There have been no head-to-head comparisons of the diagnostic accuracy of contrast-enhanced CT scanning to MRI with contrast in the evaluation of orbital and intracranial complications of sinusitis in children. In general, the contrast-enhanced CT scan has been the preferred imaging study when complications of sinusitis are suspected.[35,36] However, there are documented cases in which a contrast-enhanced CT scan has not revealed the abnormality responsible for the clinical presentation and the MRI with contrast has, especially for intracranial complications and rarely for orbital complications.[37,38] Accordingly, the most recent appropriateness criteria from the American College of Radiology endorse both MRI with contrast and contrast-enhanced CT as complementary examinations when evaluating potential complications of sinusitis.[35] The availability and speed of obtaining the contrast-enhanced CT are desirable; however, there is increasing concern regarding exposure to radiation. The MRI, although very sensitive, takes longer than the contrast-enhanced CT and often requires sedation in young children (which carries its own risks). In older children and adolescents who may not require sedation, MRI with contrast, if available, may be preferred when intracranial complications are likely. Furthermore, MRI with contrast should be performed when there is persistent clinical concern or incomplete information has been provided by the contrast-enhanced CT scan.

Key Action Statement 3

Initial Management of Acute Bacterial Sinusitis

3A: "Severe onset and worsening course" acute bacterial sinusitis. The clinician should prescribe antibiotic therapy for acute bacterial sinusitis in children with severe onset or worsening course (signs, symptoms, or both) (Evidence Quality: B; Strong Recommendation).

KAS Profile 3A

Aggregate evidence quality: B; randomized controlled trials with limitations.	
Benefit	Increase clinical cures, shorten illness duration, and may prevent suppurative complications in a high-risk patient population.
Harm	Adverse effects of antibiotics.
Cost	Direct cost of therapy.
Benefits-harm assessment	Preponderance of benefit.
Value judgments	Concern for morbidity and possible complications if untreated.
Role of patient preference	Limited.
Intentional vagueness	None.
Exclusions	None.
Strength	Strong recommendation.

3B: "Persistent illness." The clinician should either prescribe antibiotic therapy OR offer additional outpatient observation for 3 days to children with persistent illness (nasal discharge of any quality or cough or both for at least 10 days without evidence of improvement) (Evidence Quality: B; Recommendation).

The purpose of this section is to offer guidance on initial management of persistent illness sinusitis by helping clinicians choose between the following 2 strategies:

1. Antibiotic therapy, defined as initial treatment of acute bacterial sinusitis with antibiotics, with the intent of starting antibiotic therapy as soon as possible after the encounter.
2. Additional outpatient observation, defined as initial management of acute bacterial sinusitis limited to continued observation for 3 days, with commencement of antibiotic therapy if either the child does not improve clinically within several days of diagnosis or if there is clinical worsening of the child's condition at any time.

KAS Profile 3B

Aggregate evidence quality: B; randomized controlled trials with limitations.	
Benefit	Antibiotics increase the chance of improvement or cure at 10 to 14 days (number needed to treat, 3–5); additional observation may avoid the use of antibiotics with attendant cost and adverse effects.
Harm	Antibiotics have adverse effects (number needed to harm, 3) and may increase bacterial resistance. Observation may prolong illness and delay start of needed antibiotic therapy.
Cost	Direct cost of antibiotics as well as cost of adverse reactions; indirect costs of delayed recovery when observation is used.
Benefits-harm assessment	Preponderance of benefit (because both antibiotic therapy and additional observation with rescue antibiotic, if needed, are appropriate management).
Value judgments	Role for additional brief observation period for selected children with persistent illness sinusitis, similar to what is recommended for acute otitis media, despite the lack of randomized trials specifically comparing additional observation with immediate antibiotic therapy and longer duration of illness before presentation.
Role of patient preference	Substantial role in shared decision-making that should incorporate illness severity, child's quality of life, and caregiver values and concerns.
Intentional vagueness	None.
Exclusions	Children who are excluded from randomized clinical trials of acute bacterial sinusitis, as defined in the text.
Strength	Recommendation.

