as improvements of care in general PICUs. This has led to the evolution of resources and training in the provision of care through the PICU. Outcome and quality research related to admission, transfer, and discharge criteria as well as literature regarding PICU levels of care to include volume, staffing, and structure were reviewed and included in this statement as appropriate. Consequently, the purposes of this significant update are to address the transformation of the field and codify a revised set of guidelines that will enable hospitals, institutions, and individuals in developing the appropriate PICU for their community needs. The target audiences of the practice statement and guidance are broad and include critical care professionals; pediatricians; pediatric subspecialists; pediatric surgeons; pediatric surgical subspecialists; pediatric imaging physicians; and other members of the patient care team such as nurses, therapists, dieticians, pharmacists, social workers, care coordinators, and hospital administrators who make daily administrative and clinical decisions in all PICU levels of care. EXECUTIVE SUMMARY: IDENTIFICATION, EVALUATION, AND MANAGEMENT OF CHILDREN WITH AUTISM SPECTRUM DISORDER (CLINICAL REPORT)

Susan L. Hyman, MD, FAAP; Susan E. Levy, MD, MPH, FAAP; Scott M. Myers, MD, FAAP; Council on Children With Disabilities; and Section on Developmental and Behavioral Pediatrics

ABSTRACT. Autism spectrum disorder (ASD) is a common neurodevelopmental disorder with reported prevalence in the United States of 1 in 59 children (approximately 1.7%). ASD significantly influences the lives of affected children and families because they may need extensive behavioral, educational, health, and other services. Primary care providers play a critical role in identifying, diagnosing, and managing ASD in children and providing support for their families. This document provides a summary of the clinical report "Identification, Evaluation, and Management of Children with Autism Spectrum Disorder," published concurrently in the online version of *Pediatrics*. In the years since 2007, when the American Academy of Pediatrics published the clinical reports "Identification and Diagnosis of Children with Autism Spectrum Disorders" and "Management of Children with Autism Spectrum Disorders," reported prevalence rates of children with ASD have increased, understanding of potential risk factors has expanded, awareness of co-occurring medical and behavioral conditions and genetic contribution to etiology has improved, and the body of research supporting evidence-based interventions has grown substantially. The updated document discusses evaluation and treatment as a continuum in 1 publication with a table of contents to help the reader identify topic areas within the report. ASD is more commonly diagnosed than in the past, and the significant health, educational, and social needs of individuals with ASD and their families constitute an area of critical need for resources, research, and professional education. (12/19)

EXPERT WITNESS PARTICIPATION IN CIVIL AND CRIMINAL PROCEEDINGS

Stephan R. Paul, MD, JD, FAAP; Sandeep K. Narang, MD, JD, FAAP; and Committee on Medical Liability and Risk Management

ABSTRACT. The interests of the public and both the medical and legal professions are best served when scientifically sound and unbiased expert witness testimony is readily available in civil and criminal proceedings. As members of the medical community, patient advocates, and private citizens, pediatricians have ethical and professional obligations to assist in the civil and criminal judicial processes. This policy statement offers recommendations on advocacy, education, research, qualifications, standards, and ethical business practices all aimed at improving expert testimony. (2/17)

EXPERT WITNESS PARTICIPATION IN CIVIL AND CRIMINAL PROCEEDINGS (TECHNICAL REPORT)

Sandeep K. Narang, MD, JD, FAAP; Stephan R. Paul, MD, JD, FAAP; and Committee on Medical Liability and Risk Management

ABSTRACT. The interests of the public and both the medical and legal professions are best served when scientifically sound and unbiased expert witness testimony is readily available in civil and criminal proceedings. As members of the medical community, patient advocates, and private citizens, pediatricians have ethical and professional obligations to assist in the civil and criminal judicial processes. This technical report explains how the role of the expert witness differs in civil and criminal proceedings, legal and ethical standards for expert witnesses, and strategies that have been employed to deter unscientific and irresponsible testimony. A companion policy statement offers recommendations on advocacy, education, research, qualifications, standards, and ethical business practices all aimed at improving expert testimony. (2/17)

EXPOSURE TO NONTRADITIONAL PETS AT HOME AND TO ANIMALS IN PUBLIC SETTINGS: RISKS TO CHILDREN (CLINICAL REPORT)

Larry K. Pickering, MD; Nina Marano, DVM, MPH; Joseph A. Bocchini, MD; Frederick J. Angulo, DVM, PhD; and Committee on Infectious Diseases

ABSTRACT. Exposure to animals can provide many benefits during the growth and development of children. However, there are potential risks associated with animal exposures, including exposure to nontraditional pets in the home and animals in public settings. Educational materials, regulations, and guidelines have been developed to minimize these risks. Pediatricians, veterinarians, and other health care professionals can provide advice on selection of appropriate pets as well as prevention of disease transmission from nontraditional pets and when children contact animals in public settings. THE EYE EXAMINATION IN THE EVALUATION OF CHILD ABUSE (CLINICAL REPORT)

Cindy W. Christian, MD, FAAP; Alex V. Levin, MD, MHSc, FAAO, FRCSC, FAAP; Council on Child Abuse and Neglect; and Section on Ophthalmology (joint with American Association of Certified Orthoptists, American Association for Pediatric Ophthalmology and Strabismus, and American Academy of Ophthalmology)

ABSTRACT. Child abuse can cause injury to any part of the eye. The most common manifestations are retinal hemorrhages (RHs) in infants and young children with abusive head trauma (AHT). Although RHs are an important indicator of possible AHT, they

are also found in other conditions. Distinguishing the number, type, location, and pattern of RHs is important in evaluating a differential diagnosis. Eye trauma can be seen in cases of physical abuse or AHT and may prompt referral for ophthalmologic assessment. Physicians have a responsibility to consider abuse in the differential diagnosis of pediatric eye trauma. Identification and documentation of inflicted ocular trauma requires a thorough examination by an ophthalmologist, including indirect ophthalmoscopy, most optimally through a dilated pupil, especially for the evaluation of possible RHs. An eye examination is helpful in detecting abnormalities that can help identify a medical or traumatic etiology for previously well young children who experience unexpected and unexplained mental status changes with no obvious cause, children with head trauma that results in significant intracranial hemorrhage and brain injury, and children with unexplained death. FACILITIES AND EQUIPMENT FOR THE CARE OF PEDIATRIC PATIENTS IN A COMMUNITY HOSPITAL (CLINICAL REPORT)

Committee on Hospital Care

ABSTRACT. Many children who require hospitalization are admitted to community hospitals that are more accessible for families and their primary care physicians but vary substantially in their pediatric resources. The intent of this clinical report is to provide basic guidelines for furnishing and equipping a pediatric area in a community hospital. (5/03, reaffirmed 5/07, 8/13, 1/17)

FALLS FROM HEIGHTS: WINDOWS, ROOFS, AND BALCONIES

Committee on Injury and Poison Prevention

ABSTRACT. Falls of all kinds represent an important cause of child injury and death. In the United States, approximately 140 deaths from falls occur annually in children younger than 15 years. Three million children require emergency department care for fall-related injuries. This policy statement examines the epidemiology of falls from heights and recommends preventive strategies for pediatricians and other child health care professionals. Such strategies involve parent counseling, community programs, building code changes, legislation, and environmental modification, such as the installation of window guards and balcony railings. (5/01, reaffirmed 10/04, 5/07, 6/10)

FAMILIES AFFECTED BY PARENTAL SUBSTANCE USE (CLINICAL REPORT)

Vincent C. Smith, MD, MPH, FAAP; Celeste R. Wilson, MD, FAAP; and Committee on Substance Use and Prevention

ABSTRACT. Children whose parents or caregivers use drugs or alcohol are at increased risk of short- and long-term sequelae ranging from medical problems to psychosocial and behavioral challenges. In the course of providing health care services to children, pediatricians are likely to encounter families affected by parental substance use and are in a unique position to intervene. Therefore, pediatricians need to know how to assess a child's risk in the context of a parent's substance use. The purposes of this clinical report are to review some of the short-term effects of maternal substance use during pregnancy and long-term implications of fetal exposure; describe typical medical, psychiatric, and behavioral symptoms of children and adolescents in families affected by substance use; and suggest proficiencies for pediatricians involved in the care of children and adolescents of families affected by substance use, including screening families, mandated reporting requirements, and directing families to community, regional, and state resources that can address needs and problems. FATHERS' ROLES IN THE CARE AND DEVELOPMENT OF THEIR CHILDREN: THE ROLE OF PEDIATRICIANS (CLINICAL REPORT)

Michael Yogman, MD, FAAP; Craig F. Garfield, MD, FAAP; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Fathers' involvement in and influence on the health and development of their children have increased in a myriad of ways in the past 10 years and have been widely studied. The role of pediatricians in working with fathers has correspondingly increased in importance. This report reviews new studies of the epidemiology of father involvement, including nonresidential as well as residential fathers. The effects of father involvement on child outcomes are discussed within each phase of a child's development. Particular emphasis is placed on (1) fathers' involvement across childhood ages and (2) the influence of fathers' physical and mental health on their children. Implications and advice for all child health providers to encourage and support father involvement are outlined. (6/16)

THE FEMALE ATHLETE TRIAD (CLINICAL REPORT)

Amanda K. Weiss Kelly, MD, FAAP; Suzanne Hecht, MD, FACSM; and Council on Sports Medicine and Fitness

ABSTRACT. The number of girls participating in sports has increased significantly since the introduction of Title XI in 1972. As a result, more girls have been able to experience the social, educational, and health-related benefits of sports participation. However, there are risks associated with sports participation, including the female athlete triad. The triad was originally recognized as the interrelationship of amenorrhea, osteoporosis, and disordered eating, but our understanding has evolved to recognize that each of the components of the triad exists on a spectrum from optimal health to disease. The triad occurs when energy intake does not adequately compensate for exercise-related energy expenditure, leading to adverse effects on reproductive, bone, and cardiovascular health. Athletes can present with a single component or any combination of the components. The triad can have a more significant effect on the health of adolescent athletes than on adults because adolescence is a critical time for bone mass accumulation. This report outlines the current state of knowledge on the epidemiology, diagnosis, and treatment of the triad conditions. (7/16)

FERTILITY PRESERVATION FOR PEDIATRIC AND ADOLESCENT PATIENTS WITH CANCER: MEDICAL AND ETHICAL CONSIDERATIONS (CLINICAL REPORT)

Sigal Klipstein, MD, FACOG; Mary E. Fallat, MD, FAAP; Stephanie Savelli, MD, FAAP; Committee on Bioethics; Section on Hematology/Oncology; and Section on Surgery

ABSTRACT. Many cancers presenting in children and adolescents are curable with surgery, chemotherapy, and/or radiotherapy. Potential adverse consequences of treatment include sterility, infertility, or subfertility as a result of gonad removal, damage to germ cells as a result of adjuvant therapy, or damage to the pituitary and hypothalamus or uterus as a result of irradiation. In recent years, treatment of solid tumors and hematologic malignancies has been modified in an attempt to reduce damage to the gonadal axis. Simultaneously, advances in assisted reproductive technology have led to new possibilities for the prevention and treatment of infertility. This clinical report reviews the medical aspects and ethical considerations that arise when

considering fertility preservation in pediatric and adolescent patients with cancer. (2/20)

FETAL ALCOHOL SPECTRUM DISORDERS (CLINICAL REPORT)

Janet F. Williams, MD, FAAP; Vincent C. Smith, MD, MPH, FAAP; and Committee on Substance Abuse

ABSTRACT. Prenatal exposure to alcohol can damage the developing fetus and is the leading preventable cause of birth defects and intellectual and neurodevelopmental disabilities. In 1973, fetal alcohol syndrome was first described as a specific cluster of birth defects resulting from alcohol exposure in utero. Subsequently, research unequivocally revealed that prenatal alcohol exposure causes a broad range of adverse developmental effects. Fetal alcohol spectrum disorder (FASD) is the general term that encompasses the range of adverse effects associated with prenatal alcohol exposure. The diagnostic criteria for fetal alcohol syndrome are specific, and comprehensive efforts are ongoing to establish definitive criteria for diagnosing the other FASDs. A large and growing body of research has led to evidence-based FASD education of professionals and the public, broader prevention initiatives, and recommended treatment approaches based on the following premises:

- Alcohol-related birth defects and developmental disabilities are completely preventable when pregnant women abstain from alcohol use.
- Neurocognitive and behavioral problems resulting from prenatal alcohol exposure are lifelong.
- Early recognition, diagnosis, and therapy for any condition along the FASD continuum can result in improved outcomes.
- During pregnancy:
  - — no amount of alcohol intake should be considered safe;
  - — there is no safe trimester to drink alcohol;
  - — all forms of alcohol, such as beer, wine, and liquor, pose similar risk; and
  - — binge drinking poses dose-related risk to the developing fetus. (10/15)

FEVER AND ANTIPYRETIC USE IN CHILDREN (CLINICAL REPORT)

Janice E. Sullivan, MD; Henry C. Farrar, MD; Section on Clinical Pharmacology and Therapeutics; and Committee on Drugs

ABSTRACT. Fever in a child is one of the most common clinical symptoms managed by pediatricians and other health care providers and a frequent cause of parental concern. Many parents administer antipyretics even when there is minimal or no fever, because they are concerned that the child must maintain a "normal" temperature. Fever, however, is not the primary illness but is a physiologic mechanism that has beneficial effects in fighting infection. There is no evidence that fever itself worsens the course of an illness or that it causes long-term neurologic complications. Thus, the primary goal of treating the febrile child should be to improve the child's overall comfort rather than focus on the normalization of body temperature. When counseling the parents or caregivers of a febrile child, the general well-being of the child, the importance of monitoring activity, observing for signs of serious illness, encouraging appropriate fluid intake, and the safe storage of antipyretics should be emphasized. Current evidence suggests that there is no substantial difference in the safety and effectiveness of acetaminophen and ibuprofen in the care of a generally healthy child with fever. There is evidence that combining these 2 products is more effective than the use of a single agent alone; however, there are concerns that combined treatment may be more complicated and contribute to the unsafe use of these drugs. Pediatricians should also promote patient safety by advocating for simplified formulations, dosing instructions, and dosing devices. (2/11, reaffirmed 7/16)

FINANCING GRADUATE MEDICAL EDUCATION TO MEET THE NEEDS OF CHILDREN AND THE FUTURE PEDIATRICIAN WORKFORCE

Committee on Pediatric Workforce

ABSTRACT. The American Academy of Pediatrics (AAP) believes that an appropriately financed graduate medical education (GME) system is critical to ensuring that sufficient numbers of trained pediatricians are available to provide optimal health care to all children. A shortage of pediatric medical subspecialists and pediatric surgical specialists currently exists in the United States, and this shortage is likely to intensify because of the growing numbers of children with chronic health problems and special health care needs. It is equally important to maintain the supply of primary care pediatricians. The AAP, therefore, recommends that children's hospital GME positions funded by the Health Resources and Services Administration be increased to address this escalating demand for pediatric health services. The AAP also recommends that GME funding for pediatric physician training provide full financial support for all years of training necessary to meet program requirements. In addition, all other entities that gain from GME training should participate in its funding in a manner that does not influence curriculum, requirements, or outcomes. Furthermore, the AAP supports funding for training innovations that improve the health of children. Finally, the AAP recommends that all institutional recipients of GME funding allocate these funds directly to the settings where training occurs in a transparent manner. (3/16)

FINANCING OF PEDIATRIC HOME HEALTH CARE

Edwin Simpser, MD, FAAP; Mark L. Hudak, MD, FAAP; Section on Home Care; and Committee on Child Health Financing

ABSTRACT. Pediatric home health care is an effective and holistic venue of treatment of children with medical complexity or developmental disabilities who otherwise may experience frequent and/or prolonged hospitalizations or who may enter chronic institutional care. Demand for pediatric home health care is increasing while the provider base is eroding, primarily because of inadequate payment or restrictions on benefits. As a result, home care responsibilities assumed by family caregivers have increased and imposed financial, physical, and psychological burdens on the family. The Patient Protection and Affordable Care Act set forth 10 mandated essential health benefits. Home care should be considered as an integral component of the habilitative and rehabilitative services and devices benefit, even though it is not explicitly recognized as a specific category of service. Pediatric-specific home health care services should be defined clearly as components of pediatric services, the 10th essential benefit, and recognized by all payers. Payments for home health care services should be sufficient to maintain an adequate provider work force with the pediatric-specific expertise and skills to care for children with medical complexity or developmental disability. Furthermore, coordination of care among various providers and the necessary direct patient care from which these care coordination plans are developed should be required and enabled by adequate payment. The American Academy of Pediatrics advocates for high-quality care by calling for development of pediatric-specific home health regulations and the licensure and certification of pediatric home health providers. (2/17)

FIREARM-RELATED INJURIES AFFECTING THE PEDIATRIC POPULATION

Council on Injury, Violence, and Poison Prevention Executive Committee

ABSTRACT. The absence of guns from children's homes and communities is the most reliable and effective measure to prevent firearm-related injuries in children and adolescents. Adolescent suicide risk is strongly associated with firearm availability. Safe gun storage (guns unloaded and locked, ammunition locked separately) reduces children's risk of injury. Physician counseling of parents about firearm safety appears to be effective, but firearm safety education programs directed at children are ineffective. The American Academy of Pediatrics continues to support a number of specific measures to reduce the destructive effects of guns in the lives of children and adolescents, including the regulation of the manufacture, sale, purchase, ownership, and use of firearms; a ban on semiautomatic assault weapons; and the strongest possible regulations of handguns for civilian use. (10/12, reaffirmed 12/16)

http://pediatrics.aappublications.org/content/130/5/e1416

FIREWORKS-RELATED INJURIES TO CHILDREN

Committee on Injury and Poison Prevention

ABSTRACT. An estimated 8500 individuals, approximately 45% of them children younger than 15 years, were treated in US hospital emergency departments during 1999 for fireworks-related injuries. The hands (40%), eyes (20%), and head and face (20%) are the body areas most often involved. Approximately one third of eye injuries from fireworks result in permanent blindness. During 1999, 16 people died as a result of injuries associated with fireworks. Every type of legally available consumer (so-called "safe and sane") firework has been associated with serious injury or death. In 1997, 20,100 fires were caused by fireworks, resulting in $22.7 million in direct property damage. Fireworks typically cause more fires in the United States on the Fourth of July than all other causes of fire combined on that day. Pediatricians should educate parents, children, community leaders, and others about the dangers of fireworks. Fireworks for individual private use should be banned. Children and their families should be encouraged to enjoy fireworks at public fireworks displays conducted by professionals rather than purchase fireworks for home or private use. (7/01, reaffirmed 1/05, 2/08, 10/11, 11/14)

http://pediatrics.aappublications.org/content/108/1/190

FISH, SHELLFISH, AND CHILDREN'S HEALTH: AN ASSESSMENT OF BENEFITS, RISKS, AND SUSTAINABILITY (TECHNICAL REPORT)

Aaron S. Bernstein, MD, MPH, FAAP; Emily Oken, MD, MPH; Sarah de Ferranti, MD, MPH, FAAP; Council on Environmental Health; and Committee on Nutrition

ABSTRACT. American children eat relatively little fish and shellfish in comparison with other sources of animal protein, despite the health benefits that eating fish and shellfish may confer. At the same time, fish and shellfish may be sources of toxicants. This report serves to inform pediatricians about available research that elucidates health risks and benefits associated with fish and shellfish consumption in childhood as well as the sustainability of fish and shellfish harvests. (5/19)

FLUORIDE USE IN CARIES PREVENTION IN THE PRIMARY CARE SETTING (CLINICAL REPORT)

Melinda B. Clark, MD, FAAP; Martha Ann Keels, DDS, PhD; Rebecca L. Slayton, DDS, PhD; and Section on Oral Health

ABSTRACT. Dental caries remains the most common chronic disease of childhood in the United States. Caries is a largely preventable condition, and fluoride has proven effectiveness in caries prevention. This clinical report aims to clarify the use of available fluoride modalities for caries prevention in the primary care setting and to assist pediatricians in using fluoride to achieve maximum protection against dental caries, while minimizing the likelihood of enamel fluorosis. Fluoride varnish application is now considered the standard of care in pediatric primary care. This report highlights administration, billing, and payment information regarding the fluoride varnish procedure. (11/20)

FOLIC ACID FOR THE PREVENTION OF NEURAL TUBE DEFECTS

Committee on Genetics

ABSTRACT. The American Academy of Pediatrics endorses the US Public Health Service (USPHS) recommendation that all women capable of becoming pregnant consume 400 μg of folic acid daily to prevent neural tube defects (NTDs). Studies have demonstrated that periconceptional folic acid supplementation can prevent 50% or more of NTDs such as spina bifida and anencephaly. For women who have previously had an NTD-affected pregnancy, the Centers for Disease Control and Prevention (CDC) recommends increasing the intake of folic acid to 4000 μg per day beginning at least 1 month before conception and continuing through the first trimester. Implementation of these recommendations is essential for the primary prevention of these serious and disabling birth defects. Because fewer than 1 in 3 women consume the amount of folic acid recommended by the USPHS, the Academy notes that the prevention of NTDs depends on an urgent and effective campaign to close this prevention gap. FOLLOW-UP MANAGEMENT OF CHILDREN WITH TYMPANOSTOMY TUBES

Section on Otolaryngology and Bronchoesophagology

ABSTRACT. The follow-up care of children in whom tympanostomy tubes have been placed is shared by the pediatrician and the otolaryngologist. Guidelines are provided for routine follow-up evaluation, perioperative hearing assessment, and the identification of specific conditions and complications that warrant urgent otolaryngologic consultation. These guidelines have been developed by a consensus of expert opinions. (2/02)

FOOD ADDITIVES AND CHILD HEALTH

Leonardo Trasande, MD, MPP, FAAP; Rachel M. Shaffer, MPH; Sheela Sathyanarayana, MD, MPH; and Council on Environmental Health

ABSTRACT. Our purposes with this policy statement and its accompanying technical report are to review and highlight emerging child health concerns related to the use of colorings, flavorings, and chemicals deliberately added to food during processing (direct food additives) as well as substances in food contact materials, including adhesives, dyes, coatings, paper, paperboard, plastic, and other polymers, which may contaminate food as part of packaging or manufacturing equipment (indirect food additives); to make reasonable recommendations that the pediatrician might be able to adopt into the guidance provided during pediatric visits; and to propose urgently needed reforms to the current regulatory process at the US Food and Drug Administration (FDA) for food additives. Concern regarding food additives has increased in the past 2 decades, in part because of studies in which authors document endocrine disruption and other adverse health effects. In some cases, exposure to these chemicals is disproportionate among minority and

low-income populations. Regulation and oversight of many food additives is inadequate because of several key problems in the Federal Food, Drug, and Cosmetic Act. Current requirements for a "generally recognized as safe" (GRAS) designation are insufficient to ensure the safety of food additives and do not contain sufficient protections against conflict of interest. Additionally, the FDA does not have adequate authority to acquire data on chemicals on the market or reassess their safety for human health. These are critical weaknesses in the current regulatory system for food additives. Data about health effects of food additives on infants and children are limited or missing; however, in general, infants and children are more vulnerable to chemical exposures. Substantial improvements to the food additives regulatory system are urgently needed, including greatly strengthening or replacing the "generally recognized as safe" (GRAS) determination process, updating the scientific foundation of the FDA's safety assessment program, retesting all previously approved chemicals, and labeling direct additives with limited or no toxicity data. (7/18)

http://pediatrics.aappublications.org/content/142/2/e20181408

FOOD ADDITIVES AND CHILD HEALTH (TECHNICAL REPORT)

Leonardo Trasande, MD, MPP, FAAP; Rachel M. Shaffer, MPH; Sheela Sathyanarayana, MD, MPH; and Council on Environmental Health

ABSTRACT. Increasing scientific evidence suggests potential adverse effects on children's health from synthetic chemicals used as food additives, both those deliberately added to food during processing (direct) and those used in materials that may contaminate food as part of packaging or manufacturing (indirect). Concern regarding food additives has increased in the past 2 decades in part because of studies that increasingly document endocrine disruption and other adverse health effects. In some cases, exposure to these chemicals is disproportionate among minority and low-income populations. This report focuses on those food additives with the strongest scientific evidence for concern. Further research is needed to study effects of exposure over various points in the life course, and toxicity testing must be advanced to be able to better identify health concerns prior to widespread population exposure. The accompanying policy statement describes approaches policy makers and pediatricians can take to prevent the disease and disability that are increasingly being identified in relation to chemicals used as food additives, among other uses. (7/18)

FORGOING MEDICALLY PROVIDED NUTRITION AND HYDRATION IN CHILDREN (CLINICAL REPORT)

Douglas S. Diekema, MD, MPH; Jeffrey R. Botkin, MD, MPH; and Committee on Bioethics

ABSTRACT. There is broad consensus that withholding or withdrawing medical interventions is morally permissible when requested by competent patients or, in the case of patients without decision-making capacity, when the interventions no longer confer a benefit to the patient or when the burdens associated with the interventions outweigh the benefits received. The withdrawal or withholding of measures such as attempted resuscitation, ventilators, and critical care medications is common in the terminal care of adults and children. In the case of adults, a consensus has emerged in law and ethics that the medical administration of fluid and nutrition is not fundamentally different from other medical interventions such as use of ventilators; therefore, it can be forgone or withdrawn when a competent adult or legally authorized surrogate requests withdrawal or when the intervention no longer provides a net benefit to the patient. In pediatrics, forgoing or withdrawing medically administered fluids and nutrition has been more controversial because of the inability of children to make autonomous decisions and the emotional power of feeding as a basic element of the care of children. This statement reviews the medical, ethical, and legal issues relevant to the withholding or withdrawing of medically provided fluids and nutrition in children. The American Academy of Pediatrics concludes that the withdrawal of medically administered fluids and nutrition for pediatric patients is ethically acceptable in limited circumstances. Ethics consultation is strongly recommended when particularly difficult or controversial decisions are being considered. (7/09, reaffirmed 1/14)

http://pediatrics.aappublications.org/content/124/2/813

FRUIT JUICE IN INFANTS, CHILDREN, AND ADOLESCENTS: CURRENT RECOMMENDATIONS

Melvin B. Heyman, MD, FAAP; Steven A. Abrams, MD, FAAP; Section on Gastroenterology, Hepatology, and Nutrition; and Committee on Nutrition

ABSTRACT. Historically, fruit juice was recommended by pediatricians as a source of vitamin C and as an extra source of water for healthy infants and young children as their diets expanded to include solid foods with higher renal solute load. It was also sometimes recommended for children with constipation. Fruit juice is marketed as a healthy, natural source of vitamins and, in some instances, calcium. Because juice tastes good, children readily accept it. Although juice consumption has some benefits, it also has potential detrimental effects. High sugar content in juice contributes to increased calorie consumption and the risk of dental caries. In addition, the lack of protein and fiber in juice can predispose to inappropriate weight gain (too much or too little). Pediatricians need to be knowledgeable about juice to inform parents and patients on its appropriate uses. (5/17)

GASTROESOPHAGEAL REFLUX: MANAGEMENT GUIDANCE FOR THE PEDIATRICIAN (CLINICAL REPORT)

Jenifer R. Lightdale, MD, MPH; David A. Gremse, MD; and Section on Gastroenterology, Hepatology, and Nutrition

ABSTRACT. Recent comprehensive guidelines developed by the North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition define the common entities of gastroesophageal reflux (GER) as the physiologic passage of gastric contents into the esophagus and gastroesophageal reflux disease (GERD) as reflux associated with troublesome symptoms or complications. The ability to distinguish between GER and GERD is increasingly important to implement best practices in the management of acid reflux in patients across all pediatric age groups, as children with GERD may benefit from further evaluation and treatment, whereas conservative recommendations are the only indicated therapy in those with uncomplicated physiologic reflux. This clinical report endorses the rigorously developed, well-referenced North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition guidelines and likewise emphasizes important concepts for the general pediatrician. A key issue is distinguishing between clinical manifestations of GER and GERD in term infants, children, and adolescents to identify patients who can be managed with conservative treatment by the pediatrician and to refer patients who require consultation with the gastroenterologist. Accordingly, the evidence basis presented by the guidelines for diagnostic approaches as well as treatments is discussed. Lifestyle changes are emphasized as first-line therapy in both GER and GERD, whereas medications are explicitly indicated only for patients with GERD. Surgical therapies are reserved for children with intractable symptoms or who are at risk for life-threatening complications of GERD. Recent black box warnings from the US Food and Drug Administration are discussed, and caution is underlined when using promoters of gastric emptying and

motility. Finally, attention is paid to increasing evidence of inappropriate prescriptions for proton pump inhibitors in the pediatric population. (4/13)

GLOBAL CLIMATE CHANGE AND CHILDREN'S HEALTH

Council on Environmental Health
ABSTRACT. Rising global temperatures are causing major physical, chemical, and ecological changes in the planet. There is wide consensus among scientific organizations and climatologists that these broad effects, known as "climate change," are the result of contemporary human activity. Climate change poses threats to human health, safety, and security, and children are uniquely vulnerable to these threats. The effects of climate change on child health include: physical and psychological sequelae of weather disasters; increased heat stress; decreased air quality; altered disease patterns of some climate-sensitive infections; and food, water, and nutrient insecurity in vulnerable regions. The social foundations of children's mental and physical health are threatened by the specter of far-reaching effects of unchecked climate change, including community and global instability, mass migrations, and increased conflict. Given this knowledge, failure to take prompt, substantive action would be an act of injustice to all children. A paradigm shift in production and consumption of energy is both a necessity and an opportunity for major innovation, job creation, and significant, immediate associated health benefits. Pediatricians have a uniquely valuable role to play in the societal response to this global challenge. (10/15)
http://pediatrics.aappublications.org/content/136/5/992

GLOBAL CLIMATE CHANGE AND CHILDREN'S HEALTH (TECHNICAL REPORT)

Samantha Ahdoot, MD, FAAP; Susan E. Pacheco, MD, FAAP; and Council on Environmental Health
ABSTRACT. Rising global temperature is causing major physical, chemical, and ecological changes across the planet. There is wide consensus among scientific organizations and climatologists that these broad effects, known as climate change, are the result of contemporary human activity. Climate change poses threats to human health, safety, and security. Children are uniquely vulnerable to these threats. The effects of climate change on child health include physical and psychological sequelae of weather disasters, increased heat stress, decreased air quality, altered disease patterns of some climate-sensitive infections, and food, water, and nutrient insecurity in vulnerable regions. Prompt implementation of mitigation and adaptation strategies will protect children against worsening of the problem and its associated health effects. This technical report reviews the nature of climate change and its associated child health effects and supports the recommendations in the accompanying policy statement on climate change and children's health. (10/15)

GLOBAL HUMAN TRAFFICKING AND CHILD VICTIMIZATION

Jordan Greenbaum, MD; Nia Bodrick, MD, MPH, FAAP; Committee on Child Abuse and Neglect; and Section on International Child Health
ABSTRACT. Trafficking of children for labor and sexual exploitation violates basic human rights and constitutes a major global public health problem. Pediatricians and other health care professionals may encounter victims who present with infections, injuries, posttraumatic stress disorder, suicidality, or a variety of other physical or behavioral health conditions. Preventing child trafficking, recognizing victimization, and intervening appropriately require a public health approach that incorporates rigorous research on the risk factors, health impact, and effective treatment options for child exploitation as well as implementation and evaluation of primary prevention programs. Health care professionals need training to recognize possible signs of exploitation and to intervene appropriately. They need to adopt a multidisciplinary, outward-focused approach to service provision, working with nonmedical professionals in the community to assist victims. Pediatricians also need to advocate for legislation and policies that promote child rights and victim services as well as those that address the social determinants of health, which influence the vulnerability to human trafficking. This policy statement outlines major issues regarding public policy, medical education, research, and collaboration in the area of child labor and sex trafficking and provides recommendations for future work. (11/17)

GUIDANCE FOR THE ADMINISTRATION OF MEDICATION IN SCHOOL

Council on School Health
ABSTRACT. Many children who take medications require them during the school day. This policy statement is designed to guide prescribing health care professionals, school physicians, and school health councils on the administration of medications to children at school. All districts and schools need to have policies and plans in place for safe, effective, and efficient administration of medications at school. Having full-time licensed registered nurses administering all routine and emergency medications in schools is the best situation. When a licensed registered nurse is not available, a licensed practical nurse may administer medications. When a nurse cannot administer medication in school, the American Academy of Pediatrics supports appropriate delegation of nursing services in the school setting. Delegation is a tool that may be used by the licensed registered school nurse to allow unlicensed assistive personnel to provide standardized, routine health services under the supervision of the nurse and on the basis of physician guidance and school nursing assessment of the unique needs of the individual child and the suitability of delegation of specific nursing tasks. Any delegation of nursing duties must be consistent with the requirements of state nurse practice acts, state regulations, and guidelines provided by professional nursing organizations. Long-term, emergency, and short-term medications; over-the-counter medications; alternative medications; and experimental drugs that are administered as part of a clinical trial are discussed in this statement. This statement has been endorsed by the American School Health Association. (9/09, reaffirmed 2/13)

GUIDANCE ON COMPLETING A WRITTEN ALLERGY AND ANAPHYLAXIS EMERGENCY PLAN (CLINICAL REPORT)

Julie Wang, MD, FAAP; Scott H. Sicherer, MD, FAAP; and Section on Allergy and Immunology
ABSTRACT. Anaphylaxis is a potentially life-threatening, severe allergic reaction. The immediate assessment of patients having an allergic reaction and prompt administration of epinephrine, if criteria for anaphylaxis are met, promote optimal outcomes. National and international guidelines for the management of anaphylaxis, including those for management of allergic reactions at school, as well as several clinical reports from the American Academy of Pediatrics, recommend the provision of written emergency action plans to those at risk of anaphylaxis, in addition to the prescription of epinephrine autoinjectors. This clinical report provides information to help health care providers understand the role of a written, personalized allergy and

anaphylaxis emergency plan to enhance the care of children at risk of allergic reactions, including anaphylaxis. This report offers a comprehensive written plan, with advice on individualizing instructions to suit specific patient circumstances. (2/17)
http://pediatrics.aappublications.org/content/139/3/e20164005

GUIDANCE ON FORGOING LIFE-SUSTAINING MEDICAL TREATMENT

Kathryn L. Weise, MD, MA, FAAP; Alexander L. Okun, MD, FAAP; Brian S. Carter, MD, FAAP; Cindy W. Christian, MD, FAAP; Committee on Bioethics; Section on Hospice and Palliative Medicine; and Committee on Child Abuse and Neglect

ABSTRACT. Pediatric health care is practiced with the goal of promoting the best interests of the child. Treatment generally is rendered under a presumption in favor of sustaining life. However, in some circumstances, the balance of benefits and burdens to the child leads to an assessment that forgoing life-sustaining medical treatment (LSMT) is ethically supportable or advisable. Parents are given wide latitude in decision-making concerning end-of-life care for their children in most situations. Collaborative decision-making around LSMT is improved by thorough communication among all stakeholders, including medical staff, the family, and the patient, when possible, throughout the evolving course of the patient's illness. Clear communication of overall goals of care is advised to promote agreed-on plans, including resuscitation status. Perceived disagreement among the team of professionals may be stressful to families. At the same time, understanding the range of professional opinions behind treatment recommendations is critical to informing family decision-making. Input from specialists in palliative care, ethics, pastoral care, and other disciplines enhances support for families and medical staff when decisions to forgo LSMT are being considered. Understanding specific applicability of institutional, regional, state, and national regulations related to forgoing LSMT is important to practice ethically within existing legal frameworks. This guidance represents an update of the 1994 statement from the American Academy of Pediatrics on forgoing LSMT. (8/17)

GUIDANCE ON MANAGEMENT OF ASYMPTOMATIC NEONATES BORN TO WOMEN WITH ACTIVE GENITAL HERPES LESIONS (CLINICAL REPORT)

Committee on Infectious Diseases and Committee on Fetus and Newborn

ABSTRACT. Herpes simplex virus (HSV) infection of the neonate is uncommon, but genital herpes infections in adults are very common. Thus, although treating an infant with neonatal herpes is a relatively rare occurrence, managing infants potentially exposed to HSV at the time of delivery occurs more frequently. The risk of transmitting HSV to an infant during delivery is determined in part by the mother's previous immunity to HSV. Women with primary genital HSV infections who are shedding HSV at delivery are 10 to 30 times more likely to transmit the virus to their newborn infants than are women with recurrent HSV infection who are shedding virus at delivery. With the availability of commercial serological tests that reliably can distinguish type-specific HSV antibodies, it is now possible to determine the type of maternal infection and, thus, further refine management of infants delivered to women who have active genital HSV lesions. The management algorithm presented herein uses both serological and virological studies to determine the risk of HSV transmission to the neonate who is delivered to a mother with active herpetic genital lesions and tailors management accordingly. The algorithm does not address the approach to asymptomatic neonates delivered to women with a history of genital herpes but no active lesions at delivery. (1/13, reaffirmed 9/16)

GUIDELINES FOR DEVELOPING ADMISSION AND DISCHARGE POLICIES FOR THE PEDIATRIC INTENSIVE CARE UNIT (CLINICAL REPORT)

Committee on Hospital Care and Section on Critical Care (joint with Society of Critical Care Medicine Pediatric Section Admission Criteria Task Force)

ABSTRACT. These guidelines were developed to provide a reference for preparing policies on admission to and discharge from pediatric intensive care units. They represent a consensus opinion of physicians, nurses, and allied health care professionals. By using this document as a framework for developing multidisciplinary admission and discharge policies, use of pediatric intensive care units can be optimized and patients can receive the level of care appropriate for their condition. (4/99, reaffirmed 5/17)
http://pediatrics.aappublications.org/content/103/4/840

GUIDELINES FOR MONITORING AND MANAGEMENT OF PEDIATRIC PATIENTS BEFORE, DURING, AND AFTER SEDATION FOR DIAGNOSTIC AND THERAPEUTIC PROCEDURES

Charles J. Coté, MD, FAAP; Stephen Wilson, DMD, MA, PhD; and American Academy of Pediatrics (joint with American Academy of Pediatric Dentistry)

ABSTRACT. The safe sedation of children for procedures requires a systematic approach that includes the following: no administration of sedating medication without the safety net of medical/dental supervision, careful presedation evaluation for underlying medical or surgical conditions that would place the child at increased risk from sedating medications, appropriate fasting for elective procedures and a balance between the depth of sedation and risk for those who are unable to fast because of the urgent nature of the procedure, a focused airway examination for large (kissing) tonsils or anatomic airway abnormalities that might increase the potential for airway obstruction, a clear understanding of the medication's pharmacokinetic and pharmacodynamic effects and drug interactions, appropriate training and skills in airway management to allow rescue of the patient, age- and size-appropriate equipment for airway management and venous access, appropriate medications and reversal agents, sufficient numbers of appropriately trained staff to both carry out the procedure and monitor the patient, appropriate physiologic monitoring during and after the procedure, a properly equipped and staffed recovery area, recovery to the presedation level of consciousness before discharge from medical/dental supervision, and appropriate discharge instructions. This report was developed through a collaborative effort of the American Academy of Pediatrics and the American Academy of Pediatric Dentistry to offer pediatric providers updated information and guidance in delivering safe sedation to children. GUIDELINES FOR PEDIATRIC CANCER CENTERS

Section on Hematology/Oncology

ABSTRACT. Since the American Academy of Pediatrics published guidelines for pediatric cancer centers in 1986 and 1997, significant changes in the delivery of health care have prompted a review of the role of tertiary medical centers in the care of pediatric patients. The potential effect of these changes on the treatment and survival rates of children with cancer led to this revision. The intent of this statement is to delineate personnel and facilities that are essential to provide state-of-the-art care for children and adolescents with cancer. This statement emphasizes the importance of board-certified pediatric hematologists/oncologists, pediatric subspecialty consultants, and appropriately qualified pediatric medical subspecialists and pediatric surgical specialists overseeing the care of all pediatric and adolescent cancer patients and the need for facilities

available only at a tertiary center as essential for the initial management and much of the follow-up for pediatric and adolescent cancer patients. (6/04, reaffirmed 10/08, 10/18)

GUIDELINES FOR THE DETERMINATION OF BRAIN DEATH IN INFANTS AND CHILDREN: AN UPDATE OF THE 1987 TASK FORCE RECOMMENDATIONS (CLINICAL REPORT)

Thomas A. Nakagawa, MD; Stephen Ashwal, MD; Mudit Mathur, MD; Mohan Mysore, MD; Section on Critical Care; and Section on Neurology (joint with Society of Critical Care Medicine and Child Neurology Society)

ABSTRACT. *Objective.* To review and revise the 1987 pediatric brain death guidelines.

Methods. Relevant literature was reviewed. Recommendations were developed using the GRADE system.

Conclusions and Recommendations.

1. Determination of brain death in term newborns, infants and children is a clinical diagnosis based on the absence of neurologic function with a known irreversible cause of coma. Because of insufficient data in the literature, recommendations for preterm infants less than 37 weeks' gestational age are not included in this guideline.
2. Hypotension, hypothermia, and metabolic disturbances should be treated and corrected and medications that can interfere with the neurologic examination and apnea testing should be discontinued allowing for adequate clearance before proceeding with these evaluations.
3. Two examinations including apnea testing with each examination separated by an observation period are required. Examinations should be performed by different attending physicians. Apnea testing may be performed by the same physician. An observation period of 24 hours for term newborns (37 weeks' gestational age) to 30 days of age, and 12 hours for infants and children (> 30 days to 18 years) is recommended. The first examination determines the child has met the accepted neurologic examination criteria for brain death. The second examination confirms brain death based on an unchanged and irreversible condition. Assessment of neurologic function following cardiopulmonary resuscitation or other severe acute brain injuries should be deferred for 24 hours or longer if there are concerns or inconsistencies in the examination.
4. Apnea testing to support the diagnosis of brain death must be performed safely and requires documentation of an arterial $Paco_2$ 20 mm Hg above the baseline and ≥60 mm Hg with no respiratory effort during the testing period. If the apnea test cannot be safely completed, an ancillary study should be performed.
5. Ancillary studies (electroencephalogram and radionuclide cerebral blood flow) are not required to establish brain death and are not a substitute for the neurologic examination. Ancillary studies may be used to assist the clinician in making the diagnosis of brain death (1) when components of the examination or apnea testing cannot be completed safely due to the underlying medical condition of the patient; (2) if there is uncertainty about the results of the neurologic examination; (3) if a medication effect may be present; or (4) to reduce the inter-examination observation period. When ancillary studies are used, a second clinical examination and apnea test should be performed and components that can be completed must remain consistent with brain death. In this instance the observation interval may be shortened and the second neurologic examination and apnea test (or all components that are able to be completed safely) can be performed at any time thereafter.
6. Death is declared when the above criteria are fulfilled. (8/11, reaffirmed 1/15, 5/19)

GUIDELINES FOR THE ETHICAL CONDUCT OF STUDIES TO EVALUATE DRUGS IN PEDIATRIC POPULATIONS (CLINICAL REPORT)

Robert E. Shaddy, MD; Scott C. Denne, MD; Committee on Drugs; and Committee on Pediatric Research

ABSTRACT. The proper ethical conduct of studies to evaluate drugs in children is of paramount importance to all those involved in these types of studies. This report is an updated revision to the previously published guidelines from the American Academy of Pediatrics in 1995. Since the previous publication, there have been great strides made in the science and ethics of studying drugs in children. There have also been numerous legislative and regulatory advancements that have promoted the study of drugs in children while simultaneously allowing for the protection of this particularly vulnerable group. This report summarizes these changes and advances and provides a framework from which to guide and monitor the ethical conduct of studies to evaluate drugs in children. (3/10, reaffirmed 1/14, 2/18)

GUIDING PRINCIPLES FOR MANAGED CARE ARRANGEMENTS FOR THE HEALTH CARE OF NEWBORNS, INFANTS, CHILDREN, ADOLESCENTS, AND YOUNG ADULTS

Committee on Child Health Financing

ABSTRACT. By including the precepts of primary care and the medical home in the delivery of services, managed care can be effective in increasing access to a full range of health care services and clinicians. A carefully designed and administered managed care plan can minimize patient under- and overutilization of services, as well as enhance quality of care. Therefore, the American Academy of Pediatrics urges the use of the key principles outlined in this statement in designing and implementing managed care programs for newborns, infants, children, adolescents, and young adults to maximize the positive potential of managed care for pediatrics. (10/13)
http://pediatrics.aappublications.org/content/132/5/e1452

GUIDING PRINCIPLES FOR TEAM-BASED PEDIATRIC CARE

Julie P. Katkin, MD, FAAP; Susan J. Kressly, MD, FAAP; Anne R. Edwards, MD, FAAP; James M. Perrin, MD, FAAP; Colleen A. Kraft, MD, FAAP; Julia E. Richerson, MD, FAAP; Joel S. Tieder, MD, MPH, FAAP; Liz Wall; and Task Force on Pediatric Practice Change

ABSTRACT. The American Academy of Pediatrics (AAP) recognizes that children's unique and ever-changing needs depend on a variety of support systems. Key components of effective support systems address the needs of the child and family in the context of their home and community and are dynamic so that they reflect, monitor, and respond to changes as the needs of the child and family change. The AAP believes that team-based care involving medical providers and community partners (eg, teachers and state agencies) is a crucial and necessary component of providing high-quality care to children and their families. Team-based care builds on the foundation of the medical home by reaching out to a potentially broad array of participants in the life of a child and incorporating them into the care provided. Importantly, the AAP believes that a high-functioning team includes children and their families as essential partners. The overall goal of team-based care is to enhance communication and cooperation among the varied medical, social, and educational partners in a child's life to better meet the global needs of children and their families, helping them to achieve their best potential. In support of the team-based approach, the AAP urges

stakeholders to invest in infrastructure, education, and privacy-secured technology to meet the needs of children. This statement includes limited specific examples of potential team members, including health care providers and community partners, that are meant to be illustrative and in no way represent a complete or comprehensive listing of all team members who may be of importance for a specific child and family. (7/17)

GYNECOLOGIC EXAMINATION FOR ADOLESCENTS IN THE PEDIATRIC OFFICE SETTING (CLINICAL REPORT)

Paula K. Braverman, MD; Lesley Breech, MD; and Committee on Adolescence

ABSTRACT. The American Academy of Pediatrics promotes the inclusion of the gynecologic examination in the primary care setting within the medical home. Gynecologic issues are commonly seen by clinicians who provide primary care to adolescents. Some of the most common concerns include questions related to pubertal development; menstrual disorders such as dysmenorrhea, amenorrhea, oligomenorrhea, and abnormal uterine bleeding; contraception; and sexually transmitted and non–sexually transmitted infections. The gynecologic examination is a key element in assessing pubertal status and documenting physical findings. Most adolescents do not need an internal examination involving a speculum or bimanual examination. However, for cases in which more extensive examination is needed, the primary care office with the primary care clinician who has established rapport and trust with the patient is often the best setting for pelvic examination. This report reviews the gynecologic examination, including indications for the pelvic examination in adolescents and the approach to this examination in the office setting. Indications for referral to a gynecologist are included. The pelvic examination may be successfully completed when conducted without pressure and approached as a normal part of routine young women's health care. (8/10, reaffirmed 5/13)
http://pediatrics.aappublications.org/content/126/3/583

HANDOFFS: TRANSITIONS OF CARE FOR CHILDREN IN THE EMERGENCY DEPARTMENT

Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee and Emergency Nurses Association Pediatric Committee)

ABSTRACT. Transitions of care (ToCs), also referred to as handoffs or sign-outs, occur when the responsibility for a patient's care transfers from 1 health care provider to another. Transitions are common in the acute care setting and have been noted to be vulnerable events with opportunities for error. Health care is taking ideas from other high-risk industries, such as aerospace and nuclear power, to create models of structured transition processes. Although little literature currently exists to establish 1 model as superior, multiorganizational consensus groups agree that standardization is warranted and that additional work is needed to establish characteristics of ToCs that are associated with clinical or practice outcomes. The rationale for structuring ToCs, specifically those related to the care of children in the emergency setting, and a description of identified strategies are presented, along with resources for educating health care providers on ToCs. Recommendations for development, education, and implementation of transition models are included. (10/16)

HEAD LICE (CLINICAL REPORT)

Cynthia D. Devore, MD, FAAP; Gordon E. Schutze, MD, FAAP; Council on School Health; and Committee on Infectious Diseases

ABSTRACT. Head lice infestation is associated with limited morbidity but causes a high level of anxiety among parents of school-aged children. Since the 2010 clinical report on head lice was published by the American Academy of Pediatrics, newer medications have been approved for the treatment of head lice. This revised clinical report clarifies current diagnosis and treatment protocols and provides guidance for the management of children with head lice in the school setting. (4/15, reaffirmed 6/20)
http://pediatrics.aappublications.org/content/135/5/e1355

HEALTH AND MENTAL HEALTH NEEDS OF CHILDREN IN US MILITARY FAMILIES (CLINICAL REPORT)

CDR Chadley R. Huebner, MD, MPH, FAAP; Section on Uniformed Services; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Children in US military families share common experiences and unique challenges, including parental deployment and frequent relocation. Although some of the stressors of military life have been associated with higher rates of mental health disorders and increased health care use among family members, there are various factors and interventions that have been found to promote resilience. Military children often live on or near military installations, where they may attend Department of Defense–sponsored child care programs and schools and receive medical care through military treatment facilities. However, many families live in remote communities without access to these services. Because of this wide geographic distribution, military children are cared for in both military and civilian medical practices. This clinical report provides a background to military culture and offers practical guidance to assist civilian and military pediatricians caring for military children. (12/18)

HEALTH CARE ISSUES FOR CHILDREN AND ADOLESCENTS IN FOSTER CARE AND KINSHIP CARE

Council on Foster Care, Adoption, and Kinship Care; Committee on Adolescence; and Council on Early Childhood

ABSTRACT. Children and adolescents who enter foster care often do so with complicated and serious medical, mental health, developmental, oral health, and psychosocial problems rooted in their history of childhood trauma. Ideally, health care for this population is provided in a pediatric medical home by physicians who are familiar with the sequelae of childhood trauma and adversity. As youth with special health care needs, children and adolescents in foster care require more frequent monitoring of their health status, and pediatricians have a critical role in ensuring the well-being of children in out-of-home care through the provision of high-quality pediatric health services, health care coordination, and advocacy on their behalves. (9/15)
http://pediatrics.aappublications.org/content/136/4/e1131

HEALTH CARE ISSUES FOR CHILDREN AND ADOLESCENTS IN FOSTER CARE AND KINSHIP CARE (TECHNICAL REPORT)

Moira A. Szilagyi, MD, PhD; David S. Rosen, MD, MPH; David Rubin, MD, MSCE; Sarah Zlotnik, MSW, MSPH; Council on Foster Care, Adoption, and Kinship Care; Committee on Adolescence; and Council on Early Childhood

ABSTRACT. Children and adolescents involved with child welfare, especially those who are removed from their family of origin and placed in out-of-home care, often present with complex and serious physical, mental health, developmental, and psychosocial problems rooted in childhood adversity and trauma. As such, they are designated as children with special health care needs. There are many barriers to providing high-quality comprehensive health care services to children and adolescents whose lives are characterized by transience and uncertainty. Pediatricians have a critical role in ensuring the well-being of children in out-of-home care through the provision

of high-quality pediatric health services in the context of a medical home, and health care coordination and advocacy on their behalf. This technical report supports the policy statement of the same title. (9/15)
http://pediatrics.aappublications.org/content/136/4/e1142

HEALTH CARE OF YOUTH AGING OUT OF FOSTER CARE

Council on Foster Care, Adoption, and Kinship Care and Committee on Early Childhood

ABSTRACT. Youth transitioning out of foster care face significant medical and mental health care needs. Unfortunately, these youth rarely receive the services they need because of lack of health insurance. Through many policies and programs, the federal government has taken steps to support older youth in foster care and those aging out. The Fostering Connections to Success and Increasing Adoptions Act of 2008 (Pub L No. 110-354) requires states to work with youth to develop a transition plan that addresses issues such as health insurance. In addition, beginning in 2014, the Patient Protection and Affordable Care Act of 2010 (Pub L No. 111-148) makes youth aging out of foster care eligible for Medicaid coverage until age 26 years, regardless of income. Pediatricians can support youth aging out of foster care by working collaboratively with the child welfare agency in their state to ensure that the ongoing health needs of transitioning youth are met. (11/12, reaffirmed 7/17)

HEALTH CARE SUPERVISION FOR CHILDREN WITH WILLIAMS SYNDROME (CLINICAL REPORT)

Colleen A. Morris, MD; Stephen R. Braddock, MD; and Council on Genetics

ABSTRACT. This set of recommendations is designed to assist the pediatrician in caring for children with Williams syndrome (WS) who were diagnosed by using clinical features and with chromosome 7 microdeletion confirmed by fluorescence in situ hybridization, chromosome microarray, or multiplex ligation-dependent probe amplification. The recommendations in this report reflect review of the current literature, including previously peer-reviewed and published management suggestions for WS, as well as the consensus of physicians and psychologists with expertise in the care of individuals with WS. These general recommendations for the syndrome do not replace individualized medical assessment and treatment. (1/20)

HEALTH INFORMATION TECHNOLOGY AND THE MEDICAL HOME

Council on Clinical Information Technology

ABSTRACT. The American Academy of Pediatrics (AAP) supports development and universal implementation of a comprehensive electronic infrastructure to support pediatric information functions of the medical home. These functions include (1) timely and continuous management and tracking of health data and services over a patient's lifetime for all providers, patients, families, and guardians, (2) comprehensive organization and secure transfer of health data during patient-care transitions between providers, institutions, and practices, (3) establishment and maintenance of central coordination of a patient's health information among multiple repositories (including personal health records and information exchanges), (4) translation of evidence into actionable clinical decision support, and (5) reuse of archived clinical data for continuous quality improvement. The AAP supports universal, secure, and vendor-neutral portability of health information for all patients contained within the medical home across all care settings (ambulatory practices, inpatient settings, emergency departments, pharmacies, consultants, support service providers, and therapists) for multiple purposes including direct care, personal health records, public health, and registries. The AAP also supports financial incentives that promote the development of information tools that meet the needs of pediatric workflows and that appropriately recognize the added value of medical homes to pediatric care. (4/11, reaffirmed 7/15)

HEALTH SUPERVISION FOR CHILDREN WITH DOWN SYNDROME (CLINICAL REPORT)

Marilyn J. Bull, MD, and Committee on Genetics

ABSTRACT. These guidelines are designed to assist the pediatrician in caring for the child in whom a diagnosis of Down syndrome has been confirmed by chromosome analysis. Although a pediatrician's initial contact with the child is usually during infancy, occasionally the pregnant woman who has been given a prenatal diagnosis of Down syndrome will be referred for review of the condition and the genetic counseling provided. Therefore, this report offers guidance for this situation as well. (7/11, reaffirmed 9/16, 1/18)
http://pediatrics.aappublications.org/content/128/2/393

HEALTH SUPERVISION FOR CHILDREN WITH FRAGILE X SYNDROME (CLINICAL REPORT)

Joseph H. Hersh, MD; Robert A. Saul, MD; and Committee on Genetics

ABSTRACT. Fragile X syndrome (an *FMR1*–related disorder) is the most commonly inherited form of mental retardation. Early physical recognition is difficult, so boys with developmental delay should be strongly considered for molecular testing. The characteristic adult phenotype usually does not develop until the second decade of life. Girls can also be affected with developmental delay. Because multiple family members can be affected with mental retardation and other conditions (premature ovarian failure and tremor/ataxia), family history information is of critical importance for the diagnosis and management of affected patients and their families. This report summarizes issues for fragile X syndrome regarding clinical diagnosis, laboratory diagnosis, genetic counseling, related health problems, behavior management, and age-related health supervision guidelines. The diagnosis of fragile X syndrome not only involves the affected children but also potentially has significant health consequences for multiple generations in each family. (4/11)
http://pediatrics.aappublications.org/content/127/5/994

HEALTH SUPERVISION FOR CHILDREN WITH MARFAN SYNDROME (CLINICAL REPORT)

Brad T. Tinkle, MD, PhD; Howard M. Saal, MD; and Committee on Genetics

ABSTRACT. Marfan syndrome is a systemic, heritable connective tissue disorder that affects many different organ systems and is best managed by using a multidisciplinary approach. The guidance in this report is designed to assist the pediatrician in recognizing the features of Marfan syndrome as well as caring for the individual with this disorder. (9/13, 10/19)

HEALTH SUPERVISION FOR CHILDREN WITH NEUROFIBROMATOSIS TYPE 1 (CLINICAL REPORT)

David T. Miller, MD, PhD, FAAP; Debra Freedenberg, MD, PhD, FAAP; Elizabeth Schorry, MD; Nicole J. Ullrich, MD, PhD; David Viskochil, MD, PhD; Bruce R. Korf, MD, PhD, FAAP; and Council on Genetics (joint with American College of Medical Genetics and Genomics)

ABSTRACT. Neurofibromatosis type 1 (NF1) is a multisystem disorder that primarily involves the skin and peripheral nervous system. Its population prevalence is approximately 1 in 3000.

The condition is usually recognized in early childhood, when pigmentary manifestations emerge. Although NF1 is associated with marked clinical variability, most children affected follow patterns of growth and development within the normal range. Some features of NF1 can be present at birth, but most manifestations emerge with age, necessitating periodic monitoring to address ongoing health and developmental needs and minimize the risk of serious medical complications. In this report, we provide a review of the clinical criteria needed to establish a diagnosis, the inheritance pattern of NF1, its major clinical and developmental manifestations, and guidelines for monitoring and providing intervention to maximize the health and quality of life of a child affected. HEALTH SUPERVISION FOR CHILDREN WITH PRADER-WILLI SYNDROME (CLINICAL REPORT)

Shawn E. McCandless, MD, and Committee on Genetics

ABSTRACT. This set of guidelines was designed to assist the pediatrician in caring for children with Prader-Willi syndrome diagnosed by clinical features and confirmed by molecular testing. Prader-Willi syndrome provides an excellent example of how early diagnosis and management can improve the long-term outcome for some genetic disorders. (12/10)

http://pediatrics.aappublications.org/content/127/1/195

HEALTH SUPERVISION FOR CHILDREN WITH SICKLE CELL DISEASE

Section on Hematology/Oncology and Committee on Genetics

ABSTRACT. Sickle cell disease (SCD) is a group of complex genetic disorders with multisystem manifestations. This statement provides pediatricians in primary care and subspecialty practice with an overview of the genetics, diagnosis, clinical manifestations, and treatment of SCD. Specialized comprehensive medical care decreases morbidity and mortality during childhood. The provision of comprehensive care is a time-intensive endeavor that includes ongoing patient and family education, periodic comprehensive evaluations and other disease-specific health maintenance services, psychosocial care, and genetic counseling. Timely and appropriate treatment of acute illness is critical, because life-threatening complications develop rapidly. It is essential that every child with SCD receive comprehensive care that is coordinated through a medical home with appropriate expertise. (3/02, reaffirmed 1/06, 1/11, 2/16, 9/20)

http://pediatrics.aappublications.org/content/109/3/526

HEALTH SUPERVISION FOR PEOPLE WITH ACHONDROPLASIA (CLINICAL REPORT)

Julie Hoover-Fong, MD, PhD, FACMG; Charles I. Scott, MD, FAAP; Marilyn C. Jones, MD, FAAP; and Committee on Genetics

ABSTRACT. Achondroplasia is the most common short-stature skeletal dysplasia, additionally marked by rhizomelia, macrocephaly, midface hypoplasia, and normal cognition. Potential medical complications associated with achondroplasia include lower extremity long bone bowing, middle-ear dysfunction, obstructive sleep apnea, and, more rarely, cervicomedullary compression, hydrocephalus, thoracolumbar kyphosis, and central sleep apnea. This is the second revision to the original 1995 health supervision guidance from the American Academy of Pediatrics for caring for patients with achondroplasia. Although many of the previously published recommendations remain appropriate for contemporary medical care, this document highlights interval advancements in the clinical methods available to monitor for complications associated with achondroplasia. This document is intended to provide guidance for health care providers to help identify individual patients at high risk of developing serious sequelae and to enable intervention before complications develop. (5/20)

HELPING CHILDREN AND FAMILIES DEAL WITH DIVORCE AND SEPARATION (CLINICAL REPORT)

George J. Cohen, MD, FAAP; Carol C. Weitzman, MD, FAAP; Committee on Psychosocial Aspects of Child and Family Health; and Section on Developmental and Behavioral Pediatrics

ABSTRACT. For the past several years in the United States, there have been more than 800 000 divorces and parent separations annually, with over 1 million children affected. Children and their parents can experience emotional trauma before, during, and after a separation or divorce. Pediatricians can be aware of their patients' behavior and parental attitudes and behaviors that may indicate family dysfunction and that can indicate need for intervention. Age-appropriate explanation and counseling for the child and advice and guidance for the parents, as well as recommendation of reading material, may help reduce the potential negative effects of divorce. Often, referral to professionals with expertise in the social, emotional, and legal aspects of the separation and its aftermath may be helpful for these families. (11/16)

http://pediatrics.aappublications.org/content/138/6/e20163020

HIGH-DEDUCTIBLE HEALTH PLANS

Committee on Child Health Financing

ABSTRACT. High-deductible health plans (HDHPs) are insurance policies with higher deductibles than conventional plans. The Medicare Prescription Drug Improvement and Modernization Act of 2003 linked many HDHPs with tax-advantaged spending accounts. The 2010 Patient Protection and Affordable Care Act continues to provide for HDHPs in its lower-level plans on the health insurance marketplace and provides for them in employer-offered plans. HDHPs decrease the premium cost of insurance policies for purchasers and shift the risk of further payments to the individual subscriber. HDHPs reduce utilization and total medical costs, at least in the short term. Because HDHPs require out-of-pocket payment in the initial stages of care, primary care and other outpatient services as well as elective procedures are the services most affected, whereas higher-cost services in the health care system, incurred after the deductible is met, are unaffected. HDHPs promote adverse selection because healthier and wealthier patients tend to opt out of conventional plans in favor of HDHPs. Because the ill pay more than the healthy under HDHPs, families with children with special health care needs bear an increased cost burden in this model. HDHPs discourage use of nonpreventive primary care and thus are at odds with most recommendations for improving the organization of health care, which focus on strengthening primary care.

This policy statement provides background information on HDHPs, discusses the implications for families and pediatric care providers, and suggests courses of action. (4/14, reaffirmed 10/18)

HIV TESTING AND PROPHYLAXIS TO PREVENT MOTHER-TO-CHILD TRANSMISSION IN THE UNITED STATES

Committee on Pediatric AIDS

ABSTRACT. Universal HIV testing of pregnant women in the United States is the key to prevention of mother-to-child transmission of HIV. Repeat testing in the third trimester and rapid HIV testing at labor and delivery are additional strategies to further reduce the rate of perinatal HIV transmission. Prevention of mother-to-child transmission of HIV is most effective when antiretroviral drugs are received by the mother during her pregnancy and continued through delivery and then administered to the infant after birth. Antiretroviral drugs are

effective in reducing the risk of mother-to-child transmission of HIV even when prophylaxis is started for the infant soon after birth. New rapid testing methods allow identification of HIV-infected women or HIV-exposed infants in 20 to 60 minutes. The American Academy of Pediatrics recommends documented, routine HIV testing for all pregnant women in the United States after notifying the patient that testing will be performed, unless the patient declines HIV testing ("opt-out" consent or "right of refusal"). For women in labor with undocumented HIV-infection status during the current pregnancy, immediate maternal HIV testing with opt-out consent, using a rapid HIV antibody test, is recommended. Positive HIV antibody screening test results should be confirmed with immunofluorescent antibody or Western blot assay. For women with a positive rapid HIV antibody test result, antiretroviral prophylaxis should be administered promptly to the mother and newborn infant on the basis of the positive result of the rapid antibody test without waiting for results of confirmatory HIV testing. If the confirmatory test result is negative, then prophylaxis should be discontinued. For a newborn infant whose mother's HIV serostatus is unknown, the health care professional should perform rapid HIV antibody testing on the mother or on the newborn infant, with results reported to the health care professional no later than 12 hours after the infant's birth. If the rapid HIV antibody test result is positive, antiretroviral prophylaxis should be instituted as soon as possible after birth but certainly by 12 hours after delivery, pending completion of confirmatory HIV testing. The mother should be counseled not to breastfeed the infant. Assistance with immediate initiation of hand and pump expression to stimulate milk production should be offered to the mother, given the possibility that the confirmatory test result may be negative. If the confirmatory test result is negative, then prophylaxis should be stopped and breastfeeding may be initiated. If the confirmatory test result is positive, infants should receive antiretroviral prophylaxis for 6 weeks after birth, and the mother should not breastfeed the infant. (11/08, reaffirmed 6/11, 11/14, 10/20)

HOME CARE OF CHILDREN AND YOUTH WITH COMPLEX HEALTH CARE NEEDS AND TECHNOLOGY DEPENDENCIES (CLINICAL REPORT)

Ellen Roy Elias, MD; Nancy A. Murphy, MD; and Council on Children With Disabilities

ABSTRACT. Children and youth with complex medical issues, especially those with technology dependencies, experience frequent and often lengthy hospitalizations. Hospital discharges for these children can be a complicated process that requires a deliberate, multistep approach. In addition to successful discharges to home, it is essential that pediatric providers develop and implement an interdisciplinary and coordinated plan of care that addresses the child's ongoing health care needs. The goal is to ensure that each child remains healthy, thrives, and obtains optimal medical home and developmental supports that promote ongoing care at home and minimize recurrent hospitalizations. This clinical report presents an approach to discharging the child with complex medical needs with technology dependencies from hospital to home and then continually addressing the needs of the child and family in the home environment. HONORING DO-NOT-ATTEMPT-RESUSCITATION REQUESTS IN SCHOOLS

Council on School Health and Committee on Bioethics

ABSTRACT. Increasingly, children and adolescents with complex chronic conditions are living in the community. Federal legislation and regulations facilitate their participation in school. Some of these children and adolescents and their families may wish to forego life-sustaining medical treatment, including cardiopulmonary resuscitation, because they would be ineffective or because the risks outweigh the benefits. Honoring these requests in the school environment is complex because of the limited availability of school nurses and the frequent lack of supporting state legislation and regulations. Understanding and collaboration on the part of all parties is essential. Pediatricians have an important role in helping school nurses incorporate a specific action plan into the student's individualized health care plan. The action plan should include both communication and comfort-care plans. Pediatricians who work directly with schools can also help implement policies, and professional organizations can advocate for regulations and legislation that enable students and their families to effectuate their preferences. (4/10, reaffirmed 7/13, 8/16)

HOSPITAL DISCHARGE OF THE HIGH-RISK NEONATE

Committee on Fetus and Newborn

ABSTRACT. This policy statement updates the guidelines on discharge of the high-risk neonate first published by the American Academy of Pediatrics in 1998. As with the earlier document, this statement is based, insofar as possible, on published, scientifically derived information. This updated statement incorporates new knowledge about risks and medical care of the high-risk neonate, the timing of discharge, and planning for care after discharge. It also refers to other American Academy of Pediatrics publications that are relevant to these issues. This statement draws on the previous classification of high-risk infants into 4 categories: (1) the preterm infant; (2) the infant with special health care needs or dependence on technology; (3) the infant at risk because of family issues; and (4) the infant with anticipated early death. The issues of deciding when discharge is appropriate, defining the specific needs for follow-up care, and the process of detailed discharge planning are addressed as they apply in general to all 4 categories; in addition, special attention is directed to the particular issues presented by the 4 individual categories. Recommendations are given to aid in deciding when discharge is appropriate and to ensure that all necessary care will be available and well coordinated after discharge. The need for individualized planning and physician judgment is emphasized. (11/08, reaffirmed 5/11, 11/18)

THE HOSPITAL RECORD OF THE INJURED CHILD AND THE NEED FOR EXTERNAL CAUSE-OF-INJURY CODES

Committee on Injury and Poison Prevention

ABSTRACT. Proper record-keeping of emergency department visits and hospitalizations of injured children is vital for appropriate patient management. Determination and documentation of the circumstances surrounding the injury event are essential. This information not only is the basis for preventive counseling, but also provides clues about how similar injuries in other youth can be avoided. The hospital records have an important secondary purpose; namely, if sufficient information about the cause and mechanism of injury is documented, it can be subsequently coded, electronically compiled, and retrieved later to provide an epidemiologic profile of the injury, the first step in prevention at the population level. To be of greatest use, hospital records should indicate the "who, what, when, where, why, and how" of the injury occurrence and whether protective equipment (eg, a seat belt) was used. The pediatrician has two important roles in this area: to document fully the injury event and to advocate the use of standardized external cause-of-injury codes, which allow such data to be compiled and analyzed. (2/99, reaffirmed 5/02, 5/05, 10/08, 10/13)

HOSPITAL STAY FOR HEALTHY TERM NEWBORN INFANTS

William E. Benitz, MD, FAAP, and Committee on Fetus and Newborn

ABSTRACT. The hospital stay of the mother and her healthy term newborn infant should be long enough to allow identification of problems and to ensure that the mother is sufficiently recovered and prepared to care for herself and her newborn at home. The length of stay should be based on the unique characteristics of each mother-infant dyad, including the health of the mother, the health and stability of the newborn, the ability and confidence of the mother to care for herself and her newborn, the adequacy of support systems at home, and access to appropriate follow-up care in a medical home. Input from the mother and her obstetrical care provider should be considered before a decision to discharge a newborn is made, and all efforts should be made to keep a mother and her newborn together to ensure simultaneous discharge. (4/15)

HUMAN EMBRYONIC STEM CELL (HESC) AND HUMAN EMBRYO RESEARCH

Committee on Pediatric Research and Committee on Bioethics

ABSTRACT. Human embryonic stem cell research has emerged as an important platform for the understanding and treatment of pediatric diseases. From its inception, however, it has raised ethical concerns based not on the use of stem cells themselves but on objections to the source of the cells—specifically, the destruction of preimplantation human embryos. Despite differences in public opinion on this issue, a large majority of the public supports continued research using embryonic stem cells. Given the possible substantial benefit of stem cell research on child health and development, the American Academy of Pediatrics believes that funding and oversight for human embryo and embryonic stem cell research should continue. (10/12, reaffirmed 7/17)

http://pediatrics.aappublications.org/content/130/5/972

HYPOTHERMIA AND NEONATAL ENCEPHALOPATHY (CLINICAL REPORT)

Committee on Fetus and Newborn

ABSTRACT. Data from large randomized clinical trials indicate that therapeutic hypothermia, using either selective head cooling or systemic cooling, is an effective therapy for neonatal encephalopathy. Infants selected for cooling must meet the criteria outlined in published clinical trials. The implementation of cooling needs to be performed at centers that have the capability to manage medically complex infants. Because the majority of infants who have neonatal encephalopathy are born at community hospitals, centers that perform cooling should work with their referring hospitals to implement education programs focused on increasing the awareness and identification of infants at risk for encephalopathy, and the initial clinical management of affected infants. (5/14)

IDENTIFICATION, EVALUATION, AND MANAGEMENT OF CHILDREN WITH AUTISM SPECTRUM DISORDER (CLINICAL REPORT)

Susan L. Hyman, MD, FAAP; Susan E. Levy, MD, MPH, FAAP; Scott M. Myers, MD, FAAP; Council on Children With Disabilities; and Section on Developmental and Behavioral Pediatrics

ABSTRACT. Autism spectrum disorder (ASD) is a common neurodevelopmental disorder with reported prevalence in the United States of 1 in 59 children (approximately 1.7%). Core deficits are identified in 2 domains: social communication/interaction and restrictive, repetitive patterns of behavior. Children and youth with ASD have service needs in behavioral, educational, health, leisure, family support, and other areas. Standardized screening for ASD at 18 and 24 months of age with ongoing developmental surveillance continues to be recommended in primary care (although it may be performed in other settings), because ASD is common, can be diagnosed as young as 18 months of age, and has evidenced-based interventions that may improve function. More accurate and culturally sensitive screening approaches are needed. Primary care providers should be familiar with the diagnostic criteria for ASD, appropriate etiologic evaluation, and co-occurring medical and behavioral conditions (such as disorders of sleep and feeding, gastrointestinal tract symptoms, obesity, seizures, attention-deficit/hyperactivity disorder, anxiety, and wandering) that affect the child's function and quality of life. There is an increasing evidence base to support behavioral and other interventions to address specific skills and symptoms. Shared decision making calls for collaboration with families in evaluation and choice of interventions. This single clinical report updates the 2007 American Academy of Pediatrics clinical reports on the evaluation and treatment of ASD in one publication with an online table of contents and section view available through the American Academy of Pediatrics Gateway to help the reader identify topic areas within the report. IDENTIFICATION AND CARE OF HIV-EXPOSED AND HIV-INFECTED INFANTS, CHILDREN, AND ADOLESCENTS IN FOSTER CARE

Committee on Pediatric AIDS

ABSTRACT. As a consequence of the expanding human immunodeficiency virus (HIV) epidemic and major advances in medical management of HIV-exposed and HIV-infected persons, revised recommendations are provided for HIV testing of infants, children, and adolescents in foster care. Updated recommendations also are provided for the care of HIV-exposed and HIV-infected persons who are in foster care. (7/00, reaffirmed 12/16)

http://pediatrics.aappublications.org/content/106/1/149

IDENTIFYING CHILD ABUSE FATALITIES DURING INFANCY (CLINICAL REPORT)

Vincent J. Palusci, MD, MS, FAAP; Amanda J. Kay, MD, MPH, FAAP; Erich Batra, MD, FAAP; Rachel Y. Moon, MD, FAAP; Council on Child Abuse and Neglect; Section on Child Death Review and Prevention; and Task Force on Sudden Infant Death Syndrome (joint with Tracey S. Corey, MD; Thomas Andrew, MD; Michael Graham, MD; and National Association of Medical Examiners)

ABSTRACT. When a healthy infant dies suddenly and unexpectedly, it is critical to correctly determine if the death was caused by child abuse or neglect. Sudden unexpected infant deaths should be comprehensively investigated, ancillary tests and forensic procedures should be used to more-accurately identify the cause of death, and parents deserve to be approached in a nonaccusatory manner during the investigation. Missing a child abuse death can place other children at risk, and inappropriately approaching a sleep-related death as maltreatment can result in inappropriate criminal and protective services investigations. Communities can learn from these deaths by using multidisciplinary child death reviews. Pediatricians can support families during investigation, advocate for and support state policies that require autopsies and scene investigation, and advocate for establishing comprehensive and fully funded child death investigation and reviews at the local and state levels. Additional funding is also needed for research to advance our ability to prevent these deaths. (8/19)

IDENTIFYING INFANTS AND YOUNG CHILDREN WITH DEVELOPMENTAL DISORDERS IN THE MEDICAL HOME: AN ALGORITHM FOR DEVELOPMENTAL SURVEILLANCE AND SCREENING

Council on Children With Disabilities, Section on Developmental and Behavioral Pediatrics, Bright Futures Steering Committee, and Medical Home Initiatives for Children With Special Needs Project Advisory Committee

ABSTRACT. Early identification of developmental disorders is critical to the well-being of children and their families. It is an integral function of the primary care medical home and an appropriate responsibility of all pediatric health care professionals. This statement provides an algorithm as a strategy to support health care professionals in developing a pattern and practice for addressing developmental concerns in children from birth through 3 years of age. The authors recommend that developmental surveillance be incorporated at every well-child preventive care visit. Any concerns raised during surveillance should be promptly addressed with standardized developmental screening tests. In addition, screening tests should be administered regularly at the 9-, 18-, and 30-month visits. (Because the 30-month visit is not yet a part of the preventive care system and is often not reimbursable by third-party payers at this time, developmental screening can be performed at 24 months of age. In addition, because the frequency of regular pediatric visits decreases after 24 months of age, a pediatrician who expects that his or her patients will have difficulty attending a 30-month visit should conduct screening during the 24-month visit.) The early identification of developmental problems should lead to further developmental and medical evaluation, diagnosis, and treatment, including early developmental intervention. Children diagnosed with developmental disorders should be identified as children with special health care needs, and chronic-condition management should be initiated. Identification of a developmental disorder and its underlying etiology may also drive a range of treatment planning, from medical treatment of the child to family planning for his or her parents. (7/06, reaffirmed 12/09, 8/14)

http://pediatrics.aappublications.org/content/118/1/405

IDENTIFYING THE MISSHAPEN HEAD: CRANIOSYNOSTOSIS AND RELATED DISORDERS (CLINICAL REPORT)

Mark S. Dias, MD, FAAP, FAANS; Thomas Samson, MD, FAAP; Elias B. Rizk, MD, FAAP, FAANS; Lance S. Governale, MD, FAAP, FAANS; Joan T. Richtsmeier, PhD; Section on Neurologic Surgery; and Section on Plastic and Reconstructive Surgery

ABSTRACT. Pediatric care providers, pediatricians, pediatric subspecialty physicians, and other health care providers should be able to recognize children with abnormal head shapes that occur as a result of both synostotic and deformational processes. The purpose of this clinical report is to review the characteristic head shape changes, as well as secondary craniofacial characteristics, that occur in the setting of the various primary craniosynostoses and deformations. As an introduction, the physiology and genetics of skull growth as well as the pathophysiology underlying craniosynostosis are reviewed. This is followed by a description of each type of primary craniosynostosis (metopic, unicoronal, bicoronal, sagittal, lambdoid, and frontosphenoidal) and their resultant head shape changes, with an emphasis on differentiating conditions that require surgical correction from those (bathrocephaly, deformational plagiocephaly/brachycephaly, and neonatal intensive care unit-associated skill deformation, known as NICUcephaly) that do not. The report ends with a brief discussion of microcephaly as it relates to craniosynostosis as well as fontanelle closure. The intent is to improve pediatric care providers' recognition and timely referral for craniosynostosis and their differentiation of synostotic from deformational and other nonoperative head shape changes. (8/20)

IMMERSION IN WATER DURING LABOR AND DELIVERY (CLINICAL REPORT)

Committee on Fetus and Newborn (joint with American College of Obstetricians and Gynecologists Committee on Obstetric Practice)

ABSTRACT. Immersion in water has been suggested as a beneficial alternative for labor, delivery, or both and over the past decades has gained popularity in many parts of the world. Immersion in water during the first stage of labor may be associated with decreased pain or use of anesthesia and decreased duration of labor. However, there is no evidence that immersion in water during the first stage of labor otherwise improves perinatal outcomes, and it should not prevent or inhibit other elements of care. The safety and efficacy of immersion in water during the second stage of labor have not been established, and immersion in water during the second stage of labor has not been associated with maternal or fetal benefit. Given these facts and case reports of rare but serious adverse effects in the newborn, the practice of immersion in the second stage of labor (underwater delivery) should be considered an experimental procedure that only should be performed within the context of an appropriately designed clinical trial with informed consent. Facilities that plan to offer immersion in the first stage of labor need to establish rigorous protocols for candidate selection, maintenance and cleaning of tubs and immersion pools, infection control procedures, monitoring of mothers and fetuses at appropriate intervals while immersed, and immediately and safely moving women out of the tubs if maternal or fetal concerns develop. (3/14)

IMMUNIZATION INFORMATION SYSTEMS

Committee on Practice and Ambulatory Medicine

ABSTRACT. The American Academy of Pediatrics continues to support the development and implementation of immunization information systems, previously referred to as immunization registries, and other systems for the benefit of children, pediatricians, and their communities. Pediatricians and others must be aware of the value that immunization information systems have for society, the potential fiscal influences on their practice, the costs and benefits, and areas for future improvement. (9/06, reaffirmed 10/11)

http://pediatrics.aappublications.org/content/118/3/1293

IMMUNIZING PARENTS AND OTHER CLOSE FAMILY CONTACTS IN THE PEDIATRIC OFFICE SETTING (TECHNICAL REPORT)

Herschel R. Lessin, MD; Kathryn M. Edwards, MD; Committee on Practice and Ambulatory Medicine; and Committee on Infectious Diseases

ABSTRACT. Additional strategies are needed to protect children from vaccine-preventable diseases. In particular, very young infants, as well as children who are immunocompromised, are at especially high risk for developing the serious consequences of vaccine-preventable diseases and cannot be immunized completely. There is some evidence that children who become infected with these diseases are exposed to pathogens through household contacts, particularly from parents or other close family contacts. Such infections likely are attributable to adults who are not fully protected from these diseases, either because their immunity to vaccine-preventable diseases has waned over time or because they have not received a vaccine. There are many challenges that have added to low adult immunization rates in the United States. One option to increase immunization coverage for parents and close family contacts of infants and vulnerable children is to provide alternative locations for these adults to be immunized, such as the pediatric office setting. Ideally, adults

should receive immunizations in their medical homes; however, to provide greater protection to these adults and reduce the exposure of children to pathogens, immunizing parents or other adult family contacts in the pediatric office setting could increase immunization coverage for this population to protect themselves as well as children to whom they provide care. (12/11, reaffirmed 8/16)

THE IMPACT OF MARIJUANA POLICIES ON YOUTH: CLINICAL, RESEARCH, AND LEGAL UPDATE

Committee on Substance Abuse and Committee on Adolescence

ABSTRACT. This policy statement is an update of the American Academy of Pediatrics policy statement "Legalization of Marijuana: Potential Impact on Youth," published in 2004. Pediatricians have special expertise in the care of children and adolescents and may be called on to advise legislators about the potential impact of changes in the legal status of marijuana on adolescents. Parents also may look to pediatricians for advice as they consider whether to support state-level initiatives that propose to legalize the use of marijuana for medical and nonmedical purposes or to decriminalize the possession of small amounts of marijuana. This policy statement provides the position of the American Academy of Pediatrics on the issue of marijuana legalization. The accompanying technical report reviews what is currently known about the relationships of marijuana use with health and the developing brain and the legal status of marijuana and adolescents' use of marijuana to better understand how change in legal status might influence the degree of marijuana use by adolescents in the future. (2/15)
http://pediatrics.aappublications.org/content/135/3/584

THE IMPACT OF MARIJUANA POLICIES ON YOUTH: CLINICAL, RESEARCH, AND LEGAL UPDATE (TECHNICAL REPORT)

Seth Ammerman, MD, FAAP; Sheryl Ryan, MD, FAAP; William P. Adelman, MD, FAAP; Committee on Substance Abuse; and Committee on Adolescence

ABSTRACT. This technical report updates the 2004 American Academy of Pediatrics technical report on the legalization of marijuana. Current epidemiology of marijuana use is presented, as are definitions and biology of marijuana compounds, side effects of marijuana use, and effects of use on adolescent brain development. Issues concerning medical marijuana specifically are also addressed. Concerning legalization of marijuana, 4 different approaches in the United States are discussed: legalization of marijuana solely for medical purposes, decriminalization of recreational use of marijuana, legalization of recreational use of marijuana, and criminal prosecution of recreational (and medical) use of marijuana. These approaches are compared, and the latest available data are presented to aid in forming public policy. The effects on youth of criminal penalties for marijuana use and possession are also addressed, as are the effects or potential effects of the other 3 policy approaches on adolescent marijuana use. Recommendations are included in the accompanying policy statement. (2/15)
http://pediatrics.aappublications.org/content/135/3/e769

THE IMPACT OF RACISM ON CHILD AND ADOLESCENT HEALTH

Maria Trent, MD, MPH, FAAP, FSAHM; Danielle G. Dooley, MD, MPhil, FAAP; Jacqueline Dougé, MD, MPH, FAAP; Section on Adolescent Health; Council on Community Pediatrics; and Committee on Adolescence

ABSTRACT. The American Academy of Pediatrics is committed to addressing the factors that affect child and adolescent health with a focus on issues that may leave some children more vulnerable than others. Racism is a social determinant of health that has a profound impact on the health status of children, adolescents, emerging adults, and their families. Although progress has been made toward racial equality and equity, the evidence to support the continued negative impact of racism on health and well-being through implicit and explicit biases, institutional structures, and interpersonal relationships is clear. The objective of this policy statement is to provide an evidence-based document focused on the role of racism in child and adolescent development and health outcomes. By acknowledging the role of racism in child and adolescent health, pediatricians and other pediatric health professionals will be able to proactively engage in strategies to optimize clinical care, workforce development, professional education, systems engagement, and research in a manner designed to reduce the health effects of structural, personally mediated, and internalized racism and improve the health and well-being of all children, adolescents, emerging adults, and their families. (7/19)
https://pediatrics.aappublications.org/content/144/2/e20191765

THE IMPACT OF SOCIAL MEDIA ON CHILDREN, ADOLESCENTS, AND FAMILIES (CLINICAL REPORT)

Gwenn Schurgin O'Keeffe, MD; Kathleen Clarke-Pearson, MD; and Council on Communications and Media

ABSTRACT. Using social media Web sites is among the most common activity of today's children and adolescents. Any Web site that allows social interaction is considered a social media site, including social networking sites such as Facebook, MySpace, and Twitter; gaming sites and virtual worlds such as Club Penguin, Second Life, and the Sims; video sites such as YouTube; and blogs. Such sites offer today's youth a portal for entertainment and communication and have grown exponentially in recent years. For this reason, it is important that parents become aware of the nature of social media sites, given that not all of them are healthy environments for children and adolescents. Pediatricians are in a unique position to help families understand these sites and to encourage healthy use and urge parents to monitor for potential problems with cyberbullying, "Facebook depression," sexting, and exposure to inappropriate content. (3/11)
http://pediatrics.aappublications.org/content/127/4/800

IMPROVING HEALTH AND SAFETY AT CAMP

Michael J. Ambrose, MD, FAAP; Edward A. Walton, MD, FAAP; and Council on School Health

ABSTRACT. The American Academy of Pediatrics has created recommendations for health appraisal and preparation of young people before participation in day, resident, or family camps and to guide health and safety practices at camp. These recommendations are intended for parents and families, primary health care providers, and camp administration and health center staff. Although camps have diverse environments, there are general guidelines that apply to all situations and specific recommendations that are appropriate under special conditions. This policy statement has been reviewed and is supported by the American Camp Association and Association of Camp Nursing. (6/19)

INCIDENTAL FINDINGS ON BRAIN AND SPINE IMAGING IN CHILDREN (CLINICAL REPORT)

Cormac O. Maher, MD, FAAP; Joseph H. Piatt Jr, MD, FAAP; and Section on Neurologic Surgery

ABSTRACT. In recent years, the utilization of diagnostic imaging of the brain and spine in children has increased dramatically, leading to a corresponding increase in the detection of incidental findings of the central nervous system. Patients with unexpected findings on imaging are often referred for subspecialty evaluation. Even with rational use of diagnostic imaging and subspecialty consultation, the diagnostic process will always generate unexpected findings that must be explained

and managed. Familiarity with the most common findings that are discovered incidentally on diagnostic imaging of the brain and spine will assist the pediatrician in providing counseling to families and in making recommendations in conjunction with a neurosurgeon, when needed, regarding additional treatments and prognosis. INCORPORATING RECOGNITION AND MANAGEMENT OF PERINATAL DEPRESSION INTO PEDIATRIC PRACTICE

Marian F. Earls, MD, MTS, FAAP; Michael W. Yogman, MD, FAAP; Gerri Mattson, MD, MSPH, FAAP; Jason Rafferty, MD, MPH, EdM, FAAP; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Perinatal depression (PND) is the most common obstetric complication in the United States. Even when screening results are positive, mothers often do not receive further evaluation, and even when PND is diagnosed, mothers do not receive evidence-based treatments. Studies reveal that postpartum depression (PPD), a subset of PND, leads to increased costs of medical care, inappropriate medical treatment of the infant, discontinuation of breastfeeding, family dysfunction, and an increased risk of abuse and neglect. PPD, specifically, adversely affects this critical early period of infant brain development. PND is an example of an adverse childhood experience that has potential long-term adverse health complications for the mother, her partner, the infant, and the mother-infant dyad. However, PND can be treated effectively, and the stress on the infant can be buffered. Pediatric medical homes should coordinate care more effectively with prenatal providers for women with prenatally diagnosed maternal depression; establish a system to implement PPD screening at the 1-, 2-, 4-, and 6-month well-child visits; use community resources for the treatment and referral of the mother with depression; and provide support for the maternal-child (dyad) relationship, including breastfeeding support. State chapters of the American Academy of Pediatrics, working with state departments of public health, public and private payers, and maternal and child health programs, should advocate for payment and for increased training for PND screening and treatment. American Academy of Pediatrics recommends advocacy for workforce development for mental health professionals who care for young children and mother-infant dyads, and for promotion of evidence-based interventions focused on healthy attachment and parent-child relationships. (12/18)

INCORPORATING RECOGNITION AND MANAGEMENT OF PERINATAL DEPRESSION INTO PEDIATRIC PRACTICE (TECHNICAL REPORT)

Jason Rafferty, MD, MPH, EdM, FAAP; Gerri Mattson, MD, MSPH, FAAP; Marian F. Earls, MD, MTS, FAAP; Michael W. Yogman, MD, FAAP; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Perinatal depression is the most common obstetric complication in the United States, with prevalence rates of 15% to 20% among new mothers. Untreated, it can adversly affect the well-being of children and families through increasing the risk for costly complications during birth and lead to deterioration of core supports, including partner relationships and social networks. Perinatal depression contributes to long-lasting, and even permanent, consequences for the physical and mental health of parents and children, including poor family functioning, increased risk of child abuse and neglect, delayed infant development, perinatal obstetric complications, challenges with breastfeeding, and costly increases in health care use. Perinatal depression can interfere with early parent-infant interaction and attachment, leading to potentially long-term disturbances in the child's physical, emotional, cognitive, and social development. Fortunately, perinatal depression is identifiable and treatable. The US Preventive Services Task Force, Centers for Medicare and Medicaid Services, and many professional organizations recommend routine universal screening for perinatal depression in women to facilitate early evidence-based treatment and referrals, if necessary. Despite significant gains in screening rates from 2004 to 2013, a minority of pediatricians routinely screen for postpartum depression, and many mothers are still not identified or treated. Pediatric primary care clinicians, with a core mission of promoting child and family health, are in an ideal position to implement routine postpartum depression screens at several well-child visits throughout infancy and to provide mental health support through referrals and/or the interdisciplinary services of a pediatric patient-centered medical home model. INCREASING ANTIRETROVIRAL DRUG ACCESS FOR CHILDREN WITH HIV INFECTION

Committee on Pediatric AIDS and Section on International Child Health

ABSTRACT. Although there have been great gains in the prevention of pediatric HIV infection and provision of antiretroviral therapy for children with HIV infection in resource-rich countries, many barriers remain to scaling up HIV prevention and treatment for children in resource-limited areas of the world. Appropriate testing technologies need to be made more widely available to identify HIV infection in infants. Training of practitioners in the skills required to care for children with HIV infection is required to increase the number of children receiving antiretroviral therapy. Lack of availability of appropriate antiretroviral drug formulations that are easily usable and inexpensive is a major impediment to optimal care for children with HIV. The time and energy spent trying to develop liquid antiretroviral formulations might be better used in the manufacture of smaller pill sizes or crushable tablets, which are easier to dispense, transport, store, and administer to children. (4/07, reaffirmed 4/10, 4/16)

INCREASING IMMUNIZATION COVERAGE

Committee on Practice and Ambulatory Medicine and Council on Community Pediatrics

ABSTRACT. In 1977, the American Academy of Pediatrics issued a statement calling for universal immunization of all children for whom vaccines are not contraindicated. In 1995, the policy statement "Implementation of the Immunization Policy" was published by the American Academy of Pediatrics, followed in 2003 with publication of the first version of this statement, "Increasing Immunization Coverage." Since 2003, there have continued to be improvements in immunization coverage, with progress toward meeting the goals set forth in *Healthy People 2010.* Data from the 2007 National Immunization Survey showed that 90% of children 19 to 35 months of age have received recommended doses of each of the following vaccines: inactivated poliovirus (IPV), measles-mumps-rubella (MMR), varicella-zoster virus (VZB), hepatitis B virus (HBV), and *Haemophilus influenzae* type b (Hib). For diphtheria and tetanus and acellular pertussis (DTaP) vaccine, 84.5% have received the recommended 4 doses by 35 months of age. Nevertheless, the *Healthy People 2010* goal of at least 80% coverage for the full series (at least 4 doses of DTaP, 3 doses of IPV, 1 dose of MMR, 3 doses of Hib, 3 doses of HBV, and 1 dose of varicella-zoster virus vaccine) has not yet been met, and immunization coverage of adolescents continues to lag behind the goals set forth in *Healthy People 2010.* Despite these encouraging data, a vast number of new challenges that threaten continued success toward the goal of universal immunization coverage have emerged. These challenges include an increase in new vaccines and new vaccine combinations as well as a significant

number of vaccines currently under development; a dramatic increase in the acquisition cost of vaccines, coupled with a lack of adequate payment to practitioners to buy and administer vaccines; unanticipated manufacturing and delivery problems that have caused significant shortages of various vaccine products; and the rise of a public antivaccination movement that uses the Internet as well as standard media outlets to advance a position, wholly unsupported by any scientific evidence, linking vaccines with various childhood conditions, particularly autism. Much remains to be accomplished by physician organizations; vaccine manufacturers; third-party payers; the media; and local, state, and federal governments to ensure dependable vaccine supply and payments that are sufficient to continue to provide immunizations in public and private settings and to promote effective strategies to combat unjustified misstatements by the antivaccination movement.

Pediatricians should work individually and collectively at the local, state, and national levels to ensure that all children without a valid contraindication receive all childhood immunizations on time. Pediatricians and pediatric organizations, in conjunction with government agencies such as the Centers for Disease Control and Prevention, must communicate effectively with parents to maximize their understanding of the overall safety and efficacy of vaccines. Most parents and children have not experienced many of the vaccine-preventable diseases, and the general public is not well informed about the risks and sequelae of these conditions. A number of recommendations are included for pediatricians, individually and collectively, to support further progress toward the goal of universal immunization coverage of all children for whom vaccines are not contraindicated. (5/10)

THE INDIVIDUALS WITH DISABILITIES EDUCATION ACT (IDEA) FOR CHILDREN WITH SPECIAL EDUCATIONAL NEEDS (CLINICAL REPORT)

Paul H. Lipkin, MD, FAAP; Jeffrey Okamoto, MD, FAAP; Council on Children With Disabilities; and Council on School Health

ABSTRACT. The pediatric health care provider has a critical role in supporting the health and well-being of children and adolescents in all settings, including early intervention (EI), preschool, and school environments. It is estimated that 15% of children in the United States have a disability. The Individuals with Disabilities Education Act entitles every affected child in the United States from infancy to young adulthood to a free appropriate public education through EI and special education services. These services bolster development and learning of children with various disabilities. This clinical report provides the pediatric health care provider with a summary of key components of the most recent version of this law. Guidance is also provided to ensure that every child in need receives the EI and special education services to which he or she is entitled. (11/15, reaffirmed 10/19)

INDOOR ENVIRONMENTAL CONTROL PRACTICES AND ASTHMA MANAGEMENT (CLINICAL REPORT)

Elizabeth C. Matsui, MD, MHS, FAAP; Stuart L. Abramson, MD, PhD, AE-C, FAAP; Megan T. Sandel, MD, MPH, FAAP; Section on Allergy and Immunology; and Council on Environmental Health

ABSTRACT. Indoor environmental exposures, particularly allergens and pollutants, are major contributors to asthma morbidity in children; environmental control practices aimed at reducing these exposures are an integral component of asthma management. Some individually tailored environmental control practices that have been shown to reduce asthma symptoms and exacerbations are similar in efficacy and cost to controller medications. As a part of developing tailored strategies regarding environmental control measures, an environmental history can be obtained to evaluate the key indoor environmental exposures that are known to trigger asthma symptoms and exacerbations, including both indoor pollutants and allergens. An environmental history includes questions regarding the presence of pets or pests or evidence of pests in the home, as well as knowledge regarding whether the climatic characteristics in the community favor dust mites. In addition, the history focuses on sources of indoor air pollution, including the presence of smokers who live in the home or care for children and the use of gas stoves and appliances in the home. Serum allergen-specific immunoglobulin E antibody tests can be performed or the patient can be referred for allergy skin testing to identify indoor allergens that are most likely to be clinically relevant. Environmental control strategies are tailored to each potentially relevant indoor exposure and are based on knowledge of the sources and underlying characteristics of the exposure. Strategies include source removal, source control, and mitigation strategies, such as high-efficiency particulate air purifiers and allergen-proof mattress and pillow encasements, as well as education, which can be delivered by primary care pediatricians, allergists, pediatric pulmonologists, other health care workers, or community health workers trained in asthma environmental control and asthma education. INFANT FEEDING AND TRANSMISSION OF HUMAN IMMUNODEFICIENCY VIRUS IN THE UNITED STATES

Committee on Pediatric AIDS

ABSTRACT. Physicians caring for infants born to women infected with HIV are likely to be involved in providing guidance to HIV-infected mothers on appropriate infant feeding practices. It is critical that physicians are aware of the HIV transmission risk from human milk and the current recommendations for feeding HIV-exposed infants in the United States. Because the only intervention to completely prevent HIV transmission via human milk is not to breastfeed, in the United States, where clean water and affordable replacement feeding are available, the American Academy of Pediatrics recommends that HIV-infected mothers not breastfeed their infants, regardless of maternal viral load and antiretroviral therapy. INFANT METHEMOGLOBINEMIA: THE ROLE OF DIETARY NITRATE IN FOOD AND WATER (CLINICAL REPORT)

Frank R. Greer, MD; Michael Shannon, MD; Committee on Nutrition; and Committee on Environmental Health

ABSTRACT. Infants for whom formula may be prepared with well water remain a high-risk group for nitrate poisoning. This clinical report reinforces the need for testing of well water for nitrate content. There seems to be little or no risk of nitrate poisoning from commercially prepared infant foods in the United States. However, reports of nitrate poisoning from home-prepared vegetable foods for infants continue to occur. Breastfeeding infants are not at risk of methemoglobinemia even when mothers ingest water with very high concentrations of nitrate nitrogen (100 ppm). (9/05, reaffirmed 4/09)

INFECTION PREVENTION AND CONTROL IN PEDIATRIC AMBULATORY SETTINGS

Mobeen H. Rathore, MD, FAAP; Mary Anne Jackson, MD, FAAP; and Committee on Infectious Diseases

ABSTRACT. Since the American Academy of Pediatrics published its statement titled "Infection Prevention and Control in Pediatric Ambulatory Settings" in 2007, there have been significant changes that prompted this updated statement. Infection prevention and control is an integral part of pediatric practice in ambulatory medical settings as well as in hospitals.

Infection prevention and control practices should begin at the time the ambulatory visit is scheduled. All health care personnel should be educated regarding the routes of transmission and techniques used to prevent the transmission of infectious agents. Policies for infection prevention and control should be written, readily available, updated every 2 years, and enforced. Many of the recommendations for infection control and prevention from the Centers for Disease Control and Prevention for hospitalized patients are also applicable in the ambulatory setting. These recommendations include requirements for pediatricians to take precautions to identify and protect employees likely to be exposed to blood or other potentially infectious materials while on the job. In addition to emphasizing the key principles of infection prevention and control in this policy, we update those that are relevant to the ambulatory care patient. These guidelines emphasize the role of hand hygiene and the implementation of diagnosis- and syndrome-specific isolation precautions, with the exemption of the use of gloves for routine diaper changes and wiping a well child's nose or tears for most patient encounters. Additional topics include respiratory hygiene and cough etiquette strategies for patients with a respiratory tract infection, including those relevant for special populations like patients with cystic fibrosis or those in short-term residential facilities; separation of infected, contagious children from uninfected children when feasible; safe handling and disposal of needles and other sharp medical devices; appropriate use of personal protective equipment, such as gloves, gowns, masks, and eye protection; and appropriate use of sterilization, disinfection, and antisepsis. Lastly, in this policy, we emphasize the importance of public health interventions, including vaccination for patients and health care personnel, and outline the responsibilities of the health care provider related to prompt public health notification for specific reportable diseases and communication with colleagues who may be providing subsequent care of an infected patient to optimize the use of isolation precautions and limit the spread of contagions. (10/17)

INFECTIOUS COMPLICATIONS WITH THE USE OF BIOLOGIC RESPONSE MODIFIERS IN INFANTS AND CHILDREN (CLINICAL REPORT)

H. Dele Davies, MD, FAAP, and Committee on Infectious Diseases

ABSTRACT. Biologic response modifiers (BRMs) are substances that interact with and modify the host immune system. BRMs that dampen the immune system are used to treat conditions such as juvenile idiopathic arthritis, psoriatic arthritis, or inflammatory bowel disease and often in combination with other immunosuppressive agents, such as methotrexate and corticosteroids. Cytokines that are targeted include tumor necrosis factor α; interleukins (ILs) 6, 12, and 23; and the receptors for IL-1α (IL-1A) and IL-1β (IL-1B) as well as other molecules. Although the risk varies with the class of BRM, patients receiving immune-dampening BRMs generally are at increased risk of infection or reactivation with mycobacterial infections (*Mycobacterium tuberculosis* and nontuberculous mycobacteria), some viral (herpes simplex virus, varicella-zoster virus, Epstein-Barr virus, hepatitis B) and fungal (histoplasmosis, coccidioidomycosis) infections, as well as other opportunistic infections. The use of BRMs warrants careful determination of infectious risk on the basis of history (including exposure, residence, and travel and immunization history) and selected baseline screening test results. Routine immunizations should be given at least 2 weeks (inactivated or subunit vaccines) or 4 weeks (live vaccines) before initiation of BRMs whenever feasible, and inactivated influenza vaccine should be given annually. Inactivated and subunit vaccines should be given when needed while taking BRMs, but live vaccines should be avoided unless under special circumstances in consultation with an infectious diseases specialist. If the patient develops a febrile or serious respiratory illness during BRM therapy, consideration should be given to stopping the BRM while actively searching for and treating possible infectious causes. (7/16)

INFECTIOUS DISEASES ASSOCIATED WITH ORGANIZED SPORTS AND OUTBREAK CONTROL (CLINICAL REPORT)

H. Dele Davies, MD, MS, MHCM, FAAP; Mary Anne Jackson, MD, FAAP; Stephen G. Rice, MD, PhD, MPH, FAAP; Committee on Infectious Diseases; and Council on Sports Medicine and Fitness

ABSTRACT. Participation in organized sports has a variety of health benefits but also has the potential to expose the athlete to a variety of infectious diseases, some of which may produce outbreaks. Major risk factors for infection include skin-to-skin contact with athletes who have active skin infections, environmental exposures and physical trauma, and sharing of equipment and contact with contaminated fomites. Close contact that is intrinsic to team sports and psychosocial factors associated with adolescence are additional risks. Minimizing risk requires leadership by the organized sports community (including the athlete's primary care provider) and depends on outlining key hygiene behaviors, recognition, diagnosis, and treatment of common sports-related infections, and the implementation of preventive interventions. (9/17)

INFLUENZA IMMUNIZATION FOR ALL HEALTH CARE PERSONNEL: KEEP IT MANDATORY

Committee on Infectious Diseases

ABSTRACT. The purpose of this statement is to reaffirm the American Academy of Pediatrics' support for a mandatory influenza immunization policy for all health care personnel. With an increasing number of organizations requiring influenza vaccination, coverage among health care personnel has risen to 75% in the 2013 to 2014 influenza season but still remains below the Healthy People 2020 objective of 90%. Mandatory influenza immunization for all health care personnel is ethical, just, and necessary to improve patient safety. It is a crucial step in efforts to reduce health care–associated influenza infections. (9/15)

INFORMED CONSENT IN DECISION-MAKING IN PEDIATRIC PRACTICE

Committee on Bioethics

ABSTRACT. Informed consent should be seen as an essential part of health care practice; parental permission and childhood assent is an active process that engages patients, both adults and children, in health care. Pediatric practice is unique in that developmental maturation allows, over time, for increasing inclusion of the child's and adolescent's opinion in medical decision-making in clinical practice and research. (7/16)

http://pediatrics.aappublications.org/content/138/2/e20161484

INFORMED CONSENT IN DECISION-MAKING IN PEDIATRIC PRACTICE (TECHNICAL REPORT)

Aviva L. Katz, MD, FAAP; Sally A. Webb, MD, FAAP; and Committee on Bioethics

ABSTRACT. Informed consent should be seen as an essential part of health care practice; parental permission and childhood assent is an active process that engages patients, both adults and children, in their health care. Pediatric practice is unique in that developmental maturation allows, over time, for increasing inclusion of the child's and adolescent's opinion in medical decision-making in clinical practice and research. This technical report, which accompanies the policy statement "Informed Consent in Decision-Making in Pediatric Practice," was written to provide a broader background on the nature of informed

consent, surrogate decision-making in pediatric practice, information on child and adolescent decision-making, and special issues in adolescent informed consent, assent, and refusal. It is anticipated that this information will help provide support for the recommendations included in the policy statement. (7/16)
http://pediatrics.aappublications.org/content/138/2/e20161485

INJURIES ASSOCIATED WITH INFANT WALKERS

Committee on Injury and Poison Prevention
ABSTRACT. In 1999, an estimated 8800 children younger than 15 months were treated in hospital emergency departments in the United States for injuries associated with infant walkers. Thirty-four infant walker-related deaths were reported from 1973 through 1998. The vast majority of injuries occur from falls down stairs, and head injuries are common. Walkers do not help a child learn to walk; indeed, they can delay normal motor and mental development. The use of warning labels, public education, adult supervision during walker use, and stair gates have all been demonstrated to be insufficient strategies to prevent injuries associated with infant walkers. To comply with the revised voluntary standard (ASTM F977-96), walkers manufactured after June 30, 1997, must be wider than a 36-in doorway or must have a braking mechanism designed to stop the walker if 1 or more wheels drop off the riding surface, such as at the top of a stairway. Because data indicate a considerable risk of major and minor injury and even death from the use of infant walkers, and because there is no clear benefit from their use, the American Academy of Pediatrics recommends a ban on the manufacture and sale of mobile infant walkers. If a parent insists on using a mobile infant walker, it is vital that they choose a walker that meets the performance standards of ASTM F977-96 to prevent falls down stairs. Stationary activity centers should be promoted as a safer alternative to mobile infant walkers. (9/01, reaffirmed 1/05, 2/08, 10/11, 11/14)
http://pediatrics.aappublications.org/content/108/3/790

INJURY RISK OF NONPOWDER GUNS (TECHNICAL REPORT)

Committee on Injury, Violence, and Poison Prevention
ABSTRACT. Nonpowder guns (ball-bearing [BB] guns, pellet guns, air rifles, paintball guns) continue to cause serious injuries to children and adolescents. The muzzle velocity of these guns can range from approximately 150 ft/second to 1200 ft/second (the muzzle velocities of traditional firearm pistols are 750 ft/second to 1450 ft/second). Both low- and high-velocity nonpowder guns are associated with serious injuries, and fatalities can result from high-velocity guns. A persisting problem is the lack of medical recognition of the severity of injuries that can result from these guns, including penetration of the eye, skin, internal organs, and bone. Nationally, in 2000, there were an estimated 21840 (coefficient of variation: 0.0821) injuries related to nonpowder guns, with approximately 4% resulting in hospitalization. Between 1990 and 2000, the US Consumer Product Safety Commission reported 39 nonpowder gun–related deaths, of which 32 were children younger than 15 years. The introduction of high-powered air rifles in the 1970s has been associated with approximately 4 deaths per year. The advent of war games and the use of paintball guns have resulted in a number of reports of injuries, especially to the eye. Injuries associated with nonpowder guns should receive prompt medical management similar to the management of firearm-related injuries, and nonpowder guns should never be characterized as toys. (11/04, reaffirmed 2/08, 10/11)

IN-LINE SKATING INJURIES IN CHILDREN AND ADOLESCENTS

Committee on Injury and Poison Prevention and Committee on Sports Medicine and Fitness
ABSTRACT. In-line skating has become one of the fastest-growing recreational sports in the United States. Recent studies emphasize the value of protective gear in reducing the incidence of injuries. Recommendations are provided for parents and pediatricians, with special emphasis on the novice or inexperienced skater. (4/98, reaffirmed 1/02, 1/06, 1/09, 11/11)
http://pediatrics.aappublications.org/content/101/4/720

INSTITUTIONAL ETHICS COMMITTEES

Margaret Moon, MD, MPH, FAAP, and Committee on Bioethics
ABSTRACT. In hospitals throughout the United States, institutional ethics committees (IECs) have become a standard vehicle for the education of health professionals about biomedical ethics, for the drafting and review of hospital policy, and for clinical ethics case consultation. In addition, there is increasing interest in a role for the IEC in organizational ethics. Recommendations are made about the membership and structure of an IEC, and guidance is provided for those serving on an IEC. (4/19)

INSUFFICIENT SLEEP IN ADOLESCENTS AND YOUNG ADULTS: AN UPDATE ON CAUSES AND CONSEQUENCES (TECHNICAL REPORT)

Judith Owens, MD, MPH, FAAP; Adolescent Sleep Working Group; and Committee on Adolescence
ABSTRACT. Chronic sleep loss and associated sleepiness and daytime impairments in adolescence are a serious threat to the academic success, health, and safety of our nation's youth and an important public health issue. Understanding the extent and potential short- and long-term repercussions of sleep restriction, as well as the unhealthy sleep practices and environmental factors that contribute to sleep loss in adolescents, is key in setting public policies to mitigate these effects and in counseling patients and families in the clinical setting. This report reviews the current literature on sleep patterns in adolescents, factors contributing to chronic sleep loss (ie, electronic media use, caffeine consumption), and health-related consequences, such as depression, increased obesity risk, and higher rates of drowsy driving accidents. The report also discusses the potential role of later school start times as a means of reducing adolescent sleepiness. (8/14)
http://pediatrics.aappublications.org/content/134/3/e921

INTENSIVE TRAINING AND SPORTS SPECIALIZATION IN YOUNG ATHLETES

Committee on Sports Medicine and Fitness
ABSTRACT. Children involved in sports should be encouraged to participate in a variety of different activities and develop a wide range of skills. Young athletes who specialize in just one sport may be denied the benefits of varied activity while facing additional physical, physiologic, and psychologic demands from intense training and competition.

This statement reviews the potential risks of high-intensity training and sports specialization in young athletes. Pediatricians who recognize these risks can have a key role in monitoring the health of these young athletes and helping reduce risks associated with high-level sports participation. (7/00, reaffirmed 11/04, 1/06, 5/09, 10/14)
http://pediatrics.aappublications.org/content/106/1/154

INTERFERON-γ RELEASE ASSAYS FOR DIAGNOSIS OF TUBERCULOSIS INFECTION AND DISEASE IN CHILDREN (TECHNICAL REPORT)

Jeffrey R. Starke, MD, FAAP, and Committee on Infectious Diseases

ABSTRACT. Tuberculosis (TB) remains an important problem among children in the United States and throughout the world. Although diagnosis and treatment of infection with *Mycobacterium tuberculosis* (also referred to as latent tuberculosis infection [LTBI] or TB infection) remain the lynchpins of TB prevention, there is no diagnostic reference standard for LTBI. The tuberculin skin test (TST) has many limitations, including difficulty in administration and interpretation, the need for a return visit by the patient, and false-positive results caused by significant cross-reaction with *Mycobacterium bovis*–bacille Calmette-Guérin (BCG) vaccines and many nontuberculous mycobacteria. Interferon-γ release assays (IGRAs) are blood tests that measure ex vivo T-lymphocyte release of interferon-γ after stimulation by antigens specific for *M tuberculosis.* Because these antigens are not found on *M bovis*–BCG or most nontuberculous mycobacteria, IGRAs are more specific tests than the TST, yielding fewer false-positive results. However, IGRAs have little advantage over the TST in sensitivity, and both methods have reduced sensitivity in immunocompromised children, including children with severe TB disease. Both methods have a higher positive predictive value when applied to children with risk factors for LTBI. Unfortunately, neither method distinguishes between TB infection and TB disease. The objective of this technical report is to review what IGRAs are most useful for: (1) increasing test specificity in children who have received a BCG vaccine and may have a false-positive TST result; (2) using with the TST to increase sensitivity for finding LTBI in patients at high risk of developing progression from LTBI to disease; and (3) helping to diagnose TB disease. (11/14, reaffirmed 7/18)

INTERPRETATION OF DO NOT ATTEMPT RESUSCITATION ORDERS FOR CHILDREN REQUIRING ANESTHESIA AND SURGERY (CLINICAL REPORT)

Mary E. Fallat, MD, FAAP; Courtney Hardy, MD, MBA, FAAP; Section on Surgery; Section on Anesthesiology and Pain Medicine; and Committee on Bioethics

ABSTRACT. This clinical report addresses the topic of preexisting do not attempt resuscitation or limited resuscitation orders for children and adolescents undergoing anesthesia and surgery. Pertinent considerations for the clinician include the rights of children, decision-making by parents or legally approved representatives, the process of informed consent, and the roles of surgeon and anesthesiologist. A process of re-evaluation of the do not attempt resuscitation orders, called "required reconsideration," should be incorporated into the process of informed consent for surgery and anesthesia, distinguishing between goal-directed and procedure-directed approaches. The child's individual needs are best served by allowing the parent or legally approved representative and involved clinicians to consider whether full resuscitation, limitations based on procedures, or limitations based on goals is most appropriate. (4/18)

http://pediatrics.aappublications.org/content/141/5/e20180598

INTIMATE PARTNER VIOLENCE: THE ROLE OF THE PEDIATRICIAN (CLINICAL REPORT)

Jonathan D. Thackeray, MD; Roberta Hibbard, MD; M. Denise Dowd, MD, MPH; Committee on Child Abuse and Neglect; and Committee on Injury, Violence, and Poison Prevention

ABSTRACT. The American Academy of Pediatrics and its members recognize the importance of improving the physician's ability to recognize intimate partner violence (IPV) and understand its effects on child health and development and its role in the continuum of family violence. Pediatricians are in a unique position to identify abused caregivers in pediatric settings and to evaluate and treat children raised in homes in which IPV may occur. Children exposed to IPV are at increased risk of being abused and neglected and are more likely to develop adverse health, behavioral, psychological, and social disorders later in life. Identifying IPV, therefore, may be one of the most effective means of preventing child abuse and identifying caregivers and children who may be in need of treatment and/or therapy. Pediatricians should be aware of the profound effects of exposure to IPV on children. (4/10, reaffirmed 1/14, 3/19)

IODINE DEFICIENCY, POLLUTANT CHEMICALS, AND THE THYROID: NEW INFORMATION ON AN OLD PROBLEM

Council on Environmental Health

ABSTRACT. Many women of reproductive age in the United States are marginally iodine deficient, perhaps because the salt in processed foods is not iodized. Iodine deficiency, per se, can interfere with normal brain development in their offspring; in addition, it increases vulnerability to the effects of certain environmental pollutants, such as nitrate, thiocyanate, and perchlorate. Although pregnant and lactating women should take a supplement containing adequate iodide, only about 15% do so. Such supplements, however, may not contain enough iodide and may not be labeled accurately. The American Thyroid Association recommends that pregnant and lactating women take a supplement with adequate iodide. The American Academy of Pediatrics recommends that pregnant and lactating women also avoid exposure to excess nitrate, which would usually occur from contaminated well water, and thiocyanate, which is in cigarette smoke. Perchlorate is currently a candidate for regulation as a water pollutant. The Environmental Protection Agency should proceed with appropriate regulation, and the Food and Drug Administration should address the mislabeling of the iodine content of prenatal/lactation supplements. LACTOSE INTOLERANCE IN INFANTS, CHILDREN, AND ADOLESCENTS (CLINICAL REPORT)

Melvin B. Heyman, MD, MPH, and Committee on Nutrition

ABSTRACT. The American Academy of Pediatrics Committee on Nutrition presents an updated review of lactose intolerance in infants, children, and adolescents. Differences between primary, secondary, congenital, and developmental lactase deficiency that may result in lactose intolerance are discussed. Children with suspected lactose intolerance can be assessed clinically by dietary lactose elimination or by tests including noninvasive hydrogen breath testing or invasive intestinal biopsy determination of lactase (and other disaccharidase) concentrations. Treatment consists of use of lactase-treated dairy products or oral lactase supplementation, limitation of lactose-containing foods, or dairy elimination. The American Academy of Pediatrics supports use of dairy foods as an important source of calcium for bone mineral health and of other nutrients that facilitate growth in children and adolescents. If dairy products are eliminated, other dietary sources of calcium or calcium supplements need to be provided. (9/06, reaffirmed 8/12)

"LATE-PRETERM" INFANTS: A POPULATION AT RISK (CLINICAL REPORT)

William A. Engle, MD; Kay M. Tomashek, MD; Carol Wallman, MSN; and Committee on Fetus and Newborn

ABSTRACT. Late-preterm infants, defined by birth at 34⁰⁄₇ through 36⁶⁄₇ weeks' gestation, are less physiologically and metabolically mature than term infants. Thus, they are at higher risk of morbidity and mortality than term infants. The purpose of this report is to define "late preterm," recommend a change

in terminology from "near term" to "late preterm," present the characteristics of late-preterm infants that predispose them to a higher risk of morbidity and mortality than term infants, and propose guidelines for the evaluation and management of these infants after birth. (12/07, reaffirmed 5/10, 6/18)

LAWN MOWER-RELATED INJURIES TO CHILDREN

Committee on Injury and Poison Prevention

ABSTRACT. Lawn mower-related injuries to children are relatively common and can result in severe injury or death. Many amputations during childhood are caused by power mowers. Pediatricians have an important role as advocates and educators to promote the prevention of these injuries. (6/01, reaffirmed 10/04, 5/07, 6/10)
http://pediatrics.aappublications.org/content/107/6/1480

LAWN MOWER-RELATED INJURIES TO CHILDREN (TECHNICAL REPORT)

Committee on Injury and Poison Prevention

ABSTRACT. In the United States, approximately 9400 children younger than 18 years receive emergency treatment annually for lawn mower-related injuries. More than 7% of these children require hospitalization, and power mowers cause a large proportion of the amputations during childhood. Prevention of lawn mower-related injuries can be achieved by design changes of lawn mowers, guidelines for mower operation, and education of parents, child caregivers, and children. Pediatricians have an important role as advocates and educators to promote the prevention of these injuries. (6/01, reaffirmed 10/04, 5/07, 6/10)

LEARNING DISABILITIES, DYSLEXIA, AND VISION

Section on Ophthalmology and Council on Children With Disabilities (joint with American Academy of Ophthalmology, American Association for Pediatric Ophthalmology and Strabismus, and American Association of Certified Orthoptists)

ABSTRACT. Learning disabilities, including reading disabilities, are commonly diagnosed in children. Their etiologies are multifactorial, reflecting genetic influences and dysfunction of brain systems. Learning disabilities are complex problems that require complex solutions. Early recognition and referral to qualified educational professionals for evidence-based evaluations and treatments seem necessary to achieve the best possible outcome. Most experts believe that dyslexia is a language-based disorder. Vision problems can interfere with the process of learning; however, vision problems are not the cause of primary dyslexia or learning disabilities. Scientific evidence does not support the efficacy of eye exercises, behavioral vision therapy, or special tinted filters or lenses for improving the long-term educational performance in these complex pediatric neurocognitive conditions. Diagnostic and treatment approaches that lack scientific evidence of efficacy, including eye exercises, behavioral vision therapy, or special tinted filters or lenses, are not endorsed and should not be recommended. (7/09, reaffirmed 7/14)

LEARNING DISABILITIES, DYSLEXIA, AND VISION (TECHNICAL REPORT)

Sheryl M. Handler, MD; Walter M. Fierson, MD; Section on Ophthalmology; and Council on Children With Disabilities (joint with American Academy of Ophthalmology, American Association for Pediatric Ophthalmology and Strabismus, and American Association of Certified Orthoptists)

ABSTRACT. Learning disabilities constitute a diverse group of disorders in which children who generally possess at least average intelligence have problems processing information or generating output. Their etiologies are multifactorial and reflect genetic influences and dysfunction of brain systems. Reading disability, or dyslexia, is the most common learning disability. It is a receptive language-based learning disability that is characterized by difficulties with decoding, fluent word recognition, rapid automatic naming, and/or reading-comprehension skills. These difficulties typically result from a deficit in the phonologic component of language that makes it difficult to use the alphabetic code to decode the written word. Early recognition and referral to qualified professionals for evidence-based evaluations and treatments are necessary to achieve the best possible outcome. Because dyslexia is a language-based disorder, treatment should be directed at this etiology. Remedial programs should include specific instruction in decoding, fluency training, vocabulary, and comprehension. Most programs include daily intensive individualized instruction that explicitly teaches phonemic awareness and the application of phonics. Vision problems can interfere with the process of reading, but children with dyslexia or related learning disabilities have the same visual function and ocular health as children without such conditions. Currently, there is inadequate scientific evidence to support the view that subtle eye or visual problems cause or increase the severity of learning disabilities. Because they are difficult for the public to understand and for educators to treat, learning disabilities have spawned a wide variety of scientifically unsupported vision-based diagnostic and treatment procedures. Scientific evidence does not support the claims that visual training, muscle exercises, ocular pursuit-and-tracking exercises, behavioral/perceptual vision therapy, "training" glasses, prisms, and colored lenses and filters are effective direct or indirect treatments for learning disabilities. There is no valid evidence that children who participate in vision therapy are more responsive to educational instruction than children who do not participate. (3/11)

LEVELS OF NEONATAL CARE

Committee on Fetus and Newborn

ABSTRACT. Provision of risk-appropriate care for newborn infants and mothers was first proposed in 1976. This updated policy statement provides a review of data supporting evidence for a tiered provision of care and reaffirms the need for uniform, nationally applicable definitions and consistent standards of service for public health to improve neonatal outcomes. Facilities that provide hospital care for newborn infants should be classified on the basis of functional capabilities, and these facilities should be organized within a regionalized system of perinatal care. (8/12, reaffirmed 9/15)

THE LIFELONG EFFECTS OF EARLY CHILDHOOD ADVERSITY AND TOXIC STRESS (TECHNICAL REPORT)

Jack P. Shonkoff, MD; Andrew S. Garner, MD, PhD; Committee on Psychosocial Aspects of Child and Family Health; Committee on Early Childhood, Adoption, and Dependent Care; and Section on Developmental and Behavioral Pediatrics

ABSTRACT. Advances in fields of inquiry as diverse as neuroscience, molecular biology, genomics, developmental psychology, epidemiology, sociology, and economics are catalyzing an important paradigm shift in our understanding of health and disease across the lifespan. This converging, multidisciplinary science of human development has profound implications for our ability to enhance the life prospects of children and to strengthen the social and economic fabric of society. Drawing on these multiple streams of investigation, this report presents an ecobiodevelopmental framework that illustrates how early experiences and environmental influences can leave a lasting signature on the genetic predispositions that affect emerging brain architecture and long-term health. The report also examines extensive evidence of the disruptive impacts of toxic stress, offering intriguing

insights into causal mechanisms that link early adversity to later impairments in learning, behavior, and both physical and mental well-being. The implications of this framework for the practice of medicine, in general, and pediatrics, specifically, are potentially transformational. They suggest that many adult diseases should be viewed as developmental disorders that begin early in life and that persistent health disparities associated with poverty, discrimination, or maltreatment could be reduced by the alleviation of toxic stress in childhood. An ecobiodevelopmental framework also underscores the need for new thinking about the focus and boundaries of pediatric practice. It calls for pediatricians to serve as both front-line guardians of healthy child development and strategically positioned, community leaders to inform new science-based strategies that build strong foundations for educational achievement, economic productivity, responsible citizenship, and lifelong health. (12/11, reaffirmed 7/16)

THE LINK BETWEEN SCHOOL ATTENDANCE AND GOOD HEALTH

Mandy A. Allison, MD, MSPH, FAAP; Elliott Attisha, DO, FAAP; and Council on School Health

ABSTRACT. More than 6.5 million children in the United States, approximately 13% of all students, miss 15 or more days of school each year. The rates of chronic absenteeism vary between states, communities, and schools, with significant disparities based on income, race, and ethnicity. Chronic school absenteeism, starting as early as preschool and kindergarten, puts students at risk for poor school performance and school dropout, which in turn, put them at risk for unhealthy behaviors as adolescents and young adults as well as poor long-term health outcomes. Pediatricians and their colleagues caring for children in the medical setting have opportunities at the individual patient and/or family, practice, and population levels to promote school attendance and reduce chronic absenteeism and resulting health disparities. Although this policy statement is primarily focused on absenteeism related to students' physical and mental health, pediatricians may play a role in addressing absenteeism attributable to a wide range of factors through individual interactions with patients and their parents and through community-, state-, and federal-level advocacy. LITERACY PROMOTION: AN ESSENTIAL COMPONENT OF PRIMARY CARE PEDIATRIC PRACTICE

Council on Early Childhood

ABSTRACT. Reading regularly with young children stimulates optimal patterns of brain development and strengthens parent-child relationships at a critical time in child development, which, in turn, builds language, literacy, and social-emotional skills that last a lifetime. Pediatric providers have a unique opportunity to encourage parents to engage in this important and enjoyable activity with their children beginning in infancy. Research has revealed that parents listen and children learn as a result of literacy promotion by pediatricians, which provides a practical and evidence-based opportunity to support early brain development in primary care practice. The American Academy of Pediatrics (AAP) recommends that pediatric providers promote early literacy development for children beginning in infancy and continuing at least until the age of kindergarten entry by (1) advising all parents that reading aloud with young children can enhance parent-child relationships and prepare young minds to learn language and early literacy skills; (2) counseling all parents about developmentally appropriate shared-reading activities that are enjoyable for children and their parents and offer language-rich exposure to books, pictures, and the written word; (3) providing developmentally appropriate books given at health supervision visits for all high-risk, low-income young children; (4) using a robust spectrum of options to support and promote these efforts; and (5) partnering with other child advocates to influence national messaging and policies that support and promote these key early shared-reading experiences. The AAP supports federal and state funding for children's books to be provided at pediatric health supervision visits to children at high risk living at or near the poverty threshold and the integration of literacy promotion, an essential component of pediatric primary care, into pediatric resident education. This policy statement is supported by the AAP technical report "School Readiness" and supports the AAP policy statement "Early Childhood Adversity, Toxic Stress, and the Role of the Pediatrician: Translating Developmental Science Into Lifelong Health." LONG-ACTING REVERSIBLE CONTRACEPTION: SPECIFIC ISSUES FOR ADOLESCENTS (CLINICAL REPORT)

Seema Menon, MD, and Committee on Adolescence

ABSTRACT. Long-acting reversible contraceptives are the most effective methods to prevent pregnancy and also offer noncontraceptive benefits such as reducing menstrual blood flow and dysmenorrhea. The safety and efficacy of long-acting reversible contraception are well established for adolescents, but the rate of use remains low for this population. The pediatrician can play a key role in increasing access to long-acting reversible contraception for adolescents by providing accurate patient-centered contraception counseling and by understanding and addressing the barriers to use. LONG-TERM FOLLOW-UP CARE FOR PEDIATRIC CANCER SURVIVORS (CLINICAL REPORT)

Section on Hematology/Oncology (joint with Children's Oncology Group)

ABSTRACT. Progress in therapy has made survival into adulthood a reality for most children, adolescents, and young adults diagnosed with cancer today. Notably, this growing population remains vulnerable to a variety of long-term therapy-related sequelae. Systematic ongoing follow-up of these patients, therefore, is important for providing for early detection of and intervention for potentially serious late-onset complications. In addition, health counseling and promotion of healthy lifestyles are important aspects of long-term follow-up care to promote risk reduction for health problems that commonly present during adulthood. Both general and subspecialty pediatric health care providers are playing an increasingly important role in the ongoing care of childhood cancer survivors, beyond the routine preventive care, health supervision, and anticipatory guidance provided to all patients. This report is based on the guidelines that have been developed by the Children's Oncology Group to facilitate comprehensive long-term follow-up of childhood cancer survivors (www.survivorshipguidelines.org). (3/09, reaffirmed 4/13, 8/17)

MAINTAINING AND IMPROVING THE ORAL HEALTH OF YOUNG CHILDREN

Section on Oral Health

ABSTRACT. Oral health is an integral part of the overall health of children. Dental caries is a common and chronic disease process with significant short- and long-term consequences. The prevalence of dental caries for the youngest of children has not decreased over the past decade, despite improvements for older children. As health care professionals responsible for the overall health of children, pediatricians frequently confront morbidity associated with dental caries. Because the youngest children visit the pediatrician more often than they visit the dentist, it is

important that pediatricians be knowledgeable about the disease process of dental caries, prevention of the disease, and interventions available to the pediatrician and the family to maintain and restore health. (11/14, reaffirmed 1/19)

MALE ADOLESCENT SEXUAL AND REPRODUCTIVE HEALTH CARE (CLINICAL REPORT)

Arik V. Marcell, MD, MPH; Charles Wibbelsman, MD; Warren M. Seigel, MD; and Committee on Adolescence

ABSTRACT. Male adolescents' sexual and reproductive health needs often go unmet in the primary care setting. This report discusses specific issues related to male adolescents' sexual and reproductive health care in the context of primary care, including pubertal and sexual development, sexual behavior, consequences of sexual behavior, and methods of preventing sexually transmitted infections (including HIV) and pregnancy. Pediatricians are encouraged to address male adolescent sexual and reproductive health on a regular basis, including taking a sexual history, performing an appropriate examination, providing patient-centered and age-appropriate anticipatory guidance, and delivering appropriate vaccinations. Pediatricians should provide these services to male adolescent patients in a confidential and culturally appropriate manner, promote healthy sexual relationships and responsibility, and involve parents in age-appropriate discussions about sexual health with their sons. (11/11, reaffirmed 5/15)
http://pediatrics.aappublications.org/content/128/6/e1658

MALE CIRCUMCISION (TECHNICAL REPORT)

Task Force on Circumcision

ABSTRACT. Male circumcision consists of the surgical removal of some, or all, of the foreskin (or prepuce) from the penis. It is one of the most common procedures in the world. In the United States, the procedure is commonly performed during the newborn period. In 2007, the American Academy of Pediatrics (AAP) convened a multidisciplinary workgroup of AAP members and other stakeholders to evaluate the evidence regarding male circumcision and update the AAP's 1999 recommendations in this area. The Task Force included AAP representatives from specialty areas as well as members of the AAP Board of Directors and liaisons representing the American Academy of Family Physicians, the American College of Obstetricians and Gynecologists, and the Centers for Disease Control and Prevention. The Task Force members identified selected topics relevant to male circumcision and conducted a critical review of peer-reviewed literature by using the American Heart Association's template for evidence evaluation.