In contrast to the 2001 AAP guideline,[5] which recommended antibiotic therapy for all children diagnosed with acute bacterial sinusitis, this guideline allows for additional observation of children presenting with persistent illness (nasal discharge of any quality or daytime cough or both for at least 10 days without evidence of improvement). In both guidelines, however, children presenting with severe or worsening illness (which was not defined explicitly in the 2001 guideline[5]) are to receive antibiotic therapy. The rationale for this approach (Table 2) is discussed below.

Antibiotic Therapy for Acute Bacterial Sinusitis

In the United States, antibiotics are prescribed for 82% of children with acute sinusitis.[39] The rationale for antibiotic therapy of acute bacterial sinusitis is based on the recovery of bacteria in high density ($\geq 10^4$ colony-forming units/mL) in 70% of maxillary sinus aspirates obtained from children with a clinical syndrome characterized by persistent nasal discharge, daytime cough, or both.[16,40] Children who present with severe-onset acute bacterial sinusitis are presumed to have bacterial infection, because a temperature of at least 39°C/102.2°F coexisting for at least 3 consecutive days with purulent nasal discharge is not consistent with the well-documented pattern of acute viral URI. Similarly, children with worsening-course acute bacterial sinusitis have a clinical course that is also not consistent with the steady improvement that characterizes an uncomplicated viral URI.[9,10]

Three RCTs have compared antibiotic therapy with placebo for the initial management of acute bacterial sinusitis in children. Two trials by Wald et al[4,41] found an increase in cure or improvement after antibiotic therapy compared with placebo with a number needed to treat of 3 to 5 children. Most children in these studies had persistent acute bacterial sinusitis, but children with severe or worsening illness were also included. Conversely, Garbutt et al,[42] who studied only children with persistent acute bacterial sinusitis, found no difference in outcomes for antibiotic versus placebo. Another RCT by Kristo et al,[43] often cited as showing no benefit from antibiotics for acute bacterial sinusitis, will not be considered further because of methodologic flaws, including weak entry criteria and inadequate dosing of antibiotic treatment.

The guideline recommends antibiotic therapy for severe or worsening acute bacterial sinusitis because of the benefits revealed in RCTs[4,41] and a theoretically higher risk of suppurative complications than for children who present with persistent symptoms. Orbital and intracranial complications of acute bacterial sinusitis have not been observed in RCTs, even when placebo was administered; however, sample sizes have inadequate power to preclude an increased risk. This risk, however, has caused some investigators to exclude children with severe acute bacterial sinusitis from trial entry.[42]

Additional Observation for Persistent Onset Acute Bacterial Sinusitis

The guideline recommends either antibiotic therapy or an additional brief period of observation as initial management strategies for children with persistent acute bacterial sinusitis because, although there are benefits to antibiotic therapy (number needed to treat, 3–5), some children improve on their own, and the risk of suppurative complications is low.[4,41] Symptoms of persistent acute bacterial sinusitis may be mild and have varying effects on a given child's quality of life, ranging from slight (mild cough, nasal discharge) to significant (sleep disturbance, behavioral changes, school or child care absenteeism). The benefits of antibiotic therapy in some trials[4,41] must also be balanced against an increased risk of adverse events (number need to harm, 3), most often self-limited diarrhea, but also including occasional rash.[4]

Choosing between antibiotic therapy or additional observation for initial management of persistent illness sinusitis presents an opportunity for shared decision-making with families (Table 2). Factors that might influence this decision include symptom severity, the child's quality of life, recent antibiotic use, previous experience or outcomes with acute bacterial sinusitis, cost of antibiotics, ease of administration, caregiver concerns about potential adverse effects of antibiotics, persistence of respiratory symptoms, or development of complications. Values and preferences expressed by the caregiver should be taken into consideration (Table 3).

Children with persistent acute bacterial sinusitis who received antibiotic therapy in the previous 4 weeks, those with concurrent bacterial infection (eg, pneumonia, suppurative cervical adenitis, group A streptococcal pharyngitis, or acute otitis media), those with actual or suspected complications of acute bacterial sinusitis, or those with underlying conditions should generally be managed with antibiotic therapy. The latter group includes children with asthma, cystic fibrosis, immunodeficiency, previous sinus surgery, or anatomic abnormalities of the upper respiratory tract.

Limiting antibiotic use in children with persistent acute bacterial sinusitis who may improve on their own reduces common antibiotic-related adverse events, such as diarrhea, diaper dermatitis, and skin rash. The most recent RCT of acute bacterial sinusitis in children[4] found adverse events of 44% with antibiotic and 14% with placebo.