Evaluation of current evidence indicates that the health benefits of newborn male circumcision outweigh the risks; furthermore, the benefits of newborn male circumcision justify access to this procedure for families who choose it. Specific benefits from male circumcision were identified for the prevention of urinary tract infections, acquisition of HIV, transmission of some sexually transmitted infections, and penile cancer. Male circumcision does not appear to adversely affect penile sexual function/sensitivity or sexual satisfaction. It is imperative that those providing circumcision are adequately trained and that both sterile techniques and effective pain management are used. Significant acute complications are rare. In general, untrained providers who perform circumcisions have more complications than well-trained providers who perform the procedure, regardless of whether the former are physicians, nurses, or traditional religious providers.

Parents are entitled to factually correct, nonbiased information about circumcision and should receive this information from clinicians before conception or early in pregnancy, which is when parents typically make circumcision decisions. Parents should determine what is in the best interest of their child. Physicians who counsel families about this decision should provide assistance by explaining the potential benefits and risks and ensuring that parents understand that circumcision is an elective procedure. The Task Force strongly recommends the creation, revision, and enhancement of educational materials to assist parents of male infants with the care of circumcised and uncircumcised penises. The Task Force also strongly recommends the development of educational materials for providers to enhance practitioners' competency in discussing circumcision's benefits and risks with parents.

The Task Force made the following recommendations:

- Evaluation of current evidence indicates that the health benefits of newborn male circumcision outweigh the risks, and the benefits of newborn male circumcision justify access to this procedure for those families who choose it.
- Parents are entitled to factually correct, nonbiased information about circumcision that should be provided before conception and early in pregnancy, when parents are most likely to be weighing the option of circumcision of a male child.
- Physicians counseling families about elective male circumcision should assist parents by explaining, in a nonbiased manner, the potential benefits and risks and by ensuring that they understand the elective nature of the procedure.
- Parents should weigh the health benefits and risks in light of their own religious, cultural, and personal preferences, as the medical benefits alone may not outweigh these other considerations for individual families.
- Parents of newborn boys should be instructed in the care of the penis, regardless of whether the newborn has been circumcised or not.
- Elective circumcision should be performed only if the infant's condition is stable and healthy.
- Male circumcision should be performed by trained and competent practitioners, by using sterile techniques and effective pain management.
- Analgesia is safe and effective in reducing the procedural pain associated with newborn circumcision; thus, adequate analgesia should be provided whenever newborn circumcision is performed.
  - — Nonpharmacologic techniques (eg, positioning, sucrose pacifiers) alone are insufficient to prevent procedural and postprocedural pain and are not recommended as the sole method of analgesia. They should be used only as analgesic adjuncts to improve infant comfort during circumcision.
  - — If used, topical creams may cause a higher incidence of skin irritation in low birth weight infants, compared with infants of normal weight; penile nerve block techniques should therefore be chosen for this group of newborns.
- Key professional organizations (AAP, the American Academy of Family Physicians, the American College of Obstetricians and Gynecologists, the American Society of Anesthesiologists, the American College of Nurse Midwives, and other midlevel clinicians such as nurse practitioners) should work collaboratively to:
  - — Develop standards of trainee proficiency in the performance of anesthetic and procedure techniques, including suturing;
  - — Teach the procedure and analgesic techniques during postgraduate training programs;

— Develop educational materials for clinicians to enhance their own competency in discussing the benefits and risks of circumcision with parents;

— Offer educational materials to assist parents of male infants with the care of both circumcised and uncircumcised penises.

- The preventive and public health benefits associated with newborn male circumcision warrant third-party reimbursement of the procedure.

The American College of Obstetricians and Gynecologists has endorsed this technical report. (8/12)

http://pediatrics.aappublications.org/content/130/3/e756

MALTREATMENT OF CHILDREN WITH DISABILITIES (CLINICAL REPORT)

Roberta A. Hibbard, MD; Larry W. Desch, MD; Committee on Child Abuse and Neglect; and Council on Children With Disabilities

ABSTRACT. Widespread efforts are being made to increase awareness and provide education to pediatricians regarding risk factors of child abuse and neglect. The purpose of this clinical report is to ensure that children with disabilities are recognized as a population that is also at risk of maltreatment. Some conditions related to a disability can be confused with maltreatment. The need for early recognition and intervention of child abuse and neglect in this population, as well as the ways that a medical home can facilitate the prevention and early detection of child maltreatment, are the subject of this report. (5/07, reaffirmed 1/11, 4/16)

MANAGEMENT OF DENTAL TRAUMA IN A PRIMARY CARE SETTING (CLINICAL REPORT)

Martha Ann Keels, DDS, PhD, and Section on Oral Health

ABSTRACT. The American Academy of Pediatrics and its Section on Oral Health have developed this clinical report for pediatricians and primary care physicians regarding the diagnosis, evaluation, and management of dental trauma in children aged 1 to 21 years. This report was developed through a comprehensive search and analysis of the medical and dental literature and expert consensus. Guidelines published and updated by the International Association of Dental Traumatology (www.dentaltraumaguide.com) are an excellent resource for both dental and nondental health care providers. (1/14)

http://pediatrics.aappublications.org/content/133/2/e466

MANAGEMENT OF FOOD ALLERGY IN THE SCHOOL SETTING (CLINICAL REPORT)

Scott H. Sicherer, MD; Todd Mahr, MD; and Section on Allergy and Immunology

ABSTRACT. Food allergy is estimated to affect approximately 1 in 25 school-aged children and is the most common trigger of anaphylaxis in this age group. School food-allergy management requires strategies to reduce the risk of ingestion of the allergen as well as procedures to recognize and treat allergic reactions and anaphylaxis. The role of the pediatrician or pediatric health care provider may include diagnosing and documenting a potentially life-threatening food allergy, prescribing selfinjectable epinephrine, helping the child learn how to store and use the medication in a responsible manner, educating the parents of their responsibility to implement prevention strategies within and outside the home environment, and working with families, schools, and students in developing written plans to reduce the risk of anaphylaxis and to implement emergency treatment in the event of a reaction. This clinical report highlights the role of the pediatrician and pediatric health care provider in managing students with food allergies. (11/10, reaffirmed 10/20)

http://pediatrics.aappublications.org/content/126/6/1232

MANAGEMENT OF INFANTS AT RISK FOR GROUP B STREPTOCOCCAL DISEASE (CLINICAL REPORT)

Karen M. Puopolo, MD, PhD, FAAP; Ruth Lynfield, MD, FAAP; James J. Cummings, MD, MS, FAAP; Committee on Fetus and Newborn; and Committee on Infectious Diseases

ABSTRACT. Group B streptococcal (GBS) infection remains the most common cause of neonatal early-onset sepsis and a significant cause of late-onset sepsis among young infants. Administration of intrapartum antibiotic prophylaxis is the only currently available effective strategy for the prevention of perinatal GBS early-onset disease, and there is no effective approach for the prevention of late-onset disease. The American Academy of Pediatrics joins with the American College of Obstetricians and Gynecologists to reaffirm the use of universal antenatal microbiologic-based testing for the detection of maternal GBS colonization to facilitate appropriate administration of intrapartum antibiotic prophylaxis. The purpose of this clinical report is to provide neonatal clinicians with updated information regarding the epidemiology of GBS disease as well current recommendations for the evaluation of newborn infants at risk for GBS disease and for treatment of those with confirmed GBS infection. This clinical report is endorsed by the American College of Obstetricians and Gynecologists (ACOG), July 2019, and should be construed as ACOG clinical guidance. (7/19)

https://pediatrics.aappublications.org/content/144/2/e20191881

MANAGEMENT OF NEONATES BORN AT ≥35 0/7 WEEKS' GESTATION WITH SUSPECTED OR PROVEN EARLY-ONSET BACTERIAL SEPSIS (CLINICAL REPORT)

Karen M. Puopolo, MD, PhD, FAAP; William E. Benitz, MD, FAAP; Theoklis E. Zaoutis, MD, MSCE, FAAP; Committee on Fetus and Newborn; and Committee on Infectious Diseases

ABSTRACT. The incidence of neonatal early-onset sepsis (EOS) has declined substantially over the last 2 decades, primarily because of the implementation of evidence-based intrapartum antimicrobial therapy. However, EOS remains a serious and potentially fatal illness. Laboratory tests alone are neither sensitive nor specific enough to guide EOS management decisions. Maternal and infant clinical characteristics can help identify newborn infants who are at risk and guide the administration of empirical antibiotic therapy. The incidence of EOS, the prevalence and implications of established risk factors, the predictive value of commonly used laboratory tests, and the uncertainties in the risk/benefit balance of antibiotic exposures all vary significantly with gestational age at birth. Our purpose in this clinical report is to provide a summary of the current epidemiology of neonatal sepsis among infants born at ≥35 0/7 weeks' gestation and a framework for the development of evidence-based approaches to sepsis risk assessment among these infants. (11/18)

http://pediatrics.aappublications.org/content/142/6/e20182894

MANAGEMENT OF NEONATES BORN AT ≤34 6/7 WEEKS' GESTATION WITH SUSPECTED OR PROVEN EARLY-ONSET BACTERIAL SEPSIS (CLINICAL REPORT)

Karen M. Puopolo, MD, PhD, FAAP; William E. Benitz, MD, FAAP; Theoklis E. Zaoutis, MD, MSCE, FAAP; Committee on Fetus and Newborn; and Committee on Infectious Diseases

ABSTRACT. Early-onset sepsis (EOS) remains a serious and often fatal illness among infants born preterm, particularly among newborn infants of the lowest gestational age. Currently, most preterm infants with very low birth weight are treated empirically with antibiotics for risk of EOS, often for prolonged periods, in the absence of a culture-confirmed infection. Retrospective studies have revealed that antibiotic exposures after birth are associated with multiple subsequent poor outcomes among preterm infants, making the risk/benefit balance of these antibiotic treatments uncertain. Gestational age is the strongest single predictor of EOS, and the majority of preterm

births occur in the setting of other factors associated with risk of EOS, making it difficult to apply risk stratification strategies to preterm infants. Laboratory tests alone have a poor predictive value in preterm EOS. Delivery characteristics of extremely preterm infants present an opportunity to identify those with a lower risk of EOS and may inform decisions to initiate or extend antibiotic therapies. Our purpose for this clinical report is to provide a summary of the current epidemiology of preterm neonatal sepsis and provide guidance for the development of evidence-based approaches to sepsis risk assessment among preterm newborn infants. (11/18)

http://pediatrics.aappublications.org/content/142/6/e20182896

MANAGEMENT OF PEDIATRIC TRAUMA

Committee on Pediatric Emergency Medicine; Council on Injury, Violence, and Poison Prevention; Section on Critical Care; Section on Orthopaedics; Section on Surgery; and Section on Transport Medicine (joint with Pediatric Trauma Society and Society of Trauma Nurses Pediatric Committee)

ABSTRACT. Injury is still the number 1 killer of children ages 1 to 18 years in the United States (http://www.cdc.gov/nchs/fastats/children.htm). Children who sustain injuries with resulting disabilities incur significant costs not only for their health care but also for productivity lost to the economy. The families of children who survive childhood injury with disability face years of emotional and financial hardship, along with a significant societal burden. The entire process of managing childhood injury is enormously complex and varies by region. Only the comprehensive cooperation of a broadly diverse trauma team will have a significant effect on improving the care of injured children. (7/16)

http://pediatrics.aappublications.org/content/138/2/e20161569

MANAGEMENT OF TYPE 2 DIABETES MELLITUS IN CHILDREN AND ADOLESCENTS (TECHNICAL REPORT)

Shelley C. Springer, MD, MBA, MSc, JD, FAAP; Janet Silverstein, MD, FAAP; Kenneth Copeland, MD, FAAP; Kelly R. Moore, MD, FAAP; Greg E. Prazar, MD, FAAP; Terry Raymer, MD, CDE; Richard N. Shiffman, MD, FAAP; Vidhu V. Thaker, MD, FAAP; Meaghan Anderson, MS, RD, LD, CDE; Stephen J. Spann, MD, MBA, FAAFP; and Susan K. Flinn, MA

ABSTRACT. *Objective.* Over the last 3 decades, the prevalence of childhood obesity has increased dramatically in North America, ushering in a variety of health problems, including type 2 diabetes mellitus (T2DM), which previously was not typically seen until much later in life. This technical report describes, in detail, the procedures undertaken to develop the recommendations given in the accompanying clinical practice guideline, "Management of Type 2 Diabetes Mellitus in Children and Adolescents," and provides in-depth information about the rationale for the recommendations and the studies used to make the clinical practice guideline's recommendations.

Methods. A primary literature search was conducted relating to the treatment of T2DM in children and adolescents, and a secondary literature search was conducted relating to the screening and treatment of T2DM's comorbidities in children and adolescents. Inclusion criteria were prospectively and unanimously agreed on by members of the committee. An article was eligible for inclusion if it addressed treatment (primary search) or 1 of 4 comorbidities (secondary search) of T2DM, was published in 1990 or later, was written in English, and included an abstract. Only primary research inquiries were considered; review articles were considered if they included primary data or opinion. The research population had to constitute children and/or adolescents with an existing diagnosis of T2DM; studies of adult patients were considered if at least 10% of the study population was younger than 35 years. All retrieved titles, abstracts, and articles were reviewed by the consulting epidemiologist.

Results. Thousands of articles were retrieved and considered in both searches on the basis of the aforementioned criteria. From those, in the primary search, 199 abstracts were identified for possible inclusion, 58 of which were retained for systematic review. Five of these studies were classified as grade A studies, 1 as grade B, 20 as grade C, and 32 as grade D. Articles regarding treatment of T2DM selected for inclusion were divided into 4 major subcategories on the basis of type of treatment being discussed: (1) medical treatments (32 studies); (2) nonmedical treatments (9 studies); (3) provider behaviors (8 studies); and (4) social issues (9 studies). From the secondary search, an additional 336 abstracts relating to comorbidities were identified for possible inclusion, of which 26 were retained for systematic review. These articles included the following: 1 systematic review of literature regarding comorbidities of T2DM in adolescents; 5 expert opinions presenting global recommendations not based on evidence; 5 cohort studies reporting natural history of disease and comorbidities; 3 with specific attention to comorbidity patterns in specific ethnic groups (case-control, cohort, and clinical report using adult literature); 3 reporting an association between microalbuminuria and retinopathy (2 case-control, 1 cohort); 3 reporting the prevalence of nephropathy (cohort); 1 reporting peripheral vascular disease (case series); 2 discussing retinopathy (1 case-control, 1 position statement); and 3 addressing hyperlipidemia (American Heart Association position statement on cardiovascular risks; American Diabetes Association consensus statement; case series). A breakdown of grade of recommendation shows no grade A studies, 10 grade B studies, 6 grade C studies, and 10 grade D studies. With regard to screening and treatment recommendations for comorbidities, data in children are scarce, and the available literature is conflicting. Therapeutic recommendations for hypertension, dyslipidemia, retinopathy, microalbuminuria, and depression were summarized from expert guideline documents and are presented in detail in the guideline. The references are provided, but the committee did not independently assess the supporting evidence. Screening tools are provided in the Supplemental Information. (1/13)

http://pediatrics.aappublications.org/content/131/2/e648

MARIJUANA USE DURING PREGNANCY AND BREASTFEEDING: IMPLICATIONS FOR NEONATAL AND CHILDHOOD OUTCOMES (CLINICAL REPORT)

Sheryl A. Ryan, MD, FAAP; Seth D. Ammerman, MD, FAAP, FSAHM, DABAM; Mary E. O'Connor, MD, MPH, FAAP; Committee on Substance Use and Prevention; and Section on Breastfeeding

ABSTRACT. Marijuana is one of the most widely used substances during pregnancy in the United States. Emerging data on the ability of cannabinoids to cross the placenta and affect the development of the fetus raise concerns about both pregnancy outcomes and long-term consequences for the infant or child. Social media is used to tout the use of marijuana for severe nausea associated with pregnancy. Concerns have also been raised about marijuana use by breastfeeding mothers. With this clinical report, we provide data on the current rates of marijuana use among pregnant and lactating women, discuss what is known about the effects of marijuana on fetal development and later neurodevelopmental and behavioral outcomes, and address implications for education and policy. MATERNAL-FETAL INTERVENTION AND FETAL CARE CENTERS (CLINICAL REPORT)

Committee on Bioethics (joint with American College of Obstetricians and Gynecologists Committee on Ethics)

ABSTRACT. The past 2 decades have yielded profound advances in the fields of prenatal diagnosis and fetal intervention. Although fetal interventions are driven by a beneficence-based motivation to improve fetal and neonatal outcomes, advancement in fetal therapies raises ethical issues surrounding maternal autonomy and decision-making, concepts of innovation versus research, and organizational aspects within institutions in the development of fetal care centers. To safeguard the interests of both the pregnant woman and the fetus, the American College of Obstetricians and Gynecologists and the American Academy of Pediatrics make recommendations regarding informed consent, the role of research subject advocates and other independent advocates, the availability of support services, the multidisciplinary nature of fetal intervention teams, the oversight of centers, and the need to accumulate maternal and fetal outcome data. (7/11, reaffirmed 2/18)

MEDIA AND YOUNG MINDS

Council on Communications and Media

ABSTRACT. Infants, toddlers, and preschoolers are now growing up in environments saturated with a variety of traditional and new technologies, which they are adopting at increasing rates. Although there has been much hope for the educational potential of interactive media for young children, accompanied by fears about their overuse during this crucial period of rapid brain development, research in this area still remains limited. This policy statement reviews the existing literature on television, videos, and mobile/interactive technologies; their potential for educational benefit; and related health concerns for young children (0 to 5 years of age). The statement also highlights areas in which pediatric providers can offer specific guidance to families in managing their young children's media use, not only in terms of content or time limits, but also emphasizing the importance of parent-child shared media use and allowing the child time to take part in other developmentally healthy activities. (10/16)

http://pediatrics.aappublications.org/content/138/5/e20162591

MEDIA EDUCATION

Committee on Communications and Media

ABSTRACT. The American Academy of Pediatrics recognizes that exposure to mass media (eg, television, movies, video and computer games, the Internet, music lyrics and videos, newspapers, magazines, books, advertising) presents health risks for children and adolescents but can provide benefits as well. Media education has the potential to reduce the harmful effects of media and accentuate the positive effects. By understanding and supporting media education, pediatricians can play an important role in reducing harmful effects of media on children and adolescents. (9/10)

http://pediatrics.aappublications.org/content/126/5/1012

MEDIA USE IN SCHOOL-AGED CHILDREN AND ADOLESCENTS

Council on Communications and Media

ABSTRACT. This policy statement focuses on children and adolescents 5 through 18 years of age. Research suggests both benefits and risks of media use for the health of children and teenagers. Benefits include exposure to new ideas and knowledge acquisition, increased opportunities for social contact and support, and new opportunities to access health-promotion messages and information. Risks include negative health effects on weight and sleep; exposure to inaccurate, inappropriate, or unsafe content and contacts; and compromised privacy and confidentiality. Parents face challenges in monitoring their children's and their own media use and in serving as positive role models. In this new era, evidence regarding healthy media use does not support a one-size-fits-all approach. Parents and pediatricians can work together to develop a Family Media Use Plan (www.healthychildren.org/MediaUsePlan) that considers their children's developmental stages to individualize an appropriate balance for media time and consistent rules about media use, to mentor their children, to set boundaries for accessing content and displaying personal information, and to implement open family communication about media. (10/16)

MEDIATORS AND ADVERSE EFFECTS OF CHILD POVERTY IN THE UNITED STATES (TECHNICAL REPORT)

John M. Pascoe, MD, MPH, FAAP; David L. Wood, MD, MPH, FAAP; James H. Duffee, MD, MPH, FAAP; Alice Kuo, MD, PhD, MEd, FAAP; Committee on Psychosocial Aspects of Child and Family Health; and Council on Community Pediatrics

ABSTRACT. The link between poverty and children's health is well recognized. Even temporary poverty may have an adverse effect on children's health, and data consistently support the observation that poverty in childhood continues to have a negative effect on health into adulthood. In addition to childhood morbidity being related to child poverty, epidemiologic studies have documented a mortality gradient for children aged 1 to 15 years (and adults), with poor children experiencing a higher mortality rate than children from higher-income families. The global great recession is only now very slowly abating for millions of America's children and their families. At this difficult time in the history of our nation's families and immediately after the 50th anniversary year of President Lyndon Johnson's War on Poverty, it is particularly germane for the American Academy of Pediatrics, which is "dedicated to the health of all children," to publish a research-supported technical report that examines the mediators associated with the long-recognized adverse effects of child poverty on children and their families. This technical report draws on research from a number of disciplines, including physiology, sociology, psychology, economics, and epidemiology, to describe the present state of knowledge regarding poverty's negative impact on children's health and development. Children inherit not only their parents' genes but also the family ecology and its social milieu. Thus, parenting skills, housing, neighborhood, schools, and other factors (eg, medical care) all have complex relations to each other and influence how each child's genetic canvas is expressed. Accompanying this technical report is a policy statement that describes specific actions that pediatricians and other child advocates can take to attenuate the negative effects of the mediators identified in this technical report and improve the well-being of our nation's children and their families. (3/16)

http://pediatrics.aappublications.org/content/137/4/e20160340

MEDICAID POLICY STATEMENT

Committee on Child Health Financing

ABSTRACT. Medicaid insures 39% of the children in the United States. This revision of the 2005 Medicaid Policy Statement of the American Academy of Pediatrics reflects opportunities for changes in state Medicaid programs resulting from the 2010 Patient Protection and Affordable Care Act as upheld in 2012 by the Supreme Court. Policy recommendations focus on the areas of benefit coverage, financing and payment, eligibility, outreach and enrollment, managed care, and quality improvement. (4/13, reaffirmed 3/19)

MEDICAL COUNTERMEASURES FOR CHILDREN IN PUBLIC HEALTH EMERGENCIES, DISASTERS, OR TERRORISM

Disaster Preparedness Advisory Council

ABSTRACT. Significant strides have been made over the past 10 to 15 years to develop medical countermeasures (MCMs) to address potential disaster hazards, including chemical, biological, radiologic, and nuclear threats. Significant and effective collaboration between the pediatric health community, including the American Academy of Pediatrics, and federal partners, such as the Office of the Assistant Secretary for Preparedness and Response, Centers for Disease Control and Prevention, Federal Emergency Management Agency, National Institutes of Health, Food and Drug Administration, and other federal agencies, over the past 5 years has resulted in substantial gains in addressing the needs of children related to disaster preparedness in general and MCMs in particular. Yet, major gaps still remain related to MCMs for children, a population highly vulnerable to the effects of exposure to such threats, because many vaccines and pharmaceuticals approved for use by adults as MCMs do not yet have pediatric formulations, dosing information, or safety information. As a result, the nation's stockpiles and other caches (designated supply of MCMs) where pharmacotherapeutic and other MCMs are stored are less prepared to address the needs of children compared with those of adults in the event of a disaster. This policy statement provides recommendations to close the remaining gaps for the development and use of MCMs in children during public health emergencies or disasters. The progress made by federal agencies to date to address the needs of children and the shared commitment of collaboration that characterizes the current relationship between the pediatric health community and the federal agencies responsible for MCMs should encourage all child advocates to invest the necessary energy and resources now to complete the process of remedying the remaining significant gaps in preparedness. (1/16)

http://pediatrics.aappublications.org/content/137/2/e20154273

MEDICAL EMERGENCIES OCCURRING AT SCHOOL

Council on School Health

ABSTRACT. Children and adults might experience medical emergency situations because of injuries, complications of chronic health conditions, or unexpected major illnesses that occur in schools. In February 2001, the American Academy of Pediatrics issued a policy statement titled "Guidelines for Emergency Medical Care in Schools" (available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics;107/2/435). Since the release of that statement, the spectrum of potential individual student emergencies has changed significantly. The increase in the number of children with special health care needs and chronic medical conditions attending schools and the challenges associated with ensuring that schools have access to on-site licensed health care professionals on an ongoing basis have added to increasing the risks of medical emergencies in schools. The goal of this statement is to increase pediatricians' awareness of schools' roles in preparing for individual student emergencies and to provide recommendations for primary care and school physicians on how to assist and support school personnel. (10/08, reaffirmed 9/11, 4/17)

http://pediatrics.aappublications.org/content/122/4/887

MEDICAL STAFF APPOINTMENT AND DELINEATION OF PEDIATRIC PRIVILEGES IN HOSPITALS (CLINICAL REPORT)

Daniel A. Rauch, MD; Committee on Hospital Care; and Section on Hospital Medicine

ABSTRACT. The review and verification of credentials and the granting of clinical privileges are required of every hospital to ensure that members of the medical staff are competent and qualified to provide specified levels of patient care. The credentialing process involves the following: (1) assessment of the professional and personal background of each practitioner seeking privileges; (2) assignment of privileges appropriate for the clinician's training and experience; (3) ongoing monitoring of the professional activities of each staff member; and (4) periodic reappointment to the medical staff on the basis of objectively measured performance. We examine the essential elements of a credentials review for initial and renewed medical staff appointments along with suggested criteria for the delineation of clinical privileges. Sample forms for the delineation of privileges can be found on the American Academy of Pediatrics Committee on Hospital Care Web site (http://www.aap.org/visit/cmte19.htm). Because of differences among individual hospitals, no 1 method for credentialing is universally applicable. The medical staff of each hospital must, therefore, establish its own process based on the general principles reviewed in this report. The issues of medical staff membership and credentialing have become very complex, and institutions and medical staffs are vulnerable to legal action. Consequently, it is advisable for hospitals and medical staffs to obtain expert legal advice when medical staff bylaws are constructed or revised. (3/12, reaffirmed 2/16)

MEDICAL VERSUS NONMEDICAL IMMUNIZATION EXEMPTIONS FOR CHILD CARE AND SCHOOL ATTENDANCE

Committee on Practice and Ambulatory Medicine, Committee on Infectious Diseases, Committee on State Government Affairs, Council on School Health, and Section on Administration and Practice Management

ABSTRACT. Routine childhood immunizations against infectious diseases are an integral part of our public health infrastructure. They provide direct protection to the immunized individual and indirect protection to children and adults unable to be immunized via the effect of community immunity. All 50 states, the District of Columbia, and Puerto Rico have regulations requiring proof of immunization for child care and school attendance as a public health strategy to protect children in these settings and to secondarily serve as a mechanism to promote timely immunization of children by their caregivers. Although all states and the District of Columbia have mechanisms to exempt school attendees from specific immunization requirements for medical reasons, the majority also have a heterogeneous collection of regulations and laws that allow nonmedical exemptions from childhood immunizations otherwise required for child care and school attendance. The American Academy of Pediatrics (AAP) supports regulations and laws requiring certification of immunization to attend child care and school as a sound means of providing a safe environment for attendees and employees of these settings. The AAP also supports medically indicated exemptions to specific immunizations as determined for each individual child. The AAP views nonmedical exemptions to school-required immunizations as inappropriate for individual, public health, and ethical reasons and advocates for their elimination. (8/16)

MEDICATION-ASSISTED TREATMENT OF ADOLESCENTS WITH OPIOID USE DISORDERS

Committee on Substance Use and Prevention

ABSTRACT. Opioid use disorder is a leading cause of morbidity and mortality among US youth. Effective treatments, both medications and substance use disorder counseling, are available but underused, and access to developmentally appropriate treatment is severely restricted for adolescents and young adults. Resources to disseminate available therapies and to develop new treatments specifically for this age group are needed to save and improve lives of youth with opioid addiction. (8/16)

http://pediatrics.aappublications.org/content/138/3/e20161893

MENSTRUAL MANAGEMENT FOR ADOLESCENTS WITH DISABILITIES (CLINICAL REPORT)

Elisabeth H. Quint, MD; Rebecca F. O'Brien, MD; and Committee on Adolescence (joint with North American Society for Pediatric and Adolescent Gynecology)

ABSTRACT. The onset of menses for adolescents with physical or intellectual disabilities can affect their independence and add additional concerns for families at home, in schools, and in other settings. The pediatrician is the primary health care provider to explore and assist with the pubertal transition and menstrual management. Menstrual management of both normal and abnormal cycles may be requested to minimize hygiene issues, premenstrual symptoms, dysmenorrhea, heavy or irregular bleeding, contraception, and conditions exacerbated by the menstrual cycle. Several options are available for menstrual management, depending on the outcome that is desired, ranging from cycle regulation to complete amenorrhea. The use of medications or the request for surgeries to help with the menstrual cycles in teenagers with disabilities has medical, social, legal, and ethical implications. This clinical report is designed to help guide pediatricians in assisting adolescent females with intellectual and/or physical disabilities and their families in making decisions related to successfully navigating menarche and subsequent menstrual cycles. MENTAL HEALTH COMPETENCIES FOR PEDIATRIC PRACTICE

Jane Meschan Foy, MD, FAAP; Cori M. Green, MD, MS, FAAP; Marian F. Earls, MD, MTS, FAAP; Committee on Psychosocial Aspects of Child and Family Health; and Mental Health Leadership Work Group

ABSTRACT. Pediatricians have unique opportunities and an increasing sense of responsibility to promote healthy social-emotional development of children and to prevent and address their mental health and substance use conditions. In this report, the American Academy of Pediatrics updates its 2009 policy statement, which proposed competencies for providing mental health care to children in primary care settings and recommended steps toward achieving them. This 2019 policy statement affirms the 2009 statement and expands competencies in response to science and policy that have emerged since: the impact of adverse childhood experiences and social determinants on mental health, trauma-informed practice, and team-based care. Importantly, it also recognizes ways in which the competencies are pertinent to pediatric subspecialty practice. Proposed mental health competencies include foundational communication skills, capacity to incorporate mental health content and tools into health promotion and primary and secondary preventive care, skills in the psychosocial assessment and care of children with mental health conditions, knowledge and skills of evidence-based psychosocial therapy and psychopharmacologic therapy, skills to function as a team member and comanager with mental health specialists, and commitment to embrace mental health practice as integral to pediatric care. Achievement of these competencies will necessarily be incremental, requiring partnership with fellow advocates, system changes, new payment mechanisms, practice enhancements, and decision support for pediatricians in their expanded scope of practice. METABOLIC AND BARIATRIC SURGERY FOR PEDIATRIC PATIENTS WITH SEVERE OBESITY (TECHNICAL REPORT)

Christopher F. Bolling, MD, FAAP; Sarah C. Armstrong, MD, FAAP; Kirk W. Reichard, MD, MBA, FAAP; Marc P. Michalsky, MD, FACS, FAAP, FASMBS; Section on Obesity; and Section on Surgery

ABSTRACT. Severe obesity affects the health and well-being of millions of children and adolescents in the United States and is widely considered to be an "epidemic within an epidemic" that poses a major public health crisis. Currently, few effective treatments for severe obesity exist. Metabolic and bariatric surgery are existing but underuse treatment options for pediatric patients with severe obesity. Roux-en-Y gastric bypass and vertical sleeve gastrectomy are the most commonly performed metabolic and bariatric procedures in the United States and have been shown to result in sustained short-, mid-, and long-term weight loss, with associated resolution of multiple obesity-related comorbid diseases. Substantial evidence supports the safety and effectiveness of surgical weight loss for children and adolescents, and robust best practice guidelines for these procedures exist. (11/19)

https://pediatrics.aappublications.org/content/144/6/e20193224

THE METABOLIC SYNDROME IN CHILDREN AND ADOLESCENTS: SHIFTING THE FOCUS TO CARDIOMETABOLIC RISK FACTOR CLUSTERING (CLINICAL REPORT)

Sheela N. Magge, MD, MSCE, FAAP; Elizabeth Goodman, MD, MBA, FAAP; Sarah C. Armstrong, MD, FAAP; Committee on Nutrition; Section on Endocrinology; and Section on Obesity

ABSTRACT. Metabolic syndrome (MetS) was developed by the National Cholesterol Education Program Adult Treatment Panel III, identifying adults with at least 3 of 5 cardiometabolic risk factors (hyperglycemia, increased central adiposity, elevated triglycerides, decreased high-density lipoprotein cholesterol, and elevated blood pressure) who are at increased risk of diabetes and cardiovascular disease. The constellation of MetS component risk factors has a shared pathophysiology and many common treatment approaches grounded in lifestyle modification. Several attempts have been made to define MetS in the pediatric population. However, in children, the construct is difficult to define and has unclear implications for clinical care. In this Clinical Report, we focus on the importance of screening for and treating the individual risk factor components of MetS. Focusing attention on children with cardiometabolic risk factor clustering is emphasized over the need to define a pediatric MetS. (7/17)

http://pediatrics.aappublications.org/content/140/2/e20171603

METRIC UNITS AND THE PREFERRED DOSING OF ORALLY ADMINISTERED LIQUID MEDICATIONS

Committee on Drugs

ABSTRACT. Medication overdoses are a common, but preventable, problem among children. Volumetric dosing errors and the use of incorrect dosing delivery devices are 2 common sources of these preventable errors for orally administered liquid medications. To reduce errors and increase precision of drug administration, milliliter-based dosing should be used exclusively when prescribing and administering liquid medications. Teaspoon- and tablespoon-based dosing should not be used. Devices that allow for precise dose administration (preferably syringes with metric markings) should be used instead of household spoons and should be distributed with the medication. (3/15)

http://pediatrics.aappublications.org/content/135/4/784

MIND-BODY THERAPIES IN CHILDREN AND YOUTH (CLINICAL REPORT)

Section on Integrative Medicine

ABSTRACT. Mind-body therapies are popular and are ranked among the top 10 complementary and integrative medicine practices reportedly used by adults and children in the 2007–2012 National Health Interview Survey. A growing body of evidence supports the effectiveness and safety of mind-body therapies in pediatrics. This clinical report outlines popular mind-body therapies for children and youth and examines the best-available evidence for a variety of mind-body therapies and practices, including biofeedback, clinical hypnosis, guided imagery, meditation, and yoga. The report is intended to help

health care professionals guide their patients to nonpharmacologic approaches to improve concentration, help decrease pain, control discomfort, or ease anxiety. (8/16)
http://pediatrics.aappublications.org/content/138/3/e20161896

MINORS AS LIVING SOLID-ORGAN DONORS (CLINICAL REPORT)

Lainie Friedman Ross, MD, PhD; J. Richard Thistlethwaite Jr, MD, PhD; and Committee on Bioethics

ABSTRACT. In the past half-century, solid-organ transplantation has become standard treatment for a variety of diseases in children and adults. The major limitation for all transplantation is the availability of donors, and the gap between demand and supply continues to grow despite the increase in living donors. Although rare, children do serve as living donors, and these donations raise serious ethical issues. This clinical report includes a discussion of the ethical considerations regarding minors serving as living donors, using the traditional benefit/burden calculus from the perspectives of both the donor and the recipient. The report also includes an examination of the circumstances under which a minor may morally participate as a living donor, how to minimize risks, and what the informed-consent process should entail. The American Academy of Pediatrics holds that minors can morally serve as living organ donors but only in exceptional circumstances when specific criteria are fulfilled. (8/08, reaffirmed 5/11)
http://pediatrics.aappublications.org/content/122/2/454

MODEL CONTRACTUAL LANGUAGE FOR MEDICAL NECESSITY FOR CHILDREN

Committee on Child Health Financing

ABSTRACT. The term "medical necessity" is used by Medicare and Medicaid and in insurance contracts to refer to medical services that are generally recognized as appropriate for the diagnosis, prevention, or treatment of disease and injury. There is no consensus on how to define and apply the term and the accompanying rules and regulations, and as a result there has been substantial variation in medical-necessity definitions and interpretations. With this policy statement, the American Academy of Pediatrics hopes to encourage insurers to adopt more consistent medical-necessity definitions that take into account the needs of children. (7/05, reaffirmed 10/11)
http://pediatrics.aappublications.org/content/116/1/261

MOTOR DELAYS: EARLY IDENTIFICATION AND EVALUATION (CLINICAL REPORT)

Garey H. Noritz, MD; Nancy A. Murphy, MD; and Neuromotor Screening Expert Panel

ABSTRACT. Pediatricians often encounter children with delays of motor development in their clinical practices. Earlier identification of motor delays allows for timely referral for developmental interventions as well as diagnostic evaluations and treatment planning. A multidisciplinary expert panel developed an algorithm for the surveillance and screening of children for motor delays within the medical home, offering guidance for the initial workup and referral of the child with possible delays in motor development. Highlights of this clinical report include suggestions for formal developmental screening at the 9-, 18-, 30-, and 48-month well-child visits; approaches to the neurologic examination, with emphasis on the assessment of muscle tone; and initial diagnostic approaches for medical home providers. Use of diagnostic tests to evaluate children with motor delays are described, including brain MRI for children with high muscle tone, and measuring serum creatine kinase concentration of those with decreased muscle tone. The importance of pursuing diagnostic tests while concurrently referring patients to early intervention programs is emphasized. (5/13, reaffirmed 5/17)
http://pediatrics.aappublications.org/content/131/6/e2016

THE NEED TO OPTIMIZE ADOLESCENT IMMUNIZATION (CLINICAL REPORT)

Henry H. Bernstein, DO, MHCM, FAAP; Joseph A. Bocchini Jr, MD, FAAP; and Committee on Infectious Diseases

ABSTRACT. The adolescent period heralds the pediatric patient's transition into adulthood. It is a time of dynamic development during which effective preventive care measures can promote safe behaviors and the development of lifelong health habits. One of the foundations of preventive adolescent health care is timely vaccination, and every visit can be viewed as an opportunity to update and complete an adolescent's immunizations.

In the past decade, the adolescent immunization schedule has expanded to include 2 doses of quadrivalent meningococcal conjugate vaccine; 1 dose of tetanus, diphtheria, acellular pertussis, absorbed vaccine; 2 or 3 doses of human papillomavirus vaccine, depending on the child's age; and an annual influenza vaccine. In addition, during adolescent visits, health care providers can determine whether catch-up vaccination is needed to meet early childhood recommendations for hepatitis B; hepatitis A; measles, mumps, rubella; poliovirus; and varicella vaccines. New serogroup B meningococcal vaccines are now available for those at increased risk for meningococcal disease; in addition, these serogroup B meningococcal vaccines received a Category B recommendation for healthy adolescents, where individual counseling and risk–benefit evaluation based on health care provider judgements and patient preferences are indicated. This clinical report focuses on the epidemiology of adolescent vaccine-preventable diseases by reviewing the rationale for the annual universally recommended adolescent immunization schedule of the American Academy of Pediatrics, the American Academy of Family Physicians, the Centers for Disease Control and Prevention, and the American Congress of Obstetricians and Gynecologists. In addition, the barriers that negatively influence adherence to this current adolescent immunization schedule will be highlighted. (2/17)

NEEDS OF KINSHIP CARE FAMILIES AND PEDIATRIC PRACTICE

David Rubin, MD, FAAP; Sarah H. Springer, MD, FAAP; Sarah Zlotnik, MSW, MSPH; Christina D. Kang-Yi, PhD; and Council on Foster Care, Adoption, and Kinship Care

ABSTRACT. As many as 3% of children in the United States live in kinship care arrangements with caregivers who are relatives but not the biological parents of the child. A growing body of evidence suggests that children who cannot live with their biological parents fare better, overall, when living with extended family than with nonrelated foster parents. Acknowledging this, federal laws and public policies increasingly favor kinship care over nonrelative foster care when children are unable to live with their biological parents. Despite overall better outcomes, families providing kinship care experience many hardships, and the children experience many of the same adversities of children in traditional foster care. This policy statement reviews both the strengths and vulnerabilities of kinship families and suggests strategies for pediatricians to use to address the needs of individual patients and families. Strategies are also outlined for community, state, and federal advocacy on behalf of these children and their families. (3/17)
http://pediatrics.aappublications.org/content/139/4/e20170099

NEONATAL DRUG WITHDRAWAL (CLINICAL REPORT)

Mark L. Hudak, MD; Rosemarie C. Tan, MD, PhD; Committee on Drugs; and Committee on Fetus and Newborn

ABSTRACT. Maternal use of certain drugs during pregnancy can result in transient neonatal signs consistent with withdrawal or acute toxicity or cause sustained signs consistent with a lasting drug effect. In addition, hospitalized infants who are treated

with opioids or benzodiazepines to provide analgesia or sedation may be at risk for manifesting signs of withdrawal. This statement updates information about the clinical presentation of infants exposed to intrauterine drugs and the therapeutic options for treatment of withdrawal and is expanded to include evidence-based approaches to the management of the hospitalized infant who requires weaning from analgesics or sedatives. (1/12, reaffirmed 2/16)
http://pediatrics.aappublications.org/content/129/2/e540

NEONATAL OPIOID WITHDRAWAL SYNDROME (CLINICAL REPORT)

Stephen W. Patrick, MD, MPH, MS, FAAP; Wanda D. Barfield, MD, MPH, FAAP; Brenda B. Poindexter, MD, MS, FAAP; Committee on Fetus and Newborn; and Committee on Substance Use and Prevention

ABSTRACT. The opioid crisis has grown to affect pregnant women and infants across the United States, as evidenced by rising rates of opioid use disorder among pregnant women and neonatal opioid withdrawal syndrome among infants. Across the country, pregnant women lack access to evidence-based therapies, including medications for opioid use disorder, and infants with opioid exposure frequently receive variable care. In addition, public systems, such as child welfare and early intervention, are increasingly stretched by increasing numbers of children affected by the crisis. Systematic, enduring, coordinated, and holistic approaches are needed to improve care for the mother-infant dyad. In this statement, we provide an overview of the effect of the opioid crisis on the mother-infant dyad and provide recommendations for management of the infant with opioid exposure, including clinical presentation, assessment, treatment, and discharge. (10/20)

A NEW ERA IN QUALITY MEASUREMENT: THE DEVELOPMENT AND APPLICATION OF QUALITY MEASURES

Terry Adirim, MD, MPH, FAAP; Kelley Meade, MD, FAAP; Kamila Mistry, PhD, MPH; Council on Quality Improvement and Patient Safety; and Committee on Practice and Ambulatory Medicine

ABSTRACT. Quality measures are used for a variety of purposes in health care, including clinical care improvement, regulation, accreditation, public reporting, surveillance, and maintenance of certification. Most quality measures are 1 of 3 types: structure, process, or outcome. Health care quality measures should address the domains of quality across the continuum of care and reflect patient and family experience. Measure development for pediatric health care has a number of important challenges, including gaps in the evidence base; the fact that measures for most conditions must be age-specific; the long, resourceintensive development process; and the national focus on measure development for adult conditions. Numerous national organizations focus on the development and application of quality measures, including the Pediatric Quality Measures Program, which is focused solely on the development and implementation of pediatric-specific measures. Once a quality measure is developed for use in national measurement programs, the organization that develops and/or "stewards" the measure may submit the measure or set of measures for endorsement, which is recognition of the scientific soundness, usability, and relevance of the measure. Quality measures must then be disseminated and applied to improve care. Although pediatric health care providers and child health care institutions alike must continually balance time and resources needed to address multiple reporting requirements, quality measurement is an important tool for advancing high-quality and safe health care for children. This policy statement provides an overview of quality measurement and describes the opportunities for pediatric health care providers to apply quality measures to improve clinical quality and performance in the delivery of pediatric health care services. (12/16)

NEWBORN SCREENING EXPANDS: RECOMMENDATIONS FOR PEDIATRICIANS AND MEDICAL HOMES—IMPLICATIONS FOR THE SYSTEM (CLINICAL REPORT)

Newborn Screening Authoring Committee

ABSTRACT. Advances in newborn screening technology, coupled with recent advances in the diagnosis and treatment of rare but serious congenital conditions that affect newborn infants, provide increased opportunities for positively affecting the lives of children and their families. These advantages also pose new challenges to primary care pediatricians, both educationally and in response to the management of affected infants. Primary care pediatricians require immediate access to clinical and diagnostic information and guidance and have a proactive role to play in supporting the performance of the newborn screening system. Primary care pediatricians must develop office policies and procedures to ensure that newborn screening is conducted and that results are transmitted to them in a timely fashion; they must also develop strategies to use should these systems fail. In addition, collaboration with local, state, and national partners is essential for promoting actions and policies that will optimize the function of the newborn screening systems and ensure that families receive the full benefit of them. (1/08, reaffirmed 9/16)

NEWBORN SCREENING FOR BILIARY ATRESIA (TECHNICAL REPORT)

Kasper S. Wang, MD, FAAP, FACS; Section on Surgery; and Committee on Fetus and Newborn (joint with Childhood Liver Disease Research Network)

ABSTRACT. Biliary atresia is the most common cause of pediatric end-stage liver disease and the leading indication for pediatric liver transplantation. Affected infants exhibit evidence of biliary obstruction within the first few weeks after birth. Early diagnosis and successful surgical drainage of bile are associated with greater survival with the child's native liver. Unfortunately, because noncholestatic jaundice is extremely common in early infancy, it is difficult to identify the rare infant with cholestatic jaundice who has biliary atresia. Hence, the need for timely diagnosis of this disease warrants a discussion of the feasibility of screening for biliary atresia to improve outcomes. Herein, newborn screening for biliary atresia in the United States is assessed by using criteria established by the Discretionary Advisory Committee on Heritable Disorders in Newborns and Children. Published analyses indicate that newborn screening for biliary atresia by using serum bilirubin concentrations or stool color cards is potentially life-saving and cost-effective. Further studies are necessary to evaluate the feasibility, effectiveness,

and costs of potential screening strategies for early identification of biliary atresia in the United States. (11/15)

NICKEL ALLERGIC CONTACT DERMATITIS: IDENTIFICATION, TREATMENT, AND PREVENTION

Nanette B. Silverberg, MD, FAAP, FAAD; Janice L. Pelletier, MD, FAAP; Sharon E. Jacob, MD, FAAP, FAAD; Lynda C. Schneider, MD, FAAP; Section on Dermatology; and Section on Allergy and Immunology

ABSTRACT. Nickel is a ubiquitous metal added to jewelry and metallic substances for its hardening properties and because it is inexpensive. Estimates suggest that at least 1.1 million children in the United States are sensitized to nickel. Nickel allergic contact dermatitis (Ni-ACD) is the most common cutaneous delayed-type hypersensitivity reaction worldwide. The incidence among children tested has almost quadrupled over the past 3 decades. The associated morbidities include itch, discomfort, school absence, and reduced quality of life. In adulthood, individuals with Ni-ACD may have severe disabling hand eczema. The increasing rate of Ni-ACD in children has been postulated to result from early and frequent exposure to metals with high amounts of nickel release (eg, as occurs with ear piercing or with products used daily in childhood such as toys, belt buckles, and electronics).

To reduce exposure to metal sources with high nickel release by prolonged and direct contact with human skin, Denmark and the European Union legislated a directive several decades ago with the goal of reducing high nickel release and the incidence of Ni-ACD. Since then, there has been a global reduction in incidence of Ni-ACD in population-based studies of adults and studies of children and young adults being tested for allergic contact dermatitis. These data point to nickel exposure as a trigger for elicitation of Ni-ACD and, further, provide evidence that legislation can have a favorable effect on the economic and medical health of a population.

This policy statement reviews the epidemiology, history, and appearances of Ni-ACD. Examples of sources of high nickel release are discussed to highlight how difficult it is to avoid this metal in modern daily lives. Treatments are outlined, and avoidance strategies are presented. Long-term epidemiological interventions are addressed. Advocacy for smarter nickel use is reviewed. The American Academy of Pediatrics supports US legislation that advances safety standards (as modeled by the European Union) that protect children from early and prolonged skin exposure to high–nickel-releasing items. Our final aim for this article is to aid the pediatric community in developing nickel-avoidance strategies on both individual and global levels. (4/20)

NICOTINE AND TOBACCO AS SUBSTANCES OF ABUSE IN CHILDREN AND ADOLESCENTS (TECHNICAL REPORT)

Lorena M. Siqueira, MD, MSPH, FAAP, FSAHM, and Committee on Substance Use and Prevention

ABSTRACT. Nicotine is the primary pharmacologic component of tobacco, and users of tobacco products seek out its effects. The highly addictive nature of nicotine is responsible for its widespread use and difficulty with quitting. This technical report focuses on nicotine and discusses the stages of use in progression to dependence on nicotine-containing products; the physiologic characteristics, neurobiology, metabolism, pharmacogenetics, and health effects of nicotine; and acute nicotine toxicity. Finally, some newer approaches to cessation are noted. (12/16)

NONDISCRIMINATION IN PEDIATRIC HEALTH CARE

Committee on Pediatric Workforce

ABSTRACT. This policy statement is a revision of a 2001 statement and articulates the positions of the American Academy of Pediatrics on nondiscrimination in pediatric health care. It addresses both pediatricians who provide health care and the infants, children, adolescents, and young adults whom they serve. (10/07, reaffirmed 6/11, 1/15)

NONEMERGENCY ACUTE CARE: WHEN IT'S NOT THE MEDICAL HOME

Gregory P. Conners, MD, MPH, MBA, FAAP; Susan J. Kressly, MD, FAAP; James M. Perrin, MD, FAAP; Julia E. Richerson, MD, FAAP; Usha M. Sankrithi, MBBS, MPH, FAAP; Committee on Practice and Ambulatory Medicine; Committee on Pediatric Emergency Medicine; Section on Telehealth Care; Section on Emergency Medicine; Subcommittee on Urgent Care; and Task Force on Pediatric Practice Change

ABSTRACT. The American Academy of Pediatrics (AAP) affirms that the optimal location for children to receive care for acute, nonemergency health concerns is the medical home. The medical home is characterized by the AAP as a care model that "must be accessible, family centered, continuous, comprehensive, coordinated, compassionate, and culturally effective." However, some children and families use acute care services outside the medical home because there is a perceived or real benefit related to accessibility, convenience, or cost of care. Examples of such acute care entities include urgent care facilities, retail-based clinics, and commercial telemedicine services. Children deserve high-quality, appropriate, and safe acute care services wherever they access the health care system, with timely and complete communication with the medical home, to ensure coordinated and continuous care. Treatment of children under established, new, and evolving practice arrangements in acute care entities should adhere to the core principles of continuity of care and communication, best practices within a defined scope of services, pediatric-trained staff, safe transitions of care, and continuous improvement. In support of the medical home, the AAP urges stakeholders, including payers, to avoid any incentives (eg, reduced copays) that encourage visits to external entities for acute issues as a preference over the medical home. (4/17)

NONINITIATION OR WITHDRAWAL OF INTENSIVE CARE FOR HIGH-RISK NEWBORNS

Committee on Fetus and Newborn

ABSTRACT. Advances in medical technology have led to dilemmas in initiation and withdrawal of intensive care of newborn infants with a very poor prognosis. Physicians and parents together must make difficult decisions guided by their understanding of the child's best interest. The foundation for these decisions consists of several key elements: (1) direct and open communication between the health care team and the parents of the child with regard to the medical status, prognosis, and treatment options; (2) inclusion of the parents as active participants in the decision process; (3) continuation of comfort care even when intensive care is not being provided; and (4) treatment decisions that are guided primarily by the best interest of the child. (2/07, reaffirmed 5/10, 6/15)

NONINVASIVE RESPIRATORY SUPPORT (CLINICAL REPORT)

James J. Cummings, MD, FAAP; Richard A. Polin, MD, FAAP; and Committee on Fetus and Newborn

ABSTRACT. Mechanical ventilation is associated with increased survival of preterm infants but is also associated with an increased incidence of chronic lung disease (bronchopulmonary

dysplasia) in survivors. Nasal continuous positive airway pressure (nCPAP) is a form of noninvasive ventilation that reduces the need for mechanical ventilation and decreases the combined outcome of death or bronchopulmonary dysplasia. Other modes of noninvasive ventilation, including nasal intermittent positive pressure ventilation, biphasic positive airway pressure, and high-flow nasal cannula, have recently been introduced into the NICU setting as potential alternatives to mechanical ventilation or nCPAP. Randomized controlled trials suggest that these newer modalities may be effective alternatives to nCPAP and may offer some advantages over nCPAP, but efficacy and safety data are limited. (12/15)
http://pediatrics.aappublications.org/content/137/1/e20153758

NONORAL FEEDING FOR CHILDREN AND YOUTH WITH DEVELOPMENTAL OR ACQUIRED DISABILITIES (CLINICAL REPORT)

Richard C. Adams, MD, FAAP; Ellen Roy Elias, MD, FAAP; and Council on Children With Disabilities

ABSTRACT. The decision to initiate enteral feedings is multifaceted, involving medical, financial, cultural, and emotional considerations. Children who have developmental or acquired disabilities are at risk for having primary and secondary conditions that affect growth and nutritional well-being. This clinical report provides (1) an overview of clinical issues in children who have developmental or acquired disabilities that may prompt a need to consider nonoral feedings, (2) a systematic way to support the child and family in clinical decisions related to initiating nonoral feeding, (3) information on surgical options that the family may need to consider in that decision-making process, and (4) pediatric guidance for ongoing care after initiation of nonoral feeding intervention, including care of the gastrostomy tube and skin site. Ongoing medical and psychosocial support is needed after initiation of nonoral feedings and is best provided through the collaborative efforts of the family and a team of professionals that may include the pediatrician, dietitian, social worker, and/or therapists. (11/14, reaffirmed 6/19)

NONTHERAPEUTIC USE OF ANTIMICROBIAL AGENTS IN ANIMAL AGRICULTURE: IMPLICATIONS FOR PEDIATRICS (TECHNICAL REPORT)

Jerome A. Paulson, MD, FAAP; Theoklis E. Zaoutis, MD, MSCE, FAAP; Council on Environmental Health; and Committee on Infectious Diseases

ABSTRACT. Antimicrobial resistance is one of the most serious threats to public health globally and threatens our ability to treat infectious diseases. Antimicrobial-resistant infections are associated with increased morbidity, mortality, and health care costs. Infants and children are affected by transmission of susceptible and resistant food zoonotic pathogens through the food supply, direct contact with animals, and environmental pathways. The overuse and misuse of antimicrobial agents in veterinary and human medicine is, in large part, responsible for the emergence of antibiotic resistance. Approximately 80% of the overall tonnage of antimicrobial agents sold in the United States in 2012 was for animal use, and approximately 60% of those agents are considered important for human medicine. Most of the use involves the addition of low doses of antimicrobial agents to the feed of healthy animals over prolonged periods to promote growth and increase feed efficiency or at a range of doses to prevent disease. These nontherapeutic uses contribute to resistance and create new health dangers for humans. This report describes how antimicrobial agents are used in animal agriculture, reviews the mechanisms of how such use contributes to development of resistance, and discusses US and global initiatives to curb the use of antimicrobial agents in agriculture. (11/15)

OFFICE-BASED CARE FOR LESBIAN, GAY, BISEXUAL, TRANSGENDER, AND QUESTIONING YOUTH

Committee on Adolescence

ABSTRACT. The American Academy of Pediatrics issued its last statement on homosexuality and adolescents in 2004. Although most lesbian, gay, bisexual, transgender, and questioning (LGBTQ) youth are quite resilient and emerge from adolescence as healthy adults, the effects of homophobia and heterosexism can contribute to health disparities in mental health with higher rates of depression and suicidal ideation, higher rates of substance abuse, and more sexually transmitted and HIV infections. Pediatricians should have offices that are teen-friendly and welcoming to sexual minority youth. Obtaining a comprehensive, confidential, developmentally appropriate adolescent psychosocial history allows for the discovery of strengths and assets as well as risks. Referrals for mental health or substance abuse may be warranted. Sexually active LGBTQ youth should have sexually transmitted infection/HIV testing according to recommendations of the Sexually Transmitted Diseases Treatment Guidelines of the Centers for Disease Control and Prevention based on sexual behaviors. With appropriate assistance and care, sexual minority youth should live healthy, productive lives while transitioning through adolescence and young adulthood. (6/13)
http://pediatrics.aappublications.org/content/132/1/198

OFFICE-BASED CARE FOR LESBIAN, GAY, BISEXUAL, TRANSGENDER, AND QUESTIONING YOUTH (TECHNICAL REPORT)

David A. Levine, MD, and Committee on Adolescence

ABSTRACT. The American Academy of Pediatrics issued its last statement on homosexuality and adolescents in 2004. This technical report reflects the rapidly expanding medical and psychosocial literature about sexual minority youth. Pediatricians should be aware that some youth in their care may have concerns or questions about their sexual orientation or that of siblings, friends, parents, relatives, or others and should provide factual, current, nonjudgmental information in a confidential manner. Although most lesbian, gay, bisexual, transgender, and questioning (LGBTQ) youth are quite resilient and emerge from adolescence as healthy adults, the effects of homophobia and heterosexism can contribute to increased mental health issues for sexual minority youth. LGBTQ and MSM/WSW (men having sex with men and women having sex with women) adolescents, in comparison with heterosexual adolescents, have higher rates of depression and suicidal ideation, higher rates of substance abuse, and more risky sexual behaviors. Obtaining a comprehensive, confidential, developmentally appropriate adolescent psychosocial history allows for the discovery of strengths and assets as well as risks. Pediatricians should have offices that are teen-friendly and welcoming to sexual minority youth. This includes having supportive, engaging office staff members who ensure that there are no barriers to care. For transgender youth, pediatricians should provide the opportunity to acknowledge and affirm their feelings of gender dysphoria and desires to transition to the opposite gender. Referral of transgender youth to a qualified mental health professional is critical to assist with the dysphoria, to educate them, and to assess their readiness for transition. With appropriate assistance and care, sexual minority youth should live healthy, productive lives while transitioning through adolescence and young adulthood. (6/13)

OFFICE-BASED COUNSELING FOR UNINTENTIONAL INJURY PREVENTION (CLINICAL REPORT)

H. Garry Gardner, MD, and Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Unintentional injuries are the leading cause of death for children older than 1 year. Pediatricians should

include unintentional injury prevention as a major component of anticipatory guidance for infants, children, and adolescents. The content of injury-prevention counseling varies for infants, preschool-aged children, school-aged children, and adolescents. This report provides guidance on the content of unintentional injury-prevention counseling for each of those age groups. (1/07)
http://pediatrics.aappublications.org/content/119/1/202

OFF-LABEL USE OF DRUGS IN CHILDREN

Committee on Drugs

ABSTRACT. The passage of the Best Pharmaceuticals for Children Act and the Pediatric Research Equity Act has collectively resulted in an improvement in rational prescribing for children, including more than 500 labeling changes. However, off-label drug use remains an important public health issue for infants, children, and adolescents, because an overwhelming number of drugs still have no information in the labeling for use in pediatrics. The purpose of off-label use is to benefit the individual patient. Practitioners use their professional judgment to determine these uses. As such, the term "off-label" does not imply an improper, illegal, contraindicated, or investigational use. Therapeutic decision-making must always rely on the best available evidence and the importance of the benefit for the individual patient. (2/14, reaffirmed 11/20)
http://pediatrics.aappublications.org/content/133/3/563

OFF-LABEL USE OF MEDICAL DEVICES IN CHILDREN

Section on Cardiology and Cardiac Surgery and Section on Orthopaedics

ABSTRACT. Despite widespread therapeutic needs, the majority of medical and surgical devices used in children do not have approval or clearance from the Food and Drug Administration (FDA) for use in pediatric populations. The clinical need for devices to diagnose and treat diseases or conditions occurring in children has led to the widespread and necessary practice in pediatric medicine and surgery of using approved devices for "off-label" or "physician-directed" applications that are not included in FDA-approved labeling. This practice is common and often appropriate, even with the highest-risk (class III) devices. The legal and regulatory framework used by the FDA for devices is complex, and economic or market barriers to medical and surgical device development for children are significant. Given the need for pediatric medical and surgical devices and the challenges to pediatric device development, off-label use is a necessary and appropriate part of care. In addition, because of the relatively uncommon nature of pediatric conditions, FDA clearance or approval often requires other regulatory pathways (eg, Humanitarian Device Exemption), which can cause confusion among pediatricians and payers about whether a specific use, even of an approved device, is considered experimental. This policy statement describes the appropriateness of off-label use of devices in children; the use of devices approved or cleared through the FDA regulatory processes, including through the Humanitarian Device Exemption; and the important need to increase pediatric device labeling information for all devices and especially those that pose the highest risk to children. (12/16)

ONGOING PEDIATRIC HEALTH CARE FOR THE CHILD WHO HAS BEEN MALTREATED (CLINICAL REPORT)

Emalee Flaherty, MD, FAAP; Lori Legano, MD, FAAP; Sheila Idzerda, MD, FAAP; and Council on Child Abuse and Neglect

ABSTRACT. Pediatricians provide continuous medical care and anticipatory guidance for children who have been reported to state child protection agencies, including tribal child protection agencies, because of suspected child maltreatment. Because families may continue their relationships with their pediatricians after these reports, these primary care providers are in a unique position to recognize and manage the physical, developmental, academic, and emotional consequences of maltreatment and exposure to childhood adversity. Substantial information is available to optimize follow-up medical care of maltreated children. This new clinical report will provide guidance to pediatricians about how they can best oversee and foster the optimal physical health, growth, and development of children who have been maltreated and remain in the care of their biological family or are returned to their care by Child Protective Services agencies. The report describes the pediatrician's role in helping to strengthen families' and caregivers' capabilities and competencies and in promoting and maximizing high-quality services for their families in their community. Pediatricians should refer to other reports and policies from the American Academy of Pediatrics for more information about the emotional and behavioral consequences of child maltreatment and the treatment of these consequences. (3/19)

OPHTHALMOLOGIC EXAMINATIONS IN CHILDREN WITH JUVENILE RHEUMATOID ARTHRITIS (CLINICAL REPORT)

James Cassidy, MD; Jane Kivlin, MD; Carol Lindsley, MD; James Nocton, MD; Section on Rheumatology; and Section on Ophthalmology

ABSTRACT. Unlike the joints, ocular involvement with juvenile rheumatoid arthritis is most often asymptomatic; yet, the inflammation can cause serious morbidity with loss of vision. Scheduled slit-lamp examinations by an ophthalmologist at specific intervals can detect ocular disease early, and prompt treatment can prevent vision loss. (5/06, reaffirmed 10/12, 7/18)
http://pediatrics.aappublications.org/content/117/5/1843

OPTIMIZING BONE HEALTH IN CHILDREN AND ADOLESCENTS (CLINICAL REPORT)

Neville H. Golden, MD; Steven A. Abrams, MD; and Committee on Nutrition

ABSTRACT. The pediatrician plays a major role in helping optimize bone health in children and adolescents. This clinical report reviews normal bone acquisition in infants, children, and adolescents and discusses factors affecting bone health in this age group. Previous recommended daily allowances for calcium and vitamin D are updated, and clinical guidance is provided regarding weight-bearing activities and recommendations for calcium and vitamin D intake and supplementation. Routine calcium supplementation is not recommended for healthy children and adolescents, but increased dietary intake to meet daily requirements is encouraged. The American Academy of Pediatrics endorses the higher recommended dietary allowances for vitamin D advised by the Institute of Medicine and supports testing for vitamin D deficiency in children and adolescents with conditions associated with increased bone fragility. Universal screening for vitamin D deficiency is not routinely recommended in healthy children or in children with dark skin or obesity because there is insufficient evidence of the cost–benefit of such a practice in reducing fracture risk. The preferred test to assess bone health is dual-energy x-ray absorptiometry, but caution is advised when interpreting results in children and adolescents who may not yet have achieved peak bone mass. For analyses, *z* scores should be used instead of T scores, and corrections should be made for size. Office-based strategies for the pediatrician to optimize bone health are provided. This clinical report has been endorsed by American Bone Health. (9/14)
http://pediatrics.aappublications.org/content/134/4/e1229

OPTIMIZING RESOURCES IN CHILDREN'S SURGICAL CARE: AN UPDATE ON THE AMERICAN COLLEGE OF SURGEONS' VERIFICATION PROGRAM (TECHNICAL REPORT)

Kasper S. Wang, MD, FAAP; James Cummings, MD, FAAP; Ann Stark, MD, FAAP; Constance Houck, MD, MPH, FAAP; Keith Oldham, MD, FAAP; Catherine Grant, BSN, RN; Mary Fallat, MD, FAAP; Section on Surgery; Committee on Fetus and Newborn; and Section on Anesthesiology and Pain Medicine

ABSTRACT. Surgical procedures are performed in the United States in a wide variety of clinical settings and with variation in clinical outcomes. In May 2012, the Task Force for Children's Surgical Care, an ad hoc multidisciplinary group comprising physicians representing specialties relevant to pediatric perioperative care, was convened to generate recommendations to optimize the delivery of children's surgical care. This group generated a white paper detailing the consensus opinions of the involved experts. Following these initial recommendations, the American College of Surgeons (ACS), Children's Hospital Association, and Task Force for Children's Surgical Care, with input from all related perioperative specialties, developed and published specific and detailed resource and quality standards designed to improve children's surgical care (https://www.facs.org/quality-programs/childrens-surgery/childrens-surgery-verification). In 2015, with the endorsement of the American Academy of Pediatrics (https://pediatrics.aappublications.org/content/135/6/e1538), the ACS established a pilot verification program. In January 2017, after completion of the pilot program, the ACS Children's Surgery Verification Quality Improvement Program was officially launched. Verified sites are listed on the program Web site at https://www.facs.org/quality-programs/childrens-surgery/childrens-surgery-verification/centers, and more than 150 are interested in verification. This report provides an update on the ACS Children's Surgery Verification Quality Improvement Program as it continues to evolve. (4/20)

OPTIONS COUNSELING FOR THE PREGNANT ADOLESCENT PATIENT

Laurie L. Hornberger, MD, MPH, FAAP, and Committee on Adolescence

ABSTRACT. Each year, more than 500 000 girls and young women younger than 20 years become pregnant. It is important for pediatricians to have the ability and the resources in their offices to make a timely pregnancy diagnosis in their adolescent patients and provide them with nonjudgmental pregnancy options counseling. Counseling includes an unbiased discussion of the adolescent's legal options to either continue or terminate her pregnancy, supporting the adolescent in the decision-making process, and referring the adolescent to appropriate resources and services. Pediatricians who choose not to provide such discussions should promptly refer pregnant adolescent patients to a health care professional who will offer developmentally appropriate pregnancy options counseling. This approach to pregnancy options counseling has not changed since the original 1989 American Academy of Pediatrics statement on this issue. (8/17)

http://pediatrics.aappublications.org/content/140/3/e20172274

ORAL AND DENTAL ASPECTS OF CHILD ABUSE AND NEGLECT (CLINICAL REPORT)

Susan A. Fisher-Owens, MD, MPH, FAAP; James L. Lukefahr, MD, FAAP; Anupama Rao Tate, DMD, MPH; Section on Oral Health; and Committee on Child Abuse and Neglect (joint with American Academy of Pediatric Dentistry Council on Clinical Affairs, Council on Scientific Affairs, and Ad Hoc Work Group on Child Abuse and Neglect)

ABSTRACT. In all 50 states, health care providers (including dentists) are mandated to report suspected cases of abuse and neglect to social service or law enforcement agencies. The purpose of this report is to review the oral and dental aspects of physical and sexual abuse and dental neglect in children and the role of pediatric care providers and dental providers in evaluating such conditions. This report addresses the evaluation of bite marks as well as perioral and intraoral injuries, infections, and diseases that may raise suspicion for child abuse or neglect. Oral health issues can also be associated with bullying and are commonly seen in human trafficking victims. Some medical providers may receive less education pertaining to oral health and dental injury and disease and may not detect the mouth and gum findings that are related to abuse or neglect as readily as they detect those involving other areas of the body. Therefore, pediatric care providers and dental providers are encouraged to collaborate to increase the prevention, detection, and treatment of these conditions in children. (7/17)

http://pediatrics.aappublications.org/content/140/2/e20171487

ORAL HEALTH CARE FOR CHILDREN WITH DEVELOPMENTAL DISABILITIES (CLINICAL REPORT)

Kenneth W. Norwood Jr, MD; Rebecca L. Slayton, DDS, PhD; Council on Children With Disabilities; and Section on Oral Health

ABSTRACT. Children with developmental disabilities often have unmet complex health care needs as well as significant physical and cognitive limitations. Children with more severe conditions and from low-income families are particularly at risk with high dental needs and poor access to care. In addition, children with developmental disabilities are living longer, requiring continued oral health care. This clinical report describes the effect that poor oral health has on children with developmental disabilities as well as the importance of partnerships between the pediatric medical and dental homes. Basic knowledge of the oral health risk factors affecting children with developmental disabilities is provided. Pediatricians may use the report to guide their incorporation of oral health assessments and education into their well-child examinations for children with developmental disabilities. This report has medical, legal, educational, and operational implications for practicing pediatricians. (2/13, reaffirmed 6/18)

http://pediatrics.aappublications.org/content/131/3/614

ORGANIC FOODS: HEALTH AND ENVIRONMENTAL ADVANTAGES AND DISADVANTAGES (CLINICAL REPORT)

Joel Forman, MD; Janet Silverstein, MD; Committee on Nutrition; and Council on Environmental Health

ABSTRACT. The US market for organic foods has grown from $3.5 billion in 1996 to $28.6 billion in 2010, according to the Organic Trade Association. Organic products are now sold in specialty stores and conventional supermarkets. Organic products contain numerous marketing claims and terms, only some of which are standardized and regulated.

In terms of health advantages, organic diets have been convincingly demonstrated to expose consumers to fewer pesticides associated with human disease. Organic farming has been demonstrated to have less environmental impact than conventional approaches. However, current evidence does not support any meaningful nutritional benefits or deficits from eating organic compared with conventionally grown foods, and there are no well-powered human studies that directly demonstrate health benefits or disease protection as a result of consuming an organic diet. Studies also have not demonstrated any detrimental or disease-promoting effects from an organic diet. Although organic foods regularly command a significant price premium, well-designed farming studies demonstrate that costs can be competitive and yields comparable to those of conventional farming techniques. Pediatricians should incorporate this evidence when discussing the health and environmental

impact of organic foods and organic farming while continuing to encourage all patients and their families to attain optimal nutrition and dietary variety consistent with the US Department of Agriculture's MyPlate recommendations.

This clinical report reviews the health and environmental issues related to organic food production and consumption. It defines the term "organic," reviews organic food-labeling standards, describes organic and conventional farming practices, and explores the cost and environmental implications of organic production techniques. It examines the evidence available on nutritional quality and production contaminants in conventionally produced and organic foods. Finally, this report provides guidance for pediatricians to assist them in advising their patients regarding organic and conventionally produced food choices. (10/12)

http://pediatrics.aappublications.org/content/130/5/e1406

ORGANIZED SPORTS FOR CHILDREN, PREADOLESCENTS, AND ADOLESCENTS (CLINICAL REPORT)

Kelsey Logan, MD, MPH, FAAP; Steven Cuff, MD, FAAP; and Council on Sports Medicine and Fitness

ABSTRACT. Interest and participation in organized sports for children, preadolescents, and adolescents continue to grow. Because of increased participation, and younger entry age, in organized sports, appropriate practice, game schedules, and content become more important, taking into account athlete developmental stage and skills. Parental support for organized sports in general, with focus on development and fun instead of winning, has emerged as a key factor in the athlete's enjoyment of sports. Schools and community sports organizations who support multiple levels of sport (eg, recreational, competitive, elite) can include more youth who want to play sports and combat sport dropout. This report reviews the benefits and risks of organized sports as well as the roles of schools, community organizations, parents, and coaches in organized sports. It is designed to complement the American Academy of Pediatrics clinical reports "Physical Activity Assessment and Counseling in Pediatric Clinical Settings" and "Sports Specialization and Intensive Training in Young Athletes" by reviewing relevant literature on healthy organized sports for youth and providing guidance on organized sport readiness and entry. The report also provides guidance for pediatricians on counseling parents and advocating for healthy organized sports participation. (5/19)

OUT-OF-HOME PLACEMENT FOR CHILDREN AND ADOLESCENTS WITH DISABILITIES (CLINICAL REPORT)

Sandra L. Friedman, MD, MPH, FAAP; Miriam A. Kalichman, MD, FAAP; and Council on Children With Disabilities

ABSTRACT. The vast majority of children and youth with chronic and complex health conditions who also have intellectual and developmental disabilities are cared for in their homes. Social, legal, policy, and medical changes through the years have allowed for an increase in needed support within the community. However, there continues to be a relatively small group of children who live in various types of congregate care settings. This clinical report describes these settings and the care and services that are provided in them. The report also discusses reasons families choose out-of-home placement for their children, barriers to placement, and potential effects of this decision on family members. We examine the pediatrician's role in caring for children with severe intellectual and developmental disabilities and complex medical problems in the context of responding to parental inquiries about out-of-home placement and understanding factors affecting these types of decisions. Common medical problems and care issues for children residing outside the family home are reviewed. Variations in state and federal regulations, challenges in understanding local systems, and access to services are also discussed. (9/14, reaffirmed 2/19)

http://pediatrics.aappublications.org/content/134/4/836

OUT-OF-HOME PLACEMENT FOR CHILDREN AND ADOLESCENTS WITH DISABILITIES—ADDENDUM: CARE OPTIONS FOR CHILDREN AND ADOLESCENTS WITH DISABILITIES AND MEDICAL COMPLEXITY (CLINICAL REPORT)

Sandra L. Friedman, MD, MPH, FAAP; Kenneth W. Norwood Jr, MD, FAAP; and Council on Children With Disabilities

ABSTRACT. Children and adolescents with significant intellectual and developmental disabilities and complex medical problems require safe and comprehensive care to meet their medical and psychosocial needs. Ideally, such children and youth should be cared for by their families in their home environments. When this type of arrangement is not possible, there should be exploration of appropriate, alternative noncongregate community-based settings, especially alternative family homes. Government funding sources exist to support care in the community, although there is variability among states with regard to the availability of community programs and resources. It is important that families are supported in learning about options of care. Pediatricians can serve as advocates for their patients and their families to access community-based services and to increase the availability of resources to ensure that the option to live in a family home is available to all children with complex medical needs. (11/16, reaffirmed 2/19)

http://pediatrics.aappublications.org/content/138/6/e20163216

OUT-OF-SCHOOL SUSPENSION AND EXPULSION

Council on School Health

ABSTRACT. The primary mission of any school system is to educate students. To achieve this goal, the school district must maintain a culture and environment where all students feel safe, nurtured, and valued and where order and civility are expected standards of behavior. Schools cannot allow unacceptable behavior to interfere with the school district's primary mission. To this end, school districts adopt codes of conduct for expected behaviors and policies to address unacceptable behavior. In developing these policies, school boards must weigh the severity of the offense and the consequences of the punishment and the balance between individual and institutional rights and responsibilities. Out-of-school suspension and expulsion are the most severe consequences that a school district can impose for unacceptable behavior. Traditionally, these consequences have been reserved for offenses deemed especially severe or dangerous and/or for recalcitrant offenders. However, the implications and consequences of out-of-school suspension and expulsion and "zero-tolerance" are of such severity that their application and appropriateness for a developing child require periodic review. The indications and effectiveness of exclusionary discipline policies that demand automatic or rigorous application are increasingly questionable. The impact of these policies on offenders, other children, school districts, and communities is broad. Periodic scrutiny of policies should be placed not only on the need for a better understanding of the educational, emotional, and social impact of out-of-school suspension and expulsion on the individual student but also on the greater societal costs of such rigid policies. Pediatricians should be prepared to assist students and families affected by out-of-school suspension and expulsion and should be willing to guide school districts in their communities to find more effective and appropriate alternatives to exclusionary discipline policies for the developing child. A discussion of preventive strategies and alternatives to out-of-school suspension and expulsion, as well as recommendations for the role of the physician in matters of out-of-school

suspension and expulsion are included. School-wide positive behavior support/positive behavior intervention and support is discussed as an effective alternative. (2/13)

OVERCROWDING CRISIS IN OUR NATION'S EMERGENCY DEPARTMENTS: IS OUR SAFETY NET UNRAVELING?

Committee on Pediatric Emergency Medicine

ABSTRACT. Emergency departments (EDs) are a vital component in our health care safety net, available 24 hours a day, 7 days a week, for all who require care. There has been a steady increase in the volume and acuity of patient visits to EDs, now with well over 100 million Americans (30 million children) receiving emergency care annually. This rise in ED utilization has effectively saturated the capacity of EDs and emergency medical services in many communities. The resulting phenomenon, commonly referred to as ED overcrowding, now threatens access to emergency services for those who need them the most. As managers of the pediatric medical home and advocates for children and optimal pediatric health care, there is a very important role for pediatricians and the American Academy of Pediatrics in guiding health policy decision-makers toward effective solutions that promote the medical home and timely access to emergency care. OVERUSE INJURIES, OVERTRAINING, AND BURNOUT IN CHILD AND ADOLESCENT ATHLETES (CLINICAL REPORT)

Joel S. Brenner, MD, MPH, and Council on Sports Medicine and Fitness

ABSTRACT. Overuse is one of the most common etiologic factors that lead to injuries in the pediatric and adolescent athlete. As more children are becoming involved in organized and recreational athletics, the incidence of overuse injuries is increasing. Many children are participating in sports year-round and sometimes on multiple teams simultaneously. This overtraining can lead to burnout, which may have a detrimental effect on the child participating in sports as a lifelong healthy activity. One contributing factor to overtraining may be parental pressure to compete and succeed. The purpose of this clinical report is to assist pediatricians in identifying and counseling at-risk children and their families. This report supports the American Academy of Pediatrics policy statement on intensive training and sport specialization. (6/07, reaffirmed 3/11, 6/14)

OXYGEN TARGETING IN EXTREMELY LOW BIRTH WEIGHT INFANTS (CLINICAL REPORT)

James J. Cummings, MD, FAAP; Richard A. Polin, MD, FAAP; and Committee on Fetus and Newborn

ABSTRACT. The use of supplemental oxygen plays a vital role in the care of the critically ill preterm infant, but the unrestricted use of oxygen can lead to unintended harms, such as chronic lung disease and retinopathy of prematurity. An overly restricted use of supplemental oxygen may have adverse effects as well. Ideally, continuous monitoring of tissue and cellular oxygen delivery would allow clinicians to better titrate the use of supplemental oxygen, but such monitoring is not currently feasible in the clinical setting. The introduction of pulse oximetry has greatly aided the clinician by providing a relatively easy and continuous estimate of arterial oxygen saturation, but pulse oximetry has several practical, technical, and physiologic limitations. Recent randomized clinical trials comparing different pulse oximetry targets have been conducted to better inform the practice of supplemental oxygen use. This clinical report discusses the benefits and limitations of pulse oximetry for assessing oxygenation, summarizes randomized clinical trials of oxygen saturation targeting, and addresses implications for practice. PAIN ASSESSMENT AND TREATMENT IN CHILDREN WITH SIGNIFICANT IMPAIRMENT OF THE CENTRAL NERVOUS SYSTEM (CLINICAL REPORT)

Julie Hauer, MD, FAAP; Amy J. Houtrow, MD, PhD, MPH, FAAP; Section on Hospice and Palliative Medicine; and Council on Children With Disabilities

ABSTRACT. Pain is a frequent and significant problem for children with impairment of the central nervous system, with the highest frequency and severity occurring in children with the greatest impairment. Despite the significance of the problem, this population remains vulnerable to underrecognition and undertreatment of pain. Barriers to treatment may include uncertainty in identifying pain along with limited experience and fear with the use of medications for pain treatment. Behavioral pain-assessment tools are reviewed in this clinical report, along with other strategies for monitoring pain after an intervention. Sources of pain in this population include acute-onset pain attributable to tissue injury or inflammation resulting in nociceptive pain, with pain then expected to resolve after treatment directed at the source. Other sources can result in chronic intermittent pain that, for many, occurs on a weekly to daily basis, commonly attributed to gastroesophageal reflux, spasticity, and hip subluxation. Most challenging are pain sources attributable to the impaired central nervous system, requiring empirical medication trials directed at causes that cannot be identified by diagnostic tests, such as central neuropathic pain. Interventions reviewed include integrative therapies and medications, such as gabapentinoids, tricyclic antidepressants, α-agonists, and opioids. This clinical report aims to address, with evidence-based guidance, the inherent challenges with the goal to improve comfort throughout life in this vulnerable group of children. (5/17)

PARENTAL LEAVE FOR RESIDENTS AND PEDIATRIC TRAINING PROGRAMS

Section on Medical Students, Residents, and Fellowship Trainees and Committee on Early Childhood

ABSTRACT. The American Academy of Pediatrics (AAP) is committed to the development of rational, equitable, and effective parental leave policies that are sensitive to the needs of pediatric residents, families, and developing infants and that enable parents to spend adequate and good-quality time with their young children. It is important for each residency program to have a policy for parental leave that is written, that is accessible to residents, and that clearly delineates program practices regarding parental leave. At a minimum, a parental leave policy for residents and fellows should conform legally with the Family Medical Leave Act as well as with respective state laws and should meet institutional requirements of the Accreditation Council for Graduate Medical Education for accredited programs. Policies should be well formulated and communicated in a culturally sensitive manner. The AAP advocates for extension of benefits consistent with the Family Medical Leave Act to all residents and interns beginning at the time that pediatric residency training begins. The AAP recommends that regardless of gender, residents who become parents should be guaranteed 6 to 8 weeks, at a minimum, of parental leave with pay after the infant's birth. In addition, in conformance with federal law, the resident should be allowed to extend the leave time when necessary by using paid vacation time or leave without pay. Coparenting, adopting, or fostering of a child should entitle the resident, regardless of gender, to the same amount of paid leave (6–8 weeks) as a person who takes maternity/paternity leave.

Flexibility, creativity, and advanced planning are necessary to arrange schedules that optimize resident education and experience, cultivate equity in sharing workloads, and protect pregnant residents from overly strenuous work experiences at critical times of their pregnancies. (1/13, reaffirmed 4/19)

PARENTAL PRESENCE DURING TREATMENT OF EBOLA OR OTHER HIGHLY CONSEQUENTIAL INFECTION (CLINICAL REPORT)

H. Dele Davies, MD, MS, MHCM, FAAP; Carrie L. Byington, MD, FAAP; and Committee on Infectious Diseases

ABSTRACT. This clinical report offers guidance to health care providers and hospitals on options to consider regarding parental presence at the bedside while caring for a child with suspected or proven Ebola virus disease (Ebola) or other highly consequential infection. Options are presented to help meet the needs of the patient and the family while also posing the least risk to providers and health care organizations. The optimal way to minimize risk is to limit contact between the person under investigation or treatment and family members/caregivers whenever possible while working to meet the emotional support needs of both patient and family. At times, caregiver presence may be deemed to be in the best interest of the patient, and in such situations, a strong effort should be made to limit potential risks of exposure to the caregiver, health care providers, and the community. The decision to allow parental/caregiver presence should be made in consultation with a team including an infectious diseases expert and state and/or local public health authorities and should involve consideration of many factors, depending on the stage of investigation and management, including (1) a careful history, physical examination, and investigations to elucidate the likelihood of the diagnosis of Ebola or other highly consequential infection; (2) ability of the facility to offer appropriate isolation for the person under investigation and family members and to manage Ebola; (3) ability to recognize and exclude people at increased risk of worse outcomes (eg, pregnant women); and (4) ability of parent/caregiver to follow instructions, including appropriate donning and doffing of personal protective equipment. (8/16)

PARENT-PROVIDER-COMMUNITY PARTNERSHIPS: OPTIMIZING OUTCOMES FOR CHILDREN WITH DISABILITIES (CLINICAL REPORT)

Nancy A. Murphy, MD; Paul S. Carbone, MD; and Council on Children With Disabilities

ABSTRACT. Children with disabilities and their families have multifaceted medical, developmental, educational, and habilitative needs that are best addressed through strong partnerships among parents, providers, and communities. However, traditional health care systems are designed to address acute rather than chronic conditions. Children with disabilities require high-quality medical homes that provide care coordination and transitional care, and their families require social and financial supports. Integrated community systems of care that promote participation of all children are needed. The purpose of this clinical report is to explore the challenges of developing effective community-based systems of care and to offer suggestions to pediatricians and policy-makers regarding the development of partnerships among children with disabilities, their families, and health care and other providers to maximize health and well-being of these children and their families. (9/11, reaffirmed 5/17)

PARTICIPATION OF CHILDREN AND ADOLESCENTS IN LIVE CRISIS DRILLS AND EXERCISES

David J. Schonfeld, MD, FAAP; Marlene Melzer-Lange, MD, FAAP; Andrew N. Hashikawa, MD, MS, FAAP; Peter A. Gorski, MD, MPA, FAAP; Council on Children and Disasters; Council on Injury, Violence, and Poison Prevention; and Council on School Health

ABSTRACT. Children and adolescents should be included in exercises and drills to the extent that their involvement advances readiness to meet their unique needs in the event of a crisis and/or furthers their own preparedness or resiliency. However, there is also a need to be cautious about the potential psychological risks and other unintended consequences of directly involving children in live exercises and drills. These risks and consequences are especially a concern when children are deceived and led to believe there is an actual attack and not a drill and/or for high-intensity active shooter drills. High-intensity active shooter drills may involve the use of real weapons, gunfire or blanks, theatrical makeup to give a realistic image of blood or gunshot wounds, predatory and aggressive acting by the individual posing to be the shooter, or other means to simulate an actual attack, even when participants are aware that it is a drill. This policy statement outlines some of the considerations regarding the prevalent practice of live active shooter drills in schools, including the recommendations to eliminate children's involvement in high-intensity drills and exercises (with the possible exception of adolescent volunteers), prohibit deception in drills and exercises, and ensure appropriate accommodations during drills and exercises based on children's unique vulnerabilities. (8/20)

PATENT DUCTUS ARTERIOSUS IN PRETERM INFANTS (CLINICAL REPORT)

William E. Benitz, MD, FAAP, and Committee on Fetus and Newborn

ABSTRACT. Despite a large body of basic science and clinical research and clinical experience with thousands of infants over nearly 6 decades, there is still uncertainty and controversy about the significance, evaluation, and management of patent ductus arteriosus in preterm infants, resulting in substantial heterogeneity in clinical practice. The purpose of this clinical report is to summarize the evidence available to guide evaluation and treatment of preterm infants with prolonged ductal patency in the first few weeks after birth. (12/15)

PATIENT- AND FAMILY-CENTERED CARE AND THE PEDIATRICIAN'S ROLE

Committee on Hospital Care and Institute for Patient- and Family-Centered Care

ABSTRACT. Drawing on several decades of work with families, pediatricians, other health care professionals, and policy makers, the American Academy of Pediatrics provides a definition of patient- and family-centered care. In pediatrics, patient- and family-centered care is based on the understanding that the family is the child's primary source of strength and support. Further, this approach to care recognizes that the perspectives and information provided by families, children, and young adults are essential components of high-quality clinical decision-making, and that patients and family are integral partners with the health care team. This policy statement outlines the core principles of patient- and family-centered care, summarizes some of the recent literature linking patient- and family-centered care to improved health outcomes, and lists various other benefits to be expected when engaging in patient- and family-centered pediatric practice. The statement concludes with specific recommendations

for how pediatricians can integrate patient- and family-centered care in hospitals, clinics, and community settings, and in broader systems of care, as well. (1/12, reaffirmed 2/18)
http://pediatrics.aappublications.org/content/129/2/394

PATIENT- AND FAMILY-CENTERED CARE AND THE ROLE OF THE EMERGENCY PHYSICIAN PROVIDING CARE TO A CHILD IN THE EMERGENCY DEPARTMENT

Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians)

ABSTRACT. Patient- and family-centered care is an approach to health care that recognizes the role of the family in providing medical care; encourages collaboration between the patient, family, and health care professionals; and honors individual and family strengths, cultures, traditions, and expertise. Although there are many opportunities for providing patient- and family-centered care in the emergency department, there are also challenges to doing so. The American Academy of Pediatrics and the American College of Emergency Physicians support promoting patient dignity, comfort, and autonomy; recognizing the patient and family as key decision-makers in the patient's medical care; recognizing the patient's experience and perspective in a culturally sensitive manner; acknowledging the interdependence of child and parent as well as the pediatric patient's evolving independence; encouraging family-member presence; providing information to the family during interventions; encouraging collaboration with other health care professionals; acknowledging the importance of the patient's medical home; and encouraging institutional policies for patient- and family-centered care. (11/06, reaffirmed 6/09, 10/11, 9/15, 10/19)

PATIENT- AND FAMILY-CENTERED CARE COORDINATION: A FRAMEWORK FOR INTEGRATING CARE FOR CHILDREN AND YOUTH ACROSS MULTIPLE SYSTEMS

Council on Children With Disabilities and Medical Home Implementation Project Advisory Committee

ABSTRACT. Understanding a care coordination framework, its functions, and its effects on children and families is critical for patients and families themselves, as well as for pediatricians, pediatric medical subspecialists/surgical specialists, and anyone providing services to children and families. Care coordination is an essential element of a transformed American health care delivery system that emphasizes optimal quality and cost outcomes, addresses family-centered care, and calls for partnership across various settings and communities. High-quality, cost-effective health care requires that the delivery system include elements for the provision of services supporting the coordination of care across settings and professionals. This requirement of supporting coordination of care is generally true for health systems providing care for all children and youth but especially for those with special health care needs. At the foundation of an efficient and effective system of care delivery is the patient-/family-centered medical home. From its inception, the medical home has had care coordination as a core element. In general, optimal outcomes for children and youth, especially those with special health care needs, require interfacing among multiple care systems and individuals, including the following: medical, social, and behavioral professionals; the educational system; payers; medical equipment providers; home care agencies; advocacy groups; needed supportive therapies/services; and families. Coordination of care across settings permits an integration of services that is centered on the comprehensive needs of the patient and family, leading to decreased health care costs, reduction in fragmented care, and improvement in the patient/family experience of care. PATIENT- AND FAMILY-CENTERED CARE OF CHILDREN IN THE EMERGENCY DEPARTMENT (TECHNICAL REPORT)

Nanette Dudley, MD, FAAP; Alice Ackerman, MD, MBA, FAAP; Kathleen M. Brown, MD, FACEP; Sally K. Snow, BSN, RN, CPEN, FAEN; and Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee and Emergency Nurses Association Pediatric Committee)

ABSTRACT. Patient- and family-centered care is an approach to the planning, delivery, and evaluation of health care that is grounded in a mutually beneficial partnership among patients, families, and health care professionals. Providing patient- and family-centered care to children in the emergency department setting presents many opportunities and challenges. This revised technical report draws on previously published policy statements and reports, reviews the current literature, and describes the present state of practice and research regarding patient- and family-centered care for children in the emergency department setting as well as some of the complexities of providing such care. (12/14, reaffirmed 10/19)

PATIENT SAFETY IN THE PEDIATRIC EMERGENCY CARE SETTING

Committee on Pediatric Emergency Medicine

ABSTRACT. Patient safety is a priority for all health care professionals, including those who work in emergency care. Unique aspects of pediatric care may increase the risk of medical error and harm to patients, especially in the emergency care setting. Although errors can happen despite the best human efforts, given the right set of circumstances, health care professionals must work proactively to improve safety in the pediatric emergency care system. Specific recommendations to improve pediatric patient safety in the emergency department are provided in this policy statement. (12/07, reaffirmed 6/11, 7/14, 8/18)
http://pediatrics.aappublications.org/content/120/6/1367

PEDESTRIAN SAFETY

Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Each year, approximately 900 pediatric pedestrians younger than 19 years are killed. In addition, 51000 children are injured as pedestrians, and 5300 of them are hospitalized because of their injuries. Parents should be warned that young children often do not have the cognitive, perceptual, and behavioral abilities to negotiate traffic independently. Parents should also be informed about the danger of vehicle back-over injuries to toddlers playing in driveways. Because posttraumatic stress syndrome commonly follows even minor pedestrian injury, pediatricians should screen and refer for this condition as necessary. The American Academy of Pediatrics supports community- and school-based strategies that minimize a child's exposure to traffic, especially to high-speed, high-volume traffic. Furthermore, the American Academy of Pediatrics supports governmental and industry action that would lead to improvements in vehicle design, driver manuals, driver education, and data collection for the purpose of reducing pediatric pedestrian injury. (7/09, reaffirmed 8/13, 5/19)

PEDIATRIC AND ADOLESCENT MENTAL HEALTH EMERGENCIES IN THE EMERGENCY MEDICAL SERVICES SYSTEM (TECHNICAL REPORT)

Margaret A. Dolan, MD; Joel A. Fein, MD, MPH; and Committee on Pediatric Emergency Medicine

ABSTRACT. Emergency department (ED) health care professionals often care for patients with previously diagnosed psychiatric illnesses who are ill, injured, or having a behavioral crisis. In addition, ED personnel encounter children with psychiatric

illnesses who may not present to the ED with overt mental health symptoms. Staff education and training regarding identification and management of pediatric mental health illness can help EDs overcome the perceived limitations of the setting that influence timely and comprehensive evaluation. In addition, ED physicians can inform and advocate for policy changes at local, state, and national levels that are needed to ensure comprehensive care of children with mental health illnesses. This report addresses the roles that the ED and ED health care professionals play in emergency mental health care of children and adolescents in the United States, which includes the stabilization and management of patients in mental health crisis, the discovery of mental illnesses and suicidal ideation in ED patients, and approaches to advocating for improved recognition and treatment of mental illnesses in children. The report also addresses special issues related to mental illness in the ED, such as minority populations, children with special health care needs, and children's mental health during and after disasters and trauma. (4/11, reaffirmed 7/14, 4/20)

PEDIATRIC ANTHRAX CLINICAL MANAGEMENT (CLINICAL REPORT)

John S. Bradley, MD, FAAP, FIDSA, FPIDS; Georgina Peacock, MD, MPH, FAAP; Steven E. Krug, MD, FAAP; William A. Bower, MD, FIDSA; Amanda C. Cohn, MD; Dana Meaney-Delman, MD, MPH, FACOG; Andrew T. Pavia, MD, FAAP, FIDSA; Committee on Infectious Diseases; and Disaster Preparedness Advisory Council

ABSTRACT. Anthrax is a zoonotic disease caused by *Bacillus anthracis,* which has multiple routes of infection in humans, manifesting in different initial presentations of disease. Because *B anthracis* has the potential to be used as a biological weapon and can rapidly progress to systemic anthrax with high mortality in those who are exposed and untreated, clinical guidance that can be quickly implemented must be in place before any intentional release of the agent. This document provides clinical guidance for the prophylaxis and treatment of neonates, infants, children, adolescents, and young adults up to the age of 21 (referred to as "children") in the event of a deliberate *B anthracis* release and offers guidance in areas where the unique characteristics of children dictate a different clinical recommendation from adults. (4/14)
http://pediatrics.aappublications.org/content/133/5/e1411

PEDIATRIC ANTHRAX CLINICAL MANAGEMENT: EXECUTIVE SUMMARY

John S. Bradley, MD, FAAP, FIDSA, FPIDS; Georgina Peacock, MD, MPH, FAAP; Steven E. Krug, MD, FAAP; William A. Bower, MD, FIDSA; Amanda C. Cohn, MD; Dana Meaney-Delman, MD, MPH, FACOG; Andrew T. Pavia, MD, FAAP, FIDSA; Committee on Infectious Diseases; and Disaster Preparedness Advisory Council

The use of *Bacillus anthracis* as a biological weapon is considered a potential national security threat by the US government. *B anthracis* has the ability to be used as a biological weapon and to cause anthrax, which can rapidly progress to systemic disease with high mortality in those who are untreated. Therefore, clear plans for managing children after a *B anthracis* bioterror exposure event must be in place before any intentional release of the agent. This document provides a summary of the guidance contained in the clinical report (appendices cited in this executive summary refer to those in the clinical report) for diagnosis and management of anthrax, including antimicrobial treatment and postexposure prophylaxis (PEP), use of antitoxin, and recommendations for use of anthrax vaccine in neonates, infants, children, adolescents, and young adults up to the age of 21 years (referred to as "children"). (4/14)

PEDIATRIC APPLICATION OF CODING AND VALUATION SYSTEMS

David M. Kanter, MD, MBA, FAAP; Richard Lander, MD, FAAP, CIC; Richard A. Molteni, MD, FAAP; Committee on Coding and Nomenclature; and Private Payer Advocacy Advisory Committee

ABSTRACT. The American Academy of Pediatrics provides this revised policy statement to address health care changes that impact procedural and visit coding and valuation as well as the incorporation of coding principles into innovative, newer payment models. This policy statement focuses solely on recommendations, and an accompanying technical report provides supplemental coding and valuation background. (9/19)
https://pediatrics.aappublications.org/content/144/4/e20192496

PEDIATRIC APPLICATION OF CODING AND VALUATION SYSTEMS (TECHNICAL REPORT)

David M. Kanter, MD, MBA, FAAP; Richard A. Molteni, MD, FAAP; and Committee on Coding and Nomenclature

ABSTRACT. The American Academy of Pediatrics provides this technical report as supplemental background to the accompanying coding and valuation system policy statement. The rapid evolution in health care payment modeling requires that clinicians have a current appreciation of the mechanics of service representation and valuation. The accompanying policy statement provides recommendations relevant to this area, and this technical report provides a format to outline important concepts that allow for effective translation of bedside clinical events into physician payment. (9/19)
https://pediatrics.aappublications.org/content/144/4/e20192498

PEDIATRIC ASPECTS OF INPATIENT HEALTH INFORMATION TECHNOLOGY SYSTEMS (TECHNICAL REPORT)

Christoph U. Lehmann, MD, FAAP, FACMI, and Council on Clinical Information Technology

ABSTRACT. In the past 3 years, the Health Information Technology for Economic and Clinical Health Act accelerated the adoption of electronic health records (EHRs) with providers and hospitals, who can claim incentive monies related to meaningful use. Despite the increase in adoption of commercial EHRs in pediatric settings, there has been little support for EHR tools and functionalities that promote pediatric quality improvement and patient safety, and children remain at higher risk than adults for medical errors in inpatient environments. Health information technology (HIT) tailored to the needs of pediatric health care providers can improve care by reducing the likelihood of errors through information assurance and minimizing the harm that results from errors. This technical report outlines pediatric-specific concepts, child health needs and their data elements, and required functionalities in inpatient clinical information systems that may be missing in adult-oriented HIT systems with negative consequences for pediatric inpatient care. It is imperative that inpatient (and outpatient) HIT systems be adapted to improve their ability to properly support safe health care delivery for children. (2/15)
http://pediatrics.aappublications.org/content/135/3/e756

PEDIATRIC CONSIDERATIONS BEFORE, DURING, AND AFTER RADIOLOGICAL OR NUCLEAR EMERGENCIES

Jerome A. Paulson, MD, FAAP, and Council on Environmental Health

ABSTRACT. Infants, children, and adolescents can be exposed unexpectedly to ionizing radiation from nuclear power plant events, improvised nuclear or radiologic dispersal device explosions, or inappropriate disposal of radiotherapy equipment. Children are likely to experience higher external and internal radiation exposure levels than adults because of their smaller body and organ size and other physiologic characteristics, by picking up contaminated items, and through consumption

of contaminated milk or foodstuffs. This policy statement and accompanying technical report update the 2003 American Academy of Pediatrics policy statement on pediatric radiation emergencies by summarizing newer scientific knowledge from studies of the Chernobyl and Fukushima Daiichi nuclear power plant events, use of improvised radiologic dispersal devices, exposures from inappropriate disposal of radiotherapy equipment, and potential health effects from residential proximity to nuclear plants. Policy recommendations are made for providers and governments to improve future responses to these types of events. (11/18)

http://pediatrics.aappublications.org/content/142/6/e20183000

PEDIATRIC CONSIDERATIONS BEFORE, DURING, AND AFTER RADIOLOGICAL OR NUCLEAR EMERGENCIES (TECHNICAL REPORT)

Martha S. Linet, MD, MPH; Ziad Kazzi, MD; Jerome A. Paulson, MD, FAAP; and Council on Environmental Health

ABSTRACT. Infants, children, and adolescents can be exposed unexpectedly to ionizing radiation from nuclear power plant events, improvised nuclear or radiologic dispersal device explosions, or inappropriate disposal of radiotherapy equipment. Children are likely to experience higher external and internal radiation exposure levels than adults because of their smaller body and organ size and other physiologic characteristics as well as their tendency to pick up contaminated items and consume contaminated milk or foodstuffs. This technical report accompanies the revision of the 2003 American Academy of Pediatrics policy statement on pediatric radiation emergencies by summarizing newer scientific data from studies of the Chernobyl and the Fukushima Daiichi nuclear power plant events, use of improvised radiologic dispersal devices, exposures from inappropriate disposal of radiotherapy equipment, and potential health effects from residential proximity to nuclear plants. Also included are recommendations from epidemiological studies and biokinetic models to address mitigation efforts. The report includes major emphases on acute radiation syndrome, acute and long-term psychological effects, cancer risks, and other late tissue reactions after low-to-high levels of radiation exposure. Results, along with public health and clinical implications, are described from studies of the Japanese atomic bomb survivors, nuclear plant accidents (eg, Three Mile Island, Chernobyl, and Fukushima), improper disposal of radiotherapy equipment in Goiania, Brazil, and residence in proximity to nuclear plants. Measures to reduce radiation exposure in the immediate aftermath of a radiologic or nuclear disaster are described, including the diagnosis and management of external and internal contamination, use of potassium iodide, and actions in relation to breastfeeding. (11/18)

http://pediatrics.aappublications.org/content/142/6/e20183001

PEDIATRIC INTEGRATIVE MEDICINE (CLINICAL REPORT)

Hilary McClafferty, MD, FAAP; Sunita Vohra, MD, FAAP; Michelle Bailey, MD, FAAP; Melanie Brown, MD, MSE, FAAP; Anna Esparham, MD, FAAP; Dana Gerstbacher, MD, FAAP; Brenda Golianu, MD, FAAP; Anna-Kaisa Niemi, MD, PhD, FAAP, FACMG; Erica Sibinga, MD, FAAP; Joy Weydert, MD, FAAP; Ann Ming Yeh, MD; and Section on Integrative Medicine

ABSTRACT. The American Academy of Pediatrics is dedicated to optimizing the well-being of children and advancing family-centered health care. Related to this mission, the American Academy of Pediatrics recognizes the increasing use of complementary and integrative therapies for children and the subsequent need to provide reliable information and high-quality clinical resources to support pediatricians. This Clinical Report serves as an update to the original 2008 statement on complementary medicine. The range of complementary therapies is both extensive and diverse. Therefore, in-depth discussion of each therapy or product is beyond the scope of this report. Instead, our intentions are to define terms; describe epidemiology of use; outline common types of complementary therapies; review medicolegal, ethical, and research implications; review education and training for select providers of complementary therapies; provide educational resources; and suggest communication strategies for discussing complementary therapies with patients and families. (8/17)

PEDIATRIC MEDICATION SAFETY IN THE EMERGENCY DEPARTMENT

Lee Benjamin, MD, FAAP, FACEP; Karen Frush, MD, FAAP; Kathy Shaw, MD, MSCE, FAAP; Joan E. Shook, MD, MBA, FAAP; Sally K. Snow, BSN, RN, CPEN, FAEN; and Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee and Emergency Nurses Association Pediatric Emergency Medicine Committee)

ABSTRACT. Pediatric patients cared for in emergency departments (EDs) are at high risk of medication errors for a variety of reasons. A multidisciplinary panel was convened by the Emergency Medical Services for Children program and the American Academy of Pediatrics Committee on Pediatric Emergency Medicine to initiate a discussion on medication safety in the ED. Top opportunities identified to improve medication safety include using kilogram-only weight-based dosing, optimizing computerized physician order entry by using clinical decision support, developing a standard formulary for pediatric patients while limiting variability of medication concentrations, using pharmacist support within EDs, enhancing training of medical professionals, systematizing the dispensing and administration of medications within the ED, and addressing challenges for home medication administration before discharge. (2/18)

http://pediatrics.aappublications.org/content/141/3/e20174066

PEDIATRIC MENTAL HEALTH EMERGENCIES IN THE EMERGENCY MEDICAL SERVICES SYSTEM

Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians)

ABSTRACT. Emergency departments are vital in the management of pediatric patients with mental health emergencies. Pediatric mental health emergencies are an increasing part of emergency medical practice because emergency departments have become the safety net for a fragmented mental health infrastructure that is experiencing critical shortages in services in all sectors. Emergency departments must safely, humanely, and in a culturally and developmentally appropriate manner manage pediatric patients with undiagnosed and known mental illnesses, including those with mental retardation, autistic spectrum disorders, and attention-deficit/hyperactivity disorder and those experiencing a behavioral crisis. Emergency departments also manage patients with suicidal ideation, depression, escalating aggression, substance abuse, posttraumatic stress disorder, and maltreatment and those exposed to violence and unexpected deaths. Emergency departments must address not only the physical but also the mental health needs of patients during and after mass-casualty incidents and disasters. The American Academy of Pediatrics and the American College of Emergency Physicians support advocacy for increased mental health resources, including improved pediatric mental health tools for the emergency department, increased mental health insurance coverage, and adequate reimbursement at all levels; acknowledgment of the importance of the child's medical home; and promotion of education and research for mental health emergencies. PEDIATRIC METABOLIC AND BARIATRIC SURGERY: EVIDENCE, BARRIERS, AND BEST PRACTICES

Sarah C. Armstrong, MD, FAAP; Christopher F. Bolling, MD, FAAP; Marc P. Michalsky, MD, FACS, FAAP, FASMBS; Kirk W. Reichard, MD, MBA, FAAP, FACS; Section on Obesity; and Section on Surgery

ABSTRACT. Severe obesity among youth is an "epidemic within an epidemic" and portends a shortened life expectancy for today's children compared with those of their parents' generation. Severe obesity has outpaced less severe forms of childhood obesity in prevalence, and it disproportionately affects adolescents. Emerging evidence has linked severe obesity to the development and progression of multiple comorbid states, including increased cardiometabolic risk resulting in end-organ damage in adulthood. Lifestyle modification treatment has achieved moderate short-term success among young children and those with less severe forms of obesity, but no studies to date demonstrate significant and durable weight loss among youth with severe obesity. Metabolic and bariatric surgery has emerged as an important treatment for adults with severe obesity and, more recently, has been shown to be a safe and effective strategy for groups of youth with severe obesity. However, current data suggest that youth with severe obesity may not have adequate access to metabolic and bariatric surgery, especially among underserved populations. This report outlines the current evidence regarding adolescent bariatric surgery, provides recommendations for practitioners and policy makers, and serves as a companion to an accompanying technical report, "Metabolic and Bariatric Surgery for Pediatric Patients With Severe Obesity," which provides details and supporting evidence. (11/19)

PEDIATRIC OBSERVATION UNITS (CLINICAL REPORT)

Gregory P. Conners, MD, MPH, MBA; Sanford M. Melzer, MD, MBA; Committee on Hospital Care; and Committee on Pediatric Emergency Medicine

ABSTRACT. Pediatric observation units (OUs) are hospital areas used to provide medical evaluation and/or management for health-related conditions in children, typically for a well-defined, brief period. Pediatric OUs represent an emerging alternative site of care for selected groups of children who historically may have received their treatment in an ambulatory setting, emergency department, or hospital-based inpatient unit. This clinical report provides an overview of pediatric OUs, including the definitions and operating characteristics of different types of OUs, quality considerations and coding for observation services, and the effect of OUs on inpatient hospital utilization. (6/12, reaffirmed 9/15)

PEDIATRIC ORGAN DONATION AND TRANSPLANTATION

Committee on Hospital Care, Section on Surgery, and Section on Critical Care

ABSTRACT. Pediatric organ donation and organ transplantation can have a significant life-extending benefit to the young recipients of these organs and a high emotional impact on donor and recipient families. Pediatricians, pediatric medical specialists, and pediatric transplant surgeons need to be better acquainted with evolving national strategies that involve organ procurement and organ transplantation to help acquaint families with the benefits and risks of organ donation and transplantation. Efforts of pediatric professionals are needed to shape public policies to provide a system in which procurement, distribution, and cost are fair and equitable to children and adults. Major issues of concern are availability of and access to donor organs; oversight and control of the process; pediatric medical and surgical consultation and continued care throughout the organ-donation and transplantation process; ethical, social, financial, and follow-up issues; insurance-coverage issues; and public awareness of the need for organ donors of all ages. (3/10, reaffirmed 3/14, 4/19)

http://pediatrics.aappublications.org/content/125/4/822

PEDIATRIC PALLIATIVE CARE AND HOSPICE CARE COMMITMENTS, GUIDELINES, AND RECOMMENDATIONS

Section on Hospice and Palliative Medicine and Committee on Hospital Care

ABSTRACT. Pediatric palliative care and pediatric hospice care (PPC-PHC) are often essential aspects of medical care for patients who have life-threatening conditions or need end-of-life care. PPC-PHC aims to relieve suffering, improve quality of life, facilitate informed decision-making, and assist in care coordination between clinicians and across sites of care. Core commitments of PPC-PHC include being patient centered and family engaged; respecting and partnering with patients and families; pursuing care that is high quality, readily accessible, and equitable; providing care across the age spectrum and life span, integrated into the continuum of care; ensuring that all clinicians can provide basic palliative care and consult PPC-PHC specialists in a timely manner; and improving care through research and quality improvement efforts. PPC-PHC guidelines and recommendations include ensuring that all large health care organizations serving children with life-threatening conditions have dedicated interdisciplinary PPC-PHC teams, which should develop collaborative relationships between hospital- and community-based teams; that PPC-PHC be provided as integrated multimodal care and practiced as a cornerstone of patient safety and quality for patients with life-threatening conditions; that PPC-PHC teams should facilitate clear, compassionate, and forthright discussions about medical issues and the goals of care and support families, siblings, and health care staff; that PPC-PHC be part of all pediatric education and training curricula, be an active area of research and quality improvement, and exemplify the highest ethical standards; and that PPC-PHC services be supported by financial and regulatory arrangements to ensure access to high-quality PPC-PHC by all patients with life-threatening and life-shortening diseases. (10/13, reaffirmed 4/19)

http://pediatrics.aappublications.org/content/132/5/966

PEDIATRIC PRIMARY HEALTH CARE

Committee on Pediatric Workforce

ABSTRACT. Primary health care is described as accessible and affordable, first contact, continuous and comprehensive, and coordinated to meet the health needs of the individual and the family being served.

Pediatric primary health care encompasses health supervision and anticipatory guidance; monitoring physical and psychosocial growth and development; age-appropriate screening; diagnosis and treatment of acute and chronic disorders; management of serious and life-threatening illness and, when appropriate, referral of more complex conditions; and provision of first contact care as well as coordinated management of health problems requiring multiple professional services.

Pediatric primary health care for children and adolescents is family centered and incorporates community resources and strengths, needs and risk factors, and sociocultural sensitivities into strategies for care delivery and clinical practice. Pediatric primary health care is best delivered within the context of a "medical home," where comprehensive, continuously accessible and affordable care is available and delivered or supervised by qualified child health specialists.