Limiting antibiotics may also reduce the prevalence of resistant bacterial pathogens. Although this is always a desirable goal, no increase in resistant bacterial species was observed within the group of children treated with a single course of antimicrobial agents (compared with those receiving placebo) in 2 recent large studies of antibiotic versus placebo for children with acute otitis media.[44,45]

Key Action Statement 4

Clinicians should prescribe amoxicillin with or without clavulanate as first-line treatment when a decision has been made to initiate antibiotic treatment of acute bacterial sinusitis (Evidence Quality: B; Recommendation).

KAS Profile 4

Aggregate evidence quality: B; randomized controlled trials with limitations.

Benefit	Increase clinical cures with narrowest spectrum drug; stepwise increase in broadening spectrum as risk factors for resistance increase.
Harm	Adverse effects of antibiotics including development of hypersensitivity.
Cost	Direct cost of antibiotic therapy.
Benefits-harm assessment	Preponderance of benefit.
Value judgments	Concerns for not encouraging resistance if possible.
Role of patient preference	Potential for shared decision-making that should incorporate the caregiver's experiences and values.
Intentional vagueness	None.
Exclusions	May include allergy or intolerance.
Strength	Recommendation.

TABLE 2 Recommendations for Initial Use of Antibiotics for Acute Bacterial Sinusitis

Clinical Presentation	Severe Acute Bacterial Sinusitis[a]	Worsening Acute Bacterial Sinusitis[b]	Persistent Acute Bacterial Sinusitis[c]
Uncomplicated acute bacterial sinusitis without coexisting illness	Antibiotic therapy	Antibiotic therapy	Antibiotic therapy or additional observation for 3 days[d]
Acute bacterial sinusitis with orbital or intracranial complications	Antibiotic therapy	Antibiotic therapy	Antibiotic therapy
Acute bacterial sinusitis with coexisting acute otitis media, pneumonia, adenitis, or streptococcal pharyngitis	Antibiotic therapy	Antibiotic therapy	Antibiotic therapy

[a] Defined as temperature ≥39°C and purulent (thick, colored, and opaque) nasal discharge present concurrently for at least 3 consecutive days.

[b] Defined as nasal discharge or daytime cough with sudden worsening of symptoms (manifested by new-onset fever ≥38°C/100.4°F or substantial increase in nasal discharge or cough) after having experienced transient improvement of symptoms.

[c] Defined as nasal discharge (of any quality), daytime cough (which may be worse at night), or both, persisting for >10 days without improvement.

[d] Opportunity for shared decision-making with the child's family; if observation is offered, a mechanism must be in place to ensure follow-up and begin antibiotics if the child worsens at any time or fails to improve within 3 days of observation.

The purpose of this key action statement is to guide the selection of antimicrobial therapy once the diagnosis of acute bacterial sinusitis has been made. The microbiology of acute bacterial sinusitis was determined nearly 30 years ago through direct maxillary sinus aspiration in children with compatible signs and symptoms. The major bacterial pathogens recovered at that time were *Streptococcus pneumoniae* in approximately 30% of children and nontypeable *Haemophilus influenzae* and *Moraxella catarrhalis* in approximately 20% each.[16,40] Aspirates from the remaining 25% to 30% of children were sterile.

Maxillary sinus aspiration is rarely performed at the present time unless the course of the infection is unusually prolonged or severe. Although some authorities have recommended obtaining cultures from the middle meatus to determine the cause of a maxillary sinus infection, there are no data in children with acute bacterial sinusitis that have compared such cultures with cultures of a maxillary sinus aspirate. Furthermore, there are data indicating that the middle meatus in healthy children is commonly colonized with *S pneumoniae*, *H influenzae*, and *M catarrhalis*.[46]