The pediatrician, because of training (which includes 4 years of medical school education, plus an additional 3 or more years of intensive training devoted solely to all aspects of medical care for children and adolescents), coupled with the demonstrated interest in and total professional commitment to the health care of infants, children, adolescents, and young adults, is the most

appropriate provider of pediatric primary health care. (1/11, reaffirmed 10/13, 5/17, 4/20)

PEDIATRIC READINESS IN EMERGENCY MEDICAL SERVICES SYSTEMS

Brian Moore, MD, FAAP; Manish I. Shah, MD, MS, FAAP; Sylvia Owusu-Ansah, MD, MPH, FAAP; Toni Gross, MD, MPH, FAAP; Kathleen Brown, MD, FAAP; Marianne Gausche-Hill, MD, FACEP, FAAP, FAEMS; Katherine Remick, MD, FACEP, FAAP, FAEMS; Kathleen Adelgais, MD, MPH, FAAP; John Lyng, MD, FAEMS, FACEP, NRP; Lara Rappaport, MD, MPH, FAAP; Sally Snow, RN, BSN, CPEN, FAEN; Cynthia Wright-Johnson, MSN, RNC; Julie C. Leonard, MD, MPH, FAAP; Committee on Pediatric Emergency Medicine; Section on Emergency Medicine; and EMS Subcommittee (joint with American College of Emergency Physicians Emergency Medical Services Committee; Emergency Nurses Association Pediatric Committee; National Association of Emergency Medical Services Physicians Standards and Clinical Practice Committee; and National Association of Emergency Medical Technicians Medical Technicians Emergency Pediatric Care Committee)

ABSTRACT. Prehospital emergency care typically involves emergency medical technicians, paramedics, and other licensed medical providers who work in emergency medical services (EMS) systems in ground ambulances and fixed- or rotor-wing aircraft that are dispatched to an emergency when either a bystander calls 9-1-1 or when a patient requires interfacility transport for a medical illness or traumatic injury. Because prehospital emergency care of children plays a critical role in the continuum of health care, which also involves primary prevention, hospital-based acute care, rehabilitation, and return to the medical home, the unique needs of children must be addressed by EMS systems. Pediatric readiness encompasses the presence of equipment and medications, usage of guidelines and policies, availability of education and training, incorporation of performance-improvement practices, and integration of EMS physician medical oversight to equip EMS systems to deliver optimal care to children. It has been shown that emergency departments are more prepared to care for children when a pediatric emergency care coordinator is responsible for championing and making recommendations for policies, training, and resources pertinent to the emergency care of children. The specialty of EMS medicine has the potential to derive similar benefits when members of the EMS community are personally invested in pediatric patient care. Although a critical aspect of pediatric readiness in EMS involves strong EMS physician oversight of these investments, a discussion of physician oversight of pediatric care in EMS is outside the scope of this article. This topic is, however, well addressed in the National Association of Emergency Medical Services Physicians position statement "Physician Oversight of Pediatric Care in Emergency Medical Services." This policy statement is accompanied by a technical report published simultaneously in this issue of *Pediatrics*. (12/19)

PEDIATRIC READINESS IN EMERGENCY MEDICAL SERVICES SYSTEMS (TECHNICAL REPORT)

Sylvia Owusu-Ansah, MD, MPH, FAAP; Brian Moore, MD, FAAP; Manish I. Shah, MD, MS, FAAP; Toni Gross, MD, MPH, FAAP; Kathleen Brown, MD, FAAP; Marianne Gausche-Hill, MD, FACEP, FAAP, FAEMS; Katherine Remick, MD, FACEP, FAAP, FAEMS; Kathleen Adelgais, MD, MPH, FAAP; Lara Rappaport, MD, MPH, FAAP; Sally Snow, RN, BSN, CPEN, FAEN; Cynthia Wright-Johnson, MSN, RNC; Julie C. Leonard, MD, MPH, FAAP; John Lyng, MD, FAEMS, FACEP, NRP; Mary Fallat, MD, FACS, FAAP; Committee on Pediatric Emergency Medicine; Section on Emergency Medicine; EMS Subcommittee; and Section on Surgery

ABSTRACT. Ill and injured children have unique needs that can be magnified when the child's ailment is serious or life-threatening. This is especially true in the out-of-hospital environment. Providing high-quality out-of-hospital care to children requires an emergency medical services (EMS) system infrastructure designed to support the care of pediatric patients. As in the emergency department setting, it is important that all EMS agencies have the appropriate resources, including physician oversight, trained and competent staff, education, policies, medications, equipment, and supplies, to provide effective emergency care for children. Resource availability across EMS agencies is variable, making it essential that EMS medical directors, administrators, and personnel collaborate with outpatient and hospital-based pediatric experts, especially those in emergency departments, to optimize prehospital emergency care for children. The principles in the policy statement "Pediatric Readiness in Emergency Medical Services Systems" and this accompanying technical report establish a foundation on which to build optimal pediatric care within EMS systems and serve as a resource for clinical and administrative EMS leaders. (12/19)

PEDIATRIC READINESS IN THE EMERGENCY DEPARTMENT

Katherine Remick, MD, FAAP, FACEP, FAEMS; Marianne Gausche-Hill, MD, FAAP, FACEP, FAEMS; Madeline M. Joseph, MD, FAAP, FACEP; Kathleen Brown, MD, FAAP, FACEP; Sally K. Snow, BSN, RN, CPEN, FAEN; Joseph L. Wright, MD, MPH, FAAP; Committee on Pediatric Emergency Medicine; and Section on Surgery (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee and Emergency Nurses Association Pediatric Committee)

ABSTRACT. This is a revision of the previous joint Policy Statement titled "Guidelines for Care of Children in the Emergency Department." Children have unique physical and psychosocial needs that are heightened in the setting of serious or life-threatening emergencies. The majority of children who are ill and injured are brought to community hospital emergency departments (EDs) by virtue of proximity. It is therefore imperative that all EDs have the appropriate resources (medications, equipment, policies, and education) and capable staff to provide effective emergency care for children. In this Policy Statement, we outline the resources necessary for EDs to stand ready to care for children of all ages. These recommendations are consistent with the recommendations of the Institute of Medicine (now called the National Academy of Medicine) in its report "The Future of Emergency Care in the US Health System." Although resources within emergency and trauma care systems vary locally, regionally, and nationally, it is essential that ED staff, administrators, and medical directors seek to meet or exceed these recommendations to ensure that high-quality emergency care is available for all children. These updated recommendations are intended to serve as a resource for clinical and administrative leadership in EDs as they strive to improve their readiness for children of all ages. (10/18)

PEDIATRIC SUDDEN CARDIAC ARREST

Section on Cardiology and Cardiac Surgery

ABSTRACT. Pediatric sudden cardiac arrest (SCA), which can cause sudden cardiac death if not treated within minutes, has a profound effect on everyone: children, parents, family members, communities, and health care providers. Preventing the tragedy of pediatric SCA, defined as the abrupt and unexpected loss of heart function, remains a concern to all. The goal of this

statement is to increase the knowledge of pediatricians (including primary care providers and specialists) of the incidence of pediatric SCA, the spectrum of causes of pediatric SCA, disease-specific presentations, the role of patient and family screening, the rapidly evolving role of genetic testing, and finally, important aspects of secondary SCA prevention. This statement is not intended to address sudden infant death syndrome or sudden unexplained death syndrome, nor will specific treatment of individual cardiac conditions be discussed. This statement has been endorsed by the American College of Cardiology, the American Heart Association, and the Heart Rhythm Society. (3/12)
http://pediatrics.aappublications.org/content/129/4/e1094

PEDIATRICIAN GUIDANCE IN SUPPORTING FAMILIES OF CHILDREN WHO ARE ADOPTED, FOSTERED, OR IN KINSHIP CARE (CLINICAL REPORT)

Veronnie F. Jones, MD, MSPH, FAAP; Elaine E. Schulte, MD, MPH, FAAP; Douglas Waite, MD, FAAP; and Council on Foster Care, Adoption, and Kinship Care

ABSTRACT. The child welfare system strives to provide children and adolescents in foster care with a safe, nurturing environment through kinship and nonkinship foster care placement with the goal of either reunification with birth parents or adoption. Pediatricians can support families who care for children and adolescents who are fostered and adopted while attending to children's medical needs and helping each child attain their developmental potential. Although this report primarily focuses on children in the US child welfare system, private and internationally adopted children often have similar needs. (11/20)

PEDIATRICIAN WORKFORCE POLICY STATEMENT

Committee on Pediatric Workforce

ABSTRACT. This policy statement reviews important trends and other factors that affect the pediatrician workforce and the provision of pediatric health care, including changes in the pediatric patient population, pediatrician workforce, and nature of pediatric practice. The effect of these changes on pediatricians and the demand for pediatric care are discussed. The American Academy of Pediatrics (AAP) concludes that there is currently a shortage of pediatric medical subspecialists in many fields, as well as a shortage of pediatric surgical specialists. In addition, the AAP believes that the current distribution of primary care pediatricians is inadequate to meet the needs of children living in rural and other underserved areas, and more primary care pediatricians will be needed in the future because of the increasing number of children who have significant chronic health problems, changes in physician work hours, and implementation of current health reform efforts that seek to improve access to comprehensive patient- and family-centered care for all children in a medical home. The AAP is committed to being an active participant in physician workforce policy development with both professional organizations and governmental bodies to ensure a pediatric perspective on health care workforce issues. The overall purpose of this statement is to summarize policy recommendations and serve as a resource for the AAP and other stakeholders as they address pediatrician workforce issues that ultimately influence the quality of pediatric health care provided to children in the United States. (7/13)

PEDIATRICIAN-FAMILY-PATIENT RELATIONSHIPS: MANAGING THE BOUNDARIES

Committee on Bioethics

ABSTRACT. All professionals are concerned about maintaining the appropriate limits in their relationships with those they serve. Pediatricians should be aware that, under normal circumstances, caring for one's own children presents significant ethical issues. Pediatricians also must strive to maintain appropriate professional boundaries in their relationships with the family members of their patients. Pediatricians should avoid behavior that patients and parents might misunderstand as having sexual or inappropriate social meaning. Romantic and sexual involvement between physicians and patients is unacceptable. The acceptance of gifts or nonmonetary compensation for medical services has the potential to affect the professional relationship adversely. (11/09, reaffirmed 1/14, 10/20)
http://pediatrics.aappublications.org/content/124/6/1685

THE PEDIATRICIAN'S ROLE IN CHILD MALTREATMENT PREVENTION (CLINICAL REPORT)

Emalee G. Flaherty, MD; John Stirling Jr, MD; and Committee on Child Abuse and Neglect

ABSTRACT. It is the pediatrician's role to promote the child's well-being and to help parents raise healthy, well-adjusted children. Pediatricians, therefore, can play an important role in the prevention of child maltreatment. Previous clinical reports and policy statements from the American Academy of Pediatrics have focused on improving the identification and management of child maltreatment. This clinical report outlines how the pediatrician can help to strengthen families and promote safe, stable, nurturing relationships with the aim of preventing maltreatment. After describing some of the triggers and factors that place children at risk for maltreatment, the report describes how pediatricians can identify family strengths, recognize risk factors, provide helpful guidance, and refer families to programs and other resources with the goal of strengthening families, preventing child maltreatment, and enhancing child development. (9/10, reaffirmed 1/14, 7/20)
http://pediatrics.aappublications.org/content/126/4/833

THE PEDIATRICIAN'S ROLE IN FAMILY SUPPORT AND FAMILY SUPPORT PROGRAMS

Committee on Early Childhood, Adoption, and Dependent Care

ABSTRACT. Children's social, emotional, and physical health; their developmental trajectory; and the neurocircuits that are being created and reinforced in their developing brains are all directly influenced by their relationships during early childhood. The stresses associated with contemporary American life can challenge families' abilities to promote successful developmental outcomes and emotional health for their children. Pediatricians are positioned to serve as partners with families and other community providers in supporting the well-being of children and their families. The structure and support of families involve forces that are often outside the agenda of the usual pediatric health supervision visits. Pediatricians must ensure that their medical home efforts promote a holistically healthy family environment for all children. This statement recommends opportunities for pediatricians to develop their expertise in assessing the strengths and stresses in families, in counseling families about strategies and resources, and in collaborating with others in their communities to support family relationships. (11/11, reaffirmed 12/16)
http://pediatrics.aappublications.org/content/128/6/e1680

THE PEDIATRICIAN'S ROLE IN OPTIMIZING SCHOOL READINESS

Council on Early Childhood and Council on School Health

ABSTRACT. School readiness includes not only the early academic skills of children but also their physical health, language skills, social and emotional development, motivation to learn, creativity, and general knowledge. Families and communities play a critical role in ensuring children's growth in all of these areas and thus their readiness for school. Schools must be prepared to teach all children when they reach the age of school

entry, regardless of their degree of readiness. Research on early brain development emphasizes the effects of early experiences, relationships, and emotions on creating and reinforcing the neural connections that are the basis for learning. Pediatricians, by the nature of their relationships with families and children, may significantly influence school readiness. Pediatricians have a primary role in ensuring children's physical health through the provision of preventive care, treatment of illness, screening for sensory deficits, and monitoring nutrition and growth. They can promote and monitor the social-emotional development of children by providing anticipatory guidance on development and behavior, by encouraging positive parenting practices, by modeling reciprocal and respectful communication with adults and children, by identifying and addressing psychosocial risk factors, and by providing community-based resources and referrals when warranted. Cognitive and language skills are fostered through timely identification of developmental problems and appropriate referrals for services, including early intervention and special education services; guidance regarding safe and stimulating early education and child care programs; and promotion of early literacy by encouraging language-rich activities such as reading together, telling stories, and playing games. Pediatricians are also well positioned to advocate not only for children's access to health care but also for high-quality early childhood education and evidence-based family supports such as home visits, which help provide a foundation for optimal learning. (8/16)
http://pediatrics.aappublications.org/content/138/3/e20162293

THE PEDIATRICIAN'S ROLE IN SUPPORTING ADOPTIVE FAMILIES (CLINICAL REPORT)

Veronnie F. Jones, MD, PhD, MSPH; Elaine E. Schulte, MD, MPH; Committee on Early Childhood; and Council on Foster Care, Adoption, and Kinship Care

ABSTRACT. Each year, more children join families through adoption. Pediatricians have an important role in assisting adoptive families in the various challenges they may face with respect to adoption. The acceptance of the differences between families formed through birth and those formed through adoption is essential in promoting positive emotional growth within the family. It is important for pediatricians to be aware of the adoptive parents' need to be supported in their communication with their adopted children. (9/12, reaffirmed 12/16)
http://pediatrics.aappublications.org/content/130/4/e1040

THE PEDIATRICIAN'S ROLE IN THE EVALUATION AND PREPARATION OF PEDIATRIC PATIENTS UNDERGOING ANESTHESIA

Section on Anesthesiology and Pain Medicine

ABSTRACT. Pediatricians play a key role in helping prepare patients and families for anesthesia and surgery. The questions to be answered by the pediatrician fall into 2 categories. The first involves preparation: is the patient in optimal medical condition for surgery, and are the patient and family emotionally and cognitively ready for surgery? The second category concerns logistics: what communication and organizational needs are necessary to enable safe passage through the perioperative process? This revised statement updates the recommendations for the pediatrician's role in the preoperative preparation of patients. (8/14)
http://pediatrics.aappublications.org/content/134/3/634

THE PEDIATRICIAN'S ROLE IN THE PREVENTION OF MISSING CHILDREN (CLINICAL REPORT)

Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. In 2002, the *Second National Incidence Studies of Missing, Abducted, Runaway, and Thrownaway Children* report was released by the US Department of Justice, providing new data on a problem that our nation continues to face. This clinical report describes the categories of missing children, the prevalence of each, and prevention strategies that primary care pediatricians can share with parents to increase awareness and education about the safety of their children. (10/04, reaffirmed 1/15)
http://pediatrics.aappublications.org/content/114/4/1100

PEDIATRICIANS AND PUBLIC HEALTH: OPTIMIZING THE HEALTH AND WELL-BEING OF THE NATION'S CHILDREN

Alice A. Kuo, MD, PhD, FAAP; Pauline A. Thomas, MD, FAAP; Lance A. Chilton, MD, FAAP; Laurene Mascola, MD, MPH; Council on Community Pediatrics; and Section on Epidemiology, Public Health, and Evidence

ABSTRACT. Ensuring optimal health for children requires a population-based approach and collaboration between pediatrics and public health. The prevention of major threats to children's health (such as behavioral health issues) and the control and management of chronic diseases, obesity, injury, communicable diseases, and other problems cannot be managed solely in the pediatric office. The integration of clinical practice with public health actions is necessary for multiple levels of disease prevention that involve the child, family, and community. Although pediatricians and public health professionals interact frequently to the benefit of children and their families, increased integration of the 2 disciplines is critical to improving child health at the individual and population levels. Effective collaboration is necessary to ensure that population health activities include children and that the child health priorities of the American Academy of Pediatrics (AAP), such as poverty and child health, early brain and child development, obesity, and mental health, can engage federal, state, and local public health initiatives. In this policy statement, we build on the 2013 AAP Policy Statement on community pediatrics by identifying specific opportunities for collaboration between pediatricians and public health professionals that are likely to improve the health of children in communities. In the statement, we provide recommendations for pediatricians, public health professionals, and the AAP and its chapters. (1/18)

PERSONAL WATERCRAFT USE BY CHILDREN AND ADOLESCENTS

Committee on Injury and Poison Prevention

ABSTRACT. The use of personal watercraft (PWC) has increased dramatically during the past decade as have the speed and mobility of the watercraft. A similar dramatic increase in PWC-related injury and death has occurred simultaneously. No one younger than 16 years should operate a PWC. The operator and all passengers must wear US Coast Guard-approved personal flotation devices. Other safety recommendations are suggested for parents and pediatricians. (2/00, reaffirmed 5/04, 1/07, 6/10)
http://pediatrics.aappublications.org/content/105/2/452

PESTICIDE EXPOSURE IN CHILDREN

Council on Environmental Health

ABSTRACT. This statement presents the position of the American Academy of Pediatrics on pesticides. Pesticides are a collective term for chemicals intended to kill unwanted insects, plants, molds, and rodents. Children encounter pesticides daily and have unique susceptibilities to their potential toxicity. Acute poisoning risks are clear, and understanding of chronic health implications from both acute and chronic exposure are emerging. Epidemiologic evidence demonstrates associations between early life exposure to pesticides and pediatric cancers, decreased cognitive function, and behavioral problems. Related animal toxicology studies provide supportive biological plausibility for these findings. Recognizing and reducing problematic exposures will require attention to current inadequacies in medical

training, public health tracking, and regulatory action on pesticides. Ongoing research describing toxicologic vulnerabilities and exposure factors across the life span are needed to inform regulatory needs and appropriate interventions. Policies that promote integrated pest management, comprehensive pesticide labeling, and marketing practices that incorporate child health considerations will enhance safe use. (11/12)

http://pediatrics.aappublications.org/content/130/6/e1757

PESTICIDE EXPOSURE IN CHILDREN (TECHNICAL REPORT)

James R. Roberts, MD, MPH; Catherine J. Karr, MD, PhD; and Council on Environmental Health

ABSTRACT. Pesticides are a collective term for a wide array of chemicals intended to kill unwanted insects, plants, molds, and rodents. Food, water, and treatment in the home, yard, and school are all potential sources of children's exposure. Exposures to pesticides may be overt or subacute, and effects range from acute to chronic toxicity. In 2008, pesticides were the ninth most common substance reported to poison control centers, and approximately 45% of all reports of pesticide poisoning were for children. Organophosphate and carbamate poisoning are perhaps the most widely known acute poisoning syndromes, can be diagnosed by depressed red blood cell cholinesterase levels, and have available antidotal therapy. However, numerous other pesticides that may cause acute toxicity, such as pyrethroid and neonicotinoid insecticides, herbicides, fungicides, and rodenticides, also have specific toxic effects; recognition of these effects may help identify acute exposures. Evidence is increasingly emerging about chronic health implications from both acute and chronic exposure. A growing body of epidemiological evidence demonstrates associations between parental use of pesticides, particularly insecticides, with acute lymphocytic leukemia and brain tumors. Prenatal, household, and occupational exposures (maternal and paternal) appear to be the largest risks. Prospective cohort studies link early-life exposure to organophosphates and organochlorine pesticides (primarily DDT) with adverse effects on neurodevelopment and behavior. Among the findings associated with increased pesticide levels are poorer mental development by using the Bayley index and increased scores on measures assessing pervasive developmental disorder, inattention, and attention-deficit/hyperactivity disorder. Related animal toxicology studies provide supportive biological plausibility for these findings. Additional data suggest that there may also be an association between parental pesticide use and adverse birth outcomes including physical birth defects, low birth weight, and fetal death, although the data are less robust than for cancer and neurodevelopmental effects. Children's exposures to pesticides should be limited as much as possible. (11/12)

http://pediatrics.aappublications.org/content/130/6/e1765

PHOTOTHERAPY TO PREVENT SEVERE NEONATAL HYPERBILIRUBINEMIA IN THE NEWBORN INFANT 35 OR MORE WEEKS OF GESTATION (TECHNICAL REPORT)

Vinod K. Bhutani, MD, and Committee on Fetus and Newborn

ABSTRACT. *Objective.* To standardize the use of phototherapy consistent with the American Academy of Pediatrics clinical practice guideline for the management of hyperbilirubinemia in the newborn infant 35 or more weeks of gestation.

Methods. Relevant literature was reviewed. Phototherapy devices currently marketed in the United States that incorporate fluorescent, halogen, fiber-optic, or blue light-emitting diode light sources were assessed in the laboratory.

Results. The efficacy of phototherapy units varies widely because of differences in light source and configuration. The following characteristics of a device contribute to its effectiveness: (1) emission of light in the blue-to-green range that overlaps the in vivo plasma bilirubin absorption spectrum (~460–490 nm); (2) irradiance of at least 30 μW·cm–2·nm–1 (confirmed with an appropriate irradiance meter calibrated over the appropriate wavelength range); (3) illumination of maximal body surface; and (4) demonstration of a decrease in total bilirubin concentrations during the first 4 to 6 hours of exposure.

Recommendations. The intensity and spectral output of phototherapy devices is useful in predicting potential effectiveness in treating hyperbilirubinemia (group B recommendation). Clinical effectiveness should be evaluated before and monitored during use (group B recommendation). Blocking the light source or reducing exposed body surface should be avoided (group B recommendation). Standardization of irradiance meters, improvements in device design, and lower-upper limits of light intensity for phototherapy units merit further study. Comparing the in vivo performance of devices is not practical, in general, and alternative procedures need to be explored. (9/11, reaffirmed 7/14)

http://pediatrics.aappublications.org/content/128/4/e1046

PHYSICAL ACTIVITY ASSESSMENT AND COUNSELING IN PEDIATRIC CLINICAL SETTINGS (CLINICAL REPORT)

Felipe Lobelo, MD, PhD; Natalie D. Muth, MD, MPH, FAAP, FACSM; Sara Hanson, PhD; Blaise A. Nemeth, MD, FAAP; Council on Sports Medicine and Fitness; and Section on Obesity

ABSTRACT. Physical activity plays an important role in children's cardiovascular health, musculoskeletal health, mental and behavioral health, and physical, social, and cognitive development. Despite the importance in children's lives, pediatricians are unfamiliar with assessment and guidance regarding physical activity in children. With the release of the 2018 Physical Activity Guidelines by the US Department of Health and Human Services, pediatricians play a critical role in encouraging physical activity in children through assessing physical activity and physical literacy; providing guidance toward meeting recommendations by children and their families; advocating for opportunities for physical activity for all children in schools, communities, and hospitals; setting an example and remaining physically active personally; advocating for the use of assessment tools and insurance coverage of physical activity and physical literacy screening; and incorporating physical activity assessment and prescription in medical school curricula. (2/20)

PHYSICIAN HEALTH AND WELLNESS (CLINICAL REPORT)

Hilary McClafferty, MD, FAAP; Oscar W. Brown, MD, FAAP; Section on Integrative Medicine; and Committee on Practice and Ambulatory Medicine

ABSTRACT. Physician health and wellness is a critical issue gaining national attention because of the high prevalence of physician burnout. Pediatricians and pediatric trainees experience burnout at levels equivalent to other medical specialties, highlighting a need for more effective efforts to promote health and well-being in the pediatric community. This report will provide an overview of physician burnout, an update on work in the field of preventive physician health and wellness, and a discussion of emerging initiatives that have potential to promote health at all levels of pediatric training.

Pediatricians are uniquely positioned to lead this movement nationally, in part because of the emphasis placed on wellness in the Pediatric Milestone Project, a joint collaboration between the Accreditation Council for Graduate Medical Education and the American Board of Pediatrics. Updated core competencies calling for a balanced approach to health, including focus on nutrition, exercise, mindfulness, and effective stress management, signal a paradigm shift and send the message that it is time for pediatricians to cultivate a culture of wellness better aligned

with their responsibilities as role models and congruent with advances in pediatric training.

Rather than reviewing programs in place to address substance abuse and other serious conditions in distressed physicians, this article focuses on forward progress in the field, with an emphasis on the need for prevention and anticipation of predictable stressors related to burnout in medical training and practice. Examples of positive progress and several programs designed to promote physician health and wellness are reviewed. Areas where more research is needed are highlighted. (9/14)

PHYSICIAN REFUSAL TO PROVIDE INFORMATION OR TREATMENT ON THE BASIS OF CLAIMS OF CONSCIENCE

Committee on Bioethics

ABSTRACT. Health care professionals may have moral objections to particular medical interventions. They may refuse to provide or cooperate in the provision of these interventions. Such objections are referred to as conscientious objections. Although it may be difficult to characterize or validate claims of conscience, respecting the individual physician's moral integrity is important. Conflicts arise when claims of conscience impede a patient's access to medical information or care. A physician's conscientious objection to certain interventions or treatments may be constrained in some situations. Physicians have a duty to disclose to prospective patients treatments they refuse to perform. As part of informed consent, physicians also have a duty to inform their patients of all relevant and legally available treatment options, including options to which they object. They have a moral obligation to refer patients to other health care professionals who are willing to provide those services when failing to do so would cause harm to the patient, and they have a duty to treat patients in emergencies when referral would significantly increase the probability of mortality or serious morbidity. Conversely, the health care system should make reasonable accommodations for physicians with conscientious objections. (11/09, reaffirmed 1/14, 6/18)

PHYSICIAN'S ROLE IN COORDINATING CARE OF HOSPITALIZED CHILDREN (CLINICAL REPORT)

Daniel A. Rauch, MD, FAAP; Committee on Hospital Care; and Section on Hospital Medicine

ABSTRACT. The hospitalization of a child is a stressful event for the child and family. The physician responsible for the admission has an important role in directing the care of the child, communicating with the child's providers (medical and primary caregivers), and advocating for the safety of the child during the hospitalization and transition out of the hospital. These challenges remain constant across the varied facilities in which children are hospitalized. The purpose of this revised clinical report is to update pediatricians about principles to improve the coordination of care and review expectations and practice. (7/18)

PLANNED HOME BIRTH

Committee on Fetus and Newborn

ABSTRACT. The American Academy of Pediatrics concurs with the recent statement of the American College of Obstetricians and Gynecologists affirming that hospitals and birthing centers are the safest settings for birth in the United States while respecting the right of women to make a medically informed decision about delivery. This statement is intended to help pediatricians provide supportive, informed counsel to women considering home birth while retaining their role as child advocates and to summarize the standards of care for newborn infants born at home, which are consistent with standards for infants born in a medical care facility. Regardless of the circumstances of his or her birth, including location, every newborn infant deserves health care that adheres to the standards highlighted in this statement, more completely described in other publications from the American Academy of Pediatrics, including *Guidelines for Perinatal Care.* The goal of providing high-quality care to all newborn infants can best be achieved through continuing efforts by all participating health care providers and institutions to develop and sustain communications and understanding on the basis of professional interaction and mutual respect throughout the health care system. POINT-OF-CARE ULTRASONOGRAPHY BY PEDIATRIC EMERGENCY MEDICINE PHYSICIANS

Committee on Pediatric Emergency Medicine (joint with Society for Academic Emergency Medicine Academy of Emergency Ultrasound, American College of Emergency Physicians Pediatric Emergency Medicine Committee, and World Interactive Network Focused on Critical Ultrasound)

ABSTRACT. Point-of-care ultrasonography is increasingly being used to facilitate accurate and timely diagnoses and to guide procedures. It is important for pediatric emergency medicine (PEM) physicians caring for patients in the emergency department to receive adequate and continued point-of-care ultrasonography training for those indications used in their practice setting. Emergency departments should have credentialing and quality assurance programs. PEM fellowships should provide appropriate training to physician trainees. Hospitals should provide privileges to physicians who demonstrate competency in point-of-care ultrasonography. Ongoing research will provide the necessary measures to define the optimal training and competency assessment standards. Requirements for credentialing and hospital privileges will vary and will be specific to individual departments and hospitals. As more physicians are trained and more research is completed, there should be one national standard for credentialing and privileging in point-of-care ultrasonography for PEM physicians. (3/15, reaffirmed 9/19)

POINT-OF-CARE ULTRASONOGRAPHY BY PEDIATRIC EMERGENCY MEDICINE PHYSICIANS (TECHNICAL REPORT)

Jennifer R. Marin, MD, MSc; Resa E. Lewiss, MD; and Committee on Pediatric Emergency Medicine (joint with Society for Academic Emergency Medicine Academy of Emergency Ultrasound, American College of Emergency Physicians Pediatric Emergency Medicine Committee, and World Interactive Network Focused on Critical Ultrasound)

ABSTRACT. Emergency physicians have used point-of-care ultrasonography since the 1990s. Pediatric emergency medicine physicians have more recently adopted this technology. Point-of-care ultrasonography is used for various scenarios, particularly the evaluation of soft tissue infections or blunt abdominal trauma and procedural guidance. To date, there are no published statements from national organizations specifically for pediatric emergency physicians describing the incorporation of point-of-care ultrasonography into their practice. This document outlines how pediatric emergency departments may establish a formal point-of-care ultrasonography program. This task includes appointing leaders with expertise in point-of-care ultrasonography, effectively training and credentialing physicians in the department, and providing ongoing quality assurance reviews.

Point-of-care ultrasonography (US) is a bedside technology that enables clinicians to integrate clinical examination findings with real-time sonographic imaging. General emergency physicians and other specialists have used point-of-care US for many years, and more recently, pediatric emergency medicine (PEM) physicians have adopted point-of-care US as a diagnostic and

procedural adjunct. This technical report and accompanying policy statement provide a framework for point-of-care US training and point-of-care US integration into pediatric care by PEM physicians. (3/15, reaffirmed 9/19)

POSTDISCHARGE FOLLOW-UP OF INFANTS WITH CONGENITAL DIAPHRAGMATIC HERNIA (CLINICAL REPORT)

Section on Surgery and Committee on Fetus and Newborn

ABSTRACT. Infants with congenital diaphragmatic hernia often require intensive treatment after birth, have prolonged hospitalizations, and have other congenital anomalies. After discharge from the hospital, they may have long-term sequelae such as respiratory insufficiency, gastroesophageal reflux, poor growth, neurodevelopmental delay, behavior problems, hearing loss, hernia recurrence, and orthopedic deformities. Structured follow-up for these patients facilitates early recognition and treatment of these complications. In this report, follow-up of infants with congenital diaphragmatic hernia is outlined. (3/08, reaffirmed 5/11)

POSTNATAL CORTICOSTEROIDS TO PREVENT OR TREAT BRONCHOPULMONARY DYSPLASIA

Kristi L. Watterberg, MD, and Committee on Fetus and Newborn

ABSTRACT. The purpose of this revised statement is to review current information on the use of postnatal glucocorticoids to prevent or treat bronchopulmonary dysplasia in the preterm infant and to make updated recommendations regarding their use. High-dose dexamethasone (0.5 mg/kg per day) does not seem to confer additional therapeutic benefit over lower doses and is not recommended. Evidence is insufficient to make a recommendation regarding other glucocorticoid doses and preparations. The clinician must use clinical judgment when attempting to balance the potential adverse effects of glucocorticoid treatment with those of bronchopulmonary dysplasia. (9/10, reaffirmed 1/14, 9/20)
http://pediatrics.aappublications.org/content/126/4/800

POSTNATAL GLUCOSE HOMEOSTASIS IN LATE-PRETERM AND TERM INFANTS (CLINICAL REPORT)

David H. Adamkin, MD, and Committee on Fetus and Newborn

ABSTRACT. This report provides a practical guide and algorithm for the screening and subsequent management of neonatal hypoglycemia. Current evidence does not support a specific concentration of glucose that can discriminate normal from abnormal or can potentially result in acute or chronic irreversible neurologic damage. Early identification of the at-risk infant and institution of prophylactic measures to prevent neonatal hypoglycemia are recommended as a pragmatic approach despite the absence of a consistent definition of hypoglycemia in the literature. (3/11, reaffirmed 6/15)

POVERTY AND CHILD HEALTH IN THE UNITED STATES

Council on Community Pediatrics

ABSTRACT. Almost half of young children in the United States live in poverty or near poverty. The American Academy of Pediatrics is committed to reducing and ultimately eliminating child poverty in the United States. Poverty and related social determinants of health can lead to adverse health outcomes in childhood and across the life course, negatively affecting physical health, socioemotional development, and educational achievement. The American Academy of Pediatrics advocates for programs and policies that have been shown to improve the quality of life and health outcomes for children and families living in poverty. With an awareness and understanding of the effects of poverty on children, pediatricians and other pediatric health practitioners in a family-centered medical home can assess the financial stability of families, link families to resources, and coordinate care with community partners. Further research, advocacy, and continuing education will improve the ability of pediatricians to address the social determinants of health when caring for children who live in poverty. Accompanying this policy statement is a technical report that describes current knowledge on child poverty and the mechanisms by which poverty influences the health and well-being of children. (3/16)

THE POWER OF PLAY: A PEDIATRIC ROLE IN ENHANCING DEVELOPMENT IN YOUNG CHILDREN (CLINICAL REPORT)

Michael Yogman, MD, FAAP; Andrew Garner, MD, PhD, FAAP; Jeffrey Hutchinson, MD, FAAP; Kathy Hirsh-Pasek, PhD; Roberta Michnick Golinkoff, PhD; Committee on Psychosocial Aspects of Child and Family Health; and Council on Communications and Media

ABSTRACT. Children need to develop a variety of skill sets to optimize their development and manage toxic stress. Research demonstrates that developmentally appropriate play with parents and peers is a singular opportunity to promote the social-emotional, cognitive, language, and self-regulation skills that build executive function and a prosocial brain. Furthermore, play supports the formation of the safe, stable, and nurturing relationships with all caregivers that children need to thrive.

Play is not frivolous: it enhances brain structure and function and promotes executive function (ie, the process of learning, rather than the content), which allow us to pursue goals and ignore distractions.

When play and safe, stable, nurturing relationships are missing in a child's life, toxic stress can disrupt the development of executive function and the learning of prosocial behavior; in the presence of childhood adversity, play becomes even more important. The mutual joy and shared communication and attunement (harmonious serve and return interactions) that parents and children can experience during play regulate the body's stress response. This clinical report provides pediatric providers with the information they need to promote the benefits of play and to write a prescription for play at well visits to complement reach out and read. At a time when early childhood programs are pressured to add more didactic components and less playful learning, pediatricians can play an important role in emphasizing the role of a balanced curriculum that includes the importance of playful learning for the promotion of healthy child development. PRACTICAL APPROACHES TO OPTIMIZE ADOLESCENT IMMUNIZATION (CLINICAL REPORT)

Henry H. Bernstein, DO, MHCM, FAAP; Joseph A. Bocchini Jr, MD, FAAP; and Committee on Infectious Diseases

ABSTRACT. With the expansion of the adolescent immunization schedule during the past decade, immunization rates notably vary by vaccine and by state. Addressing barriers to improving adolescent vaccination rates is a priority. Every visit can be viewed as an opportunity to update and complete an adolescent's immunizations. It is essential to continue to focus and refine the appropriate techniques in approaching the adolescent patient and parent in the office setting. Health care providers must continuously strive to educate their patients and develop skills that can help parents and adolescents overcome vaccine hesitancy. Research on strategies to achieve higher vaccination rates is ongoing, and it is important to increase the knowledge and implementation of these strategies. This clinical report focuses on increasing adherence to the universally recommended vaccines in the annual adolescent immunization schedule of the American Academy of Pediatrics, the American

Academy of Family Physicians, the Centers for Disease Control and Prevention, and the American Congress of Obstetricians and Gynecologists. This will be accomplished by (1) examining strategies that heighten confidence in immunizations and address patient and parental concerns to promote adolescent immunization and (2) exploring how best to approach the adolescent and family to improve immunization rates. (2/17)

PREMEDICATION FOR NONEMERGENCY ENDOTRACHEAL INTUBATION IN THE NEONATE (CLINICAL REPORT)

Praveen Kumar, MD; Susan E. Denson, MD; Thomas J. Mancuso, MD; Committee on Fetus and Newborn; and Section on Anesthesiology and Pain Medicine

ABSTRACT. Endotracheal intubation is a common procedure in newborn care. The purpose of this clinical report is to review currently available evidence on use of premedication for intubation, identify gaps in knowledge, and provide guidance for making decisions about the use of premedication. (2/10, reaffirmed 8/13, 5/18)
http://pediatrics.aappublications.org/content/125/3/608

THE PRENATAL VISIT (CLINICAL REPORT)

Michael Yogman, MD, FAAP; Arthur Lavin, MD, FAAP; George Cohen, MD, FAAP; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. A pediatric prenatal visit during the third trimester is recommended for all expectant families as an important first step in establishing a child's medical home, as recommended by *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents, Fourth Edition*. As advocates for children and their families, pediatricians can support and guide expectant parents in the prenatal period. Prenatal visits allow general pediatricians to establish a supportive and trusting relationship with both parents, gather basic information from expectant parents, offer information and advice regarding the infant, and may identify psychosocial risks early and high-risk conditions that may require special care. There are several possible formats for this first visit. The one used depends on the experience and preference of the parents, the style of the pediatrician's practice, and pragmatic issues of payment. (6/18)

PREPARATION FOR EMERGENCIES IN THE OFFICES OF PEDIATRICIANS AND PEDIATRIC PRIMARY CARE PROVIDERS

Committee on Pediatric Emergency Medicine

ABSTRACT. High-quality pediatric emergency care can be provided only through the collaborative efforts of many health care professionals and child advocates working together throughout a continuum of care that extends from prevention and the medical home to prehospital care, to emergency department stabilization, to critical care and rehabilitation, and finally to a return to care in the medical home. At times, the office of the pediatric primary care provider will serve as the entry site into the emergency care system, which comprises out-of-hospital emergency medical services personnel, emergency department nurses and physicians, and other emergency and critical care providers. Recognizing the important role of pediatric primary care providers in the emergency care system for children and understanding the capabilities and limitations of that system are essential if pediatric primary care providers are to offer the best chance at intact survival for every child who is brought to the office with an emergency. Optimizing pediatric primary care provider office readiness for emergencies requires consideration of the unique aspects of each office practice, the types of patients and emergencies that might be seen, the resources on site, and the resources of the larger emergency care system of which the pediatric primary care provider's office is a part. Parent education regarding prevention, recognition, and response to emergencies, patient triage, early recognition and stabilization of pediatric emergencies in the office, and timely transfer to an appropriate facility for definitive care are important responsibilities of every pediatric primary care provider. In addition, pediatric primary care providers can collaborate with out-of-hospital and hospital-based providers and advocate for the best-quality emergency care for their patients. PRESCRIBING ASSISTIVE-TECHNOLOGY SYSTEMS: FOCUS ON CHILDREN WITH IMPAIRED COMMUNICATION (CLINICAL REPORT)

Larry W. Desch, MD; Deborah Gaebler-Spira, MD; and Council on Children With Disabilities

ABSTRACT. This clinical report defines common terms of use and provides information on current practice, research, and limitations of assistive technology that can be used in systems for communication. The assessment process to determine the best devices for use with a particular child (ie, the best fit of a device) is also reviewed. The primary care pediatrician, as part of the medical home, plays an important role in the interdisciplinary effort to provide appropriate assistive technology and may be asked to make a referral for assessment or prescribe a particular device. This report provides resources to assist pediatricians in this role and reviews the interdisciplinary team functional evaluation using standardized assessments; the multiple funding opportunities available for obtaining devices and ways in which pediatricians can assist families with obtaining them; the training necessary to use these systems once the devices are procured; the follow-up evaluation to ensure that the systems are meeting their goals; and the leadership skills needed to advocate for this technology. The American Academy of Pediatrics acknowledges the need for key resources to be identified in the community and recognizes that these resources are a shared medical, educational, therapeutic, and family responsibility. Although this report primarily deals with assistive technology specific for communication impairments, many of the details in this report also can aid in the acquisition and use of other types of assistive technology. PRESCRIBING PHYSICAL, OCCUPATIONAL, AND SPEECH THERAPY SERVICES FOR CHILDREN WITH DISABILITIES (CLINICAL REPORT)

Amy Houtrow, MD, PhD, MPH, FAAP, FAAPMR; Nancy Murphy, MD, FAAP, FAAPMR; and Council on Children With Disabilities

ABSTRACT. Pediatric health care providers are frequently responsible for prescribing physical, occupational, and speech therapies and monitoring therapeutic progress for children with temporary or permanent disabilities in their practices. This clinical report will provide pediatricians and other pediatric health care providers with information about how best to manage the therapeutic needs of their patients in the medical home by reviewing the International Classification of Functioning, Disability and Health; describing the general goals of habilitative and rehabilitative therapies; delineating the types, locations, and benefits of therapy services; and detailing how to write a therapy prescription and include therapists in the medical home neighborhood. (3/19)

PREVENTING OBESITY AND EATING DISORDERS IN ADOLESCENTS (CLINICAL REPORT)

Neville H. Golden, MD, FAAP; Marcie Schneider, MD, FAAP; Christine Wood, MD, FAAP; Committee on Nutrition; Committee on Adolescence; and Section on Obesity

ABSTRACT. Obesity and eating disorders (EDs) are both prevalent in adolescents. There are concerns that obesity prevention efforts may lead to the development of an ED. Most adolescents who develop an ED did not have obesity previously, but some teenagers, in an attempt to lose weight, may develop an ED. This clinical report addresses the interaction between obesity prevention and EDs in teenagers, provides the pediatrician with evidence-informed tools to identify behaviors that predispose to both obesity and EDs, and provides guidance about obesity and ED prevention messages. The focus should be on a healthy lifestyle rather than on weight. Evidence suggests that obesity prevention and treatment, if conducted correctly, do not predispose to EDs. (8/16)

http://pediatrics.aappublications.org/content/138/3/e20161649

PREVENTION AND MANAGEMENT OF PROCEDURAL PAIN IN THE NEONATE: AN UPDATE

Committee on Fetus and Newborn and Section on Anesthesiology and Pain Medicine

ABSTRACT. The prevention of pain in neonates should be the goal of all pediatricians and health care professionals who work with neonates, not only because it is ethical but also because repeated painful exposures have the potential for deleterious consequences. Neonates at greatest risk of neurodevelopmental impairment as a result of preterm birth (ie, the smallest and sickest) are also those most likely to be exposed to the greatest number of painful stimuli in the NICU. Although there are major gaps in knowledge regarding the most effective way to prevent and relieve pain in neonates, proven and safe therapies are currently underused for routine minor, yet painful procedures. Therefore, every health care facility caring for neonates should implement (1) a pain-prevention program that includes strategies for minimizing the number of painful procedures performed and (2) a pain assessment and management plan that includes routine assessment of pain, pharmacologic and nonpharmacologic therapies for the prevention of pain associated with routine minor procedures, and measures for minimizing pain associated with surgery and other major procedures. (1/16, reaffirmed 7/20)

PREVENTION OF AGRICULTURAL INJURIES AMONG CHILDREN AND ADOLESCENTS

Committee on Injury and Poison Prevention and Committee on Community Health Services

ABSTRACT. Although the annual number of farm deaths to children and adolescents has decreased since publication of the 1988 American Academy of Pediatrics statement, "Rural Injuries," the rate of nonfatal farm injuries has increased. Approximately 100 unintentional injury deaths occur annually to children and adolescents on US farms, and an additional 22 000 injuries to children younger than 20 years occur on farms. Relatively few adolescents are employed on farms compared with other types of industry, yet the proportion of fatalities in agriculture is higher than that for any other type of adolescent employment. The high mortality and severe morbidity associated with farm injuries require continuing and improved injury-control strategies. This statement provides recommendations for pediatricians regarding patient and community education as well as public advocacy related to agricultural injury prevention in childhood and adolescence. (10/01, reaffirmed 1/07, 11/11)

http://pediatrics.aappublications.org/content/108/4/1016

PREVENTION OF CHILDHOOD LEAD TOXICITY

Council on Environmental Health

ABSTRACT. Blood lead concentrations have decreased dramatically in US children over the past 4 decades, but too many children still live in housing with deteriorated lead-based paint and are at risk for lead exposure with resulting lead-associated cognitive impairment and behavioral problems. Evidence continues to accrue that commonly encountered blood lead concentrations, even those below 5 μg/dL (50 ppb), impair cognition; there is no identified threshold or safe level of lead in blood. From 2007 to 2010, approximately 2.6% of preschool children in the United States had a blood lead concentration ≥5 μg/dL (≥50 ppb), which represents about 535 000 US children 1 to 5 years of age. Evidence-based guidance is available for managing increased lead exposure in children, and reducing sources of lead in the environment, including lead in housing, soil, water, and consumer products, has been shown to be cost-beneficial. Primary prevention should be the focus of policy on childhood lead toxicity. (6/16)

http://pediatrics.aappublications.org/content/138/1/e20161493

PREVENTION OF CHOKING AMONG CHILDREN

Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Choking is a leading cause of morbidity and mortality among children, especially those aged 3 years or younger. Food, coins, and toys are the primary causes of choking-related injury and death. Certain characteristics, including shape, size, and consistency, of certain toys and foods increase their potential to cause choking among children. Childhood choking hazards should be addressed through comprehensive and coordinated prevention activities. The US Consumer Product Safety Commission (CPSC) should increase efforts to ensure that toys that are sold in retail store bins, vending machines, or on the Internet have appropriate choking-hazard warnings; work with manufacturers to improve the effectiveness of recalls of products that pose a choking risk to children; and increase efforts to prevent the resale of these recalled products via online auction sites. Current gaps in choking-prevention standards for children's toys should be reevaluated and addressed, as appropriate, via revisions to the standards established under the Child Safety Protection Act, the Consumer Product Safety Improvement Act, or regulation by the CPSC. Prevention of food-related choking among children in the United States has been inadequately addressed at the federal level. The US Food and Drug Administration should establish a systematic, institutionalized process for examining and addressing the hazards of food-related choking. This process should include the establishment of the necessary surveillance, hazard evaluation, enforcement, and public education activities to prevent food-related choking among children. While maintaining its highly cooperative arrangements with the CPSC and the US Department of Agriculture, the Food and Drug Administration should have the authority to address choking-related risks of all food products, including meat products that fall under the jurisdiction of the US Department of Agriculture. The existing National Electronic Injury Surveillance System–All Injury Program of the CPSC should be modified to conduct more-detailed surveillance of choking on food among children. Food manufacturers should design new foods and redesign existing foods to avoid shapes, sizes, textures, and other characteristics that increase choking risk to children, to the extent possible. Pediatricians, dentists, and other infant and child health care providers should provide choking-prevention counseling to parents as an integral part of anticipatory guidance activities. (2/10, reaffirmed 10/19)

PREVENTION OF DROWNING

Sarah A. Denny, MD, FAAP; Linda Quan, MD, FAAP; Julie Gilchrist, MD, FAAP; Tracy McCallin, MD, FAAP; Rohit Shenoi, MD, FAAP; Shabana Yusuf, MD, Med, FAAP; Benjamin Hoffman, MD, FAAP; Jeffrey Weiss, MD, FAAP; and Council on Injury, Violence, and Poison Prevention

ABSTRACT. Drowning is a leading cause of injury-related death in children. In 2017, drowning claimed the lives of almost 1000 US children younger than 20 years. A number of strategies are available to prevent these tragedies. As educators and advocates, pediatricians can play an important role in the prevention of drowning. (4/19)

https://pediatrics.aappublications.org/content/143/5/e20190850

PREVENTION OF SEXUAL HARASSMENT IN THE WORKPLACE AND EDUCATIONAL SETTINGS

Committee on Pediatric Workforce

ABSTRACT. The American Academy of Pediatrics is committed to working to ensure that workplaces and educational settings in which pediatricians spend time are free of sexual harassment. The purpose of this statement is to heighten awareness and sensitivity to this important issue, recognizing that institutions, clinics, and office-based practices may have existing policies. THE PREVENTION OF UNINTENTIONAL INJURY AMONG AMERICAN INDIAN AND ALASKA NATIVE CHILDREN: A SUBJECT REVIEW (CLINICAL REPORT)

Committee on Native American Child Health and Committee on Injury and Poison Prevention

ABSTRACT. Among ethnic groups in the United States, American Indian and Alaska Native (AI/AN) children experience the highest rates of injury mortality and morbidity. Injury mortality rates for AI/AN children have decreased during the past quarter century, but remain almost double the rate for all children in the United States. The Indian Health Service (IHS), the federal agency with the primary responsibility for the health care of AI/AN people, has sponsored an internationally recognized injury prevention program designed to reduce the risk of injury death by addressing community-specific risk factors. Model programs developed by the IHS and tribal governments have led to successful outcomes in motor vehicle occupant safety, drowning prevention, and fire safety. Injury prevention programs in tribal communities require special attention to the sovereignty of tribal governments and the unique cultural aspects of health care and communication. Pediatricians working with AI/AN children on reservations or in urban environments are strongly urged to collaborate with tribes and the IHS to create community-based coalitions and develop programs to address highly preventable injury-related mortality and morbidity. Strong advocacy also is needed to promote childhood injury prevention as an important priority for federal agencies and tribes. (12/99, reaffirmed 12/02 COIVPP, 5/03 CONACH, 1/06, 9/08)

THE PRIMARY CARE PEDIATRICIAN AND THE CARE OF CHILDREN WITH CLEFT LIP AND/OR CLEFT PALATE (CLINICAL REPORT)

Charlotte W. Lewis, MD, MPH, FAAP; Lisa S. Jacob, DDS, MS; Christoph U. Lehmann, MD, FAAP, FACMI; and Section on Oral Health

ABSTRACT. Orofacial clefts, specifically cleft lip and/or cleft palate (CL/P), are among the most common congenital anomalies. CL/P vary in their location and severity and comprise 3 overarching groups: cleft lip (CL), cleft lip with cleft palate (CLP), and cleft palate alone (CP). CL/P may be associated with one of many syndromes that could further complicate a child's needs. Care of patients with CL/P spans prenatal diagnosis into adulthood. The appropriate timing and order of specific cleft-related care are important factors for optimizing outcomes; however, care should be individualized to meet the specific needs of each patient and family. Children with CL/P should receive their specialty cleft-related care from a multidisciplinary cleft or craniofacial team with sufficient patient and surgical volume to promote successful outcomes. The primary care pediatrician at the child's medical home has an essential role in making a timely diagnosis and referral; providing ongoing health care maintenance, anticipatory guidance, and acute care; and functioning as an advocate for the patient and a liaison between the family and the craniofacial/cleft team. This document provides background on CL/P and multidisciplinary team care, information about typical timing and order of cleft-related care, and recommendations for cleft/craniofacial teams and primary care pediatricians in the care of children with CL/P. PRINCIPLES OF CHILD HEALTH CARE FINANCING

Mark L. Hudak, MD, FAAP; Mark E. Helm, MD, MBA, FAAP; Patience H. White, MD, MA, FAAP, FACP; and Committee on Child Health Financing

ABSTRACT. After passage of the Patient Protection and Affordable Care Act, more children and young adults have become insured and have benefited from health care coverage than at any time since the creation of the Medicaid program in 1965. From 2009 to 2015, the uninsurance rate for children younger than 19 years fell from 9.7% to 5.3%, whereas the uninsurance rate for young adults 19 to 25 years of age declined from 31.7% to 14.5%. Nonetheless, much work remains to be done. The American Academy of Pediatrics (AAP) believes that the United States can and should ensure that all children, adolescents, and young adults from birth through the age of 26 years who reside within its borders have affordable access to high-quality and comprehensive health care, regardless of their or their families' incomes. Public and private health insurance should safeguard existing benefits for children and take further steps to cover the full array of essential health care services recommended by the AAP. Each family should be able to afford the premiums, deductibles, and other cost-sharing provisions of the plan. Health plans providing these benefits should ensure, insofar as possible, that families have a choice of professionals and facilities with expertise in the care of children within a reasonable distance of their residence. Traditional and innovative payment methodologies by public and private payers should be structured to guarantee the economic viability of the pediatric medical home and of other pediatric specialty and subspecialty practices to address developing shortages in the pediatric specialty and subspecialty workforce, to promote the use of health information technology, to improve population health and the experience of care, and to encourage the delivery of evidence-based and quality health care in the medical home, as well as in other outpatient, inpatient, and home settings. All current and future health care insurance plans should incorporate the principles for child health financing outlined in this statement. Espousing the core principle to do no harm, the AAP believes that the United States must not sacrifice any of the hard-won gains for our children. Medicaid, as the largest single payer of health care for children and young adults, should remain true to its origins as an entitlement program; in other words, future fiscal or regulatory reforms of Medicaid should not reduce the eligibility and scope of benefits for children and young adults below current levels nor jeopardize children's access to care. Proposed Medicaid funding "reforms" (eg, institution of block grant, capped allotment, or per-capita capitation payments to states) will achieve their goal of securing cost savings but will

inevitably compel states to reduce enrollee eligibility, trim existing benefits (such as Early and Periodic Screening, Diagnostic, and Treatment), and/or compromise children's access to necessary and timely care through cuts in payments to providers and delivery systems. In fact, the AAP advocates for increased Medicaid funding to improve access to essential care for existing enrollees, fund care for eligible but uninsured children once they enroll, and accommodate enrollment growth that will occur in states that choose to expand Medicaid eligibility. The AAP also calls for Congress to extend funding for the Children's Health Insurance Program, a plan vital to the 8.9 million children it covered in fiscal year 2016, for a minimum of 5 years. (8/17)

PRINCIPLES OF FINANCING THE MEDICAL HOME FOR CHILDREN

Jonathan Price, MD, FAAP; Mary L. Brandt, MD, FACS, FAAP; Mark L. Hudak, MD, FAAP; and Committee on Child Health Financing

ABSTRACT. A well-implemented and adequately funded medical home not only is the best approach to optimize the health of the individual patient but also can function as an effective instrument for improving population health. Key financing elements to providing quality, effective, comprehensive care in the pediatric medical home include the following: (1) first dollar coverage without deductibles, copays, or other cost-sharing for necessary preventive care services as recommended by *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents;* (2) adoption of a uniform definition of medical necessity across payers that embraces services that promote optimal growth and development and prevent, diagnose, and treat the full range of pediatric physical, mental, behavioral, and developmental conditions, in accord with evidence-based science or evidence-informed expert opinion; (3) payment models that promote appropriate use of pediatric primary care and pediatric specialty services and discourage inappropriate, inefficient, or excessive use of medical services; and (4) payment models that strengthen the patient- and family-physician relationship and do not impose additional administrative burdens that will only erode the effectiveness of the medical home. These goals can be met by designing payment models that provide adequate funding of the cost of medical encounters, care coordination, population health services, and quality improvement activities; provide incentives for quality and effectiveness of care; and ease administrative burdens. (12/19)

PRINCIPLES OF PEDIATRIC PATIENT SAFETY: REDUCING HARM DUE TO MEDICAL CARE

Brigitta U. Mueller, MD, MHCM, CPPS, CPHQ, FAAP; Daniel Robert Neuspiel, MD, MPH, FAAP; Erin R. Stucky Fisher, MD, FAAP; Council on Quality Improvement and Patient Safety; and Committee on Hospital Care

ABSTRACT. Pediatricians render care in an increasingly complex environment, which results in multiple opportunities to cause unintended harm. National awareness of patient safety risks has grown since the National Academy of Medicine (formerly the Institute of Medicine) published its report "To Err Is Human: Building a Safer Health System" in 1999. Patients and society as a whole continue to challenge health care providers to examine their practices and implement safety solutions. The depth and breadth of harm incurred by the practice of medicine is still being defined as reports continue to reveal a variety of avoidable errors, from those that involve specific high-risk medications to those that are more generalizable, such as patient misidentification and diagnostic error. Pediatric health care providers in all practice environments benefit from having a working knowledge of patient safety language. Pediatric providers should serve as advocates for best practices and policies with the goal of attending to risks that are unique to children, identifying and supporting a culture of safety, and leading efforts to eliminate avoidable harm in any setting in which medical care is rendered to children. In this Policy Statement, we provide an update to the 2011 Policy Statement "Principles of Pediatric Patient Safety: Reducing Harm Due to Medical Care." (1/19)

PROBIOTICS AND PREBIOTICS IN PEDIATRICS (CLINICAL REPORT)

Dan W. Thomas, MD; Frank R. Greer, MD; Committee on Nutrition; and Section on Gastroenterology, Hepatology, and Nutrition

ABSTRACT. This clinical report reviews the currently known health benefits of probiotic and prebiotic products, including those added to commercially available infant formula and other food products for use in children. Probiotics are supplements or foods that contain viable microorganisms that cause alterations of the microflora of the host. Use of probiotics has been shown to be modestly effective in randomized clinical trials (RCTs) in (1) treating acute viral gastroenteritis in healthy children; and (2) preventing antibiotic-associated diarrhea in healthy children. There is some evidence that probiotics prevent necrotizing enterocolitis in very low birth weight infants (birth weight between 1000 and 1500 g), but more studies are needed. The results of RCTs in which probiotics were used to treat childhood *Helicobacter pylori* gastritis, irritable bowel syndrome, chronic ulcerative colitis, and infantile colic, as well as in preventing childhood atopy, although encouraging, are preliminary and require further confirmation. Probiotics have not been proven to be beneficial in treating or preventing human cancers or in treating children with Crohn disease. There are also safety concerns with the use of probiotics in infants and children who are immunocompromised, chronically debilitated, or seriously ill with indwelling medical devices.

Prebiotics are supplements or foods that contain a nondigestible food ingredient that selectively stimulates the favorable growth and/or activity of indigenous probiotic bacteria. Human milk contains substantial quantities of prebiotics. There is a paucity of RCTs examining prebiotics in children, although there may be some long-term benefit of prebiotics for the prevention of atopic eczema and common infections in healthy infants. Confirmatory well-designed clinical research studies are necessary. (11/10)

PROCEDURES FOR THE EVALUATION OF THE VISUAL SYSTEM BY PEDIATRICIANS (CLINICAL REPORT)

Sean P. Donahue, MD, PhD, FAAP; Cynthia N. Baker, MD, FAAP; Committee on Practice and Ambulatory Medicine; and Section on Ophthalmology (joint with American Association of Certified Orthoptists, American Association for Pediatric Ophthalmology and Strabismus, and American Academy of Ophthalmology)

ABSTRACT. Vision screening is crucial for the detection of visual and systemic disorders. It should begin in the newborn nursery and continue throughout childhood. This clinical report provides details regarding methods for pediatricians to use for screening. (12/15)
http://pediatrics.aappublications.org/content/137/1/e20153597

PROFESSIONALISM IN PEDIATRICS (TECHNICAL REPORT)

Mary E. Fallat, MD; Jacqueline Glover, PhD; and Committee on Bioethics

ABSTRACT. The purpose of this report is to provide a concrete overview of the ideal standards of behavior and professional practice to which pediatricians should aspire and by which students and residents can be evaluated. Recognizing that the

ideal is not always achievable in the practical sense, this document details the key components of professionalism in pediatric practice with an emphasis on core professional values for which pediatricians should strive and that will serve as a moral compass needed to provide quality care for children and their families. (10/07, reaffirmed 5/11)
http://pediatrics.aappublications.org/content/120/4/e1123

PROFESSIONALISM IN PEDIATRICS: STATEMENT OF PRINCIPLES

Committee on Bioethics

ABSTRACT. The purpose of this statement is to delineate the concept of professionalism within the context of pediatrics and to provide a brief statement of principles to guide the behavior and professional practice of pediatricians. (10/07, reaffirmed 5/11)
http://pediatrics.aappublications.org/content/120/4/895

PROMOTING EDUCATION, MENTORSHIP, AND SUPPORT FOR PEDIATRIC RESEARCH

Committee on Pediatric Research

ABSTRACT. Pediatricians play a key role in advancing child health research to best attain and improve the physical, mental, and social health and well-being of all infants, children, adolescents, and young adults. Child health presents unique issues that require investigators who specialize in pediatric research. In addition, the scope of the pediatric research enterprise is transdisciplinary and includes the full spectrum of basic science, translational, community-based, health services, and child health policy research. Although most pediatricians do not directly engage in research, knowledge of research methodologies and approaches promotes critical evaluation of scientific literature, the practice of evidence-based medicine, and advocacy for evidence-based child health policy. This statement includes specific recommendations to promote further research education and support at all levels of pediatric training, from premedical to continuing medical education, as well as recommendations to increase support and mentorship for research activities. Pediatric research is crucial to the American Academy of Pediatrics' goal of improving the health of all children. The American Academy of Pediatrics continues to promote and encourage efforts to facilitate the creation of new knowledge and ways to reduce barriers experienced by trainees, practitioners, and academic faculty pursuing research. (4/14, reaffirmed 2/18)
http://pediatrics.aappublications.org/content/133/5/943

PROMOTING FOOD SECURITY FOR ALL CHILDREN

Council on Community Pediatrics and Committee on Nutrition

ABSTRACT. Sixteen million US children (21%) live in households without consistent access to adequate food. After multiple risk factors are considered, children who live in households that are food insecure, even at the lowest levels, are likely to be sick more often, recover from illness more slowly, and be hospitalized more frequently. Lack of adequate healthy food can impair a child's ability to concentrate and perform well in school and is linked to higher levels of behavioral and emotional problems from preschool through adolescence. Food insecurity can affect children in any community, not only traditionally underserved ones. Pediatricians can play a central role in screening and identifying children at risk for food insecurity and in connecting families with needed community resources. Pediatricians should also advocate for federal and local policies that support access to adequate healthy food for an active and healthy life for all children and their families. (10/15)

PROMOTING OPTIMAL DEVELOPMENT: IDENTIFYING INFANTS AND YOUNG CHILDREN WITH DEVELOPMENTAL DISORDERS THROUGH DEVELOPMENTAL SURVEILLANCE AND SCREENING (CLINICAL REPORT)

Paul H. Lipkin, MD, FAAP; Michelle M. Macias, MD, FAAP; Council on Children With Disabilities; and Section on Developmental and Behavioral Pediatrics

ABSTRACT. Early identification and intervention for developmental disorders are critical to the well-being of children and are the responsibility of pediatric professionals as an integral function of the medical home. This report models a universal system of developmental surveillance and screening for the early identification of conditions that affect children's early and long-term development and achievement, followed by ongoing care. These conditions include autism, deafness/hard-of-hearing, intellectual and motor disabilities, behavioral conditions, and those seen in other medical conditions. Developmental surveillance is supported at every health supervision visit, as is as the administration of standardized screening tests at the 9-, 18-, and 30-month visits. Developmental concerns elicited on surveillance at any visit should be followed by standardized developmental screening testing or direct referral to intervention and specialty medical care. Special attention to surveillance is recommended at the 4- to 5-year well-child visit, prior to entry into elementary education, with screening completed if there are any concerns. Developmental surveillance includes bidirectional communication with early childhood professionals in child care, preschools, Head Start, and other programs, including home visitation and parenting, particularly around developmental screening. The identification of problems should lead to developmental and medical evaluations, diagnosis, counseling, and treatment, in addition to early developmental intervention. Children with diagnosed developmental disorders are identified as having special health care needs, with initiation of chronic condition management in the pediatric medical home. (12/19)

https://pediatrics.aappublications.org/content/145/1/e20193449

PROMOTING OPTIMAL DEVELOPMENT: SCREENING FOR BEHAVIORAL AND EMOTIONAL PROBLEMS (CLINICAL REPORT)

Carol Weitzman, MD, FAAP; Lynn Wegner, MD, FAAP; Section on Developmental and Behavioral Pediatrics; Committee on Psychosocial Aspects of Child and Family Health; and Council on Early Childhood (joint with Society for Developmental and Behavioral Pediatrics)

ABSTRACT. By current estimates, at any given time, approximately 11% to 20% of children in the United States have a behavioral or emotional disorder, as defined in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition.* Between 37% and 39% of children will have a behavioral or emotional disorder diagnosed by 16 years of age, regardless of geographic location in the United States. Behavioral and emotional problems and concerns in children and adolescents are not being reliably identified or treated in the US health system. This clinical report focuses on the need to increase behavioral screening and offers potential changes in practice and the health system, as well as the research needed to accomplish this. This report also (1) reviews the prevalence of behavioral and emotional disorders, (2) describes factors affecting the emergence of behavioral and emotional problems, (3) articulates the current state of detection of these problems in pediatric primary care, (4) describes barriers to screening and means to overcome those barriers, and (5) discusses potential changes at a practice and systems level that are needed to facilitate successful behavioral and emotional screening. Highlighted and discussed are the many factors at the level

of the pediatric practice, health system, and society contributing to these behavioral and emotional problems. (1/15)
http://pediatrics.aappublications.org/content/135/2/384

PROMOTING THE PARTICIPATION OF CHILDREN WITH DISABILITIES IN SPORTS, RECREATION, AND PHYSICAL ACTIVITIES (CLINICAL REPORT)

Nancy A. Murphy, MD; Paul S. Carbone, MD; and Council on Children With Disabilities

ABSTRACT. The benefits of physical activity are universal for all children, including those with disabilities. The participation of children with disabilities in sports and recreational activities promotes inclusion, minimizes deconditioning, optimizes physical functioning, and enhances overall well-being. Despite these benefits, children with disabilities are more restricted in their participation, have lower levels of fitness, and have higher levels of obesity than their peers without disabilities. Pediatricians and parents may overestimate the risks or overlook the benefits of physical activity in children with disabilities. Well-informed decisions regarding each child's participation must consider overall health status, individual activity preferences, safety precautions, and availability of appropriate programs and equipment. Health supervision visits afford pediatricians, children with disabilities, and parents opportunities to collaboratively generate goal-directed activity "prescriptions." Child, family, financial, and societal barriers to participation need to be directly identified and addressed in the context of local, state, and federal laws. The goal is inclusion for all children with disabilities in appropriate activities. This clinical report discusses the importance of physical activity, recreation, and sports participation for children with disabilities and offers practical suggestions to pediatric health care professionals for the promotion of participation. (5/08, reaffirmed 1/12, 6/18)

PROMOTING THE WELL-BEING OF CHILDREN WHOSE PARENTS ARE GAY OR LESBIAN

Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. To promote optimal health and well-being of all children, the American Academy of Pediatrics (AAP) supports access for all children to (1) civil marriage rights for their parents and (2) willing and capable foster and adoptive parents, regardless of the parents' sexual orientation. The AAP has always been an advocate for, and has developed policies to support, the optimal physical, mental, and social health and well-being of all infants, children, adolescents, and young adults. In so doing, the AAP has supported families in all their diversity, because the family has always been the basic social unit in which children develop the supporting and nurturing relationships with adults that they need to thrive. Children may be born to, adopted by, or cared for temporarily by married couples, nonmarried couples, single parents, grandparents, or legal guardians, and any of these may be heterosexual, gay or lesbian, or of another orientation. Children need secure and enduring relationships with committed and nurturing adults to enhance their life experiences for optimal social-emotional and cognitive development. Scientific evidence affirms that children have similar developmental and emotional needs and receive similar parenting whether they are raised by parents of the same or different genders. If a child has 2 living and capable parents who choose to create a permanent bond by way of civil marriage, it is in the best interests of their child(ren) that legal and social institutions allow and support them to do so, irrespective of their sexual orientation. If 2 parents are not available to the child, adoption or foster parenting remain acceptable options to provide a loving home for a child and should be available without regard to the sexual orientation of the parent(s). (3/13)
http://pediatrics.aappublications.org/content/131/4/827

PROMOTING THE WELL-BEING OF CHILDREN WHOSE PARENTS ARE GAY OR LESBIAN (TECHNICAL REPORT)

Ellen C. Perrin, MD, MA; Benjamin S. Siegel, MD; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Extensive data available from more than 30 years of research reveal that children raised by gay and lesbian parents have demonstrated resilience with regard to social, psychological, and sexual health despite economic and legal disparities and social stigma. Many studies have demonstrated that children's well-being is affected much more by their relationships with their parents, their parents' sense of competence and security, and the presence of social and economic support for the family than by the gender or the sexual orientation of their parents. Lack of opportunity for same-gender couples to marry adds to families' stress, which affects the health and welfare of all household members. Because marriage strengthens families and, in so doing, benefits children's development, children should not be deprived of the opportunity for their parents to be married. Paths to parenthood that include assisted reproductive techniques, adoption, and foster parenting should focus on competency of the parents rather than their sexual orientation. (3/13)

PROMOTION OF HEALTHY WEIGHT-CONTROL PRACTICES IN YOUNG ATHLETES (CLINICAL REPORT)

Rebecca L. Carl, MD, MS, FAAP; Miriam D. Johnson, MD, FAAP; Thomas J. Martin, MD, FAAP; and Council on Sports Medicine and Fitness

ABSTRACT. Children and adolescents may participate in sports that favor a particular body type. Some sports, such as gymnastics, dance, and distance running, emphasize a slim or lean physique for aesthetic or performance reasons. Participants in weight-class sports, such as wrestling and martial arts, may attempt weight loss so they can compete at a lower weight class. Other sports, such as football and bodybuilding, highlight a muscular physique; young athletes engaged in these sports may desire to gain weight and muscle mass. This clinical report describes unhealthy methods of weight loss and gain as well as policies and approaches used to curb these practices. The report also reviews healthy strategies for weight loss and weight gain and provides recommendations for pediatricians on how to promote healthy weight control in young athletes. (8/17)

PROTECTING CHILDREN FROM SEXUAL ABUSE BY HEALTH CARE PROVIDERS

Committee on Child Abuse and Neglect

ABSTRACT. Sexual abuse or exploitation of children is never acceptable. Such behavior by health care providers is particularly concerning because of the trust that children and their families place on adults in the health care profession. The American Academy of Pediatrics strongly endorses the social and moral prohibition against sexual abuse or exploitation of children by health care providers. The academy opposes any such sexual abuse or exploitation by providers, particularly by the academy's members. Health care providers should be trained to recognize and abide by appropriate provider-patient boundaries. Medical institutions should screen staff members for a history of child abuse issues, train them to respect and maintain appropriate boundaries, and establish policies and procedures to receive and investigate concerns about patient abuse. Each person has a responsibility to ensure the safety of children in health care settings and to scrupulously follow appropriate legal and ethical reporting and investigation procedures. (6/11, reaffirmed 10/14, 1/20)
http://pediatrics.aappublications.org/content/128/2/407

PROTECTING CHILDREN FROM TOBACCO, NICOTINE, AND TOBACCO SMOKE (TECHNICAL REPORT)

Harold J. Farber, MD, MSPH, FAAP; Judith Groner, MD, FAAP; Susan Walley, MD, FAAP; Kevin Nelson, MD, PhD, FAAP; and Section on Tobacco Control

ABSTRACT. This technical report serves to provide the evidence base for the American Academy of Pediatrics' policy statements "Clinical Practice Policy to Protect Children From Tobacco, Nicotine, and Tobacco Smoke" and "Public Policy to Protect Children From Tobacco, Nicotine, and Tobacco Smoke." Tobacco use and involuntary exposure are major preventable causes of morbidity and premature mortality in adults and children. Tobacco dependence almost always starts in childhood or adolescence. Electronic nicotine delivery systems are rapidly gaining popularity among youth, and their significant harms are being documented. In utero tobacco smoke exposure, in addition to increasing the risk of preterm birth, low birth weight, stillbirth, placental abruption, and sudden infant death, has been found to increase the risk of obesity and neurodevelopmental disorders. Actions by pediatricians can help to reduce children's risk of developing tobacco dependence and reduce children's involuntary tobacco smoke exposure. Public policy actions to protect children from tobacco are essential to reduce the toll that the tobacco epidemic takes on our children. (10/15, reaffirmed 6/20)

http://pediatrics.aappublications.org/content/136/5/e1439

PROVIDING A PRIMARY CARE MEDICAL HOME FOR CHILDREN AND YOUTH WITH CEREBRAL PALSY (CLINICAL REPORT)

Gregory S. Liptak, MD, MPH; Nancy A. Murphy, MD; and Council on Children With Disabilities

ABSTRACT. All primary care providers will care for children with cerebral palsy in their practice. In addition to well-child and acute illness care, the role of the medical home in the management of these children includes diagnosis, planning for interventions, authorizing treatments, and follow-up. Optimizing health and well-being for children with cerebral palsy and their families entails family-centered care provided in the medical home; comanagement is the most common model. This report reviews the aspects of care specific to cerebral palsy that a medical home should provide beyond the routine health care needed by all children. (10/11, reaffirmed 11/14, 8/18)

http://pediatrics.aappublications.org/content/128/5/e1321

PROVIDING A PRIMARY CARE MEDICAL HOME FOR CHILDREN AND YOUTH WITH SPINA BIFIDA (CLINICAL REPORT)

Robert Burke, MD, MPH; Gregory S. Liptak, MD, MPH; and Council on Children With Disabilities

ABSTRACT. The pediatric primary care provider in the medical home has a central and unique role in the care of children with spina bifida. The primary care provider addresses not only the typical issues of preventive and acute health care but also the needs specific to these children. Optimal care requires communication and comanagement with pediatric medical and developmental subspecialists, surgical specialists, therapists, and community providers. The medical home provider is essential in supporting the family and advocating for the child from the time of entry into the practice through adolescence, which includes transition and transfer to adult health care. This report reviews aspects of care specific to the infant with spina bifida (particularly myelomeningocele) that will facilitate optimal medical, functional, and developmental outcomes. (11/11, reaffirmed 2/15, 7/18)

http://pediatrics.aappublications.org/content/128/6/e1645

PROVIDING CARE FOR CHILDREN AND ADOLESCENTS FACING HOMELESSNESS AND HOUSING INSECURITY

Council on Community Pediatrics

ABSTRACT. Child health and housing security are closely intertwined, and children without homes are more likely to suffer from chronic disease, hunger, and malnutrition than are children with homes. Homeless children and youth often have significant psychosocial development issues, and their education is frequently interrupted. Given the overall effects that homelessness can have on a child's health and potential, it is important for pediatricians to recognize the factors that lead to homelessness, understand the ways that homelessness and its causes can lead to poor health outcomes, and when possible, help children and families mitigate some of the effects of homelessness. Through practice change, partnership with community resources, awareness, and advocacy, pediatricians can help optimize the health and well-being of children affected by homelessness. (5/13, reaffirmed 10/16)

http://pediatrics.aappublications.org/content/131/6/1206

PROVIDING CARE FOR CHILDREN IN IMMIGRANT FAMILIES

Julie M. Linton, MD, FAAP; Andrea Green, MDCM, FAAP; and Council on Community Pediatrics

ABSTRACT. Children in immigrant families (CIF), who represent 1 in 4 children in the United States, represent a growing and ever more diverse US demographic that pediatric medical providers nationwide will increasingly encounter in clinical care. Immigrant children are those born outside the United States to non–US citizen parents, and CIF are defined as those who are either foreign born or have at least 1 parent who is foreign born. Some families immigrate for economic or educational reasons, and others come fleeing persecution and seeking safe haven. Some US-born children with a foreign-born parent may share vulnerabilities with children who themselves are foreign born, particularly regarding access to care and other social determinants of health. Therefore, the larger umbrella term of CIF is used in this statement. CIF, like all children, have diverse experiences that interact with their biopsychosocial development. CIF may face inequities that can threaten their health and well-being, and CIF also offer strengths and embody resilience that can surpass challenges experienced before and during integration. This policy statement describes the evolving population of CIF in the United States, briefly introduces core competencies to enhance care within a framework of cultural humility and safety, and discusses barriers and opportunities at the practice and systems levels. Practice-level recommendations describe how pediatricians can promote health equity for CIF through careful attention to core competencies in clinical care, thoughtful community engagement, and system-level support. Advocacy and policy recommendations offer ways pediatricians can advocate for policies that promote health equity for CIF. (8/19)

https://pediatrics.aappublications.org/content/144/3/e20192077

PROVIDING CARE FOR INFANTS BORN AT HOME

Kristi Watterberg, MD, FAAP, and Committee on Fetus and Newborn

ABSTRACT. The American Academy of Pediatrics (AAP) believes that current data show that hospitals and accredited birth centers are the safest settings for birth in the United States. The AAP does not recommend planned home birth, which has been reported to be associated with a twofold to threefold increase in infant mortality in the United States. The AAP recognizes that women may choose to plan a home birth. This statement is intended to help pediatricians provide constructive, informed counsel to women considering home birth while retaining their role as child advocates and to summarize appropriate care for newborn infants born at home that is consistent with care

provided for infants born in a medical care facility. Regardless of the circumstances of his or her birth, including location, every newborn infant deserves health care consistent with that highlighted in this statement, which is more completely described in other publications from the AAP, including *Guidelines for Perinatal Care* and the *Textbook of Neonatal Resuscitation*. All health care clinicians and institutions should promote communications and understanding on the basis of professional interaction and mutual respect. (4/20)

PROVIDING PSYCHOSOCIAL SUPPORT TO CHILDREN AND FAMILIES IN THE AFTERMATH OF DISASTERS AND CRISES (CLINICAL REPORT)

David J. Schonfeld, MD, FAAP; Thomas Demaria, PhD; Disaster Preparedness Advisory Council; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Disasters have the potential to cause short- and long-term effects on the psychological functioning, emotional adjustment, health, and developmental trajectory of children. This clinical report provides practical suggestions on how to identify common adjustment difficulties in children in the aftermath of a disaster and to promote effective coping strategies to mitigate the impact of the disaster as well as any associated bereavement and secondary stressors. This information can serve as a guide to pediatricians as they offer anticipatory guidance to families or consultation to schools, child care centers, and other child congregate care sites. Knowledge of risk factors for adjustment difficulties can serve as the basis for mental health triage. The importance of basic supportive services, psychological first aid, and professional self-care are discussed. Stress is intrinsic to many major life events that children and families face, including the experience of significant illness and its treatment. The information provided in this clinical report may, therefore, be relevant for a broad range of patient encounters, even outside the context of a disaster. Most pediatricians enter the profession because of a heartfelt desire to help children and families most in need. If adequately prepared and supported, pediatricians who are able to draw on their skills to assist children, families, and communities to recover after a disaster will find the work to be particularly rewarding. (9/15)

http://pediatrics.aappublications.org/content/136/4/e1120

PSYCHOLOGICAL MALTREATMENT (CLINICAL REPORT)

Roberta Hibbard, MD; Jane Barlow, DPhil; Harriet MacMillan, MD; Committee on Child Abuse and Neglect (joint with American Academy of Child and Adolescent Psychiatry Child Maltreatment and Violence Committee)

ABSTRACT. Psychological or emotional maltreatment of children may be the most challenging and prevalent form of child abuse and neglect. Caregiver behaviors include acts of omission (ignoring need for social interactions) or commission (spurning, terrorizing); may be verbal or nonverbal, active or passive, and with or without intent to harm; and negatively affect the child's cognitive, social, emotional, and/or physical development. Psychological maltreatment has been linked with disorders of attachment, developmental and educational problems, socialization problems, disruptive behavior, and later psychopathology. Although no evidence-based interventions that can prevent psychological maltreatment have been identified to date, it is possible that interventions shown to be effective in reducing overall types of child maltreatment, such as the Nurse Family Partnership, may have a role to play. Furthermore, prevention before occurrence will require both the use of universal interventions aimed at promoting the type of parenting that is now recognized to be necessary for optimal child development, alongside the use of targeted interventions directed at improving parental sensitivity to a child's cues during infancy and later parent-child interactions. Intervention should, first and foremost, focus on a thorough assessment and ensuring the child's safety. Potentially effective treatments include cognitive behavioral parenting programs and other psychotherapeutic interventions. The high prevalence of psychological abuse in advanced Western societies, along with the serious consequences, point to the importance of effective management. Pediatricians should be alert to the occurrence of psychological maltreatment and identify ways to support families who have risk indicators for, or evidence of, this problem. (7/12, reaffirmed 4/16)

http://pediatrics.aappublications.org/content/130/2/372

PSYCHOSOCIAL FACTORS IN CHILDREN AND YOUTH WITH SPECIAL HEALTH CARE NEEDS AND THEIR FAMILIES (CLINICAL REPORT)

Gerri Mattson, MD, MSPH, FAAP; Dennis Z. Kuo, MD, MHS, FAAP; Committee on Psychosocial Aspects of Child and Family Health; and Council on Children With Disabilities

ABSTRACT. Children and youth with special health care needs (CYSHCN) and their families may experience a variety of internal (ie, emotional and behavioral) and external (ie, interpersonal, financial, housing, and educational) psychosocial factors that can influence their health and wellness. Many CYSHCN and their families are resilient and thrive. Medical home teams can partner with CYSHCN and their families to screen for, evaluate, and promote psychosocial health to increase protective factors and ameliorate risk factors. Medical home teams can promote protective psychosocial factors as part of coordinated, comprehensive chronic care for CYSHCN and their families. A team-based care approach may entail collaboration across the care spectrum, including youth, families, behavioral health providers, specialists, child care providers, schools, social services, and other community agencies. The purpose of this clinical report is to raise awareness of the impact of psychosocial factors on the health and wellness of CYSHCN and their families. This clinical report provides guidance for pediatric providers to facilitate and coordinate care that can have a positive influence on the overall health, wellness, and quality of life of CYSHCN and their families. (12/18)

https://pediatrics.aappublications.org/content/143/1/e20183171

PSYCHOSOCIAL SUPPORT FOR YOUTH LIVING WITH HIV (CLINICAL REPORT)

Jaime Martinez, MD, FAAP; Rana Chakraborty, MD, FAAP; and Committee on Pediatric AIDS

ABSTRACT. This clinical report provides guidance for the pediatrician in addressing the psychosocial needs of adolescents and young adults living with HIV, which can improve linkage to care and adherence to life-saving antiretroviral (ARV) therapy. Recent national case surveillance data for youth (defined here as adolescents and young adults 13 to 24 years of age) revealed that the burden of HIV/AIDS fell most heavily and disproportionately on African American youth, particularly males having sex with males. To effectively increase linkage to care and sustain adherence to therapy, interventions should address the immediate drivers of ARV compliance and also address factors that provide broader social and structural support for HIV-infected adolescents and young adults. Interventions should address psychosocial development, including lack of future orientation, inadequate educational attainment and limited health literacy, failure to focus on the long-term consequences of near-term risk behaviors, and coping ability. Associated challenges are closely linked to the structural environment. Individual case management is essential to linkage to and retention in care, ARV adherence, and management of associated comorbidities. Integrating these skills into pediatric and adolescent HIV practice in a

medical home setting is critical, given the alarming increase in new HIV infections in youth in the United States. (2/14)
http://pediatrics.aappublications.org/content/133/3/558

A PUBLIC HEALTH RESPONSE TO OPIOID USE IN PREGNANCY

Stephen W. Patrick, MD, MPH, MS, FAAP; Davida M. Schiff, MD, FAAP; and Committee on Substance Use and Prevention

ABSTRACT. The use of opioids during pregnancy has grown rapidly in the past decade. As opioid use during pregnancy increased, so did complications from their use, including neonatal abstinence syndrome. Several state governments responded to this increase by prosecuting and incarcerating pregnant women with substance use disorders; however, this approach has no proven benefits for maternal or infant health and may lead to avoidance of prenatal care and a decreased willingness to engage in substance use disorder treatment programs. A public health response, rather than a punitive approach to the opioid epidemic and substance use during pregnancy, is critical, including the following: a focus on preventing unintended pregnancies and improving access to contraception; universal screening for alcohol and other drug use in women of childbearing age; knowledge and informed consent of maternal drug testing and reporting practices; improved access to comprehensive obstetric care, including opioid-replacement therapy; gender-specific substance use treatment programs; and improved funding for social services and child welfare systems. The American College of Obstetricians and Gynecologists supports the value of this clinical document as an educational tool (December 2016). (2/17)
http://pediatrics.aappublications.org/content/139/3/e20164070

PUBLIC POLICIES TO REDUCE SUGARY DRINK CONSUMPTION IN CHILDREN AND ADOLESCENTS

Natalie D. Muth, MD, MPH, RDN, FAAP; William H. Dietz, MD, PhD, FAAP; Sheela N. Magge, MD, MSCE, FAAP; Rachel K. Johnson, PhD, MPH, RD, FAHA; Section on Obesity; and Committee on Nutrition (joint with American Heart Association)

ABSTRACT. Excess consumption of added sugars, especially from sugary drinks, poses a grave health threat to children and adolescents, disproportionately affecting children of minority and low-income communities. Public policies, such as those detailed in this statement, are needed to decrease child and adolescent consumption of added sugars and improve health. (3/19)
https://pediatrics.aappublications.org/content/143/4/e20190282

PUBLIC POLICY TO PROTECT CHILDREN FROM TOBACCO, NICOTINE, AND TOBACCO SMOKE

Section on Tobacco Control

ABSTRACT. Tobacco use and tobacco smoke exposure are among the most important health threats to children, adolescents, and adults. There is no safe level of tobacco smoke exposure. The developing brains of children and adolescents are particularly vulnerable to the development of tobacco and nicotine dependence. Tobacco is unique among consumer products in that it causes disease and death when used exactly as intended. Tobacco continues to be heavily promoted to children and young adults. Flavored and alternative tobacco products, including little cigars, chewing tobacco, and electronic nicotine delivery systems, are gaining popularity among youth. This statement describes important evidence-based public policy actions that, when implemented, will reduce tobacco product use and tobacco smoke exposure among youth and, by doing so, improve the health of children and young adults. QUALITY EARLY EDUCATION AND CHILD CARE FROM BIRTH TO KINDERGARTEN

Elaine A. Donoghue, MD, FAAP, and Council on Early Childhood

ABSTRACT. High-quality early education and child care for young children improves physical and cognitive outcomes for the children and can result in enhanced school readiness. Preschool education can be viewed as an investment (especially for at-risk children), and studies show a positive return on that investment. Barriers to high-quality early childhood education include inadequate funding and staff education as well as variable regulation and enforcement. Steps that have been taken to improve the quality of early education and child care include creating multidisciplinary, evidence-based child care practice standards; establishing state quality rating and improvement systems; improving federal and state regulations; providing child care health consultation; and initiating other innovative partnerships. Pediatricians have a role in promoting quality early education and child care for all children not only in the medical home but also at the community, state, and national levels. (7/17)

RACE, ETHNICITY, AND SOCIOECONOMIC STATUS IN RESEARCH ON CHILD HEALTH

Tina L. Cheng, MD, MPH, FAAP; Elizabeth Goodman, MD, FAAP; and Committee on Pediatric Research

ABSTRACT. An extensive literature documents the existence of pervasive and persistent child health, development, and health care disparities by race, ethnicity, and socioeconomic status (SES). Disparities experienced during childhood can result in a wide variety of health and health care outcomes, including adult morbidity and mortality, indicating that it is crucial to examine the influence of disparities across the life course. Studies often collect data on the race, ethnicity, and SES of research participants to be used as covariates or explanatory factors. In the past, these variables have often been assumed to exert their effects through individual or genetically determined biologic mechanisms. However, it is now widely accepted that these variables have important social dimensions that influence health. SES, a multidimensional construct, interacts with and confounds analyses of race and ethnicity. Because SES, race, and ethnicity are often difficult to measure accurately, leading to the potential for misattribution of causality, thoughtful consideration should be given to appropriate measurement, analysis, and interpretation of such factors. Scientists who study child and adolescent health and development should understand the multiple measures used to assess race, ethnicity, and SES, including their validity and shortcomings and potential confounding of race and ethnicity with SES. The American Academy of Pediatrics (AAP) recommends that research on eliminating health and health care disparities related to race, ethnicity, and SES be a priority. Data on race, ethnicity, and SES should be collected in research on child health to improve their definitions and increase understanding of how these factors and their complex interrelationships affect child health. Furthermore, the AAP believes that researchers should consider both biological and social mechanisms of action of race, ethnicity, and SES as they relate to the aims and hypothesis of the specific area of investigation. It is important to measure these variables, but it is not sufficient to use these variables alone as explanatory for differences in disease, morbidity, and outcomes without attention to the social and biologic influences they have on health throughout the life course. The AAP recommends more research, both in the United States and internationally, on measures of race, ethnicity, and SES and how these complex constructs affect health care and health outcomes throughout the life course. RADIATION RISK TO CHILDREN FROM COMPUTED TOMOGRAPHY (CLINICAL REPORT)

Alan S. Brody, MD; Donald P. Frush, MD; Walter Huda, PhD; Robert L. Brent, MD, PhD; and Section on Radiology

ABSTRACT. Imaging studies that use ionizing radiation are an essential tool for the evaluation of many disorders of childhood. Ionizing radiation is used in radiography, fluoroscopy, angiography, and computed tomography scanning. Computed tomography is of particular interest because of its relatively high radiation dose and wide use. Consensus statements on radiation risk suggest that it is reasonable to act on the assumption that low-level radiation may have a small risk of causing cancer. The medical community should seek ways to decrease radiation exposure by using radiation doses as low as reasonably achievable and by performing these studies only when necessary. There is wide agreement that the benefits of an indicated computed tomography scan far outweigh the risks. Pediatric health care professionals' roles in the use of computed tomography on children include deciding when a computed tomography scan is necessary and discussing the risk with patients and families. Radiologists should be a source of consultation when forming imaging strategies and should create specific protocols with scanning techniques optimized for pediatric patients. Families and patients should be encouraged to ask questions about the risks and benefits of computed tomography scanning. The information in this report is provided to aid in decision-making and discussions with the health care team, patients, and families. (9/07)

RECOGNITION AND MANAGEMENT OF IATROGENICALLY INDUCED OPIOID DEPENDENCE AND WITHDRAWAL IN CHILDREN (CLINICAL REPORT)

Jeffrey Galinkin, MD, FAAP; Jeffrey Lee Koh, MD, FAAP; Committee on Drugs; and Section on Anesthesiology and Pain Medicine

ABSTRACT. Opioids are often prescribed to children for pain relief related to procedures, acute injuries, and chronic conditions. Round-the-clock dosing of opioids can produce opioid dependence within 5 days. According to a 2001 consensus paper from the American Academy of Pain Medicine, American Pain Society, and American Society of Addiction Medicine, dependence is defined as "a state of adaptation that is manifested by a drug class specific withdrawal syndrome that can be produced by abrupt cessation, rapid dose reduction, decreasing blood level of the drug, and/or administration of an antagonist." Although the experience of many children undergoing iatrogenically induced withdrawal may be mild or goes unreported, there is currently no guidance for recognition or management of withdrawal for this population. Guidance on this subject is available only for adults and primarily for adults with substance use disorders. The guideline will summarize existing literature and provide readers with information currently not available in any single source specific for this vulnerable pediatric population. (12/13)

http://pediatrics.aappublications.org/content/133/1/152

RECOGNITION AND MANAGEMENT OF MEDICAL COMPLEXITY (CLINICAL REPORT)

Dennis Z. Kuo, MD, MHS, FAAP; Amy J. Houtrow, MD, PhD, MPH, FAAP; and Council on Children With Disabilities

ABSTRACT. Children with medical complexity have extensive needs for health services, experience functional limitations, and are high resource utilizers. Addressing the needs of this population to achieve high-value health care requires optimizing care within the medical home and medical neighborhood. Opportunities exist for health care providers, payers, and policy makers to develop strategies to enhance care delivery and to decrease costs. Important outcomes include decreasing unplanned hospital admissions, decreasing emergency department use, ensuring access to health services, limiting out-of-pocket expenses for families, and improving patient and family experiences, quality of life, and satisfaction with care. This report describes the population of children with medical complexity and provides strategies to optimize medical and health outcomes. (11/16)

http://pediatrics.aappublications.org/content/138/6/e20163021

RECOGNIZING AND RESPONDING TO MEDICAL NEGLECT (CLINICAL REPORT)

Carole Jenny, MD, MBA, and Committee on Child Abuse and Neglect

ABSTRACT. A caregiver may fail to recognize or respond to a child's medical needs for a variety of reasons. An effective response by a health care professional to medical neglect requires a comprehensive assessment of the child's needs, the parents' resources, the parents' efforts to provide for the needs of the child, and options for ensuring optimal health for the child. Such an assessment requires clear, 2-way communication between the family and the health care professional. Physicians should consider the least intrusive options for managing cases of medical neglect that ensure the health and safety of the child. (12/07, reaffirmed 1/11, 2/16)

RECOMMENDATIONS FOR PREVENTION AND CONTROL OF INFLUENZA IN CHILDREN, 2020–2021

Committee on Infectious Diseases

ABSTRACT. This statement updates the recommendations of the American Academy of Pediatrics for the routine use of influenza vaccine and antiviral medications in the prevention and treatment of influenza in children during the 2020–2021 season.

The American Academy of Pediatrics (AAP) recommends routine influenza immunization of all children without medical contraindications, starting at 6 months of age. Influenza vaccination is an important intervention to protect vulnerable populations and reduce the burden of respiratory illnesses during the severe acute respiratory syndrome-coronavirus 2 (SARS-CoV-2) pandemic. Any licensed, recommended, age-appropriate vaccine available can be administered, without preference for one product or formulation over another.

Antiviral treatment of influenza with any licensed, recommended, age-appropriate influenza antiviral medication is recommended for children with suspected or confirmed influenza who are hospitalized, have severe or progressive disease, or have underlying conditions that increase their risk of complications of influenza. Antiviral treatment may be considered for any previously healthy, symptomatic outpatient not at high risk for influenza complications in whom an influenza diagnosis is confirmed or suspected, if treatment can be initiated within 48 hours of illness onset, and for children whose siblings or household contacts either are younger than 6 months or have a high-risk condition that predisposes them to complications of influenza. RECOMMENDATIONS FOR SEROGROUP B MENINGOCOCCAL VACCINE FOR PERSONS 10 YEARS AND OLDER

Committee on Infectious Diseases

ABSTRACT. This policy statement provides recommendations for the prevention of serogroup B meningococcal disease through the use of 2 newly licensed serogroup B meningococcal vaccines: MenB-FHbp (Trumenba; Wyeth Pharmaceuticals, a subsidiary

of Pfizer, Philadelphia, PA) and MenB-4C (Bexsero; Novartis Vaccines, Siena, Italy). Both vaccines are approved for use in persons 10 through 25 years of age. MenB-FHbp is licensed as a 2- or 3-dose series, and MenB-4C is licensed as a 2-dose series for all groups. Either vaccine is recommended for routine use in persons 10 years and older who are at increased risk of serogroup B meningococcal disease (category A recommendation). Persons at increased risk of meningococcal serogroup B disease include the following: (1) persons with persistent complement component diseases, including inherited or chronic deficiencies in C3, C5–C9, properdin, factor D, or factor H, or persons receiving eculizumab (Soliris; Alexion Pharmaceuticals, Cheshire, CT), a monoclonal antibody that acts as a terminal complement inhibitor by binding C5 and inhibiting cleavage of C5 to C5A; (2) persons with anatomic or functional asplenia, including sickle cell disease; and (3) healthy persons at increased risk because of a serogroup B meningococcal disease outbreak. Both serogroup B meningococcal vaccines have been shown to be safe and immunogenic and are licensed by the US Food and Drug Administration for individuals between the ages of 10 and 25 years. On the basis of epidemiologic and antibody persistence data, the American Academy of Pediatrics agrees with the Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention that either vaccine may be administered to healthy adolescents and young adults 16 through 23 years of age (preferred ages are 16 through 18 years) to provide short-term protection against most strains of serogroup B meningococcal disease (category B recommendation). REDUCING INJURY RISK FROM BODY CHECKING IN BOYS' YOUTH ICE HOCKEY

Council on Sports Medicine and Fitness
ABSTRACT. Ice hockey is an increasingly popular sport that allows intentional collision in the form of body checking for males but not for females. There is a two- to threefold increased risk of all injury, severe injury, and concussion related to body checking at all levels of boys' youth ice hockey. The American Academy of Pediatrics reinforces the importance of stringent enforcement of rules to protect player safety as well as educational interventions to decrease unsafe tactics. To promote ice hockey as a lifelong recreational pursuit for boys, the American Academy of Pediatrics recommends the expansion of nonchecking programs and the restriction of body checking to elite levels of boys' youth ice hockey, starting no earlier than 15 years of age. (5/14, reaffirmed 7/18)
http://pediatrics.aappublications.org/content/133/6/1151

REDUCING THE NUMBER OF DEATHS AND INJURIES FROM RESIDENTIAL FIRES

Committee on Injury and Poison Prevention
ABSTRACT. Smoke inhalation, severe burns, and death from residential fires are devastating events, most of which are preventable. In 1998, approximately 381 500 residential structure fires resulted in 3250 non-firefighter deaths, 17 175 injuries, and approximately $4.4 billion in property loss. This statement reviews important prevention messages and intervention strategies related to residential fires. It also includes recommendations for pediatricians regarding office anticipatory guidance, work in the community, and support of regulation and legislation that could result in a decrease in the number of fire-related injuries and deaths to children. (6/00)
http://pediatrics.aappublications.org/content/105/6/1355

REFERRAL TO PEDIATRIC SURGICAL SPECIALISTS

Surgical Advisory Panel
ABSTRACT. The American Academy of Pediatrics, with the collaboration of the Surgical Sections of the American Academy of Pediatrics, has created referral recommendations intended to serve as voluntary practice parameters to assist general pediatricians in determining when and to whom to refer their patients for pediatric surgical specialty care. It is recognized that these recommendations may be difficult to implement, because communities vary in terms of access to major pediatric medical centers. Limited access does not negate the value of the recommendations, however, because the child who needs specialized surgical and anesthetic care is best served by the skills of the appropriate pediatric surgical team. Major congenital anomalies, malignancies, major trauma, and chronic illnesses (including those associated with preterm birth) in infants and children should be managed by pediatric medical subspecialists and pediatric surgical specialists at pediatric referral centers that can provide expertise in many areas, including the pediatric medical subspecialties and surgical specialties of pediatric radiology, pediatric anesthesiology, pediatric pathology, and pediatric intensive care. The optimal management of the child with complex problems, chronic illness, or disabilities requires coordination, communication, and cooperation of the pediatric surgical specialist with the child's primary care pediatrician or physician. (1/14)

RELIEF OF PAIN AND ANXIETY IN PEDIATRIC PATIENTS IN EMERGENCY MEDICAL SYSTEMS (CLINICAL REPORT)

Joel A. Fein, MD, MPH; William T. Zempsky, MD, MPH; Joseph P. Cravero, MD; Committee on Pediatric Emergency Medicine; and Section on Anesthesiology and Pain Medicine
ABSTRACT. Control of pain and stress for children is a vital component of emergency medical care. Timely administration of analgesia affects the entire emergency medical experience and can have a lasting effect on a child's and family's reaction to current and future medical care. A systematic approach to pain management and anxiolysis, including staff education and protocol development, can provide comfort to children in the emergency setting and improve staff and family satisfaction. (10/12, reaffirmed 9/15)
http://pediatrics.aappublications.org/content/130/5/e1391

RESCUE MEDICINE FOR EPILEPSY IN EDUCATION SETTINGS (CLINICAL REPORT)

Adam L. Hartman, MD, FAAP; Cynthia Di Laura Devore, MD; Section on Neurology; and Council on School Health
ABSTRACT. Children and adolescents with epilepsy may experience prolonged seizures in school-associated settings (eg, during transportation, in the classroom, or during sports activities). Prolonged seizures may evolve into status epilepticus. Administering a seizure rescue medication can abort the seizure and may obviate the need for emergency medical services and subsequent care in an emergency department. In turn, this may save patients from the morbidity of more invasive interventions and the cost of escalated care. There are significant variations in prescribing practices for seizure rescue medications, partly because of inconsistencies between jurisdictions in legislation and professional practice guidelines among potential first responders (including school staff). There also are potential liability issues for prescribers, school districts, and unlicensed assistive personnel who might administer the seizure rescue medications. This clinical report highlights issues that providers

may consider when prescribing seizure rescue medications and creating school medical orders and/or action plans for students with epilepsy. Collaboration among prescribing providers, families, and schools may be useful in developing plans for the use of seizure rescue medications. (12/15)
http://pediatrics.aappublications.org/content/137/1/e20153876

RESISTANCE TRAINING FOR CHILDREN AND ADOLESCENTS (CLINICAL REPORT)

Paul R. Stricker, MD, FAAP; Avery D. Faigenbaum, EdD, FACSM, FNSCA; Teri M. McCambridge, MD, FAAP; and Council on Sports Medicine and Fitness

ABSTRACT. Resistance training is becoming more important as an integral part of comprehensive sport training regimens, school physical education classes, and after-school fitness programs. The increasing number of youth who are involved in sport activities, coupled with the health problems of inactivity and being overweight, have resulted in increased interest in resistance training. Secular declines in measures of muscular fitness in modern-day youth highlight the need for participation in youth resistance training for nonathletes as well as athletes. Parents often ask pediatricians to offer advice regarding the safety, benefits, and implementation of an effective resistance-training program. This report is a revision of the 2008 American Academy of Pediatrics policy statement and reviews current information and research on the benefits and risks of resistance training for children and adolescents. https://pediatrics.aappublications.org/content/145/4/e20200204

RESPIRATORY SUPPORT IN PRETERM INFANTS AT BIRTH

Committee on Fetus and Newborn

ABSTRACT. Current practice guidelines recommend administration of surfactant at or soon after birth in preterm infants with respiratory distress syndrome. However, recent multicenter randomized controlled trials indicate that early use of continuous positive airway pressure with subsequent selective surfactant administration in extremely preterm infants results in lower rates of bronchopulmonary dysplasia/death when compared with treatment with prophylactic or early surfactant therapy. Continuous positive airway pressure started at or soon after birth with subsequent selective surfactant administration may be considered as an alternative to routine intubation with prophylactic or early surfactant administration in preterm infants. (12/13)
http://pediatrics.aappublications.org/content/133/1/171

RESPONDING TO PARENTAL REFUSALS OF IMMUNIZATION OF CHILDREN (CLINICAL REPORT)

Douglas S. Diekema, MD, MPH, and Committee on Bioethics

ABSTRACT. The American Academy of Pediatrics strongly endorses universal immunization. However, for childhood immunization programs to be successful, parents must comply with immunization recommendations. The problem of parental refusal of immunization for children is an important one for pediatricians. The goal of this report is to assist pediatricians in understanding the reasons parents may have for refusing to immunize their children, review the limited circumstances under which parental refusals should be referred to child protective services agencies or public health authorities, and provide practical guidance to assist the pediatrician faced with a parent who is reluctant to allow immunization of his or her child. (5/05, reaffirmed 1/09, 11/12)
http://pediatrics.aappublications.org/content/115/5/1428

RESPONSIBLE INNOVATION IN CHILDREN'S SURGICAL CARE

Section on Surgery and Committee on Bioethics (joint with American Pediatric Surgical Association New Technology Committee)

ABSTRACT. Advances in medical care may occur when a change in practice incorporates a new treatment or methodology. In surgery, this may involve the translation of a completely novel concept into a new procedure or device or the adaptation of existing treatment approaches or technology to a new clinical application. Regardless of the specifics, innovation should have, as its primary goal, the enhancement of care leading to improved outcomes from the patient's perspective. This policy statement examines innovation as it pertains to surgical care, focusing on some of the definitions that help differentiate applied innovation or innovative therapy from research. The ethical challenges and the potential for conflict of interest for surgeons or institutions seeking to offer innovative surgical therapy are examined. The importance of engaging patients and families as "innovation partners" to ensure complete transparency of expectations from the patient's and provider's perspectives is also examined, with specific emphasis on cultural competence and mutually respectful approaches. A framework for identifying, evaluating, and safely implementing innovative surgical therapy in children is provided. (12/16)
http://pediatrics.aappublications.org/content/139/1/e20163437

RETURNING TO LEARNING FOLLOWING A CONCUSSION (CLINICAL REPORT)

Mark E. Halstead, MD, FAAP; Karen McAvoy, PsyD; Cynthia D. Devore, MD, FAAP; Rebecca Carl, MD, FAAP; Michael Lee, MD, FAAP; Kelsey Logan, MD, FAAP; Council on Sports Medicine and Fitness; and Council on School Health

ABSTRACT. Following a concussion, it is common for children and adolescents to experience difficulties in the school setting. Cognitive difficulties, such as learning new tasks or remembering previously learned material, may pose challenges in the classroom. The school environment may also increase symptoms with exposure to bright lights and screens or noisy cafeterias and hallways. Unfortunately, because most children and adolescents look physically normal after a concussion, school officials often fail to recognize the need for academic or environmental adjustments. Appropriate guidance and recommendations from the pediatrician may ease the transition back to the school environment and facilitate the recovery of the child or adolescent. This report serves to provide a better understanding of possible factors that may contribute to difficulties in a school environment after a concussion and serves as a framework for the medical home, the educational home, and the family home to guide the student to a successful and safe return to learning. (10/13, reaffirmed 7/18)

http://pediatrics.aappublications.org/content/126/1/191

THE ROLE OF INTEGRATED CARE IN A MEDICAL HOME FOR PATIENTS WITH A FETAL ALCOHOL SPECTRUM DISORDER (CLINICAL REPORT)

Renee M. Turchi, MD, MPH, FAAP; Vincent C. Smith, MD, MPH, FAAP; Committee on Substance Use and Prevention; and Council on Children With Disabilities

ABSTRACT. Fetal alcohol spectrum disorder (FASD) is an umbrella term used to describe preventable birth defects and intellectual and/or developmental disabilities resulting from prenatal alcohol exposure. The American Academy of Pediatrics has a previous clinical report in which diagnostic criteria for a child with an FASD are discussed and tools to assist pediatricians with its management can be found. This clinical report is intended to foster pediatrician awareness of approaches for screening for prenatal alcohol exposure in clinical practice, to guide management of a child with an FASD after the diagnosis is made, and to summarize available resources for FASD management. (9/18)

http://pediatrics.aappublications.org/content/142/4/e20182333

THE ROLE OF PEDIATRICIANS IN GLOBAL HEALTH

Parminder S. Suchdev, MD, MPH, FAAP; Cynthia R. Howard, MD, MPHTM, FAAP; Section on International Child Health

ABSTRACT. Ninety percent of the world's children live in low- and middle-income countries, where barriers to health contribute to significant child morbidity and mortality. The American Academy of Pediatrics is dedicated to the health and well-being of *all* children. To fulfill this promise, this policy statement defines the role of the pediatrician in global health and provides a specific set of recommendations directed to all pediatricians, emphasizing the importance of global health as an integral function of the profession of pediatrics. (11/18)

http://pediatrics.aappublications.org/content/142/6/e20182997

ROLE OF PULSE OXIMETRY IN EXAMINING NEWBORNS FOR CONGENITAL HEART DISEASE: A SCIENTIFIC STATEMENT FROM THE AHA AND AAP

William T. Mahle, MD; Jane W. Newburger, MD, MPH; G. Paul Matherne, MD; Frank C. Smith, MD; Tracey R. Hoke, MD; Robert Koppel, MD; Samuel S. Gidding, MD; Robert H. Beekman III, MD; Scott D. Grosse, PhD; on behalf of Section on Cardiology and Cardiac Surgery and Committee of Fetus and Newborn (joint with American Heart Association Congenital Heart Defects Committee of the Council on Cardiovascular Disease in the Young, Council on Cardiovascular Nursing, and Interdisciplinary Council on Quality of Care and Outcomes Research)

ABSTRACT. *Background.* The purpose of this statement is to address the state of evidence on the routine use of pulse oximetry in newborns to detect critical congenital heart disease (CCHD).

Methods and Results. A writing group appointed by the American Heart Association and the American Academy of Pediatrics reviewed the available literature addressing current detection methods for CCHD, burden of missed and/or delayed diagnosis of CCHD, rationale of oximetry screening, and clinical studies of oximetry in otherwise asymptomatic newborns. MEDLINE database searches from 1966 to 2008 were done for English-language papers using the following search terms: congenital heart disease, pulse oximetry, physical examination, murmur, echocardiography, fetal echocardiography, and newborn screening. The reference lists of identified papers were also searched. Published abstracts from major pediatric scientific meetings in 2006 to 2008 were also reviewed. The American Heart Association classification of recommendations and levels of evidence for practice guidelines were used. In an analysis of pooled studies of oximetry assessment performed after 24 hours of life, the estimated sensitivity for detecting CCHD was 69.6%, and the positive predictive value was 47.0%; however, sensitivity varied dramatically among studies from 0% to 100%. False-positive screens that required further evaluation occurred in only 0.035% of infants screened after 24 hours.

Conclusions. Currently, CCHD is not detected in some newborns until after their hospital discharge, which results in significant morbidity and occasional mortality. Furthermore, routine pulse oximetry performed on asymptomatic newborns after 24 hours of life, but before hospital discharge, may detect CCHD. Routine pulse oximetry performed after 24 hours in hospitals that have on-site pediatric cardiovascular services incurs very low cost and risk of harm. Future studies in larger populations and across a broad range of newborn delivery systems are needed to determine whether this practice should become standard of care in the routine assessment of the neonate. (8/09)

http://pediatrics.aappublications.org/content/124/2/823

THE ROLE OF THE PEDIATRICIAN IN PRIMARY PREVENTION OF OBESITY (CLINICAL REPORT)

Stephen R. Daniels, MD, PhD, FAAP; Sandra G. Hassink, MD, FAAP; and Committee on Nutrition

ABSTRACT. The adoption of healthful lifestyles by individuals and families can result in a reduction in many chronic diseases and conditions of which obesity is the most prevalent. Obesity prevention, in addition to treatment, is an important public health priority. This clinical report describes the rationale for pediatricians to be an integral part of the obesity-prevention effort. In addition, the 2012 Institute of Medicine report "Accelerating Progress in Obesity Prevention" includes health care providers as a crucial component of successful weight control. Research on obesity prevention in the pediatric care setting as well as evidence-informed practical approaches and targets for prevention are reviewed. Pediatricians should use a longitudinal, developmentally appropriate life-course approach to help identify children early on the path to obesity and base prevention efforts on family dynamics and reduction in high-risk dietary and activity behaviors. They should promote a diet free of sugar-sweetened beverages, of fewer foods with high caloric density, and of increased intake of fruits and vegetables. It is also important to promote a lifestyle with reduced sedentary behavior and with 60 minutes of daily moderate to vigorous physical activity. This report also identifies important gaps in evidence that need to be filled by future research. (6/15)

http://pediatrics.aappublications.org/content/136/1/e275

THE ROLE OF THE PEDIATRICIAN IN RURAL EMERGENCY MEDICAL SERVICES FOR CHILDREN

Committee on Pediatric Emergency Medicine

ABSTRACT. In rural America, pediatricians can play a key role in the development, implementation, and ongoing supervision of emergency medical services for children (EMSC). Pediatricians may represent the only source of pediatric expertise for a large region and are a vital resource for rural physicians (eg, general and family practice, emergency medicine) and other rural health care professionals (physician assistants, nurse practitioners, and emergency medical technicians), providing education about management and prevention of pediatric illness and injury; appropriate equipment for the acutely ill or injured child; and acute, chronic, and rehabilitative care. In addition to providing clinical expertise, the pediatrician may be involved in quality assurance, clinical protocol development, and advocacy, and may serve as a liaison between emergency medical services and other entities working with children (eg, school nurses, child care centers, athletic programs, and programs for children with special health care needs). (10/12, reaffirmed 9/15)

http://pediatrics.aappublications.org/content/130/5/978

ROLE OF THE PEDIATRICIAN IN YOUTH VIOLENCE PREVENTION

Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Youth violence continues to be a serious threat to the health of children and adolescents in the United States. It is crucial that pediatricians clearly define their role and develop the appropriate skills to address this threat effectively. From a clinical perspective, pediatricians should become familiar with *Connected Kids: Safe, Strong, Secure,* the American Academy of Pediatrics' primary care violence prevention protocol. Using this material, practices can incorporate preventive education, screening for risk, and linkages to community-based counseling and treatment resources. As advocates, pediatricians may bring newly developed information regarding key risk factors such as exposure to firearms, teen dating violence, and bullying to the attention of local and national policy makers. This policy statement refines the developing role of pediatricians in youth violence prevention and emphasizes the importance of this issue in the strategic agenda of the American Academy of Pediatrics. (6/09, reaffirmed 4/19)

ROLE OF THE SCHOOL NURSE IN PROVIDING SCHOOL HEALTH SERVICES

Council on School Health

ABSTRACT. The American Academy of Pediatrics recognizes the important role school nurses play in promoting the optimal biopsychosocial health and well-being of school-aged children in the school setting. Although the concept of a school nurse has existed for more than a century, uniformity among states and school districts regarding the role of a registered professional nurse in schools and the laws governing it are lacking. By understanding the benefits, roles, and responsibilities of school nurses working as a team with the school physician, as well as their contributions to school-aged children, pediatricians can collaborate with, support, and promote school nurses in their own communities, thus improving the health, wellness, and safety of children and adolescents. (5/16)

http://pediatrics.aappublications.org/content/137/6/e20160852

ROLE OF THE SCHOOL PHYSICIAN

Council on School Health

ABSTRACT. The American Academy of Pediatrics recognizes the important role physicians play in promoting the optimal biopsychosocial well-being of children in the school setting. Although the concept of a school physician has existed for more than a century, uniformity among states and school districts regarding physicians in schools and the laws governing it are lacking. By understanding the roles and contributions physicians can make to schools, pediatricians can support and promote school physicians in their communities and improve health and safety for children. (12/12, reaffirmed 1/19)

ROUTINE NEUROIMAGING OF THE PRETERM BRAIN (CLINICAL REPORT)

Ivan L. Hand, MD, FAAP; Renée A. Shellhaas, MD, MS, FAAP; Sarah S. Milla, MD, FAAP; Committee on Fetus and Newborn; Section on Neurology; and Section on Radiology

ABSTRACT. Neuroimaging of the preterm infant is a common assessment performed in the NICU. Timely and focused studies can be used for diagnostic, therapeutic, and prognostic information. However, significant variability exists among neonatal units as to which modalities are used and when imaging studies are obtained. Appropriate timing and selection of neuroimaging studies can help identify neonates with brain injury who may require therapeutic intervention or who may be at risk for neurodevelopmental impairment. This clinical report reviews the different modalities of imaging broadly available to the clinician. Evidence-based indications for each modality, optimal timing of examinations, and prognostic value are discussed. (10/20)

RUNAWAY YOUTH: CARING FOR THE NATION'S LARGEST SEGMENT OF MISSING CHILDREN (CLINICAL REPORT)

Thresia B. Gambon, MD, MPH, MBA, FAAP; Janna R. Gewirtz O'Brien, MD, FAAP; Committee on Psychosocial Aspects of Child and Family Health; and Council on Community Pediatrics

ABSTRACT. The largest segment of missing children in the United States includes runaways, children who run away from home, and thrownaways, children who are told to leave or stay away from home by a household adult. Although estimates vary, as many as 1 in 20 youth run away from home annually. These unaccompanied youth have unique health needs, including high rates of trauma, mental illness, substance use, pregnancy, and sexually transmitted infections. While away, youth who run away are at high risk for additional trauma, victimization, and violence. Runaway and thrownaway youth have high unmet health care needs and limited access to care. Several populations are at particular high risk for runaway episodes, including victims of abuse and neglect; lesbian, gay, bisexual, transgender, and questioning youth; and youth in protective custody. Pediatricians and other health care professionals have a critical role to play in supporting runaway youth, addressing their unique health needs, fostering positive relationships within their families and with other supportive adults, and connecting them with available community resources. This report provides clinical guidance for pediatricians and other health care professionals regarding (1) the identification of adolescents who are at risk for running away or being thrown away and (2) the management of the unique medical, mental health, and social needs of these youth. In partnership with national, state, and local resources, pediatricians can significantly reduce risk and improve long-term outcomes for runaway youth. (1/20)

SAFE SLEEP AND SKIN-TO-SKIN CARE IN THE NEONATAL PERIOD FOR HEALTHY TERM NEWBORNS (CLINICAL REPORT)

Lori Feldman-Winter, MD, MPH, FAAP; Jay P. Goldsmith, MD, FAAP; Committee on Fetus and Newborn; and Task Force on Sudden Infant Death Syndrome

ABSTRACT. Skin-to-skin care (SSC) and rooming-in have become common practice in the newborn period for healthy newborns with the implementation of maternity care practices that support breastfeeding as delineated in the World Health Organization's "Ten Steps to Successful Breastfeeding." SSC and rooming-in are supported by evidence that indicates that the implementation of these practices increases overall and exclusive breastfeeding, safer and healthier transitions, and improved maternal-infant bonding. In some cases, however, the practice of SSC and rooming-in may pose safety concerns, particularly with regard to sleep. There have been several recent case reports and case series of severe and sudden unexpected postnatal collapse in the neonatal period among otherwise healthy newborns and near fatal or fatal events related to sleep, suffocation, and falls from adult hospital beds. Although these are largely case reports, there are potential dangers of unobserved SSC immediately after birth and throughout the postpartum hospital period as well as with unobserved rooming-in for at-risk situations. Moreover,

behaviors that are modeled in the hospital after birth, such as sleep position, are likely to influence sleeping practices after discharge. Hospitals and birthing centers have found it difficult to develop policies that will allow SSC and rooming-in to continue in a safe manner. This clinical report is intended for birthing centers and delivery hospitals caring for healthy newborns to assist in the establishment of appropriate SSC and safe sleep policies. (8/16)

SAFE TRANSPORTATION OF PRETERM AND LOW BIRTH WEIGHT INFANTS AT HOSPITAL DISCHARGE (CLINICAL REPORT)

Marilyn J. Bull, MD; William A. Engle, MD; Committee on Injury, Violence, and Poison Prevention; and Committee on Fetus and Newborn

ABSTRACT. Safe transportation of preterm and low birth weight infants requires special considerations. Both physiologic immaturity and low birth weight must be taken into account to properly position such infants. This clinical report provides guidelines for pediatricians and other caregivers who counsel parents of preterm and low birth weight infants about car safety seats. (4/09, reaffirmed 8/13, 6/18)

SCHOOL BUS TRANSPORTATION OF CHILDREN WITH SPECIAL HEALTH CARE NEEDS

Joseph O'Neil, MD, MPH, FAAP; Benjamin D. Hoffman, MD, FAAP; and Council on Injury, Violence, and Poison Prevention

ABSTRACT. School systems are responsible for ensuring that children with special needs are safely transported on all forms of federally approved transportation provided by the school system. A plan to provide the most current and proper support to children with special transportation needs should be developed by the Individualized Education Program team, including the parent, school transportation director, and school nurse, in conjunction with physician orders and recommendations. With this statement, we provide current guidance for the protection of child passengers with specific health care needs. Guidance that applies to general school transportation should be followed, inclusive of staff training, provision of nurses or aides if needed, and establishment of a written emergency evacuation plan as well as a comprehensive infection control program. Researchers provide the basis for recommendations concerning occupant securement for children in wheelchairs and children with other special needs who are transported on a school bus. Pediatricians can help their patients by being aware of guidance for restraint systems for children with special needs and by remaining informed of new resources. Pediatricians can also play an important role at the state and local level in the development of school bus specifications. (4/18)

SCHOOL READINESS (TECHNICAL REPORT)

P. Gail Williams, MD, FAAP; Marc Alan Lerner, MD, FAAP; Council on Early Childhood; and Council on School Health

ABSTRACT. School readiness includes the readiness of the individual child, the school's readiness for children, and the ability of the family and community to support optimal early child development. It is the responsibility of schools to meet the needs of all children at all levels of readiness. Children's readiness for kindergarten should become an outcome measure for a coordinated system of community-based programs and supports for the healthy development of young children. Our rapidly expanding insights into early brain and child development have revealed that modifiable factors in a child's early experience can greatly affect that child's health and learning trajectories. Many children in the United States enter kindergarten with limitations in their social, emotional, cognitive, and physical development that might have been significantly diminished or eliminated through early identification and attention to child and family needs. A strong correlation between social-emotional development and school and life success, combined with alarming rates of preschool expulsion, point toward the urgency of leveraging opportunities to support social-emotional development and address behavioral concerns early. Pediatric primary care providers have access to the youngest children and their families. Pediatricians can promote and use community supports, such as home visiting programs, quality early care and education programs, family support programs and resources, early intervention services, children's museums, and libraries, which are important for addressing school readiness and are too often underused by populations who can benefit most from them. When these are not available, pediatricians can support the development of such resources. The American Academy of Pediatrics affords pediatricians many opportunities to improve the physical, social-emotional, and educational health of young children, in conjunction with other advocacy groups. This technical report provides an updated version of the previous iteration from the American Academy of Pediatrics published in 2008. (7/19)

SCHOOL START TIMES FOR ADOLESCENTS

Adolescent Sleep Working Group, Committee on Adolescence, and Council on School Health

ABSTRACT. The American Academy of Pediatrics recognizes insufficient sleep in adolescents as an important public health issue that significantly affects the health and safety, as well as the academic success, of our nation's middle and high school students. Although a number of factors, including biological changes in sleep associated with puberty, lifestyle choices, and academic demands, negatively affect middle and high school students' ability to obtain sufficient sleep, the evidence strongly implicates earlier school start times (ie, before 8:30 AM) as a key modifiable contributor to insufficient sleep, as well as circadian rhythm disruption, in this population. Furthermore, a substantial body of research has now demonstrated that delaying school start times is an effective countermeasure to chronic sleep loss and has a wide range of potential benefits to students with regard to physical and mental health, safety, and academic achievement. The American Academy of Pediatrics strongly supports the efforts of school districts to optimize sleep in students and urges high schools and middle schools to aim for start times that allow students the opportunity to achieve optimal levels of sleep (8.5–9.5 hours) and to improve physical (eg, reduced obesity risk) and mental (eg, lower rates of depression) health, safety (eg, drowsy driving crashes), academic performance, and quality of life. (8/14)

SCHOOL TRANSPORTATION SAFETY

Committee on Injury, Violence, and Poison Prevention and Council on School Health

ABSTRACT. This policy statement replaces the previous version published in 1996. It provides new information, studies, regulations, and recommendations related to the safe transportation of children to and from school and school-related activities. Pediatricians can play an important role at the patient/family, community, state, and national levels as child advocates and consultants to schools and early education programs about transportation safety. (7/07, reaffirmed 10/11)

http://pediatrics.aappublications.org/content/120/1/213

SCHOOL-AGED CHILDREN WHO ARE NOT PROGRESSING ACADEMICALLY: CONSIDERATIONS FOR PEDIATRICIANS (CLINICAL REPORT)

Celiane Rey-Casserly, PhD; Laura McGuinn, MD, FAAP; Arthur Lavin, MD, FAAP; Committee on Psychosocial Aspects of Child and Family Health; Section on Developmental and Behavioral Pediatrics

ABSTRACT. Pediatricians and other pediatric primary care providers may be consulted when families have concerns that their child is not making expected progress in school. Pediatricians care not only for an increasingly diverse population of children who may have behavioral, psychological, and learning difficulties but also for increasing numbers of children with complex and chronic medical problems that can affect the development of the central nervous system and can present with learning and academic concerns. In many instances, pediatric providers require additional information about the nature of cognitive, psychosocial, and educational difficulties that affect their school-aged patients. Our purpose for this report is to describe the current state of the science regarding educational achievement to inform pediatricians' decisions regarding further evaluation of a child's challenges. In this report, we review commonly available options for psychological evaluation and/or treatment, medical referrals, and/or recommendations for referral for eligibility determinations at school and review strategies for collaborating with families, schools, and specialists to best serve children and families. (9/19)

https://pediatrics.aappublications.org/content/144/4/e20192520

SCHOOL-BASED HEALTH CENTERS AND PEDIATRIC PRACTICE

Council on School Health

ABSTRACT. School-based health centers (SBHCs) have become an important method of health care delivery for the youth of our nation. Although they only represent 1 aspect of a coordinated school health program approach, SBHCs have provided access to health care services for youth confronted with age, financial, cultural, and geographic barriers. A fundamental principle of SBHCs is to create an environment of service coordination and collaboration that addresses the health needs and well-being of youth with health disparities or poor access to health care services. Some pediatricians have concerns that these centers are in conflict with the primary care provider's medical home. This policy provides an overview of SBHCs and some of their documented benefits, addresses the issue of potential conflict with the medical home, and provides recommendations that support the integration and coordination of SBHCs and the pediatric medical home practice. (1/12, reaffirmed 6/17)

SCOPE OF HEALTH CARE BENEFITS FOR CHILDREN FROM BIRTH THROUGH AGE 26

Committee on Child Health Financing

ABSTRACT. The optimal health of all children is best achieved with access to appropriate and comprehensive health care benefits. This policy statement outlines and defines the recommended set of health insurance benefits for children through age 26. The American Academy of Pediatrics developed a set of recommendations concerning preventive care services for children, adolescents, and young adults. These recommendations are compiled in the publication *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents,* third edition. The Bright Futures recommendations were referenced as a standard for access and design of age-appropriate health insurance benefits for infants, children, adolescents, and young adults in the Patient Protection and Affordable Care Act of 2010 (Pub L No. 114–148). (12/11)

http://pediatrics.aappublications.org/content/129/1/185

SCOPE OF PRACTICE ISSUES IN THE DELIVERY OF PEDIATRIC HEALTH CARE

Committee on Pediatric Workforce

ABSTRACT. The American Academy of Pediatrics (AAP) believes that optimal pediatric health care depends on a team-based approach with supervision by a physician leader, preferably a pediatrician. The pediatrician, here defined to include not only pediatric generalists but all pediatric medical subspecialists, all surgical specialists, and internal medicine/pediatric physicians, is uniquely qualified to manage, coordinate, and supervise the entire spectrum of pediatric care, from diagnosis through all stages of treatment, in all practice settings. The AAP recognizes the valuable contributions of nonphysician clinicians, including nurse practitioners and physician assistants, in delivering optimal pediatric care. However, the expansion of the scope of practice of nonphysician pediatric clinicians raises critical public policy and child health advocacy concerns. Pediatricians should serve as advocates for optimal pediatric care in state legislatures, public policy forums, and the media and should pursue opportunities to resolve scope of practice conflicts outside state legislatures. The AAP affirms the importance of appropriate documentation and standards in pediatric education, training, skills, clinical competencies, examination, regulation, and patient care to ensure safety and quality health care for all infants, children, adolescents, and young adults. (5/13, reaffirmed 10/15)

SCREENING EXAMINATION OF PREMATURE INFANTS FOR RETINOPATHY OF PREMATURITY

Walter M. Fierson, MD, FAAP, and Section on Ophthalmology (joint with American Academy of Ophthalmology, American Association for Pediatric Ophthalmology and Strabismus, and American Association of Certified Orthoptists)

ABSTRACT. This policy statement revises a previous statement on screening of preterm infants for retinopathy of prematurity (ROP) that was published in 2013. ROP is a pathologic process that occurs in immature retinal tissue and can progress to a tractional retinal detachment, which may then result in visual loss or blindness. For more than 3 decades, treatment of severe ROP that markedly decreases the incidence of this poor visual outcome has been available. However, severe, treatment-requiring ROP must be diagnosed in a timely fashion to be treated effectively. The sequential nature of ROP requires that infants who are at-risk and preterm be examined at proper times and intervals to detect the changes of ROP before they become destructive. This statement presents the attributes of an effective program to detect and treat ROP, including the timing of initial and follow-up examinations. (11/18)

http://pediatrics.aappublications.org/content/142/6/e20183061

SCREENING FOR NONVIRAL SEXUALLY TRANSMITTED INFECTIONS IN ADOLESCENTS AND YOUNG ADULTS

Committee on Adolescence (joint with Society for Adolescent Health and Medicine)

ABSTRACT. Prevalence rates of many sexually transmitted infections (STIs) are highest among adolescents. If nonviral STIs are detected early, they can be treated, transmission to others can be eliminated, and sequelae can be averted. The US Preventive Services Task Force and the Centers for Disease Control and Prevention have published chlamydia, gonorrhea, and syphilis screening guidelines that recommend screening those at risk on the basis of epidemiologic and clinical outcomes data. This policy statement specifically focuses on these curable, nonviral STIs and reviews the evidence for nonviral STI screening in adolescents, communicates the value of screening, and outlines recommendations for routine nonviral STI screening of adolescents. (6/14)

http://pediatrics.aappublications.org/content/134/1/e302

SCREENING FOR RETINOPATHY IN THE PEDIATRIC PATIENT WITH TYPE 1 DIABETES MELLITUS (CLINICAL REPORT)

Gregg T. Lueder, MD; Janet Silverstein, MD; Section on Ophthalmology; and Section on Endocrinology (joint with American Association for Pediatric Ophthalmology and Strabismus)

ABSTRACT. Diabetic retinopathy (DR) is the leading cause of blindness in young adults in the United States. Early identification and treatment of DR can decrease the risk of vision loss in affected patients. This clinical report reviews the risk factors for the development of DR and screening guidance for pediatric patients with type 1 diabetes mellitus. (7/05, reaffirmed 1/09, 7/14, 11/19)

SELECTING APPROPRIATE TOYS FOR YOUNG CHILDREN IN THE DIGITAL ERA (CLINICAL REPORT)

Aleeya Healey, MD, FAAP; Alan Mendelsohn, MD, FAAP; and Council on Early Childhood

ABSTRACT. Play is essential to optimal child development because it contributes to the cognitive, physical, social, and emotional well-being of children and youth. It also offers an ideal and significant opportunity for parents and other caregivers to engage fully with children using toys as an instrument of play and interaction. The evolution of societal perceptions of toys from children's playthings to critical facilitators of early brain and child development has challenged caregivers in deciding which toys are most appropriate for their children. This clinical report strives to provide pediatric health care providers with evidence-based information that can be used to support caregivers as they choose toys for their children. The report highlights the broad definition of a toy; consideration of potential benefits and possible harmful effects of toy choices on child development; and the promotion of positive caregiving and development when toys are used to engage caregivers in play-based interactions with their children that are rich in language, pretending, problem-solving, and creativity. The report aims to address the evolving replacement of more traditional toys with digital media–based virtual "toys" and the lack of evidence for similar benefits in child development. Furthermore, this report briefly addresses the role of toys in advertising and/or incentive programs and aims to bring awareness regarding safety and health hazards associated with toy availability and accessibility in public settings, including some health care settings. SENSORY INTEGRATION THERAPIES FOR CHILDREN WITH DEVELOPMENTAL AND BEHAVIORAL DISORDERS

Section on Complementary and Integrative Medicine and Council on Children With Disabilities

ABSTRACT. Sensory-based therapies are increasingly used by occupational therapists and sometimes by other types of therapists in treatment of children with developmental and behavioral disorders. Sensory-based therapies involve activities that are believed to organize the sensory system by providing vestibular, proprioceptive, auditory, and tactile inputs. Brushes, swings, balls, and other specially designed therapeutic or recreational equipment are used to provide these inputs. However, it is unclear whether children who present with sensory-based problems have an actual "disorder" of the sensory pathways of the brain or whether these deficits are characteristics associated with other developmental and behavioral disorders. Because there is no universally accepted framework for diagnosis, sensory processing disorder generally should not be diagnosed. Other developmental and behavioral disorders must always be considered, and a thorough evaluation should be completed. Difficulty tolerating or processing sensory information is a characteristic that may be seen in many developmental behavioral disorders, including autism spectrum disorders, attention-deficit/hyperactivity disorder, developmental coordination disorders, and childhood anxiety disorders.