Recent estimates of the microbiology of acute sinusitis have, of necessity, been based primarily on that of acute otitis media (AOM), a condition with relatively easy access to infective fluid through performance of tympanocentesis and one with a similar pathogenesis to acute bacterial sinusitis.[47,48] The 3 most common bacterial pathogens recovered from the middle ear fluid of children with AOM are the same as those that have been associated with acute bacterial sinusitis: *S pneumoniae*, nontypeable *H influenzae*, and *M catarrhalis*.[49] The proportion of each has varied from study to study depending on criteria used for diagnosis of AOM, patient characteristics, and bacteriologic techniques. Recommendations since the year 2000 for the routine use in infants of 7-valent and, more recently, 13-valent pneumococcal conjugate vaccine (PCV-13) have been associated with a decrease in recovery of *S pneumoniae* from ear fluid of children with AOM and a relative increase in the incidence of infections attributable to *H influenzae*.[50] Thus, on the basis of the proportions of bacteria found in middle ear infections, it is estimated that *S pneumoniae* and *H influenzae* are currently each responsible for approximately 30% of cases of acute bacterial sinusitis in children, and *M catarrhalis* is responsible for approximately 10%. These percentages are contingent on the assumption that approximately one-quarter of aspirates of maxillary sinusitis would still be sterile, as reported in earlier studies. *Staphylococcus aureus* is rarely isolated from sinus aspirates in children with acute bacterial sinusitis, and with the exception of acute maxillary sinusitis associated with infections of dental origin,[51] respiratory anaerobes are also rarely recovered.[40,52] Although *S aureus* is a very infrequent cause of acute bacterial sinusitis in children, it is a significant pathogen in the orbital and intracranial complications of sinusitis. The reasons for this discrepancy are unknown.

Antimicrobial susceptibility patterns for *S pneumoniae* vary considerably from community to community. Isolates obtained from surveillance centers nationwide indicate that, at the present time, 10% to 15% of upper respiratory tract isolates of *S pneumoniae* are nonsusceptible to penicillin[53,54]; however, values for penicillin nonsusceptibility as high as 50% to 60% have been reported in some areas.[55,56] Of the organisms that are resistant, approximately half are highly resistant to penicillin and the remaining half are intermediate in resistance. [53,54,56–59] Between 10% and 42% of *H influenzae*[56–59] and close to 100% of *M catarrhalis* are likely to be β-lactamase positive and nonsusceptible to amoxicillin. Because of dramatic geographic variability in the prevalence of β-lactamase–positive *H influenzae*, it is extremely desirable for the practitioner to be familiar with local patterns of susceptibility. Risk factors for the presence of organisms

likely to be resistant to amoxicillin include attendance at child care, receipt of antimicrobial treatment within the previous 30 days, and age younger than 2 years.[50,55,60]

Amoxicillin remains the antimicrobial agent of choice for first-line treatment of uncomplicated acute bacterial sinusitis in situations in which antimicrobial resistance is not suspected. This recommendation is based on amoxicillin's effectiveness, safety, acceptable taste, low cost, and relatively narrow microbiologic spectrum. For children aged 2 years or older with uncomplicated acute bacterial sinusitis that is mild to moderate in degree of severity who do not attend child care and who have not been treated with an antimicrobial agent within the last 4 weeks, amoxicillin is recommended at a standard dose of 45 mg/kg per day in 2 divided doses. In communities with a high prevalence of nonsusceptible *S pneumoniae* (>10%, including intermediate- and high-level resistance), treatment may be initiated at 80 to 90 mg/kg per day in 2 divided doses, with a maximum of 2 g per dose.[55] This high-dose amoxicillin therapy is likely to achieve sinus fluid concentrations that are adequate to overcome the resistance of *S pneumoniae,* which is attributable to alteration in penicillin-binding proteins on the basis of data derived from patients with AOM.[61] If, within the next several years after licensure of PCV-13, a continuing decrease in isolates of *S pneumoniae* (including a decrease in isolates of nonsusceptible *S pneumoniae)* and an increase in β-lactamase–producing *H influenzae* are observed, standard-dose amoxicillin-clavulanate (45 mg/kg per day) may be most appropriate.

Patients presenting with moderate to severe illness as well as those younger than 2 years, attending child care, or who have recently been treated with an antimicrobial may receive high-dose amoxicillin-clavulanate (80–90 mg/kg per day of the amoxicillin component with 6.4 mg/kg per day of clavulanate in 2 divided doses with a maximum of 2 g per dose). The potassium clavulanate levels are adequate to inhibit all β-lactamase–producing *H influenzae* and *M catarrhalis*.[56,59]

A single 50-mg/kg dose of ceftriaxone, given either intravenously or intramuscularly, can be used for children who are vomiting, unable to tolerate oral medication, or unlikely to be adherent to the initial doses of antibiotic.[62–64] The 3 major bacterial pathogens involved in acute bacterial sinusitis are susceptible to ceftriaxone in 95% to 100% of cases.[56,58,59] If clinical improvement is observed at 24 hours, an oral antibiotic can be substituted to complete the course of therapy. Children who are still significantly febrile or symptomatic at 24 hours may require additional parenteral doses before switching to oral therapy.