Occupational therapy with the use of sensory-based therapies may be acceptable as one of the components of a comprehensive treatment plan. However, parents should be informed that the amount of research regarding the effectiveness of sensory integration therapy is limited and inconclusive. Important roles for pediatricians and other clinicians may include discussing these limitations with parents, talking with families about a trial period of sensory integration therapy, and teaching families how to evaluate the effectiveness of a therapy. (5/12)

SEXUAL AND REPRODUCTIVE HEALTH CARE SERVICES IN THE PEDIATRIC SETTING (CLINICAL REPORT)

Arik V. Marcell, MD, MPH; Gale R. Burstein, MD, MPH; and Committee on Adolescence

ABSTRACT. Pediatricians are an important source of health care for adolescents and young adults and can play a significant role in addressing their patients' sexual and reproductive health needs, including preventing unintended pregnancies and sexually transmitted infections (STIs), including HIV, and promoting healthy relationships. STIs, HIV, and unintended pregnancy are all preventable health outcomes with potentially serious permanent sequelae; the highest rates of STIs, HIV, and unintended pregnancy are reported among adolescents and young adults. Office visits present opportunities to provide comprehensive education and health care services to adolescents and young adults to prevent STIs, HIV, and unintended pregnancies. The American Academy of Pediatrics, other professional medical organizations, and the government have guidelines and recommendations regarding the provision of sexual and reproductive health information and services. However, despite these recommendations, recent studies have revealed that there is substantial room for improvement in actually delivering the recommended services. The purpose of this clinical report is to assist pediatricians to operationalize the provision of various aspects of sexual and reproductive health care into their practices and to provide guidance on overcoming barriers to providing this care routinely while maximizing opportunities for confidential health services delivery in their offices. (10/17)

http://pediatrics.aappublications.org/content/140/5/e20172858

SEXUALITY EDUCATION FOR CHILDREN AND ADOLESCENTS (CLINICAL REPORT)

Cora C. Breuner, MD, MPH, FAAP; Gerri Mattson, MD, MSPH, FAAP; Committee on Adolescence; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. The purpose of this clinical report is to provide pediatricians updated research on evidence-based sexual and reproductive health education conducted since the original clinical report on the subject was published by the American Academy of Pediatrics in 2001. Sexuality education is defined as teaching about human sexuality, including intimate relationships, human sexual anatomy, sexual reproduction, sexually transmitted infections, sexual activity, sexual orientation, gender identity, abstinence, contraception, and reproductive rights and responsibilities. Developmentally appropriate and evidence-based education about human sexuality and sexual reproduction over time provided by pediatricians, schools, other professionals, and parents is important to help children and adolescents make informed, positive, and safe choices about healthy relationships, responsible sexual activity, and their reproductive health. Sexuality education has been shown to help to prevent and reduce the risks of adolescent pregnancy, HIV, and sexually transmitted infections for children and adolescents with and

without chronic health conditions and disabilities in the United States. (7/16)
http://pediatrics.aappublications.org/content/138/2/e20161348

SEXUALITY OF CHILDREN AND ADOLESCENTS WITH DEVELOPMENTAL DISABILITIES (CLINICAL REPORT)

Nancy A. Murphy, MD; Ellen Roy Elias, MD; for Council on Children With Disabilities

ABSTRACT. Children and adolescents with developmental disabilities, like all children, are sexual persons. However, attention to their complex medical and functional issues often consumes time that might otherwise be invested in addressing the anatomic, physiologic, emotional, and social aspects of their developing sexuality. This report discusses issues of puberty, contraception, psychosexual development, sexual abuse, and sexuality education specific to children and adolescents with disabilities and their families. Pediatricians, in the context of the medical home, are encouraged to discuss issues of sexuality on a regular basis, ensure the privacy of each child and adolescent, promote self-care and social independence among persons with disabilities, advocate for appropriate sexuality education, and provide ongoing education for children and adolescents with developmental disabilities and their families. (7/06, reaffirmed 12/09, 7/13, 11/17)
http://pediatrics.aappublications.org/content/118/1/398

SHARED DECISION-MAKING AND CHILDREN WITH DISABILITIES: PATHWAYS TO CONSENSUS (CLINICAL REPORT)

Richard C. Adams, MD, FAAP; Susan E. Levy, MD, MPH, FAAP; and Council on Children With Disabilities

ABSTRACT. Shared decision-making (SDM) promotes family and clinician collaboration, with ultimate goals of improved health and satisfaction. This clinical report provides a basis for a systematic approach to the implementation of SDM by clinicians for children with disabilities. Often in the discussion of treatment plans, there are gaps between the child's/family's values, priorities, and understanding of perceived "best choices" and those of the clinician. When conducted well, SDM affords an appropriate balance incorporating voices of all stakeholders, ultimately supporting both the child/family and clinician. With increasing knowledge of and functional use of SDM skills, the clinician will become an effective partner in the decision-making process with families, providing family-centered care. The outcome of the process will support the beneficence of the physician, the authority of the family, and the autonomy and well-being of the child. (5/17)

SHOPPING CART–RELATED INJURIES TO CHILDREN

Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Shopping cart–related injuries to children are common and can result in severe injury or even death. Most injuries result from falls from carts or cart tip-overs, and injuries to the head and neck represent three fourths of cases. The current US standard for shopping carts should be revised to include clear and effective performance criteria to prevent falls from carts and cart tip-overs. Pediatricians have an important role as educators, researchers, and advocates to promote the prevention of these injuries. (8/06, reaffirmed 4/09, 8/13)
http://pediatrics.aappublications.org/content/118/2/825

SHOPPING CART–RELATED INJURIES TO CHILDREN (TECHNICAL REPORT)

Gary A. Smith, MD, DrPH, for Committee on Injury, Violence, and Poison Prevention

ABSTRACT. An estimated 24 200 children younger than 15 years, 20 700 (85%) of whom were younger than 5 years, were treated in US hospital emergency departments in 2005 for shopping cart–related injuries. Approximately 4% of shopping cart–related injuries to children younger than 15 years require admission to the hospital. Injuries to the head and neck represent three fourths of all injuries. Fractures account for 45% of all hospitalizations. Deaths have occurred from falls from shopping carts and cart tip-overs. Falls are the most common mechanism of injury and account for more than half of injuries associated with shopping carts. Cart tip-overs are the second most common mechanism, responsible for up to one fourth of injuries and almost 40% of shopping cart–related injuries among children younger than 2 years. Public-awareness initiatives, education programs, and parental supervision, although important, are not enough to prevent these injuries effectively. European Standard EN 1929-1:1998 and joint Australian/New Zealand Standard AS/NZS 3847.1:1999 specify requirements for the construction, performance, testing, and safety of shopping carts and have been implemented as national standards in 21 countries. A US performance standard for shopping carts (ASTM [American Society for Testing and Materials] F2372-04) was established in July 2004; however, it does not adequately address falls and cart tip-overs, which are the leading mechanisms of shopping cart–related injuries to children. The current US standard for shopping carts should be revised to include clear and effective performance criteria for shopping cart child-restraint systems and cart stability to prevent falls from carts and cart tip-overs. This is imperative to decrease the number and severity of shopping cart–related injuries to children. Recommendations from the American Academy of Pediatrics regarding prevention of shopping cart–related injuries are included in the accompanying policy statement. (8/06, reaffirmed 4/09, 8/13)
http://pediatrics.aappublications.org/content/118/2/e540

SIDS AND OTHER SLEEP-RELATED INFANT DEATHS: EVIDENCE BASE FOR 2016 UPDATED RECOMMENDATIONS FOR A SAFE INFANT SLEEPING ENVIRONMENT (TECHNICAL REPORT)

Rachel Y. Moon, MD, FAAP, and Task Force on Sudden Infant Death Syndrome

ABSTRACT. Approximately 3500 infants die annually in the United States from sleep-related infant deaths, including sudden infant death syndrome (SIDS), ill-defined deaths, and accidental suffocation and strangulation in bed. After an initial decrease in the 1990s, the overall sleep-related infant death rate has not declined in more recent years. Many of the modifiable and nonmodifiable risk factors for SIDS and other sleep-related infant deaths are strikingly similar. The American Academy of Pediatrics recommends a safe sleep environment that can reduce the risk of all sleep-related infant deaths. Recommendations for a safe sleep environment include supine positioning, use of a firm sleep surface, room-sharing without bed-sharing, and avoidance of soft bedding and overheating. Additional recommendations for SIDS risk reduction include avoidance of exposure to smoke, alcohol, and illicit drugs; breastfeeding; routine immunization; and use of a pacifier. New evidence and rationale for recommendations are presented for skin-to-skin care for newborn infants, bedside and in-bed sleepers, sleeping on couches/armchairs and in sitting devices, and use of soft bedding after 4 months of age. In addition, expanded recommendations for infant sleep location are included. The recommendations and strength of evidence for each recommendation are published in the accompanying policy statement, "SIDS and Other Sleep-Related Infant Deaths: Updated 2016 Recommendations for a Safe Infant Sleeping Environment," which is included in this issue. (10/16)
http://pediatrics.aappublications.org/content/138/5/e20162940

SIDS AND OTHER SLEEP-RELATED INFANT DEATHS: UPDATED 2016 RECOMMENDATIONS FOR A SAFE INFANT SLEEPING ENVIRONMENT

Task Force on Sudden Infant Death Syndrome

ABSTRACT. Approximately 3500 infants die annually in the United States from sleep-related infant deaths, including sudden infant death syndrome (SIDS; International Classification of Diseases, 10th Revision [ICD-10], R95), ill-defined deaths (ICD-10 R99), and accidental suffocation and strangulation in bed (ICD-10 W75). After an initial decrease in the 1990s, the overall death rate attributable to sleep-related infant deaths has not declined in more recent years. Many of the modifiable and nonmodifiable risk factors for SIDS and other sleep-related infant deaths are strikingly similar. The American Academy of Pediatrics recommends a safe sleep environment that can reduce the risk of all sleep-related infant deaths. Recommendations for a safe sleep environment include supine positioning, the use of a firm sleep surface, room-sharing without bed-sharing, and the avoidance of soft bedding and overheating. Additional recommendations for SIDS reduction include the avoidance of exposure to smoke, alcohol, and illicit drugs; breastfeeding; routine immunization; and use of a pacifier. New evidence is presented for skin-to-skin care for newborn infants, use of bedside and in-bed sleepers, sleeping on couches/armchairs and in sitting devices, and use of soft bedding after 4 months of age. The recommendations and strength of evidence for each recommendation are included in this policy statement. The rationale for these recommendations is discussed in detail in the accompanying technical report (www.pediatrics.org/cgi/doi/10.1542/peds.2016-2940). (10/16)

http://pediatrics.aappublications.org/content/138/5/e20162938

SKATEBOARD AND SCOOTER INJURIES

Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Skateboard-related injuries account for an estimated 50 000 emergency department visits and 1500 hospitalizations among children and adolescents in the United States each year. Nonpowered scooter-related injuries accounted for an estimated 9400 emergency department visits between January and August 2000, and 90% of these patients were children younger than 15 years. Many such injuries can be avoided if children and youth do not ride in traffic, if proper protective gear is worn, and if, in the absence of close adult supervision, skateboards and scooters are not used by children younger than 10 and 8 years, respectively. (3/02, reaffirmed 5/05, 10/08, 10/13)

SKIN-TO-SKIN CARE FOR TERM AND PRETERM INFANTS IN THE NEONATAL ICU (CLINICAL REPORT)

Jill Baley, MD, and Committee on Fetus and Newborn

ABSTRACT. "Kangaroo mother care" was first described as an alternative method of caring for low birth weight infants in resource-limited countries, where neonatal mortality and infection rates are high because of overcrowded nurseries, inadequate staffing, and lack of equipment. Intermittent skin-to-skin care (SSC), a modified version of kangaroo mother care, is now being offered in resource-rich countries to infants needing neonatal intensive care, including those who require ventilator support or are extremely premature. SSC significantly improves milk production by the mother and is associated with a longer duration of breastfeeding. Increased parent satisfaction, better sleep organization, a longer duration of quiet sleep, and decreased pain perception during procedures have also been reported in association with SSC. Despite apparent physiologic stability during SSC, it is prudent that infants in the NICU have continuous cardiovascular monitoring and that care be taken to verify correct head positioning for airway patency as well as the stability of the endotracheal tube, arterial and venous access devices, and other life support equipment. (8/15)

SNACKS, SWEETENED BEVERAGES, ADDED SUGARS, AND SCHOOLS

Council on School Health and Committee on Nutrition

ABSTRACT. Concern over childhood obesity has generated a decade-long reformation of school nutrition policies. Food is available in school in 3 venues: federally sponsored school meal programs; items sold in competition to school meals, such as a la carte, vending machines, and school stores; and foods available in myriad informal settings, including packed meals and snacks, bake sales, fundraisers, sports booster sales, in-class parties, or other school celebrations. High-energy, low-nutrient beverages, in particular, contribute substantial calories, but little nutrient content, to a student's diet. In 2004, the American Academy of Pediatrics recommended that sweetened drinks be replaced in school by water, white and flavored milks, or 100% fruit and vegetable beverages. Since then, school nutrition has undergone a significant transformation. Federal, state, and local regulations and policies, along with alternative products developed by industry, have helped decrease the availability of nutrient-poor foods and beverages in school. However, regular access to foods of high energy and low quality remains a school issue, much of it attributable to students, parents, and staff. Pediatricians, aligning with experts on child nutrition, are in a position to offer a perspective promoting nutrient-rich foods within calorie guidelines to improve those foods brought into or sold in schools. A positive emphasis on nutritional value, variety, appropriate portion, and encouragement for a steady improvement in quality will be a more effective approach for improving nutrition and health than simply advocating for the elimination of added sugars. SNOWMOBILING HAZARDS

Committee on Injury and Poison Prevention

ABSTRACT. Snowmobiles continue to pose a significant risk to children younger than 15 years and adolescents and young adults 15 through 24 years of age. Head injuries remain the leading cause of mortality and serious morbidity, arising largely from snowmobilers colliding, falling, or overturning during operation. Children also were injured while being towed in a variety of conveyances by snowmobiles. No uniform code of state laws governs the use of snowmobiles by children and youth. Because evidence is lacking to support the effectiveness of operator safety certification and because many children and adolescents do not have the required strength and skills to operate a snowmobile safely, the recreational operation of snowmobiles by persons younger than 16 years is not recommended. Snowmobiles should not be used to tow persons on a tube, tire, sled, or saucer. Furthermore, a graduated licensing program is advised for snowmobilers 16 years and older. Both active and passive snowmobile injury prevention strategies are suggested, as well as recommendations for manufacturers to make safer equipment for snowmobilers of all ages. SOCCER INJURIES IN CHILDREN AND ADOLESCENTS (CLINICAL REPORT)

Andrew Watson, MD, MS, FAAP; Jeffrey M. Mjaanes, MD, FAAP; Council on Sports Medicine and Fitness

ABSTRACT. Participation in youth soccer in the United States continues to increase steadily, with a greater percentage of preadolescent participants than perhaps any other youth sport. Despite the wide-ranging health benefits of participation in organized sports, injuries occur and represent a threat to the health

and performance of young athletes. Youth soccer has a greater reported injury rate than many other contact sports, and recent studies suggest that injury rates are increasing. Large increases in the incidence of concussions in youth soccer have been reported, and anterior cruciate ligament injuries remain a significant problem in this sport, particularly among female athletes. Considerable new research has identified a number of modifiable risk factors for lower-extremity injuries and concussion, and several prevention programs have been identified to reduce the risk of injury. Rule enforcement and fair play also serve an important role in reducing the risk of injury among youth soccer participants. This report provides an updated review of the relevant literature as well as recommendations to promote the safe participation of children and adolescents in soccer. (10/19)

SPECIAL REQUIREMENTS OF ELECTRONIC HEALTH RECORD SYSTEMS IN PEDIATRICS (CLINICAL REPORT)

S. Andrew Spooner, MD, MS, and Council on Clinical Information Technology

ABSTRACT. Some functions of an electronic health record system are much more important in providing pediatric care than in adult care. Pediatricians commonly complain about the absence of these "pediatric functions" when they are not available in electronic health record systems. To stimulate electronic health record system vendors to recognize and incorporate pediatric functionality into pediatric electronic health record systems, this clinical report reviews the major functions of importance to child health care providers. Also reviewed are important but less critical functions, any of which might be of major importance in a particular clinical context. The major areas described here are immunization management, growth tracking, medication dosing, data norms, and privacy in special pediatric populations. The American Academy of Pediatrics believes that if the functions described in this document are supported in all electronic health record systems, these systems will be more useful for patients of all ages. SPECTRUM OF NONINFECTIOUS HEALTH EFFECTS FROM MOLDS

Committee on Environmental Health

ABSTRACT. Molds are eukaryotic (possessing a true nucleus) nonphotosynthetic organisms that flourish both indoors and outdoors. For humans, the link between mold exposure and asthma exacerbations, allergic rhinitis, infections, and toxicities from ingestion of mycotoxin-contaminated foods are well known. However, the cause-and-effect relationship between inhalational exposure to mold and other untoward health effects (eg, acute idiopathic pulmonary hemorrhage in infants and other illnesses and health complaints) requires additional investigation. Pediatricians play an important role in the education of families about mold, its adverse health effects, exposure prevention, and remediation procedures. (12/06, reaffirmed 9/16)
http://pediatrics.aappublications.org/content/118/6/2582

SPECTRUM OF NONINFECTIOUS HEALTH EFFECTS FROM MOLDS (TECHNICAL REPORT)

Lynnette J. Mazur, MD, MPH; Janice Kim, MD, PhD, MPH; and Committee on Environmental Health

ABSTRACT. Molds are multicellular fungi that are ubiquitous in outdoor and indoor environments. For humans, they are both beneficial (for the production of antimicrobial agents, chemotherapeutic agents, and vitamins) and detrimental. Exposure to mold can occur through inhalation, ingestion, and touching moldy surfaces. Adverse health effects may occur through allergic, infectious, irritant, or toxic processes. The cause-and-effect relationship between mold exposure and allergic and infectious illnesses is well known. Exposures to toxins via the gastrointestinal tract also are well described. However, the cause-and-effect relationship between inhalational exposure to mold toxins and other untoward health effects (eg, acute idiopathic pulmonary hemorrhage in infants and other illnesses and health complaints) is controversial and requires additional investigation. In this report we examine evidence of fungal-related illnesses and the unique aspects of mold exposure to children. Mold-remediation procedures are also discussed. (12/06, reaffirmed 9/16)

SPORT-RELATED CONCUSSION IN CHILDREN AND ADOLESCENTS (CLINICAL REPORT)

Mark E. Halstead, MD, FAAP; Kevin D. Walter, MD, FAAP; Kody Moffatt, MD, FAAP; and Council on Sports Medicine and Fitness

ABSTRACT. Sport-related concussion is an important topic in nearly all sports and at all levels of sport for children and adolescents. Concussion knowledge and approaches to management have progressed since the American Academy of Pediatrics published its first clinical report on the subject in 2010. Concussion's definition, signs, and symptoms must be understood to diagnose it and rule out more severe intracranial injury. Pediatric health care providers should have a good understanding of diagnostic evaluation and initial management strategies. Effective management can aid recovery and potentially reduce the risk of long-term symptoms and complications. Because concussion symptoms often interfere with school, social life, family relationships, and athletics, a concussion may affect the emotional well-being of the injured athlete. Because every concussion has its own unique spectrum and severity of symptoms, individualized management is appropriate. The reduction, not necessarily elimination, of physical and cognitive activity is the mainstay of treatment. A full return to activity and/or sport is accomplished by using a stepwise program while evaluating for a return of symptoms. An understanding of prolonged symptoms and complications will help the pediatric health care provider know when to refer to a specialist. Additional research is needed in nearly all aspects of concussion in the young athlete. This report provides education on the current state of sport-related concussion knowledge, diagnosis, and management in children and adolescents. (11/18)

SPORTS DRINKS AND ENERGY DRINKS FOR CHILDREN AND ADOLESCENTS: ARE THEY APPROPRIATE? (CLINICAL REPORT)

Committee on Nutrition and Council on Sports Medicine and Fitness

ABSTRACT. Sports and energy drinks are being marketed to children and adolescents for a wide variety of inappropriate uses. Sports drinks and energy drinks are significantly different products, and the terms should not be used interchangeably. The primary objectives of this clinical report are to define the ingredients of sports and energy drinks, categorize the similarities and differences between the products, and discuss misuses and abuses. Secondary objectives are to encourage screening during annual physical examinations for sports and energy drink use, to understand the reasons why youth consumption is widespread, and to improve education aimed at decreasing or eliminating the inappropriate use of these beverages by children and adolescents. Rigorous review and analysis of the literature reveal that caffeine and other stimulant substances contained in energy drinks have no place in the diet of children and adolescents. Furthermore, frequent or excessive intake of caloric sports drinks can substantially increase the risk for overweight or obesity in children and adolescents. Discussion regarding the appropriate use of sports drinks in the youth athlete who participates regularly in endurance or high-intensity sports and vigorous

physical activity is beyond the scope of this report. (5/11, reaffirmed 7/17)
http://pediatrics.aappublications.org/content/127/6/1182

SPORTS SPECIALIZATION AND INTENSIVE TRAINING IN YOUNG ATHLETES (CLINICAL REPORT)

Joel S. Brenner, MD, MPH, FAAP, and Council on Sports Medicine and Fitness

ABSTRACT. Sports specialization is becoming the norm in youth sports for a variety of reasons. When sports specialization occurs too early, detrimental effects may occur, both physically and psychologically. If the timing is correct and sports specialization is performed under the correct conditions, the athlete may be successful in reaching specific goals. Young athletes who train intensively, whether specialized or not, can also be at risk of adverse effects on the mind and body. The purpose of this clinical report is to assist pediatricians in counseling their young athlete patients and their parents regarding sports specialization and intensive training. This report supports the American Academy of Pediatrics clinical report "Overuse Injuries, Overtraining, and Burnout in Child and Adolescent Athletes." (8/16)
http://pediatrics.aappublications.org/content/138/3/e20162148

STANDARD TERMINOLOGY FOR FETAL, INFANT, AND PERINATAL DEATHS (CLINICAL REPORT)

Wanda D. Barfield, MD, MPH, FAAP, and Committee on Fetus and Newborn

ABSTRACT. Accurately defining and reporting perinatal deaths (ie, fetal and infant deaths) is a critical first step in understanding the magnitude and causes of these important events. In addition to obstetric health care providers, neonatologists and pediatricians should have easy access to current and updated resources that clearly provide US definitions and reporting requirements for live births, fetal deaths, and infant deaths. Correct identification of these vital events will improve local, state, and national data so that these deaths can be better addressed and prevented. (4/16)
http://pediatrics.aappublications.org/content/137/5/e20160551

STANDARDIZATION OF INPATIENT HANDOFF COMMUNICATION (CLINICAL REPORT)

Jennifer A. Jewell, MD, FAAP, and Committee on Hospital Care

ABSTRACT. Handoff communication is identified as an integral part of hospital care. Throughout medical communities, inadequate handoff communication is being highlighted as a significant risk to patients. The complexity of hospitals and the number of providers involved in the care of hospitalized patients place inpatients at high risk of communication lapses. This miscommunication and the potential resulting harm make effective handoffs more critical than ever. Although hospitalized patients are being exposed to many handoffs each day, this report is limited to describing the best handoff practices between providers at the time of shift change. (10/16)
http://pediatrics.aappublications.org/content/138/5/e20162681

STANDARDS FOR HEALTH INFORMATION TECHNOLOGY TO ENSURE ADOLESCENT PRIVACY

Committee on Adolescence and Council on Clinical Information Technology

ABSTRACT. Privacy and security of health information is a basic expectation of patients. Despite the existence of federal and state laws safeguarding the privacy of health information, health information systems currently lack the capability to allow for protection of this information for minors. This policy statement reviews the challenges to privacy for adolescents posed by commercial health information technology systems and recommends basic principles for ideal electronic health record systems. This policy statement has been endorsed by the Society for Adolescent Health and Medicine. (10/12, reaffirmed 12/18)
http://pediatrics.aappublications.org/content/130/5/987

STANDARDS FOR PEDIATRIC CANCER CENTERS

Section on Hematology/Oncology

ABSTRACT. Since the American Academy of Pediatrics–published guidelines for pediatric cancer centers in 1986, 1997, and 2004, significant changes in the delivery of health care have prompted a review of the role of medical centers in the care of pediatric patients. The potential effect of these changes on the treatment and survival rates of children with cancer led to this revision. The intent of this statement is to delineate personnel, capabilities, and facilities that are essential to provide state-of-the-art care for children, adolescents, and young adults with cancer. This statement emphasizes the importance of board-certified pediatric hematologists/oncologists and appropriately qualified pediatric medical subspecialists and pediatric surgical specialists overseeing patient care and the need for specialized facilities as essential for the initial management and much of the follow-up for pediatric, adolescent, and young adult patients with cancer. For patients without practical access to a pediatric cancer center, care may be provided locally by a primary care physician or adult oncologist but at the direction of a pediatric oncologist. (7/14, reaffirmed 10/18)

STIGMA EXPERIENCED BY CHILDREN AND ADOLESCENTS WITH OBESITY

Stephen J. Pont, MD, MPH, FAAP; Rebecca Puhl, PhD, FTOS; Stephen R. Cook, MD, MPH, FAAP, FTOS; Wendelin Slusser, MD, MS, FAAP; and Section on Obesity (joint with The Obesity Society)

ABSTRACT. The stigmatization of people with obesity is widespread and causes harm. Weight stigma is often propagated and tolerated in society because of beliefs that stigma and shame will motivate people to lose weight. However, rather than motivating positive change, this stigma contributes to behaviors such as binge eating, social isolation, avoidance of health care services, decreased physical activity, and increased weight gain, which worsen obesity and create additional barriers to healthy behavior change. Furthermore, experiences of weight stigma also dramatically impair quality of life, especially for youth. Health care professionals continue to seek effective strategies and resources to address the obesity epidemic; however, they also frequently exhibit weight bias and stigmatizing behaviors. This policy statement seeks to raise awareness regarding the prevalence and negative effects of weight stigma on pediatric patients and their families and provides 6 clinical practice and 4 advocacy recommendations regarding the role of pediatricians in addressing weight stigma. In summary, these recommendations include improving the clinical setting by modeling best practices for nonbiased behaviors and language; using empathetic and empowering counseling techniques, such as motivational interviewing, and addressing weight stigma and bullying in the clinic visit; advocating for inclusion of training and education about weight stigma in medical schools, residency programs, and continuing medical education programs; and empowering families to be advocates to address weight stigma in the home environment and school setting. (11/17)

STRATEGIES FOR PREVENTION OF HEALTH CARE–ASSOCIATED INFECTIONS IN THE NICU (CLINICAL REPORT)

Richard A. Polin, MD; Susan Denson, MD; Michael T. Brady, MD; Committee on Fetus and Newborn; and Committee on Infectious Diseases

ABSTRACT. Health care–associated infections in the NICU result in increased morbidity and mortality, prolonged lengths of stay, and increased medical costs. Neonates are at high risk of acquiring health care–associated infections because of impaired host-defense mechanisms, limited amounts of protective endogenous flora on skin and mucosal surfaces at time of birth, reduced barrier function of their skin, use of invasive procedures and devices, and frequent exposure to broad-spectrum antibiotic agents. This clinical report reviews management and prevention of health care–associated infections in newborn infants. (3/12, reaffirmed 2/16)

SUBSTANCE USE SCREENING, BRIEF INTERVENTION, AND REFERRAL TO TREATMENT

Committee on Substance Use and Prevention

ABSTRACT. The enormous public health impact of adolescent substance use and its preventable morbidity and mortality show the need for the health care sector, including pediatricians and the medical home, to increase its capacity related to substance use prevention, detection, assessment, and intervention. The American Academy of Pediatrics published its policy statement "Substance Use Screening, Brief Intervention, and Referral to Treatment for Pediatricians" in 2011 to introduce the concepts and terminology of screening, brief intervention, and referral to treatment (SBIRT) and to offer clinical guidance about available substance use screening tools and intervention procedures. This policy statement is a revision of the 2011 SBIRT statement. An accompanying clinical report updates clinical guidance for adolescent SBIRT. (6/16)

http://pediatrics.aappublications.org/content/138/1/e20161210

SUBSTANCE USE SCREENING, BRIEF INTERVENTION, AND REFERRAL TO TREATMENT (CLINICAL REPORT)

Sharon J. L. Levy, MD, MPH, FAAP; Janet F. Williams, MD, FAAP; and Committee on Substance Use and Prevention

ABSTRACT. The enormous public health impact of adolescent substance use and its preventable morbidity and mortality highlight the need for the health care sector, including pediatricians and the medical home, to increase its capacity regarding adolescent substance use screening, brief intervention, and referral to treatment (SBIRT). The American Academy of Pediatrics first published a policy statement on SBIRT and adolescents in 2011 to introduce SBIRT concepts and terminology and to offer clinical guidance about available substance use screening tools and intervention procedures. This clinical report provides a simplified adolescent SBIRT clinical approach that, in combination with the accompanying updated policy statement, guides pediatricians in implementing substance use prevention, detection, assessment, and intervention practices across the varied clinical settings in which adolescents receive health care. (6/16)

http://pediatrics.aappublications.org/content/138/1/e20161211

SUICIDE AND SUICIDE ATTEMPTS IN ADOLESCENTS (CLINICAL REPORT)

Benjamin Shain, MD, PhD, and Committee on Adolescence

ABSTRACT. Suicide is the second leading cause of death for adolescents 15 to 19 years old. This report updates the previous statement of the American Academy of Pediatrics and is intended to assist pediatricians, in collaboration with other child and adolescent health care professionals, in the identification and management of the adolescent at risk for suicide. Suicide risk can only be reduced, not eliminated, and risk factors provide no more than guidance. Nonetheless, care for suicidal adolescents may be improved with the pediatrician's knowledge, skill, and comfort with the topic, as well as ready access to appropriate community resources and mental health professionals. (6/16, reaffirmed 10/20)

http://pediatrics.aappublications.org/content/138/1/e20161420

SUPPLEMENTAL SECURITY INCOME (SSI) FOR CHILDREN AND YOUTH WITH DISABILITIES

Council on Children With Disabilities

ABSTRACT. The Supplemental Security Income (SSI) program remains an important source of financial support for low-income families of children with special health care needs and disabling conditions. In most states, SSI eligibility also qualifies children for the state Medicaid program, providing access to health care services. The Social Security Administration (SSA), which administers the SSI program, considers a child disabled under SSI if there is a medically determinable physical or mental impairment or combination of impairments that results in marked and severe functional limitations. The impairment(s) must be expected to result in death or have lasted or be expected to last for a continuous period of at least 12 months. The income and assets of families of children with disabilities are also considered when determining financial eligibility. When an individual with a disability becomes an adult at 18 years of age, the SSA considers only the individual's income and assets. The SSA considers an adult to be disabled if there is a medically determinable impairment (or combination of impairments) that prevents substantial gainful activity for at least 12 continuous months. SSI benefits are important for youth with chronic conditions who are transitioning to adulthood. The purpose of this statement is to provide updated information about the SSI medical and financial eligibility criteria and the disability-determination process. This statement also discusses how pediatricians can help children and youth when they apply for SSI benefits. (11/09, reaffirmed 2/15)

http://pediatrics.aappublications.org/content/124/6/1702

SUPPORTING THE FAMILY AFTER THE DEATH OF A CHILD (CLINICAL REPORT)

Esther Wender, MD, and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. The death of a child can have a devastating effect on the family. The pediatrician has an important role to play in supporting the parents and any siblings still in his or her practice after such a death. Pediatricians may be poorly prepared to provide this support. Also, because of the pain of confronting the grief of family members, they may be reluctant to become involved. This statement gives guidelines to help the pediatrician provide such support. It describes the grief reactions that can be expected in family members after the death of a child. Ways of supporting family members are suggested, and other helpful resources in the community are described. The goal of this guidance is to prevent outcomes that may impair the health and development of affected parents and children. (11/12, reaffirmed 12/16)

http://pediatrics.aappublications.org/content/130/6/1164

SUPPORTING THE GRIEVING CHILD AND FAMILY (CLINICAL REPORT)

David J. Schonfeld, MD, FAAP; Thomas Demaria, PhD; Committee on Psychosocial Aspects of Child and Family Health; and Disaster Preparedness Advisory Council

ABSTRACT. The death of someone close to a child often has a profound and lifelong effect on the child and results in a range of both short- and long-term reactions. Pediatricians, within a patient-centered medical home, are in an excellent position to provide anticipatory guidance to caregivers and to offer

assistance and support to children and families who are grieving. This clinical report offers practical suggestions on how to talk with grieving children to help them better understand what has happened and its implications and to address any misinformation, misinterpretations, or misconceptions. An understanding of guilt, shame, and other common reactions, as well an appreciation of the role of secondary losses and the unique challenges facing children in communities characterized by chronic trauma and cumulative loss, will help the pediatrician to address factors that may impair grieving and children's adjustment and to identify complicated mourning and situations when professional counseling is indicated. Advice on how to support children's participation in funerals and other memorial services and to anticipate and address grief triggers and anniversary reactions is provided so that pediatricians are in a better position to advise caregivers and to offer consultation to schools, early education and child care facilities, and other child congregate care sites. Pediatricians often enter their profession out of a profound desire to minimize the suffering of children and may find it personally challenging when they find themselves in situations in which they are asked to bear witness to the distress of children who are acutely grieving. The importance of professional preparation and self-care is therefore emphasized, and resources are recommended. (8/16)

http://pediatrics.aappublications.org/content/138/3/e20162147

SUPPORTING THE HEALTH CARE TRANSITION FROM ADOLESCENCE TO ADULTHOOD IN THE MEDICAL HOME (CLINICAL REPORT)

Patience H. White, MD, MA, FAAP, FACP; W. Carl Cooley, MD, FAAP; American Academy of Pediatrics (joint with Transitions Clinical Report Authoring Group, American Academy of Family Physicians, and American College of Physicians)

ABSTRACT. Risk and vulnerability encompass many dimensions of the transition from adolescence to adulthood. Transition from pediatric, parent-supervised health care to more independent, patient-centered adult health care is no exception. The tenets and algorithm of the original 2011 clinical report, "Supporting the Health Care Transition from Adolescence to Adulthood in the Medical Home," are unchanged. This updated clinical report provides more practice-based quality improvement guidance on key elements of transition planning, transfer, and integration into adult care for all youth and young adults. It also includes new and updated sections on definition and guiding principles, the status of health care transition preparation among youth, barriers, outcome evidence, recommended health care transition processes and implementation strategies using quality improvement methods, special populations, education and training in pediatric onset conditions, and payment options. The clinical report also includes new recommendations pertaining to infrastructure, education and training, payment, and research. (10/18)

http://pediatrics.aappublications.org/content/142/5/e20182587

SURFACTANT REPLACEMENT THERAPY FOR PRETERM AND TERM NEONATES WITH RESPIRATORY DISTRESS (CLINICAL REPORT)

Richard A. Polin, MD, FAAP; Waldemar A. Carlo, MD, FAAP; and Committee on Fetus and Newborn

ABSTRACT. Respiratory failure secondary to surfactant deficiency is a major cause of morbidity and mortality in preterm infants. Surfactant therapy substantially reduces mortality and respiratory morbidity for this population. Secondary surfactant deficiency also contributes to acute respiratory morbidity in late-preterm and term neonates with meconium aspiration syndrome, pneumonia/sepsis, and perhaps pulmonary hemorrhage; surfactant replacement may be beneficial for these infants. This statement summarizes the evidence regarding indications, administration, formulations, and outcomes for surfactant-replacement therapy. The clinical strategy of intubation, surfactant administration, and extubation to continuous positive airway pressure and the effect of continuous positive airway pressure on outcomes and surfactant use in preterm infants are also reviewed. (12/13)

http://pediatrics.aappublications.org/content/133/1/156

TACKLING IN YOUTH FOOTBALL

Council on Sports Medicine and Fitness

ABSTRACT. American football remains one of the most popular sports for young athletes. The injuries sustained during football, especially those to the head and neck, have been a topic of intense interest recently in both the public media and medical literature. The recognition of these injuries and the potential for long-term sequelae have led some physicians to call for a reduction in the number of contact practices, a postponement of tackling until a certain age, and even a ban on high school football. This statement reviews the literature regarding injuries in football, particularly those of the head and neck, the relationship between tackling and football-related injuries, and the potential effects of limiting or delaying tackling on injury risk. (10/15, reaffirmed 7/20)

http://pediatrics.aappublications.org/content/136/5/e1419

TARGETED REFORMS IN HEALTH CARE FINANCING TO IMPROVE THE CARE OF ADOLESCENTS AND YOUNG ADULTS

Arik V. Marcell, MD, MPH, FAAP; Cora C. Breuner, MD, MPH, FAAP; Lawrence Hammer, MD, FAAP; Mark L. Hudak, MD, FAAP; Committee on Adolescence; and Committee on Child Health Financing

ABSTRACT. Significant changes have occurred in the commercial and government insurance marketplace after the passage of 2 federal legislation acts, the Patient Protection and Affordable Care Act of 2010 and the Paul Wellstone and Pete Domenici Mental Health Parity and Addiction Equity Act of 2008. Despite the potential these 2 acts held to improve the health care of adolescents and young adults (AYAs), including the financing of care, there are barriers to achieving this goal. In the first quarter of 2016, 13.7% of individuals 18 to 24 years of age still lacked health insurance. Limitations in the scope of benefits coverage and inadequate provider payment can curtail access to health care for AYAs, particularly care related to sexual and reproductive health and mental and behavioral health. Some health plans impose financial barriers to access because they require families to absorb high cost-sharing expenses (eg, deductibles, copayments, and coinsurance). Finally, challenges of confidentiality inherent in the billing and insurance claim practices of some health insurance plans can discourage access to health care in the absence of other obstacles and interfere with provision of confidential care. This policy statement summarizes the current state of impediments that AYA, including those with special health care needs, face in accessing timely and appropriate health care and that providers face in serving these patients. These impediments include limited scope of benefits, high cost sharing, inadequate provider payment, and insufficient confidentiality protections. With this statement, we aim to improve both access to health care by AYAs and providers' delivery of developmentally appropriate health care for these patients through the presentation of an overview of the issues, specific recommendations for reform of health care financing for AYAs, and practical actions that pediatricians and other providers can take to advocate for appropriate payments for providing health care to AYAs. (11/18)

http://pediatrics.aappublications.org/content/142/6/e20182998

THE TEEN DRIVER

Elizabeth M. Alderman, MD, FAAP, FSAHM; Brian D. Johnston, MD, MPH, FAAP; Committee on Adolescence; and Council on Injury, Violence, and Poison Prevention

ABSTRACT. For many teenagers, obtaining a driver's license is a rite of passage, conferring the ability to independently travel to school, work, or social events. However, immaturity, inexperience, and risky behavior put newly licensed teen drivers at risk. Motor vehicle crashes are the most common cause of mortality and injury for adolescents and young adults in developed countries. Teen drivers (15–19 years of age) have the highest rate of motor vehicle crashes among all age groups in the United States and contribute disproportionately to traffic fatalities. In addition to the deaths of teen drivers, more than half of 8- to 17-year-old children who die in car crashes are killed as passengers of drivers younger than 20 years of age. This policy statement, in which we update the previous 2006 iteration of this policy statement, is used to reflect new research on the risks faced by teen drivers and offer advice for pediatricians counseling teen drivers and their families. (9/18)

TELEMEDICINE FOR EVALUATION OF RETINOPATHY OF PREMATURITY (TECHNICAL REPORT)

Walter M. Fierson, MD, FAAP; Antonio Capone Jr, MD; and Section on Ophthalmology (joint with American Academy of Ophthalmology and American Association of Certified Orthoptists)

ABSTRACT. Retinopathy of prematurity (ROP) remains a significant threat to vision for extremely premature infants despite the availability of therapeutic modalities capable, in most cases, of managing this disorder. It has been shown in many controlled trials that application of therapies at the appropriate time is essential to successful outcomes in premature infants affected by ROP. Bedside binocular indirect ophthalmoscopy has been the standard technique for diagnosis and monitoring of ROP in these patients. However, implementation of routine use of this screening method for at-risk premature infants has presented challenges within our existing care systems, including relative local scarcity of qualified ophthalmologist examiners in some locations and the remote location of some NICUs. Modern technology, including the development of wide-angle ocular digital fundus photography, coupled with the ability to send digital images electronically to remote locations, has led to the development of telemedicine-based remote digital fundus imaging (RDFI-TM) evaluation techniques. These techniques have the potential to allow the diagnosis and monitoring of ROP to occur in lieu of the necessity for some repeated on-site examinations in NICUs. This report reviews the currently available literature on RDFI-TM evaluations for ROP and outlines pertinent practical and risk management considerations that should be used when including RDFI-TM in any new or existing ROP care structure. (12/14)

TELEMEDICINE: PEDIATRIC APPLICATIONS (TECHNICAL REPORT)

Bryan L. Burke Jr, MD, FAAP; R. W. Hall, MD, FAAP; and Section on Telehealth Care

ABSTRACT. Telemedicine is a technological tool that is improving the health of children around the world. This report chronicles the use of telemedicine by pediatricians and pediatric medical and surgical specialists to deliver inpatient and outpatient care, educate physicians and patients, and conduct medical research. It also describes the importance of telemedicine in responding to emergencies and disasters and providing access to pediatric care to remote and underserved populations. Barriers to telemedicine expansion are explained, such as legal issues, inadequate payment for services, technology costs and sustainability, and the lack of technology infrastructure on a national scale. Although certain challenges have constrained more widespread implementation, telemedicine's current use bears testimony to its effectiveness and potential. Telemedicine's widespread adoption will be influenced by the implementation of key provisions of the Patient Protection and Affordable Care Act, technological advances, and growing patient demand for virtual visits. (6/15)

http://pediatrics.aappublications.org/content/136/1/e293

TESTING FOR DRUGS OF ABUSE IN CHILDREN AND ADOLESCENTS (CLINICAL REPORT)

Sharon Levy, MD, MPH, FAAP; Lorena M. Siqueira, MD, MSPH, FAAP; and Committee on Substance Abuse

ABSTRACT. Drug testing is often used as part of an assessment for substance use in children and adolescents. However, the indications for drug testing and guidance on how to use this procedure effectively are not clear. The complexity and invasiveness of the procedure and limitations to the information derived from drug testing all affect its utility. The objective of this clinical report is to provide guidance to pediatricians and other clinicians on the efficacy and efficient use of drug testing on the basis of a review of the nascent scientific literature, policy guidelines, and published clinical recommendations. (5/14)

http://pediatrics.aappublications.org/content/133/6/e1798

TOWARD TRANSPARENT CLINICAL POLICIES

Steering Committee on Quality Improvement and Management

ABSTRACT. Clinical policies of professional societies such as the American Academy of Pediatrics are valued highly, not only by clinicians who provide direct health care to children but also by many others who rely on the professional expertise of these organizations, including parents, employers, insurers, and legislators. The utility of a policy depends, in large part, on the degree to which its purpose and basis are clear to policy users, an attribute known as the policy's transparency. This statement describes the critical importance and special value of transparency in clinical policies, guidelines, and recommendations; helps identify obstacles to achieving transparency; and suggests several approaches to overcome these obstacles. (3/08, reaffirmed 2/14)

TRAMPOLINE SAFETY IN CHILDHOOD AND ADOLESCENCE

Council on Sports Medicine and Fitness

ABSTRACT. Despite previous recommendations from the American Academy of Pediatrics discouraging home use of trampolines, recreational use of trampolines in the home setting continues to be a popular activity among children and adolescents. This policy statement is an update to previous statements, reflecting the current literature on prevalence, patterns, and mechanisms of trampoline-related injuries. Most trampoline injuries occur with multiple simultaneous users on the mat. Cervical spine injuries often occur with falls off the trampoline or with attempts at somersaults or flips. Studies on the efficacy of trampoline safety measures are reviewed, and although there is a paucity of data, current implementation of safety measures have not appeared to mitigate risk substantially. Therefore, the home use of trampolines is strongly discouraged. The role of trampoline as a competitive sport and in structured training settings is reviewed, and recommendations for enhancing safety in these environments are made. (9/12, reaffirmed 7/15)

THE TRANSFER OF DRUGS AND THERAPEUTICS INTO HUMAN BREAST MILK: AN UPDATE ON SELECTED TOPICS (CLINICAL REPORT)

Hari Cheryl Sachs, MD, FAAP, and Committee on Drugs

ABSTRACT. Many mothers are inappropriately advised to discontinue breastfeeding or avoid taking essential medications because of fears of adverse effects on their infants. This cautious approach may be unnecessary in many cases, because only a small proportion of medications are contraindicated in breastfeeding mothers or associated with adverse effects on their infants. Information to inform physicians about the extent of excretion for a particular drug into human milk is needed but may not be available. Previous statements on this topic from the American Academy of Pediatrics provided physicians with data concerning the known excretion of specific medications into breast milk. More current and comprehensive information is now available on the Internet, as well as an application for mobile devices, at LactMed (http://toxnet.nlm.nih.gov). Therefore, with the exception of radioactive compounds requiring temporary cessation of breastfeeding, the reader will be referred to LactMed to obtain the most current data on an individual medication. This report discusses several topics of interest surrounding lactation, such as the use of psychotropic therapies, drugs to treat substance abuse, narcotics, galactagogues, and herbal products, as well as immunization of breastfeeding women. A discussion regarding the global implications of maternal medications and lactation in the developing world is beyond the scope of this report. The World Health Organization offers several programs and resources that address the importance of breastfeeding (see http://www.who.int/topics/breastfeeding/en/). (8/13, reaffirmed 5/18)

TRANSPORTING CHILDREN WITH SPECIAL HEALTH CARE NEEDS

Joseph O'Neil, MD, MPH, FAAP; Benjamin Hoffman, MD, FAAP; and Council on Injury, Violence, and Poison Prevention

ABSTRACT. Children with special health care needs should have access to proper resources for safe transportation as do typical children. This policy statement reviews important considerations for transporting children with special health care needs and provides current guidance for the protection of children with specific health care needs, including those with airway obstruction, orthopedic conditions or procedures, developmental delays, muscle tone abnormalities, challenging behaviors, and gastrointestinal disorders. (4/19)

THE TREATMENT OF NEUROLOGICALLY IMPAIRED CHILDREN USING PATTERNING

Committee on Children With Disabilities

ABSTRACT. This statement reviews patterning as a treatment for children with neurologic impairments. This treatment is based on an outmoded and oversimplified theory of brain development. Current information does not support the claims of proponents that this treatment is efficacious, and its use continues to be unwarranted. (11/99, reaffirmed 11/02, 1/06, 8/10, 4/14, 5/18)

TRUTH, RECONCILIATION, AND TRANSFORMATION: CONTINUING ON THE PATH TO EQUITY

Board of Directors

ABSTRACT. One year ago, the American Academy of Pediatrics (AAP) published a landmark policy statement identifying racism as a core social determinant of health and a driver of health inequities. Seventy-five years ago, the AAP admitted its first Black members, Drs Alonzo deGrate Smith and Roland Boyd Scott. As the AAP continues to evolve its equity agenda, it is essential that the tortuous experiences of Drs deGrate Smith and Scott on their pathway to AAP membership be truthfully acknowledged and reckoned with. ULTRAVIOLET RADIATION: A HAZARD TO CHILDREN AND ADOLESCENTS

Council on Environmental Health and Section on Dermatology

ABSTRACT. Ultraviolet radiation (UVR) causes the 3 major forms of skin cancer: basal cell carcinoma; squamous cell carcinoma; and cutaneous malignant melanoma. Public awareness of the risk is not optimal, overall compliance with sun protection is inconsistent, and melanoma rates continue to rise. The risk of skin cancer increases when people overexpose themselves to sun and intentionally expose themselves to artificial sources of UVR. Yet, people continue to sunburn, and teenagers and adults alike remain frequent visitors to tanning parlors. Pediatricians should provide advice about UVR exposure during health-supervision visits and at other relevant times. Advice includes avoiding sunburning, wearing clothing and hats, timing activities (when possible) before or after periods of peak sun exposure, wearing protective sunglasses, and applying and reapplying sunscreen. Advice should be framed in the context of promoting outdoor physical activity. Adolescents should be strongly discouraged from visiting tanning parlors. Sun exposure and vitamin D status are intertwined. Cutaneous vitamin D production requires sunlight exposure, and many factors, such as skin pigmentation, season, and time of day, complicate efficiency of cutaneous vitamin D production that results from sun exposure. Adequate vitamin D is needed for bone health. Accumulating information suggests a beneficial influence of vitamin D on many health conditions. Although vitamin D is available through the diet, supplements, and incidental sun exposure, many children have low vitamin D concentrations. Ensuring vitamin D adequacy while promoting sun-protection strategies will require renewed attention to children's use of dietary and supplemental vitamin D. (2/11, reaffirmed 9/16)

http://pediatrics.aappublications.org/content/127/3/588

ULTRAVIOLET RADIATION: A HAZARD TO CHILDREN AND ADOLESCENTS (TECHNICAL REPORT)

Sophie J. Balk, MD; Council on Environmental Health; and Section on Dermatology

ABSTRACT. Sunlight sustains life on earth. Sunlight is essential for vitamin D synthesis in the skin. The sun's ultraviolet rays can be hazardous, however, because excessive exposure causes skin cancer and other adverse health effects. Skin cancer is a major public health problem; more than 2 million new cases are diagnosed in the United States each year. Ultraviolet radiation (UVR) causes the 3 major forms of skin cancer: basal cell carcinoma; squamous cell carcinoma; and cutaneous malignant melanoma. Exposure to UVR from sunlight and artificial sources early in life elevates the risk of developing skin cancer. Approximately 25% of sun exposure occurs before 18 years of age. The risk of skin cancer is increased when people overexpose themselves to sun and intentionally expose themselves to artificial sources of UVR. Public awareness of the risk is not optimal, compliance with sun protection is inconsistent, and skin-cancer rates continue to rise in all age groups including the younger population. People continue to sunburn, and teenagers and adults are frequent visitors to tanning parlors. Sun exposure and vitamin D status are intertwined. Adequate vitamin D is needed for bone health in children and adults. In addition, there is accumulating information suggesting a beneficial influence of vitamin D on various health conditions. Cutaneous vitamin D production requires sunlight,

and many factors complicate the efficiency of vitamin D production that results from sunlight exposure. Ensuring vitamin D adequacy while promoting sun-protection strategies, therefore, requires renewed attention to evaluating the adequacy of dietary and supplemental vitamin D. Daily intake of 400 IU of vitamin D will prevent vitamin D deficiency rickets in infants. The vitamin D supplementation amounts necessary to support optimal health in older children and adolescents are less clear. This report updates information on the relationship of sun exposure to skin cancer and other adverse health effects, the relationship of exposure to artificial sources of UVR and skin cancer, sun-protection methods, vitamin D, community skin-cancer–prevention efforts, and the pediatrician's role in preventing skin cancer. In addition to pediatricians' efforts, a sustained public health effort is needed to change attitudes and behaviors regarding UVR exposure. (2/11, reaffirmed 9/16)

UMBILICAL CORD CARE IN THE NEWBORN INFANT (CLINICAL REPORT)

Dan Stewart, MD, FAAP; William Benitz, MD, FAAP; and Committee on Fetus and Newborn

ABSTRACT. Postpartum infections remain a leading cause of neonatal morbidity and mortality worldwide. A high percentage of these infections may stem from bacterial colonization of the umbilicus, because cord care practices vary in reflection of cultural traditions within communities and disparities in health care practices globally. After birth, the devitalized umbilical cord often proves to be an ideal substrate for bacterial growth and also provides direct access to the bloodstream of the neonate. Bacterial colonization of the cord not infrequently leads to omphalitis and associated thrombophlebitis, cellulitis, or necrotizing fasciitis. Various topical substances continue to be used for cord care around the world to mitigate the risk of serious infection. More recently, particularly in high-resource countries, the treatment paradigm has shifted toward dry umbilical cord care. This clinical report reviews the evidence underlying recommendations for care of the umbilical cord in different clinical settings. (8/16)

UNDERSTANDING LIABILITY RISKS AND PROTECTIONS FOR PEDIATRIC PROVIDERS DURING DISASTERS

Robin L. Altman, MD, FAAP; Karen A. Santucci, MD, FAAP; Michael R. Anderson, MD, MBA, FAAP; William M. McDonnell, MD, JD, FAAP; and Committee on Medical Liability and Risk Management

ABSTRACT. Although most health care providers will go through their careers without experiencing a major disaster in their local communities, if one does occur, it can be life and career altering. The American Academy of Pediatrics has been at the forefront of providing education and advocacy on the critical importance of disaster preparedness. From experiences over the past decade, new evidence and analysis have broadened our understanding that the concept of preparedness is also applicable to addressing the unique professional liability risks that can occur when caring for patients and families during a disaster. In our recommendations in this policy statement, we target pediatric health care providers, advocates, and policy makers and address how individuals, institutions, and government can work together to strengthen the system of liability protections during disasters so that appropriate and timely care can be delivered with minimal fear of legal reprisal or confusion. (2/19)

https://pediatrics.aappublications.org/content/143/3/e20183892

UNDERSTANDING LIABILITY RISKS AND PROTECTIONS FOR PEDIATRIC PROVIDERS DURING DISASTERS (TECHNICAL REPORT)

Robin L. Altman, MD, FAAP; Karen A. Santucci, MD, FAAP; Michael R. Anderson, MD, MBA, FAAP; William M. McDonnell, MD, JD, FAAP; and Committee on Medical Liability and Risk Management

ABSTRACT. Although most health care providers will go through their careers without experiencing a major disaster in their local communities, if one does occur, it can be life and career altering. The American Academy of Pediatrics has been in the forefront of providing education and advocacy on the critical importance of disaster preparedness. From experiences over the past decade, new evidence and analysis have broadened our understanding that the concept of preparedness is also applicable to addressing the unique professional liability risks that can occur when caring for patients and families during a disaster. Concepts explored in this technical report will help to inform pediatric health care providers, advocates, and policy makers about the complexities of how providers are currently protected, with a focus on areas of unappreciated liability. The timeliness of this technical report is emphasized by the fact that during the time of its development (ie, late summer and early fall of 2017), the United States went through an extraordinary period of multiple, successive, and overlapping disasters within a concentrated period of time of both natural and man-made causes. In a companion policy statement (www.pediatrics.org/cgi/doi/10.1542/peds.2018-3892), recommendations are offered on how individuals, institutions, and governments can work together to strengthen the system of liability protections during disasters so that appropriate and timely care can be delivered with minimal fear of legal reprisal or confusion. (2/19)

UNIQUE NEEDS OF THE ADOLESCENT

Elizabeth M. Alderman, MD, FSAHM, FAAP; Cora C. Breuner, MD, MPH, FAAP; and Committee on Adolescence

ABSTRACT. Adolescence is the transitional bridge between childhood and adulthood; it encompasses developmental milestones that are unique to this age group. Healthy cognitive, physical, sexual, and psychosocial development is both a right and a responsibility that must be guaranteed for all adolescents to successfully enter adulthood. There is consensus among national and international organizations that the unique needs of adolescents must be addressed and promoted to ensure the health of all adolescents. This policy statement outlines the special health challenges that adolescents face on their journey and transition to adulthood and provides recommendations for those who care for adolescents, their families, and the communities in which they live. (11/19)

UPDATE OF NEWBORN SCREENING AND THERAPY FOR CONGENITAL HYPOTHYROIDISM (CLINICAL REPORT)

Susan R. Rose, MD; Section on Endocrinology; and Committee on Genetics (joint with Rosalind S. Brown, MD; American Thyroid Association; and Lawson Wilkins Pediatric Endocrine Society)

ABSTRACT. Unrecognized congenital hypothyroidism leads to mental retardation. Newborn screening and thyroid therapy started within 2 weeks of age can normalize cognitive development. The primary thyroid-stimulating hormone screening has become standard in many parts of the world. However, newborn thyroid screening is not yet universal in some countries. Initial dosage of 10 to 15 μg/kg levothyroxine is recommended. The goals of thyroid hormone therapy should be to maintain frequent evaluations of total thyroxine or free thyroxine in the upper half of the reference range during the first 3 years of

life and to normalize the serum thyroid-stimulating hormone concentration to ensure optimal thyroid hormone dosage and compliance.

Improvements in screening and therapy have led to improved developmental outcomes in adults with congenital hypothyroidism who are now in their 20s and 30s. Thyroid hormone regimens used today are more aggressive in targeting early correction of thyroid-stimulating hormone than were those used 20 or even 10 years ago. Thus, newborn infants with congenital hypothyroidism today may have an even better intellectual and neurologic prognosis. Efforts are ongoing to establish the optimal therapy that leads to maximum potential for normal development for infants with congenital hypothyroidism.

Remaining controversy centers on infants whose abnormality in neonatal thyroid function is transient or mild and on optimal care of very low birth weight or preterm infants. Of note, thyroid-stimulating hormone is not elevated in central hypothyroidism. An algorithm is proposed for diagnosis and management.

Physicians must not relinquish their clinical judgment and experience in the face of normal newborn thyroid test results. Hypothyroidism can be acquired after the newborn screening. When clinical symptoms and signs suggest hypothyroidism, regardless of newborn screening results, serum free thyroxine and thyroid-stimulating hormone determinations should be performed. (6/06, reaffirmed 12/11)

UPDATED GUIDANCE FOR PALIVIZUMAB PROPHYLAXIS AMONG INFANTS AND YOUNG CHILDREN AT INCREASED RISK OF HOSPITALIZATION FOR RESPIRATORY SYNCYTIAL VIRUS INFECTION

Committee on Infectious Diseases and Bronchiolitis Guidelines Committee

ABSTRACT. Palivizumab was licensed in June 1998 by the Food and Drug Administration for the reduction of serious lower respiratory tract infection caused by respiratory syncytial virus (RSV) in children at increased risk of severe disease. Since that time, the American Academy of Pediatrics has updated its guidance for the use of palivizumab 4 times as additional data became available to provide a better understanding of infants and young children at greatest risk of hospitalization attributable to RSV infection. The updated recommendations in this policy statement reflect new information regarding the seasonality of RSV circulation, palivizumab pharmacokinetics, the changing incidence of bronchiolitis hospitalizations, the effect of gestational age and other risk factors on RSV hospitalization rates, the mortality of children hospitalized with RSV infection, the effect of prophylaxis on wheezing, and palivizumab-resistant RSV isolates. (7/14, reaffirmed 2/19)

http://pediatrics.aappublications.org/content/134/2/415

UPDATED GUIDANCE FOR PALIVIZUMAB PROPHYLAXIS AMONG INFANTS AND YOUNG CHILDREN AT INCREASED RISK OF HOSPITALIZATION FOR RESPIRATORY SYNCYTIAL VIRUS INFECTION (TECHNICAL REPORT)

Committee on Infectious Diseases and Bronchiolitis Guidelines Committee

ABSTRACT. Guidance from the American Academy of Pediatrics (AAP) for the use of palivizumab prophylaxis against respiratory syncytial virus (RSV) was first published in a policy statement in 1998. Guidance initially was based on the result from a single randomized, placebo-controlled clinical trial conducted in 1996–1997 describing an overall reduction in RSV hospitalization rate from 10.6% among placebo recipients to 4.8% among children who received prophylaxis. The results of a second randomized, placebo-controlled trial of children with hemodynamically significant heart disease were published in 2003 and revealed a reduction in RSV hospitalization rate from 9.7% in control subjects to 5.3% among prophylaxis recipients. Because no additional controlled trials regarding efficacy were published, AAP guidance has been updated periodically to reflect the most recent literature regarding children at greatest risk of severe disease. Since the last update in 2012, new data have become available regarding the seasonality of RSV circulation, palivizumab pharmacokinetics, the changing incidence of bronchiolitis hospitalizations, the effects of gestational age and other risk factors on RSV hospitalization rates, the mortality of children hospitalized with RSV infection, and the effect of prophylaxis on wheezing and palivizumab-resistant RSV isolates. These data enable further refinement of AAP guidance to most clearly focus on those children at greatest risk. (7/14)

http://pediatrics.aappublications.org/content/134/2/e620

UPDATES ON AN AT-RISK POPULATION: LATE-PRETERM AND EARLY-TERM INFANTS (CLINICAL REPORT)

Dan L. Stewart, MD, FAAP; Wanda D. Barfield, MD, MPH, FAAP, RADM, USPHS; Committee on Fetus and Newborn

ABSTRACT. The American Academy of Pediatrics published a clinical report on late-preterm (LPT) infants in 2007 that was largely based on a summary of a 2005 workshop convened by the *Eunice Kennedy Shriver* National Institute of Child Health and Human Development, at which a change in terminology from "near term" to "late preterm" was proposed. This paradigm-shifting recommendation had a remarkable impact: federal agencies (the Centers for Disease Control and Prevention), professional societies (the American Academy of Pediatrics and American College of Obstetricians and Gynecologists), and organizations (March of Dimes) initiated nationwide monitoring and educational plans that had a significant effect on decreasing the rates of iatrogenic LPT deliveries. However, there is now an evolving concern. After nearly a decade of steady decreases in the LPT birth rate that largely contributed to the decline in total US preterm birth rates, the birth rate in LPT infants has been inching upward since 2015. In addition, evidence revealed by strong population health research demonstrates that being born as an early-term infant poses a significant risk to an infant's survival, growth, and development. In this report, we summarize the initial progress and discuss the potential reasons for the current trends in LPT and early-term birth rates and propose research recommendations. (10/19)

USE OF CHAPERONES DURING THE PHYSICAL EXAMINATION OF THE PEDIATRIC PATIENT

Committee on Practice and Ambulatory Medicine

ABSTRACT. Physicians should always communicate the scope and nature of the physical examination to be performed to the pediatric patient and his or her parent. This statement addresses the use of chaperones and issues of patient comfort, confidentiality, and privacy. The use of a chaperone should be a shared decision between the patient and physician. In some states, the use of a chaperone is mandated by state regulations. (4/11, 11/17)

http://pediatrics.aappublications.org/content/127/5/991

USE OF INHALED NITRIC OXIDE IN PRETERM INFANTS (CLINICAL REPORT)

Praveen Kumar, MD, FAAP, and Committee on Fetus and Newborn

ABSTRACT. Nitric oxide, an important signaling molecule with multiple regulatory effects throughout the body, is an important tool for the treatment of full-term and late-preterm infants with persistent pulmonary hypertension of the newborn and hypoxemic respiratory failure. Several randomized controlled trials have evaluated its role in the management of preterm infants

≤34 weeks' gestational age with varying results. The purpose of this clinical report is to summarize the existing evidence for the use of inhaled nitric oxide in preterm infants and provide guidance regarding its use in this population. (12/13)
http://pediatrics.aappublications.org/content/133/1/164

THE USE OF NONNUTRITIVE SWEETENERS IN CHILDREN

Carissa M. Baker-Smith, MD, MPH, FAAP; Sarah D. de Ferranti, MD, MPH, FAAP; William J. Cochran, MD, FAAP; Committee on Nutrition; and Section on Gastroenterology, Hepatology, and Nutrition

ABSTRACT. The prevalence of nonnutritive sweeteners (NNSs) in the food supply has increased over time. Not only are more children and adolescents consuming NNSs, but they are also consuming a larger quantity of NNSs in the absence of strong scientific evidence to refute or support the safety of these agents. This policy statement from the American Academy of Pediatrics is intended to provide the pediatric provider with a review of (1) previous steps taken for approved use of NNSs, (2) existing data regarding the safety of NNS use in the general pediatric population, (3) what is known regarding the potential benefits and/or adverse effects of NNS use in children and adolescents, (4) identified gaps in existing knowledge and potential areas of future research, and (5) suggested talking points that pediatricians may use when discussing NNS use with families. (10/19)
https://pediatrics.aappublications.org/content/144/5/e20192765

USE OF PERFORMANCE-ENHANCING SUBSTANCES (CLINICAL REPORT)

Michele LaBotz, MD, FAAP; Bernard A. Griesemer, MD, FAAP; and Council on Sports Medicine and Fitness

ABSTRACT. Performance-enhancing substances (PESs) are used commonly by children and adolescents in attempts to improve athletic performance. More recent data reveal that these same substances often are used for appearance-related reasons as well. PESs include both legal over-the-counter dietary supplements and illicit pharmacologic agents. This report reviews the current epidemiology of PES use in the pediatric population, as well as information on those PESs in most common use. Concerns regarding use of legal PESs include high rates of product contamination, correlation with future use of anabolic androgenic steroids, and adverse effects on the focus and experience of youth sports participation. The physical maturation and endogenous hormone production that occur in adolescence are associated with large improvements in strength and athletic performance. For most young athletes, PES use does not produce significant gains over those seen with the onset of puberty and adherence to an appropriate nutrition and training program. (6/16)
http://pediatrics.aappublications.org/content/138/1/e20161300

THE USE OF SYSTEMIC AND TOPICAL FLUOROQUINOLONES (CLINICAL REPORT)

Mary Anne Jackson, MD, FAAP; Gordon E. Schutze, MD, FAAP; and Committee on Infectious Diseases

ABSTRACT. Appropriate prescribing practices for fluoroquinolones, as well as all antimicrobial agents, are essential as evolving resistance patterns are considered, additional treatment indications are identified, and the toxicity profile of fluoroquinolones in children has become better defined. Earlier recommendations for systemic therapy remain; expanded uses of fluoroquinolones for the treatment of certain infections are outlined in this report. Prescribing clinicians should be aware of specific adverse reactions associated with fluoroquinolones, and their use in children should continue to be limited to the treatment of infections for which no safe and effective alternative exists or in situations in which oral fluoroquinolone treatment represents a reasonable alternative to parenteral antimicrobial therapy. (10/16)
http://pediatrics.aappublications.org/content/138/5/e20162706

THE USE OF TELEMEDICINE TO ADDRESS ACCESS AND PHYSICIAN WORKFORCE SHORTAGES

Committee on Pediatric Workforce

ABSTRACT. The use of telemedicine technologies by primary care pediatricians, pediatric medical subspecialists, and pediatric surgical specialists (henceforth referred to as "pediatric physicians") has the potential to transform the practice of pediatrics. The purpose of this policy statement is to describe the expected and potential impact that telemedicine will have on pediatric physicians' efforts to improve access and physician workforce shortages. The policy statement also describes how the American Academy of Pediatrics can advocate for its members and their patients to best use telemedicine technologies to improve access to care, provide more patient- and family-centered care, increase efficiencies in practice, enhance the quality of care, and address projected shortages in the clinical workforce. As the use of telemedicine increases, it is likely to impact health care access, quality, and education and costs of care. Telemedicine technologies, applied to the medical home and its collaborating providers, have the potential to improve current models of care by increasing communication among clinicians, resulting in more efficient, higher quality, and less expensive care. Such a model can serve as a platform for providing more continuous care, linking primary and specialty care to support management of the needs of complex patients. In addition, telemedicine technologies can be used to efficiently provide pediatric physicians working in remote locations with ongoing medical education, increasing their ability to care for more complex patients in their community, reducing the burdens of travel on patients and families, and supporting the medical home. On the other hand, telemedicine technologies used for episodic care by nonmedical home providers have the potential to disrupt continuity of care and to create redundancy and imprudent use of health care resources. Fragmentation should be avoided, and telemedicine, like all primary and specialty services, should be coordinated through the medical home. (6/15, reaffirmed 5/19)
http://pediatrics.aappublications.org/content/136/1/202

VIRTUAL VIOLENCE

Council on Communications and Media

ABSTRACT. In the United States, exposure to media violence is becoming an inescapable component of children's lives. With the rise in new technologies, such as tablets and new gaming platforms, children and adolescents increasingly are exposed to what is known as "virtual violence." This form of violence is not experienced physically; rather, it is experienced in realistic ways via new technology and ever more intense and realistic games. The American Academy of Pediatrics continues to be concerned about children's exposure to virtual violence and the effect it has on their overall health and well-being. This policy statement aims to summarize the current state of scientific knowledge regarding the effects of virtual violence on children's attitudes and behaviors and to make specific recommendations for pediatricians, parents, industry, and policy makers. (7/16)

VISUAL SYSTEM ASSESSMENT IN INFANTS, CHILDREN, AND YOUNG ADULTS BY PEDIATRICIANS

Committee on Practice and Ambulatory Medicine and Section on Ophthalmology (joint with American Association of Certified Orthoptists, American Association for Pediatric Ophthalmology and Strabismus, and American Academy of Ophthalmology)

ABSTRACT. Appropriate visual assessments help identify children who may benefit from early interventions to correct or improve vision. Examination of the eyes and visual system should begin in the nursery and continue throughout both childhood and adolescence during routine well-child visits

in the medical home. Newborn infants should be examined using inspection and red reflex testing to detect structural ocular abnormalities, such as cataract, corneal opacity, and ptosis. Instrument-based screening, if available, should be first attempted between 12 months and 3 years of age and at annual well-child visits until acuity can be tested directly. Direct testing of visual acuity can often begin by 4 years of age, using age-appropriate symbols (optotypes). Children found to have an ocular abnormality or who fail a vision assessment should be referred to a pediatric ophthalmologist or an eye care specialist appropriately trained to treat pediatric patients. (12/15)

WITHHOLDING OR TERMINATION OF RESUSCITATION IN PEDIATRIC OUT-OF-HOSPITAL TRAUMATIC CARDIOPULMONARY ARREST

Committee on Pediatric Emergency Medicine (joint with American College of Surgeons Committee on Trauma and National Association of EMS Physicians)

ABSTRACT. This multiorganizational literature review was undertaken to provide an evidence base for determining whether recommendations for out-of-hospital termination of resuscitation could be made for children who are victims of traumatic cardiopulmonary arrest. Although there is increasing acceptance of out-of-hospital termination of resuscitation for adult traumatic cardiopulmonary arrest when there is no expectation of a good outcome, children are routinely excluded from state termination-of-resuscitation protocols. The decision to withhold resuscitative efforts in a child under specific circumstances (decapitation or dependent lividity, rigor mortis, etc) is reasonable. If there is any doubt as to the circumstances or timing of the traumatic cardiopulmonary arrest, under the current status of limiting termination of resuscitation in the field to persons older than 18 years in most states, resuscitation should be initiated and continued until arrival to the appropriate facility. If the patient has arrested, resuscitation has already exceeded 30 minutes, and the nearest facility is more than 30 minutes away, involvement of parents and family of these children in the decision-making process with assistance and guidance from medical professionals should be considered as part of an emphasis on family-centered care because the evidence suggests that either death or a poor outcome is inevitable. (3/14, reaffirmed 6/20)

YOUTH PARTICIPATION AND INJURY RISK IN MARTIAL ARTS (CLINICAL REPORT)

Rebecca A. Demorest, MD, FAAP; Chris Koutures, MD, FAAP; and Council on Sports Medicine and Fitness

ABSTRACT. The martial arts can provide children and adolescents with vigorous levels of physical exercise that can improve overall physical fitness. The various types of martial arts encompass noncontact basic forms and techniques that may have a lower relative risk of injury. Contact-based sparring with competitive training and bouts have a higher risk of injury. This clinical report describes important techniques and movement patterns in several types of martial arts and reviews frequently reported injuries encountered in each discipline, with focused discussions of higher risk activities. Some of these higher risk activities include blows to the head and choking or submission movements that may cause concussions or significant head injuries. The roles of rule changes, documented benefits of protective equipment, and changes in training recommendations in attempts to reduce injury are critically assessed. This information is intended to help pediatric health care providers counsel patients and families in encouraging safe participation in martial arts. (11/16)

ADVANCED PRACTICE REGISTERED NURSE: ROLE, PREPARATION, AND SCOPE OF PRACTICE

National Association of Neonatal Nurses

ABSTRACT. In recent years, the National Association of Neonatal Nurses (NANN) and the National Association of Neonatal Nurse Practitioners (NANNP) have developed several policy statements on neonatal advanced practice registered nurse (APRN) workforce, education, competency, fatigue, safety, and scope of practice. This position paper is a synthesis of previous efforts and discusses the role, preparation, and scope of practice of the neonatal APRN. (1/14)

ANTENATAL CORTICOSTEROID THERAPY FOR FETAL MATURATION

American College of Obstetricians and Gynecologists

ABSTRACT. Corticosteroid administration before anticipated preterm birth is one of the most important antenatal therapies available to improve newborn outcomes. A single course of corticosteroids is recommended for pregnant women between 24 0/7 weeks and 33 6/7 weeks of gestation who are at risk of preterm delivery within 7 days, including for those with ruptured membranes and multiple gestations. It also may be considered for pregnant women starting at 23 0/7 weeks of gestation who are at risk of preterm delivery within 7 days, based on a family's decision regarding resuscitation, irrespective of membrane rupture status and regardless of fetal number. Administration of betamethasone may be considered in pregnant women between 34 0/7 weeks and 36 6/7 weeks of gestation who are at risk of preterm birth within 7 days, and who have not received a previous course of antenatal corticosteroids. A single repeat course of antenatal corticosteroids should be considered in women who are less than 34 0/7 weeks of gestation who are at risk of preterm delivery within 7 days, and whose prior course of antenatal corticosteroids was administered more than 14 days previously. Rescue course corticosteroids could be provided as early as 7 days from the prior dose, if indicated by the clinical scenario. Continued surveillance of long-term outcomes after in utero corticosteroid exposure should be supported. Quality improvement strategies to optimize appropriate and timely antenatal corticosteroid administration are encouraged. (8/17)

APPROPRIATE USE CRITERIA FOR INITIAL TRANSTHORACIC ECHOCARDIOGRAPHY IN OUTPATIENT PEDIATRIC CARDIOLOGY

American College of Cardiology Appropriate Use Task Force

ABSTRACT. The American College of Cardiology (ACC) participated in a joint project with the American Society of Echocardiography, the Society of Pediatric Echocardiography, and several other subspecialty societies and organizations to establish and evaluate Appropriate Use Criteria (AUC) for the initial use of outpatient pediatric echocardiography. Assumptions for the AUC were identified, including the fact that all indications assumed a first-time transthoracic echocardiographic study in an outpatient setting for patients without previously known heart disease. The definitions for frequently used terminology in outpatient pediatric cardiology were established using published guidelines and standards and expert opinion. These AUC serve as a guide to help clinicians in the care of children with possible heart disease, specifically in terms of when a transthoracic echocardiogram is warranted as an initial diagnostic modality in the outpatient setting. They are also a useful tool for education and provide the infrastructure for future quality improvement initiatives as well as research in healthcare delivery, outcomes, and resource utilization.

To complete the AUC process, the writing group identified 113 indications based on common clinical scenarios and/or published clinical practice guidelines, and each indication was classified into 1 of 9 categories of common clinical presentations, including palpitations, syncope, chest pain, and murmur. A separate, independent rating panel evaluated each indication using a scoring scale of 1 to 9, thereby designating each indication as "Appropriate" (median score 7 to 9), "May Be Appropriate" (median score 4 to 6), or "Rarely Appropriate" (median score 1 to 3). Fifty-three indications were identified as Appropriate, 28 as May Be Appropriate, and 32 as Rarely Appropriate. (11/14)

CHILDREN'S SURGERY VERIFICATION

OPTIMAL RESOURCES FOR CHILDREN'S SURGICAL CARE

American College of Surgeons

EXECUTIVE SUMMARY. The Task Force for Children's Surgical Care, an ad hoc multidisciplinary group of invited leaders in relevant disciplines, assembled initially from April 30 to May 1, 2012, in Rosemont, IL, and subsequently in 2013, 2014, and 2015 to consider approaches to optimize the delivery of children's surgical care in today's competitive national health care environment. Specifically, a mismatch between individual patient needs and available clinical resources for some infants and children receiving surgical care is recognized as a problem in the United States and elsewhere. Although this phenomenon is apparent to most practitioners involved with children's surgical care, comprehensive data are not available, and relevant data are imperfect. The scope of this problem is unknown at present. However, the situation does periodically, and possibly systematically, result in suboptimal patient outcomes.

The composition of the task force is detailed in Appendix 4. The Children's Hospital Association and the American College of Surgeons (ACS) provided support. The group represented key disciplines and perspectives. Published literature and data were used when available, and expert opinion when not, as the basis for these recommendations. The objective was to develop consensus recommendations that would be of use to relevant policymakers and to providers.

Principles regarding resource standards, quality-improvement and safety processes, data collection, and a verification process were initially published in March 2014 [*J Am Coll Surg*. 2014;218(3):479–487]. This document details those principles in a specific manner designed to inform and direct a verification process to be conducted by the ACS and the ACS Children's Surgery Verification Committee.

Notably, there are a number of excellent children's specialty hospitals in the United States whose scope of service is more narrow than delineated in this document. A separate process will be used to develop relevant standards for those institutions to achieve the vision of prospectively matching institutional resources with individual patient needs. (12/15)

COLLABORATION IN PRACTICE: IMPLEMENTING TEAM-BASED CARE

American College of Obstetricians and Gynecologists Task Force on Collaborative Practice

INTRODUCTION. Quality, efficiency, and value are necessary characteristics of our evolving health care system. Team-based care will work toward the Triple Aim of 1) improving the experience of care of individuals and families; 2) improving the health of populations; and 3) lowering per capita costs. It also should respond to emerging demands and reduce undue burdens on health care providers. Team-based care has the ability to more effectively meet the core expectations of the health care system proposed by the Institute of Medicine. These expectations require that care be safe, effective, patient centered, timely, efficient, and equitable. This report outlines a mechanism that all specialties and practices can use to achieve these expectations.

The report was written by the interprofessional Task Force on Collaborative Practice and is intended to appeal to multiple specialties (eg, internal medicine, pediatrics, family medicine, and women's health) and professions (eg, nurse practitioners, certified nurse–midwives/certified midwives, physician assistants, physicians, clinical pharmacists, and advanced practice registered nurses). This document provides a framework for organizations or practices across all specialties to develop team-based care. In doing so, it offers a map to help practices navigate the increasingly complex and continuously evolving health care system. The guidance presented is a result of the task force's work and is based on current evidence and expert consensus. The task force challenges and welcomes all medical specialties to gather additional data on how and what types of team-based care best accomplish the Triple Aim and the Institute of Medicine's expectations of health care. (3/16)

CONFIDENTIALITY PROTECTIONS FOR ADOLESCENTS AND YOUNG ADULTS IN THE HEALTH CARE BILLING AND INSURANCE CLAIMS PROCESS

Society for Adolescent Health and Medicine

ABSTRACT. The importance of protecting confidential health care for adolescents and young adults is well documented. State and federal confidentiality protections exist for both minors and young adults, although the laws vary among states, particularly for minors. However, such confidentiality is potentially violated by billing practices and in the processing of health insurance claims. To address this problem, policies and procedures should be established so that health care billing and insurance claims processes do not impede the ability of providers to deliver essential health care services on a confidential basis to adolescents and young adults covered as dependents on a family's health insurance plan. (3/16)

CONSENSUS COMMUNICATION ON EARLY PEANUT INTRODUCTION AND THE PREVENTION OF PEANUT ALLERGY IN HIGH-RISK INFANTS

Primary contributors: David M. Fleischer, MD; Scott Sicherer, MD; Matthew Greenhawt, MD; Dianne Campbell, MB BS, FRACP, PhD; Edmond Chan, MD; Antonella Muraro, MD, PhD; Susanne Halken, MD; Yitzhak Katz, MD; Motohiro Ebisawa, MD, PhD; Lawrence Eichenfield, MD; Hugh Sampson, MD; Gideon Lack, MB, BCh; and George Du Toit, MB, BCh

INTRODUCTION AND RATIONALE. Peanut allergy is an increasingly troubling global health problem affecting between 1% and 3% of children in many westernized countries. Although multiple methods of measurement have been used and specific estimates differ, there appears to have been a sudden increase in the number of cases in the past 10- to 15-year period, suggesting that the prevalence might have tripled in some countries, such as the United States. Extrapolating the currently estimated prevalence, this translates to nearly 100 000 new cases annually (in the United States and United Kingdom), affecting some 1 in 50 primary school-aged children in the United States, Canada, the United Kingdom, and Australia. A similar increase in incidence is now being noted in developing countries, such as Ghana.

The purpose of this brief communication is to highlight emerging evidence for existing allergy prevention guidelines regarding potential benefits of supporting early rather than delayed peanut introduction during the period of complementary food introduction in infants. A recent study entitled ''Randomized trial of peanut consumption in infants at risk for peanut allergy'' demonstrated a successful 11% to 25% absolute reduction in the risk of peanut allergy in high-risk infants (and a relative risk reduction of up to 80%) if peanut was introduced between 4 and 11 months of age. In light of the significance of these findings, this document serves to better inform the decision-making process for health care providers regarding such potential benefits of early peanut introduction. More formal guidelines regarding early-life, complementary feeding practices and the risk of allergy development will follow in the next year from the National Institute of Allergy and Infectious Diseases (NIAID)–sponsored Working Group and the European Academy of Allergy and Clinical Immunology (EAACI), and thus this document should be considered interim guidance. (8/15)

CONSENSUS STATEMENT: ABUSIVE HEAD TRAUMA IN INFANTS AND YOUNG CHILDREN

Arabinda Kumar Choudhary; Sabah Servaes; Thomas L. Slovis; Vincent J. Palusci; Gary L. Hedlund; Sandeep K. Narang; Joëlle Anne Moreno; Mark S. Dias; Cindy W. Christian; Marvin D. Nelson Jr; V. Michelle Silvera; Susan Palasis; Maria Raissaki; Andrea Rossi; and Amaka C. Offiah

ABSTRACT. Abusive head trauma (AHT) is the leading cause of fatal head injuries in children younger than 2 years. A multidisciplinary team bases this diagnosis on history, physical examination, imaging and laboratory findings. Because the etiology of the injury is multifactorial (shaking, shaking and impact, impact, etc.) the current best and inclusive term is AHT. There is no controversy concerning the medical validity of the existence of AHT, with multiple components including subdural hematoma, intracranial and spinal changes, complex retinal hemorrhages, and rib and other fractures that are inconsistent with the provided mechanism of trauma. The workup must exclude medical diseases that can mimic AHT. However, the courtroom has become a forum for speculative theories that cannot be reconciled with generally accepted medical literature. There is no reliable medical evidence that the following processes are causative in the constellation of injuries of AHT: cerebral sinovenous thrombosis, hypoxic-ischemic injury, lumbar puncture or dysphagic choking/vomiting. There is no substantiation, at a time remote from birth, that an asymptomatic birth-related subdural hemorrhage can result in rebleeding and sudden collapse. Further, a diagnosis of AHT is a medical conclusion, not a legal determination of the intent of the perpetrator or a diagnosis of murder. We hope that this consensus document reduces confusion by recommending to judges and jurors the tools necessary to distinguish genuine evidence-based opinions of the relevant medical community from legal arguments or etiological speculations that are unwarranted by the clinical findings, medical evidence and evidence-based literature. (5/18)

CONSENSUS STATEMENT: DEFINITIONS FOR CONSISTENT EMERGENCY DEPARTMENT METRICS

DEFINING PEDIATRIC MALNUTRITION: A PARADIGM SHIFT TOWARD ETIOLOGY-RELATED DEFINITIONS

American Society for Parenteral and Enteral Nutrition

ABSTRACT. Lack of a uniform definition is responsible for underrecognition of the prevalence of malnutrition and its impact on outcomes in children. A pediatric malnutrition definitions workgroup reviewed existing pediatric age group English-language literature from 1955 to 2011, for relevant references related to 5 domains of the definition of *malnutrition* that were *a priori* identified: anthropometric parameters, growth, chronicity of malnutrition, etiology and pathogenesis, and developmental/functional outcomes. Based on available evidence and an iterative process to arrive at multidisciplinary consensus in the group, these domains were included in the overall construct of a new definition. Pediatric malnutrition (undernutrition) is defined as an imbalance between nutrient requirements and intake that results in cumulative deficits of energy, protein, or micronutrients that may negatively affect growth, development, and other relevant outcomes. A summary of the literature is presented and a new classification scheme is proposed that incorporates chronicity, etiology, mechanisms of nutrient imbalance, severity of malnutrition, and its impact on outcomes. Based on its etiology, malnutrition is either *illness related* (secondary to 1 or more diseases/injury) or *non–illness related*, (caused by environmental/behavioral factors), or both. Future research must focus on the relationship between inflammation and illness-related malnutrition. We anticipate that the definition of malnutrition will continue to evolve with improved understanding of the processes that lead to and complicate the treatment of this condition. A uniform definition should permit future research to focus on the impact of pediatric malnutrition on functional outcomes and help solidify the scientific basis for evidence-based nutrition practices. (3/13)

DELAYED UMBILICAL CORD CLAMPING AFTER BIRTH

American College of Obstetricians and Gynecologists

ABSTRACT. Delayed umbilical cord clamping appears to be beneficial for term and preterm infants. In term infants, delayed umbilical cord clamping increases hemoglobin levels at birth and improves iron stores in the first several months of life, which may have a favorable effect on developmental outcomes. There is a small increase in jaundice that requires phototherapy in this group of infants. Consequently, health care providers adopting delayed umbilical cord clamping in term infants should ensure that mechanisms are in place to monitor for and treat neonatal jaundice. In preterm infants, delayed umbilical cord clamping is associated with significant neonatal benefits, including improved transitional circulation, better establishment of red blood cell volume, decreased need for blood transfusion, and lower incidence of necrotizing enterocolitis and intraventricular hemorrhage. Delayed umbilical cord clamping was not associated with an increased risk of postpartum hemorrhage or increased blood loss at delivery, nor was it associated with a difference in postpartum hemoglobin levels or the need for blood transfusion. Given the benefits to most newborns and concordant with other professional organizations, the American College of Obstetricians and Gynecologists now recommends a delay in umbilical cord clamping in vigorous term and preterm infants for at least 30–60 seconds after birth. The ability to provide delayed umbilical cord clamping may vary among institutions and settings; decisions in those circumstances are best made by the team caring for the mother–infant dyad. (1/17)

EPIDEMIOLOGY IN FIREARM VIOLENCE PREVENTION

Amy B. Davis; James A. Gaudino; Colin L. Soskolne; Wael K. Al-Delaimy; and International Network for Epidemiology in Policy

INTRODUCTION. Firearm violence has reached pandemic levels, with some countries experiencing high injury and death rates from privately owned guns and firearms (hereinafter collectively referred to as 'firearms'). Significant factors in the increase in deaths and injuries from privately held firearms include the ease of obtaining these arms and, most importantly, the growing lethality of these weapons.

Society cannot be satisfied with reactive responses only in treating victims' physical and psychological wounds after these occurrences; more must be done proactively to prevent firearm violence and address societal circumstances that either facilitate or impede it. Where they exist, well-intended policies fail to adequately protect people from firearm violence, often because they mainly focus on the purchase and illegal uses of guns while neglecting underlying social determinants of the violent uses of firearms.

Laws intended to curb firearm violence are often not enforced, are inadequate or do not address local societal factors of crime, mental well-being, poverty or low education in the relevant communities. These considerations point to the need for a multisectoral approach in which the public health sciences would play a pivotal role in preventing harms relating to firearm violence with a greater focus on its causes. Evidence-based multicomponent interventions, often shown by systematic reviews to be the most effective to address complex, community-level health issues, are needed but are not well-defined to address firearm violence. To both advance understanding of and to guide community-level public health services and actions needed to prevent firearm violence, decision-makers need to rely more on surveillance, research and programme evaluation by public health organizations, schools and universities.

Epidemiologists have unique interdisciplinary tools for addressing the contributors and barriers to preventing and mitigating injury, including firearm violence. These include quantitative, qualitative and social epidemiological methods. Interventions to prevent and mitigate the problem are currently under-developed, under-funded and under-utilized, particularly in the USA. The problem could be addressed by putting in place a robust evidence base to inform policy decisions. Additionally, public health can create, scale up and evaluate interventions designed to address social and behavioural factors associated with firearm violence. We call on governments, community leaders and community members to take meaningful action to support public health in addressing the problem of firearm violence. (4/18)

ETHICAL CONSIDERATION FOR INCLUDING WOMEN AS RESEARCH PARTICIPANTS

American College of Obstetricians and Gynecologists

ABSTRACT. Inclusion of women in research studies is necessary for valid inferences about health and disease in women. The generalization of results from trials conducted in men may yield erroneous conclusions that fail to account for the biologic differences between men and women. Although significant changes in research design and practice have led to an increase in the proportion of women included in research trials, knowledge gaps remain because of a continued lack of inclusion of women, especially those who are pregnant, in premarketing research trials. This document provides a historical overview of issues surrounding women as participants in research trials, followed by an ethical framework and discussion of the issues of informed consent, contraception requirements, intimate partner consent, and the appropriate inclusion of pregnant women in research studies. EVIDENCE-BASED MANAGEMENT OF SICKLE CELL DISEASE: EXPERT PANEL REPORT, 2014

National Heart, Lung, and Blood Institute (2014)

FACULTY COMPETENCIES FOR GLOBAL HEALTH

Academic Pediatric Association Global Health Task Force

International partnerships among medical professionals from different countries are an increasingly common form of clinical and academic collaboration. Global health partnerships can include a variety of activities and serve multiple purposes in the areas of research, medical education and training, health system improvement, and clinical care. Competency domains, introduced by the Accreditation Council for Graduate Medical Education and the American Board of Medical Specialties in 1999, are now widely accepted to provide an organized, structured set of interrelated competencies, mostly for medical trainees. Although there are now competency domains and specific competencies recommended for pediatric trainees pursuing further professional training in global child health, none of these addresses competencies for faculty in global health.

In 2010 the Academic Pediatric Association established a Global Health Task Force to provide a forum for communication and collaboration for diverse pediatric academic societies and groups to advance global child health. Given the burgeoning demand for global health training, and particularly in light of a new global perspective on health education, as outlined in a Lancet Commission Report: *Health Professionals for a New Century: Transforming Education to Strengthen Health Systems in an Interdependent World,* in 2012 the Global Health Task Force noted the lack of defined faculty competencies and decided to develop a set of global health competencies for pediatric faculty engaged in the teaching and practice of global health. Using some of the principles suggested by Milner, et al. to define a competency framework, four domains were chosen, adapted from existing collaborative practice competencies. A fifth domain was added to address some of the unique challenges of global health practice encountered when working outside of one's own culture and health system. The domains are described below and specific competencies are provided for faculty working in global health research, education, administration, and clinical practice. (6/14)

GUIDELINES FOR FIELD TRIAGE OF INJURED PATIENTS

IMPORTANCE AND IMPLEMENTATION OF TRAINING IN CARDIOPULMONARY RESUSCITATION AND AUTOMATED EXTERNAL DEFIBRILLATION IN SCHOOLS

American Heart Association Emergency Cardiovascular Care Committee; Council on Cardiopulmonary, Critical Care, Perioperative and Resuscitation; Council on Cardiovascular Diseases in the Young; Council on Cardiovascular Nursing; Council on Clinical Cardiology; and Advocacy Coordinating Committee

ABSTRACT. In 2003, the International Liaison Committee on Resuscitation published a consensus document on education in resuscitation that strongly recommended that "…instruction in CPR [cardiopulmonary resuscitation] be incorporated as a standard part of the school curriculum." The next year the American Heart Association (AHA) recommended that schools "…establish a goal to train every teacher in CPR and first aid and train all students in CPR" as part of their preparation for a response to medical emergencies on campus.

Since that time, there has been an increased interest in legislation that would mandate that school curricula include training in CPR or CPR and automated external defibrillation. Laws or curriculum content standards in 36 states (as of the 2009–2010 school year) now encourage the inclusion of CPR training programs in school curricula. The language in those laws and standards varies greatly, ranging from a suggestion that students "recognize" the steps of CPR to a requirement for certification in CPR. Not surprisingly, then, implementation is not uniform among states, even those whose laws or standards encourage CPR training in schools in the strongest language. This statement recommends that training in CPR and familiarization with automated external defibrillators (AEDs) should be required elements of secondary school curricula and provides the rationale for implementation of CPR training, as well as guidance in overcoming barriers to implementation. (2/11)

MENSTRUATION IN GIRLS AND ADOLESCENTS: USING THE MENSTRUAL CYCLE AS A VITAL SIGN

American College of Obstetricians and Gynecologists Committee on Adolescent Health Care

ABSTRACT. Despite variations worldwide and within the U.S. population, median age at menarche has remained relatively stable—between 12 years and 13 years—across well-nourished populations in developed countries. Environmental factors, including socioeconomic conditions, nutrition, and access to preventive health care, may influence the timing and progression of puberty. A number of medical conditions can cause abnormal uterine bleeding, characterized by unpredictable timing and variable amount of flow. Clinicians should educate girls and their caretakers (eg, parents or guardians) about what to expect of a first menstrual period and the range for normal cycle length of subsequent menses. Identification of abnormal menstrual patterns in adolescence may improve early identification of potential health concerns for adulthood. It is important for clinicians to have an understanding of the menstrual patterns of adolescent girls, the ability to differentiate between normal and abnormal menstruation, and the skill to know how to evaluate the adolescent girl patient. By including an evaluation of the menstrual cycle as an additional vital sign, clinicians reinforce its importance in assessing overall health status for patients and caretakers. (12/15)

MULTILINGUAL CHILDREN: BEYOND MYTHS AND TOWARD BEST PRACTICES

Society for Research in Child Development

ABSTRACT. Multilingualism is an international fact of life and increasing in the United States. Multilingual families are exceedingly diverse, and policies relevant to them should take this into account. The quantity and quality of a child's exposure to responsive conversation spoken by fluent adults predicts both monolingual and multilingual language and literacy achievement. Contexts supporting optimal multilingualism involve early exposure to high quality conversation in each language, along with continued support for speaking both languages. Parents who are not fluent in English should not be told to speak English instead of their native language to their children; children require fluent input, and fluent input in another language will transfer to learning a second or third language. Messages regarding optimal multilingual practices should be made available to families using any and all available methods for delivering such information, including home visitation programs, healthcare settings, center-based early childhood programs, and mass media. (2013)

NATIONAL ADOPTION CENTER: OPEN RECORDS

National Adoption Center

The National Adoption Center believes that it is an inalienable right of all citizens, including adopted adults, to have unencumbered access to their original birth certificates. In keeping with this position, we believe that copies of both the original and the amended birth certificate should be given to the adoptive family at the time of finalization unless specifically denied by the birthparents. In any case, the National Adoption Center advocates that the adoptee, at age 18, be granted access to his/her original birth certificate. (6/00)

NEONATAL ENCEPHALOPATHY AND NEUROLOGIC OUTCOME, SECOND EDITION

American College of Obstetricians and Gynecologists Task Force on Neonatal Encephalopathy

In the first edition of this report, the Task Force on Neonatal Encephalopathy and Cerebral Palsy outlined criteria deemed essential to establish a causal link between intrapartum hypoxic events and cerebral palsy. It is now known that there are multiple potential causal pathways that lead to cerebral palsy in term infants, and the signs and symptoms of neonatal encephalopathy may range from mild to severe, depending on the nature and timing of the brain injury. Thus, for the current edition, the Task Force on Neonatal Encephalopathy determined that a broader perspective may be more fruitful. This conclusion reflects the sober recognition that knowledge gaps still preclude a definitive test or set of markers that accurately identifies, with high sensitivity and specificity, an infant in whom neonatal encephalopathy is attributable to an acute intrapartum event. The information necessary for assessment of likelihood can be derived from a comprehensive evaluation of all potential contributing factors in cases of neonatal encephalopathy. This is the broader perspective championed in the current report. If a comprehensive etiologic evaluation is not possible, the term hypoxic–ischemic encephalopathy should best be replaced by neonatal encephalopathy because neither hypoxia nor ischemia can be assumed to have been the unique initiating causal mechanism. The title of this report has been changed from *Neonatal Encephalopathy and Cerebral Palsy: Defining the Pathogenesis and Pathophysiology* to *Neonatal Encephalopathy and Neurologic Outcome* to indicate that an array of developmental outcomes may arise after neonatal encephalopathy in addition to cerebral palsy. (4/14)

NEURODEVELOPMENTAL OUTCOMES IN CHILDREN WITH CONGENITAL HEART DISEASE: EVALUATION AND MANAGEMENT; A SCIENTIFIC STATEMENT FROM THE AMERICAN HEART ASSOCIATION

American Heart Association (7/12)

THE NEUROLOGIST'S ROLE IN SUPPORTING TRANSITION TO ADULT HEALTH CARE

Lawrence W. Brown, MD; Peter Camfield, MD, FRCPC; Melissa Capers, MA; Greg Cascino, MD; Mary Ciccarelli, MD; Claudio M. de Gusmao, MD; Stephen M. Downs, MD; Annette Majnemer, PhD, FCAHS; Amy Brin Miller, MSN; Christina SanInocencio, MS; Rebecca Schultz, PhD; Anne Tilton, MD; Annick Winokur, BS; and Mary Zupanc, MD

ABSTRACT. The child neurologist has a critical role in planning and coordinating the successful transition from the pediatric to adult health care system for youth with neurologic conditions. Leadership in appropriately planning a youth's transition and in care coordination among health care, educational, vocational, and community services providers may assist in preventing gaps in care, delayed entry into the adult care system, and/or health crises for their adolescent patients. Youth whose neurologic conditions result in cognitive or physical disability and their families may need additional support during this transition, given the legal and financial considerations that may be required. Eight common principles that define the child neurologist's role in a successful transition process have been outlined by a multidisciplinary panel convened by the Child Neurology Foundation are introduced and described. The authors of this consensus statement recognize the current paucity of evidence for successful transition models and outline areas for future consideration. *Neurology.* 2016;87:1–6. (7/16)

NONINHERITED RISK FACTORS AND CONGENITAL CARDIOVASCULAR DEFECTS: CURRENT KNOWLEDGE

American Heart Association

ABSTRACT. Prevention of congenital cardiovascular defects has been hampered by a lack of information about modifiable risk factors for abnormalities in cardiac development. Over the past decade, there have been major breakthroughs in the understanding of inherited causes of congenital heart disease, including the identification of specific genetic abnormalities for some types of malformations. Although relatively less information has been available on noninherited modifiable factors that may have an adverse effect on the fetal heart, there is a growing body of epidemiological literature on this topic. This statement summarizes the currently available literature on potential fetal exposures that might alter risk for cardiovascular defects. Information is summarized for periconceptional multivitamin or folic acid intake, which may reduce the risk of cardiac disease in the fetus, and for additional types of potential exposures that may increase the risk, including maternal illnesses, maternal therapeutic and nontherapeutic drug exposures, environmental exposures, and paternal exposures. Information is highlighted regarding definitive risk factors such as maternal rubella; phenylketonuria; pregestational diabetes; exposure to thalidomide, vitamin A cogeners, or retinoids; and indomethacin tocolysis. Caveats regarding interpretation of possible exposure-outcome relationships from case-control studies are given because this type of study has provided most of the available information. Guidelines for prospective parents that could reduce the likelihood that their child will have a major cardiac malformation are given. Issues related to pregnancy monitoring are discussed. Knowledge gaps and future sources of new information on risk factors are described. (*Circulation.* 2007;115:2995–3014.) (6/07)

NUSINERSEN USE IN SPINAL MUSCULAR ATROPHY

David Michelson, MD; Emma Ciafaloni, MD; Stephen Ashwal, MD; Elliot Lewis, Pushpa Narayanaswami, MBBS; Maryam Oskoui, MD, MSc; Melissa J. Armstrong, MD, MSc; and American Academy of Neurology

ABSTRACT. *Objective.* To identify the level of evidence for use of nusinersen to treat spinal muscular atrophy (SMA) and review clinical considerations regarding use.

Methods. The author panel systematically reviewed nusinersen clinical trials for patients with SMA and assigned level of evidence statements based on the American Academy of Neurology's 2017 therapeutic classification of evidence scheme. Safety information, regulatory decisions, and clinical context were also reviewed.

Results. Four published clinical trials were identified, 3 of which were rated above Class IV. There is Class III evidence that in infants with homozygous deletions or mutations of *SMN1,* nusinersen improves the probability of permanent ventilation-free survival at 24 months vs a well-defined historical cohort. There is Class I evidence that in term infants with SMA and 2 copies of *SMN2,* treatment with nusinersen started in individuals younger than 7 months results in a better motor milestone response and higher rates of event-free survival than sham control. There is Class I evidence that in children aged 2–12 years with SMA symptom onset after 6 months of age, nusinersen results in greater improvement in motor function at 15 months than sham control. Nusinersen was safe and well-tolerated.

Clinical context. Evidence of efficacy is currently highest for treatment of infantile- and childhood-onset SMA in the early and middle symptomatic phases. While approved indications for nusinersen use in North America and Europe are broad, payer coverage for populations outside those in clinical trials remain variable. Evidence, availability, cost, and patient preferences all influence decision-making regarding nusinersen use. (10/18)

ORTHOPTISTS AS PHYSICIAN EXTENDERS

American Association for Pediatric Ophthalmology and Strabismus (5/15)

PERINATAL PALLIATIVE CARE

American College of Obstetricians and Gynecologists

ABSTRACT. Perinatal palliative care refers to a coordinated care strategy that comprises options for obstetric and newborn care that include a focus on maximizing quality of life and comfort for newborns with a variety of conditions considered to be life-limiting in early infancy. With a dual focus on ameliorating suffering and honoring patient values, perinatal palliative care can be provided concurrently with life-prolonging treatment. The focus of this document, however, involves the provision of exclusively palliative care without intent to prolong life in the context of a life-limiting condition, otherwise known as perinatal palliative comfort care. Once a life-limiting diagnosis is suspected antenatally, the tenets of informed consent require that the pregnant patient be given information of sufficient depth and breadth to make an informed, voluntary choice for her care. Health care providers are encouraged to model effective, compassionate communication that respects patient cultural beliefs and values and to promote shared decision making with patients. Perinatal palliative comfort care is one of several options along a spectrum of care, which includes pregnancy termination (abortion) and full neonatal resuscitation and treatment, that should be presented to pregnant patients faced with pregnancies complicated by life-limiting fetal conditions. If a patient opts to pursue perinatal palliative comfort care, a multidisciplinary team should be identified with the infrastructure and support to administer this care. The perinatal palliative care team should prepare families for the possibility that there may be differences of opinion between family members before and after the delivery of the infant, and that there may be differences between parents and the neonatal care providers about appropriate postnatal therapies, especially if the postnatal diagnosis and prognosis differ substantially from antenatal predictions. Procedures for resolving such differences should be discussed with families ahead of time. (8/19)

A PRACTICAL GUIDE FOR PRIMARY CARE PHYSICIANS: INSTRUMENT-BASED VISION SCREENING IN CHILDREN

Children's Eye Foundation

SUMMARY. In January 2016 a new joint policy statement from the American Academy of Pediatrics (AAP), American Academy of Ophthalmology (AAO), American Association

for Pediatric Ophthalmology and Strabismus (AAPOS) and American Association of Certified Orthoptists (AACO) regarding the pediatric eye examination was published. The updated policy statement, published in the journal *Pediatrics,* incorporates earlier and routine visual assessments using instrument-based screening to help identify children who may benefit from early intervention to improve vision (or correct vision problems). Instrument-based screening technology is revolutionizing early detection and prevention of amblyopia by allowing screening of more children and at a younger age.

This guide for primary care physicians is produced by the Children's Eye Foundation of AAPOS to provide information regarding instrument-based screening. Early detection and treatment of amblyopia is key to preventing unnecessary blindness, and primary care physicians play a critical role in its detection through vision screening in the preschool and school age groups. (2016)

PREVENTION AND CONTROL OF MENINGOCOCCAL DISEASE: RECOMMENDATIONS OF THE ADVISORY COMMITTEE ON IMMUNIZATION PRACTICES (ACIP)

Centers for Disease Control and Prevention

SUMMARY. Meningococcal disease describes the spectrum of infections caused by *Neisseria meningitidis,* including meningitidis, bacteremia, and bacteremic pneumonia. Two quadrivalent meningococcal polysaccharide-protein conjugate vaccines that provide protection against meningococcal serogroups A, C, W, and Y (MenACWY-D [Menactra, manufactured by Sanofi Pasteur, Inc., Swiftwater, Pennsylvania] and MenACWY-CRM [Menveo, manufactured by Novartis Vaccines, Cambridge, Massachusetts]) are licensed in the United States for use among persons aged 2 through 55 years. MenACWY-D also is licensed for use among infants and toddlers aged 9 through 23 months. Quadrivalent meningococcal polysaccharide vaccine (MPSV4 [Menommune, manufactured by Sanofi Pasteur, Inc., Swiftwater, Pennsylvania]) is the only vaccine licensed for use among persons aged ≥56 years. A bivalent meningococcal polysaccharide protein conjugate vaccine that provides protection against meningococcal serogroups C and Y along with *Haemophilus influenzae* type b (Hib) (Hib-MenCY-TT [MenHibrix, manufactured by GlaxoSmithKline Biologicals, Rixensart, Belgium]) is licensed for use in children aged 6 weeks through 18 months.

This report compiles and summarizes all recommendations from CDC's Advisory Committee on Immunization Practices (ACIP) regarding prevention and control of meningococcal disease in the United States, specifically the changes in the recommendations published since 2005 (CDC. Prevention and control of meningococcal disease: recommendations of the Advisory Committee on Immunization Practices [ACIP]. *MMWR* 2005;54 Adobe PDF file [No. RR-7]). As a comprehensive summary of previously published recommendations, this report does not contain any new recommendations; it is intended for use by clinicians as a resource. ACIP recommends routine vaccination with a quadrivalent meningococcal conjugate vaccine (MenACWY) for adolescents aged 11 or 12 years, with a booster dose at age 16 years. ACIP also recommends routine vaccination for persons at increased risk for meningococcal disease (i.e., persons who have persistent complement component deficiencies, persons who have anatomic or functional asplenia, microbiologists who routinely are exposed to isolates of *N. meningitidis,* military recruits, and persons who travel to or reside in areas in which meningococcal disease is hyperendemic or epidemic). Guidelines for antimicrobial chemoprophylaxis and for evaluation and management of suspected outbreaks of meningococcal disease also are provided. (3/13)

PREVENTION OF GROUP B STREPTOCOCCAL EARLY-ONSET DISEASE IN NEWBORNS

American College of Obstetricians and Gynecologists Committee on Obstetric Practice

ABSTRACT. Group B streptococcus (GBS) is the leading cause of newborn infection (1). The primary risk factor for neonatal GBS early-onset disease (EOD) is maternal colonization of the genitourinary and gastrointestinal tracts. Approximately 50% of women who are colonized with GBS will transmit the bacteria to their newborns. Vertical transmission usually occurs during labor or after rupture of membranes. In the absence of intrapartum antibiotic prophylaxis, 1–2% of those newborns will develop GBS EOD. Other risk factors include gestational age of less than 37 weeks, very low birth weight, prolonged rupture of membranes, intraamniotic infection, young maternal age, and maternal black race. The key obstetric measures necessary for effective prevention of GBS EOD continue to include universal prenatal screening by vaginal–rectal culture, correct specimen collection and processing, appropriate implementation of intrapartum antibiotic prophylaxis, and coordination with pediatric care providers. The American College of Obstetricians and Gynecologists now recommends performing universal GBS screening between 36 0/7 and 37 6/7 weeks of gestation. All women whose vaginal–rectal cultures at 36 0/7 and 37 6/7 weeks of gestation are positive for GBS should receive appropriate intrapartum antibiotic prophylaxis unless a prelabor cesarean birth is performed in the setting of intact membranes. Although a shorter duration of recommended intrapartum antibiotics is less effective than 4 or more hours of prophylaxis, 2 hours of antibiotic exposure has been shown to reduce GBS vaginal colony counts and decrease the frequency of a clinical neonatal sepsis diagnosis. Obstetric interventions, when necessary, should not be delayed solely to provide 4 hours of antibiotic administration before birth. This Committee Opinion, including Table 1, Box 2, and Figures 1–3, updates and replaces the obstetric components of the CDC 2010 guidelines, "Prevention of Perinatal Group B Streptococcal Disease: Revised Guidelines From CDC, 2010." (6/19)

RECOMMENDED AMOUNT OF SLEEP FOR PEDIATRIC POPULATIONS: A CONSENSUS STATEMENT OF THE AMERICAN ACADEMY OF SLEEP MEDICINE

Shalini Paruthi, MD; Lee J. Brooks, MD; Carolyn D'Ambrosio, MD; Wendy A. Hall, PhD, RN; Suresh Kotagal, MD; Robin M. Lloyd, MD; Beth A. Malow, MD, MS; Kiran Maski, MD; Cynthia Nichols, PhD; Stuart F. Quan, MD; Carol L. Rosen, MD; Matthew M. Troester, DO; and Merrill S. Wise, MD

Background and Methodology. Healthy sleep requires adequate duration, appropriate timing, good quality, regularity, and the absence of sleep disturbances or disorders. Sleep duration is a frequently investigated sleep measure in relation to health. A panel of 13 experts in sleep medicine and research used a modified RAND Appropriateness Method to develop recommendations regarding the sleep duration range that promotes optimal health in children aged 0–18 years. The expert panel reviewed published scientific evidence addressing the relationship between sleep duration and health using a broad set of National Library of Medicine Medical Subject Headings (MeSH) terms and no date restrictions, which resulted in a total of 864 scientific articles. The process was further guided by the Oxford grading system. The panel focused on seven health categories with the best available evidence in relation to sleep duration: general health, cardiovascular health, metabolic health, mental health, immunologic function, developmental health, and human performance. Consistent with the RAND Appropriateness Method, multiple rounds of evidence review, discussion, and voting were conducted to arrive at the final recommendations. The process to

develop these recommendations was conducted over a 10-month period and concluded with a meeting held February 19–21, 2016, in Chicago, Illinois. (6/16)

SCREENING CHILDREN AT RISK FOR RETINOBLASTOMA: CONSENSUS REPORT FROM THE AMERICAN ASSOCIATION OF OPHTHALMIC ONCOLOGISTS AND PATHOLOGISTS

Alison H. Skalet, MD, PhD; Dan S. Gombos, MD; Brenda L. Gallie, MD; Jonathan W. Kim, MD; Carol L. Shields, MD; Brian P. Marr, MD; Sharon E. Plon, MD, PhD; and Patricia Chévez-Barrios, MD

Purpose: To provide a set of surveillance guidelines for children at risk for development of retinoblastoma.

Design: Consensus panel.

Participants: Expert panel of ophthalmic oncologists, pathologists, and geneticists.

Methods: A group of members of the American Association of Ophthalmic Oncologists and Pathologists (AAOOP) with support of the American Association for Pediatric Ophthalmology and Strabismus and the American Academy of Pediatrics (AAP) was convened. The panel included representative ophthalmic oncologists, pathologists, and geneticists from retinoblastoma referral centers located in various geographic regions who met and discussed screening approaches for retinoblastoma. A patient "at risk" was defined as a person with a family history of retinoblastoma in a parent, sibling, or first- or second-degree relative.

Main Outcome Measures: Screening recommendations for children at risk for retinoblastoma.

Results: Consensus statement from the panel: (1) Dedicated ophthalmic screening is recommended for all children at risk for retinoblastoma above the population risk. (2) Frequency of examinations is adjusted on the basis of expected risk for *RB1* mutation. (3) Genetic counseling and testing clarify the risk for retinoblastoma in children with a family history of the disease. (4) Examination schedules are stratified on the basis of high-, intermediate-, and low-risk children. (5) Children at high risk for retinoblastoma require more frequent screening, which may preferentially be examinations under anesthesia.

Conclusions: Risk stratification including genetic testing and counseling serves as the basis for screening of children at elevated risk for development of retinoblastoma. (10/17)

SCREENING FOR IDIOPATHIC SCOLIOSIS IN ADOLESCENTS—POSITION STATEMENT

American Academy of Orthopedic Surgeons, Scoliosis Research Society, and Pediatric Orthopedic Society of North America

ABSTRACT. The Scoliosis Research Society (SRS), American Academy of Orthopedic Surgeons (AAOS), Pediatric Orthopedic Society of North America (POSNA), and American Academy of Pediatrics (AAP) believe that there has been additional useful research in the early detection and management of adolescent idiopathic scoliosis (AIS) since the review performed by the United States Preventive Services Task Force (USPSTF) in 2004. This information should be available for use by patients, treating health care providers, and policy makers in assessing the relative risks and benefits of the early identification and management of AIS.

The AAOS, SRS, POSNA, and AAP believe that there are documented benefits of earlier detection and non-surgical management of AIS, earlier identification of severe deformities that are surgically treated, and of incorporating screening of children for AIS by knowledgeable health care providers as a part of their care. (9/15)

SKIING AND SNOWBOARDING INJURY PREVENTION

Canadian Paediatric Society

ABSTRACT. Skiing and snowboarding are popular recreational and competitive sport activities for children and youth. Injuries associated with both activities are frequent and can be serious. There is new evidence documenting the benefit of wearing helmets while skiing and snowboarding, as well as data refuting suggestions that helmet use may increase the risk of neck injury. There is also evidence to support using wrist guards while snowboarding. There is poor uptake of effective preventive measures such as protective equipment use and related policy. Physicians should have the information required to counsel children, youth and families regarding safer snow sport participation, including helmet use, wearing wrist guards for snowboarding, training and supervision, the importance of proper equipment fitting and binding adjustment, sun safety and avoiding substance use while on the slopes. (1/12, reaffirmed 1/20)

SPINAL MOTION RESTRICTION IN THE TRAUMA PATIENT—A JOINT POSITION STATEMENT

Peter E. Fischer, MD, MS; Debra G. Perina, MD; Theodore R. Delbridge, MD, MPH; Mary E. Fallat, MD; Jeffrey P. Salomone, MD; Jimm Dodd, MS, MA; Eileen M. Bulger, MD; and Mark L. Gestring, MD

ABSTRACT. The American College of Surgeons Committee on Trauma (ACS-COT), American College of Emergency Physicians (ACEP), and the National Association of EMS Physicians (NAEMSP) have previously offered varied guidance on the role of backboards and spinal immobilization in out-of-hospital situations. This updated consensus statement on spinal motion restriction in the trauma patient represents the collective positions of the ACS-COT, ACEP and NAEMSP. It has further been formally endorsed by a number of national stakeholder organizations. This updated uniform guidance is intended for use by emergency medical services (EMS) personnel, EMS medical directors, emergency physicians, trauma surgeons, and nurses as they strive to improve the care of trauma victims within their respective domains. (8/18)

SUPPLEMENT TO THE JCIH 2007 POSITION STATEMENT: PRINCIPLES AND GUIDELINES FOR EARLY INTERVENTION AFTER CONFIRMATION THAT A CHILD IS DEAF OR HARD OF HEARING

Joint Committee on Infant Hearing

PREFACE. This document is a supplement to the recommendations in the year 2007 position statement of the Joint Committee on Infant Hearing (JCIH) and provides comprehensive guidelines for early hearing detection and intervention (EHDI) programs on establishing strong early intervention (EI) systems with appropriate expertise to meet the needs of children who are deaf or hard of hearing (D/HH).

EI services represent the purpose and goal of the entire EHDI process. Screening and confirmation that a child is D/HH are largely meaningless without appropriate, individualized, targeted and high-quality intervention. For the infant or young child who is D/HH to reach his or her full potential, carefully designed individualized intervention must be implemented promptly, utilizing service providers with optimal knowledge and skill levels and providing services on the basis of research, best practices, and proven models.

The delivery of EI services is complex and requires individualization to meet the identified needs of the child and family. Because of the diverse needs of the population of children who are D/HH and their families, well-controlled intervention studies are challenging. At this time, few comparative effectiveness studies have been conducted. Randomized controlled trials are particularly difficult for ethical reasons, making it challenging

to establish causal links between interventions and outcomes. EI systems must partner with colleagues in research to document what works for children and families and to strengthen the evidence base supporting practices.

Despite limitations and gaps in the evidence, the literature does contain research studies in which all children who were D/HH had access to the same well-defined EI service. These studies indicate that positive outcomes are possible, and they provide guidance about key program components that appear to promote these outcomes. This EI services document, drafted by teams of professionals with extensive expertise in EI programs for children who are D/HH and their families, relied on literature searches, existing systematic reviews, and recent professional consensus statements in developing this set of guidelines.

Terminology presented a challenge throughout document development. The committee noted that many of the frequently occurring terms necessary within the supplement may not reflect the most contemporary understanding and/or could convey inaccurate meaning. Rather than add to the lack of clarity or consensus and to avoid introducing new terminology to stakeholders, the committee opted to use currently recognized terms consistently herein and will monitor the emergence and/or development of new descriptors before the next JCIH consensus statement.

For purposes of this supplement:

- *Language* refers to all spoken and signed languages.
- *Early intervention* (EI), according to part C of the Individuals with Disabilities Education Improvement Act (IDEA) of 2004, is the process of providing services, education, and support to young children who are deemed to have an established condition, those who are evaluated and deemed to have a diagnosed physical or mental condition (with a high probability of resulting in a developmental delay), those who have an existing delay, or those who are at risk of developing a delay or special need that may affect their development or impede their education.
- *Communication* is used in lieu of terms such as communication options, methods, opportunities, approaches, etc.
- *Deaf or hard of hearing* (D/HH) is intended to be inclusive of all children with congenital and acquired hearing loss, unilateral and bilateral hearing loss, all degrees of hearing loss from minimal to profound, and all types of hearing loss (sensorineural, auditory neuropathy spectrum disorder, permanent conductive, and mixed).
- *Core knowledge and skills* is used to describe the expertise needed to provide appropriate EI that will optimize the development and well-being of infants/children and their families. Core knowledge and skills will differ according to the roles of individuals within the EI system (eg, service coordinator or EI provider).

This supplement to JCIH 2007 focuses on the practices of EI providers outside of the primary medical care and specialty medical care realms, rather than including the full spectrum of necessary medical, audiologic, and educational interventions. For more information about the recommendations for medical follow-up, primary care surveillance for related medical conditions, and specialty medical care and monitoring, the reader is encouraged to reference the year 2007 position statement of the JCIH as well as any subsequent revision. When an infant is confirmed to be D/HH, the importance of ongoing medical and audiologic management and surveillance both in the medical home and with the hearing health professionals, the otolaryngologist and the audiologist, cannot be overstated. A comprehensive discussion of those services is beyond the scope of this document. (3/13)

TIMING OF UMBILICAL CORD CLAMPING AFTER BIRTH

American College of Obstetricians and Gynecologists Committee on Obstetric Practice (12/12)

WEIGHING ALL PATIENTS IN KILOGRAMS

Emergency Nurses Association (9/16)

YEAR 2007 POSITION STATEMENT: PRINCIPLES AND GUIDELINES FOR EARLY HEARING DETECTION AND INTERVENTION PROGRAMS

Joint Committee on Infant Hearing

ABSTRACT. The Joint Committee on Infant Hearing (JCIH) endorses early detection of and intervention for infants with hearing loss. The goal of early hearing detection and intervention (EHDI) is to maximize linguistic competence and literacy development for children who are deaf or hard of hearing. Without appropriate opportunities to learn language, these children will fall behind their hearing peers in communication, cognition, reading, and social-emotional development. Such delays may result in lower educational and employment levels in adulthood. To maximize the outcome for infants who are deaf or hard of hearing, the hearing of all infants should be screened at no later than 1 month of age. Those who do not pass screening should have a comprehensive audiological evaluation at no later than 3 months of age. Infants with confirmed hearing loss should receive appropriate intervention at no later than 6 months of age from health care and education professionals with expertise in hearing loss and deafness in infants and young children. Regardless of previous hearing-screening outcomes, all infants with or without risk factors should receive ongoing surveillance of communicative development beginning at 2 months of age during well-child visits in the medical home. EHDI systems should guarantee seamless transitions for infants and their families through this process. (10/07)

APPENDIX 1

PPI: AAP Partnership for Policy Implementation

BACKGROUND

The American Academy of Pediatrics (AAP) develops policies that promote optimal physical, mental, and social health and well-being for all infants, children, adolescents, and young adults. These documents are valued highly not only by clinicians who provide direct health care to children but by members of other organizations who share similar goals and by parents, payers, and legislators. To increase clarity and action of AAP clinical guidance and recommendations for physicians at the point of care, the AAP formed the Partnership for Policy Implementation (PPI). The PPI is a group of pediatric medical informaticians who partner with authors of AAP clinical practice guidelines and clinical reports to assure that clinical recommendations are stated with the precision needed to implement them in an electronic health record (EHR) system. Partnership for Policy Implementation volunteers focus on helping content experts develop clinical guidance that specifies exactly who is to do what, for whom, and under what circumstances.

VISION

The vision of the PPI is that all AAP clinical recommendations include clear guidance on how pediatricians can implement those recommendations into their patient care and that AAP clinical guidance can be easily incorporated within EHR decision-support systems.

MISSION

The mission of the PPI is to facilitate implementation of AAP recommendations at the point of care by ensuring that AAP documents are written in a practical, action-oriented fashion with unambiguous recommendations.

WHAT THE PPI IS

The PPI is a network of pediatric informaticians who work with AAP authors and clinical practice guideline subcommittees throughout the writing process.

Contributions of the PPI to the AAP writing process include disambiguation and specification; development of clear definitions; clearly defined logic; implementation techniques; action-oriented recommendations, including clinical algorithms; transparency of the evidence base for recommendations; and health information technology (HIT) standard development.

WHAT THE PPI HAS ACCOMPLISHED

Since inception of the PPI, more than 30 statements have been published using the PPI process, covering a wide variety of child health topics, including attention-deficit/hyperactivity disorder in children and adolescents (*Pediatrics.* 2019;144[4]:e20192528), influenza prevention and control (*Pediatrics.* 2020;146[4]:e2020024588), infantile hemangiomas (*Pediatrics.* 2019;143[1]:e20183475), maintenance intravenous fluids (*Pediatrics.* 2018;142[6]:e20183083), child passenger safety (*Pediatrics.* 2018;142[5]:e20182460), and high blood pressure in children and adolescents (*Pediatrics.* 2018;142[3]:e20182096).

One example of how a statement developed using the PPI process has gained broader acceptance is the AAP annual influenza statement. Since 2007, the Centers for Disease Control and Prevention has adopted components of the PPI statement (specifically, the clinical algorithm) within its own statement on the same topic.

WHAT THE PPI IS DOING NOW

In addition to creating practical, action-oriented guidance that pediatricians can use at the point of care, the PPI works to make it easier for these recommendations to be incorporated into electronic systems. To date, the PPI has focused its involvement on the statement development process. Involvement of the PPI during the writing process helps produce a clear, more concise document. As these standards of care become well documented, the PPI can begin to focus on building or mapping pediatric vocabulary; once solidified, this vocabulary can be built into EHR systems. The standards of care can also be matched to various logical and functional HIT standards that already exist today. Through this work, the PPI improves AAP policy documents by providing specific guidance to pediatricians at the point of care, helping ensure that EHRs are designed to assist pediatricians in providing optimal care for children. The PPI developed a short video that provides an overview of its mission and process. This video is available on the PPI website (https://www.aap.org/en-us/professional-resources/quality-improvement/Pages/Partnership-for-Policy-Implementation.aspx) as well as the AAP YouTube channel at www.youtube.com/watch?v=woTfeoNcxn4.

The PPI continues to expand and mentor new members. For more information on the application process and about the PPI, please visit its website (https://www.aap.org/en-us/professional-resources/quality-improvement/Pages/Partnership-for-Policy-Implementation.aspx) or contact Kymika Okechukwu (kokechukwu@aap.org or 630/626-6317).

Pediatric Clinical Practice Guidelines & Policies

A Compendium of Evidence-based Research for Pediatric Practice
21st Edition

eBook access included!

Clinical practice guidelines have long provided physicians with an evidence-based decision-making tool for managing common pediatric conditions. Policies issued and endorsed by the American Academy of Pediatrics (AAP) represent the AAP position on child health care issues.

More than 40 clinical practice guidelines and more than 600 policy statements, clinical reports, and technical reports have been combined into this 21st edition of *Pediatric Clinical Practice Guidelines & Policies* book and eBook, giving you even easier access to the important clinical and policy information you need.

Manual includes

- Complete AAP clinical practice guidelines
- Complete 2020 AAP policy statements and clinical and technical reports
- Appendixes on the AAP Partnership for Policy Implementation and AAP acronyms
- Quick Reference Tools, including coding tips, patient education handouts, and more
- Five-section organization for ease of use

Clinical practice guidelines included in this edition cover the following pediatric conditions:

- Attention-deficit/hyperactivity disorder
- Autism spectrum disorder
- Brief resolved unexplained events
- Bronchiolitis
- Cardiovascular health
- Cerebral palsy
- Cerumen impaction
- Congenital muscular dystrophy
- Depression
- Diabetes
- Duchenne muscular dystrophy
- Dysplasia of the hip
- Febrile seizures
- Food allergy
- Hemorrhage
- High blood pressure
- HIV
- Hyperbilirubinemia
- Infantile hemangiomas
- Infantile spasms
- Intravascular catheter-related infections
- Intravenous fluids
- Medullary thyroid carcinoma
- Migraine headache
- Nosebleed (epistaxis)—***New!***
- Otitis media
- Palliative care
- Positional plagiocephaly
- Rhinoplasty
- Seizure
- Septic shock and sepsis-associated organ dysfunction—***New!***
- Sinusitis
- Sleep apnea
- Status epilepticus
- Telehealth
- Thyroid nodules and differentiated thyroid cancer
- Tobacco use
- Turner syndrome
- Urinary tract infection