The treatment of patients with presumed allergy to penicillin has been controversial. However, recent publications indicate that the risk of a serious allergic reaction to second- and third-generation cephalosporins in patients with penicillin or amoxicillin allergy appears to be almost nil and no greater than the risk among patients without such allergy.[65–67] Thus, patients allergic to amoxicillin with a non–type 1 (late or delayed, >72 hours) hypersensitivity reaction can safely be treated with cefdinir, cefuroxime, or cefpodoxime.[66–68] Patients with a history of a serious type 1 immediate or accelerated (anaphylactoid) reaction to amoxicillin can also safely be treated with cefdinir, cefuroxime, or cefpodoxime. In both circumstances, clinicians may wish to determine individual tolerance by referral to an allergist for penicillin and/or cephalosporin skin-testing before initiation of therapy.[66–68] The susceptibility of *S pneumoniae* to cefdinir, cefpodoxime, and cefuroxime varies from 60% to 75%,[56–59] and the susceptibility of *H influenzae* to these agents varies from 85% to 100%.[56,58] In young children (<2 years) with a serious type 1 hypersensitivity to penicillin and moderate or more severe sinusitis, it may be prudent to use a combination of clindamycin (or linezolid) and cefixime to achieve the most comprehensive coverage against both resistant *S pneumoniae* and *H influenzae*. Linezolid has excellent activity against all *S pneumoniae*, including penicillin-resistant strains, but lacks activity against *H influenzae* and *M catarrhalis*. Alternatively, a quinolone, such as levofloxacin, which has a high level of activity against both *S pneumoniae* and *H influenzae*, may be prescribed.[57,58] Although the use of quinolones is usually restricted because of concerns for toxicity, cost, and emerging resistance, their use in this circumstance can be justified.

Pneumococcal and *H influenzae* surveillance studies have indicated that resistance of these organisms to trimethoprim-sulfamethoxazole and azithromycin is sufficient to preclude their use for treatment of acute bacterial sinusitis in patients with penicillin hypersensitivity.[56,58,59,69]

The optimal duration of antimicrobial therapy for patients with acute bacterial sinusitis has not received systematic study. Recommendations based on clinical observations have varied widely, from 10 to 28 days of treatment. An alternative suggestion has been made that antibiotic therapy be continued for 7 days after the patient becomes free of signs and symptoms.[5] This strategy has the advantage of individualizing the treatment of each patient, results in a minimum course of 10 days, and

avoids prolonged antimicrobial therapy in patients who are asymptomatic and therefore unlikely to adhere to the full course of treatment.[5]

Patients who are acutely ill and appear toxic when first seen (see below) can be managed with 1 of 2 options. Consultation can be requested from an otolaryngologist for consideration of maxillary sinus aspiration (with appropriate analgesia/anesthesia) to obtain a sample of sinus secretions for Gram stain, culture, and susceptibility testing so that antimicrobial therapy can be adjusted precisely. Alternatively, inpatient therapy can be initiated with intravenous cefotaxime or ceftriaxone, with referral to an otolaryngologist if the patient's condition worsens or fails to show improvement within 48 hours. If a complication is suspected, management will differ depending on the site and severity.

A recent guideline was published by the Infectious Diseases Society of America for acute bacterial rhinosinusitis in children and adults.[70] Their recommendation for initial empirical antimicrobial therapy for acute bacterial sinusitis in children was amoxicillin-clavulanate based on the concern that there is an increasing prevalence of *H influenzae* as a cause of sinusitis since introduction of the pneumococcal conjugate vaccines and an increasing prevalence of β-lactamase production among these strains. In contrast, this guideline from the AAP allows either amoxicillin or amoxicillin-clavulanate as first-line empirical therapy and is therefore inclusive of the Infectious Diseases Society of America's recommendation. Unfortunately, there are scant data available regarding the precise microbiology of acute bacterial sinusitis in the post–PCV-13 era. Prospective surveillance of nasopharyngeal cultures may be helpful in completely aligning these recommendations in the future.

Key Action Statement 5A

Clinicians should reassess initial management if there is either a caregiver report of worsening (progression of initial signs/symptoms or appearance of new signs/symptoms) OR failure to improve (lack of reduction in all presenting signs/symptoms) within 72 hours of initial management (Evidence Quality: C; Recommendation).

KAS Profile 5A

Aggregate evidence quality: C; observational studies	
Benefits	Identification of patients who may have been misdiagnosed, those at risk of complications, and those who require a change in management.
Harm	Delay of up to 72 hours in changing therapy if patient fails to improve.
Cost	Additional provider and caregiver time and resources.
Benefits-harm assessment	Preponderance of benefit.
Value judgments	Use of 72 hours to assess progress may result in excessive classification as treatment failures if premature; emphasis on importance of worsening illness in defining treatment failures.
Role of patient preferences	Caregivers determine whether the severity of the patient's illness justifies the report to clinician of the patient's worsening or failure to improve.
Intentional vagueness	None.
Exclusions	Patients with severe illness, poor general health, complicated sinusitis, immune deficiency, previous sinus surgery, or coexisting bacterial illness.
Strength	Recommendation.

The purpose of this key action statement is to ensure that patients with acute bacterial sinusitis who fail to improve symptomatically after initial management are reassessed to be certain that they have been correctly diagnosed and to consider initiation of alternate therapy to hasten resolution of symptoms and avoid complications. "Worsening" is defined as progression of presenting signs or symptoms of acute bacterial sinusitis or onset of new signs or symptoms. "Failure to improve" is lack of reduction in presenting signs or symptoms of acute bacterial sinusitis by 72 hours after diagnosis and initial management; patients with persistent but improving symptoms do not meet this definition.

The rationale for using 72 hours as the time to assess treatment failure for acute bacterial sinusitis is based on clinical outcomes in RCTs. Wald et al[41] found that 18 of 35 patients (51%) receiving placebo demonstrated symptomatic improvement within 3 days of initiation of treatment; only an additional 3 patients receiving placebo (9%) improved between days 3 and 10. In the same study, 48 of 58 patients (83%) receiving antibiotics were cured or improved within 3 days; at 10 days, the overall rate of improvement was 79%, suggesting that no additional patients improved between days 3 and 10. In a more recent study, 17 of 19 children who ultimately failed initial therapy with either antibiotic or placebo demonstrated failure to improve within 72 hours.[4] Although Garbutt et al[42] did not report the percentage of patients who improved by day 3, they did demonstrate that the majority of improvement in symptoms occurred within

the first 3 days of study entry whether they received active treatment or placebo.

Reporting of either worsening or failure to improve implies a shared responsibility between clinician and caregiver. Although the clinician should educate the caregiver regarding the anticipated reduction in symptoms within 3 days, it is incumbent on the caregiver to appropriately notify the clinician of concerns regarding worsening or failure to improve. Clinicians should emphasize the importance of reassessing those children whose symptoms are worsening whether or not antibiotic therapy was prescribed. Reassessment may be indicated before the 72-hour mark if the patient is substantially worse, because it may indicate the development of complications or a need for parenteral therapy. Conversely, in some cases, caregivers may think that symptoms are not severe enough to justify a change to an antibiotic with a less desirable safety profile or even the time, effort, and resources required for reassessment. Accordingly, the circumstances under which caregivers report back to the clinician and the process by which such reporting occurs should be discussed at the time the initial management strategy is determined.

Key Action Statement 5B

If the diagnosis of acute bacterial sinusitis is confirmed in a child with worsening symptoms or failure to improve in 72 hours, then clinicians may change the antibiotic therapy for the child initially managed with antibiotic OR initiate antibiotic treatment of the child initially managed with observation (Evidence Quality: D; Option based on expert opinion, case reports, and reasoning from first principles).

KAS Profile 5B

Aggregate evidence quality: D; expert opinion and reasoning from first principles.	
Benefit	Prevention of complications, administration of effective therapy.
Harm	Adverse effects of secondary antibiotic therapy.
Cost	Direct cost of medications, often substantial for second-line agents.
Benefits-harm assessment	Preponderance of benefit.
Value judgments	Clinician must determine whether cost and adverse effects associated with change in antibiotic is justified given the severity of illness.
Role of patient preferences	Limited in patients whose symptoms are severe or worsening, but caregivers of mildly affected children who are failing to improve may reasonably defer change in antibiotic.
Intentional vagueness	None.
Exclusions	None.
Strength	Option.

The purpose of this key action statement is to ensure optimal antimicrobial treatment of children with acute bacterial sinusitis whose symptoms worsen or fail to respond to the initial intervention to prevent complications and reduce symptom severity and duration (see Table 4).

Clinicians who are notified by a caregiver that a child's symptoms are worsening or failing to improve should confirm that the clinical diagnosis of acute bacterial sinusitis corresponds to the patient's pattern of illness, as defined in Key Action Statement 1. If caregivers report worsening of symptoms at any time in a patient for whom observation was the initial intervention, the clinician should begin treatment as discussed in Key Action Statement 4. For patients whose symptoms are mild and who have failed to improve but have not worsened, initiation of antimicrobial agents or continued observation (for up to 3 days) is reasonable.

If caregivers report worsening of symptoms after 3 days in a patient initially treated with antimicrobial agents, current signs and symptoms should be reviewed to determine whether acute bacterial sinusitis is still the best diagnosis. If sinusitis is still the best diagnosis, infection with drug-resistant bacteria is probable, and an alternate antimicrobial agent may be administered. Face-to-face reevaluation of the patient is desirable. Once the decision is made to change medications, the clinician should consider the limitations of the initial antibiotic coverage, the anticipated susceptibility of residual bacterial pathogens, and the ability of antibiotics to adequately penetrate the site of infection. Cultures of sinus or nasopharyngeal secretions in patients with initial antibiotic failure have identified a large percentage of bacteria with resistance to the original antibiotic.[71,72] Furthermore, multidrug-resistant *S pneumoniae* and β-lactamase–positive *H influenzae* and *M catarrhalis* are more commonly isolated after previous antibiotic exposure.[73–78] Unfortunately, there are no studies in children that have investigated the microbiology of treatment failure in acute bacterial sinusitis or cure rates using second-line antimicrobial agents. As a result, the likelihood of adequate antibiotic coverage for resistant organisms must be

addressed by extrapolations from studies of acute otitis media in children and sinusitis in adults and by using the results of data generated in vitro. A general guide to management of the child who worsens in 72 hours is shown in Table 4.

NO RECOMMENDATION

Adjuvant Therapy

Potential adjuvant therapy for acute sinusitis might include intranasal corticosteroids, saline nasal irrigation or lavage, topical or oral decongestants, mucolytics, and topical or oral antihistamines. A recent Cochrane review on decongestants, antihistamines, and nasal irrigation for acute sinusitis in children found no appropriately designed studies to determine the effectiveness of these interventions.[79]

Intranasal Steroids

The rationale for the use of intranasal corticosteroids in acute bacterial sinusitis is that an antiinflammatory agent may reduce the swelling around the sinus ostia and encourage drainage, thereby hastening recovery. However, there are limited data on how much inflammation is present, whether the inflammation is responsive to steroids, and whether there are differences in responsivity according to age. Nonetheless, there are several RCTs in adolescents and adults, most of which do show significant differences compared with placebo or active comparator that favor intranasal steroids in the reduction of symptoms and the patient's global assessment of overall improvement.[80–85] Several studies in adults with acute bacterial sinusitis provide data supporting the use of intranasal steroids as either monotherapy or adjuvant therapy to antibiotics.[81,86] Only one study did not show efficacy.[85]

There have been 2 trials of intranasal steroids performed exclusively in children: one comparing intranasal corticosteroids versus an oral decongestant[87] and the other comparing intranasal corticosteroids with placebo.[88] These studies showed a greater rate of complete resolution[87] or greater reduction in symptoms in patients receiving the steroid preparation, although the effects were modest.[88] It is important to note that nearly all of these studies (both those reported in children and adults) suffered from substantial methodologic problems. Examples of these methodologic problems are as follows: (1) variable inclusion criteria for sinusitis, (2) mixed populations of allergic and nonallergic subjects, and (3) different outcome criteria. All of these factors make deriving a clear conclusion difficult. Furthermore, the lack of stringent criteria in selecting the subject population increases the chance that the subjects had viral URIs or even persistent allergies rather than acute bacterial sinusitis.

The intranasal steroids studied to date include budesonide, flunisolide, fluticasone, and mometasone. There is no reason to believe that one steroid would be more effective than another, provided equivalent doses are used.

Potential harm in using nasal steroids in children with acute sinusitis includes the increased cost of therapy, difficulty in effectively administering nasal sprays in young children, nasal irritation and epistaxis, and potential systemic adverse effects of steroid use. Fortunately, no clinically significant steroid adverse effects have been discovered in studies in children.[89–96]

Saline Irrigation

Saline nasal irrigation or lavage (not saline nasal spray) has been used to remove debris from the nasal cavity and temporarily reduce tissue edema (hypertonic saline) to promote drainage from the sinuses. There have been very few RCTs using saline nasal irrigation or lavage in acute sinusitis, and these have had mixed results.[97,98] The 1 study in children showed greater improvement in nasal airflow and quality of life as well as a better rate of improvement in total symptom score when compared with placebo in patients treated with antibiotics and decongestants.[98] There are 2 Cochrane reviews published on the use of saline nasal irrigation in acute sinusitis in adults that showed variable results. One review published in 2007[99] concluded that it is a beneficial adjunct, but the other, published in 2010,[100] concluded that most trials were too small or contained too high a risk of bias to be confident about benefits.

Nasal Decongestants, Mucolytics, and Antihistamines

Data are insufficient to make any recommendations about the use of oral or topical nasal decongestants, mucolytics, or oral or nasal spray antihistamines as adjuvant therapy for acute bacterial sinusitis in children.[79] It is the opinion of the expert panel that antihistamines should not be used for the primary indication of acute bacterial sinusitis in any child, although such therapy might be helpful in reducing typical allergic symptoms in patients with atopy who also have acute sinusitis.

OTHER RELATED CONDITIONS

Recurrence of Acute Bacterial Sinusitis

Recurrent acute bacterial sinusitis (RABS) is an uncommon occurrence in healthy children and must be distinguished from recurrent URIs, exacerbations of allergic rhinitis, and chronic sinusitis. The former is defined by episodes of bacterial infection of the paranasal sinuses lasting fewer than 30 days and separated by intervals of

TABLE 3 Parent Information Regarding Initial Management of Acute Bacterial Sinusitis

How common are sinus infections in children?	Thick, colored, or cloudy mucus from your child's nose frequently occurs with a common cold or viral infection and does not by itself mean your child has sinusitis. In fact, fewer than 1 in 15 children get a true bacterial sinus infection during or after a common cold.
How can I tell if my child has bacterial sinusitis or simply a common cold?	Most colds have a runny nose with mucus that typically starts out clear, becomes cloudy or colored, and improves by about 10 d. Some colds will also include fever (temperature >38°C [100.4°F]) for 1 to 2 days. In contrast, acute bacterial sinusitis is likely when the pattern of illness is persistent, severe, or worsening. 1. *Persistent* sinusitis is the most common type, defined as runny nose (of any quality), daytime cough (which may be worse at night), or both for at least 10 days without improvement. 2. *Severe* sinusitis is present when fever (temperature ≥39°C [102.2°F]) lasts for at least 3 days in a row and is accompanied by nasal mucus that is thick, colored, or cloudy. 3. *Worsening* sinusitis starts with a viral cold, which begins to improve but then worsens when bacteria take over and cause new-onset fever (temperature ≥38°C [100.4°F]) or a substantial increase in daytime cough or runny nose.
If my child has sinusitis, should he or she take an antibiotic?	Children with *persistent* sinusitis may be managed with either an antibiotic or with an additional brief period of observation, allowing the child up to another 3 days to fight the infection and improve on his or her own. The choice to treat or observe should be discussed with your doctor and may be based on your child's quality of life and how much of a problem the sinusitis is causing. In contrast, all children diagnosed with *severe* or *worsening* sinusitis should start antibiotic treatment to help them recover faster and more often.
Why not give all children with acute bacterial sinusitis an immediate antibiotic?	Some episodes of *persistent* sinusitis include relatively mild symptoms that may improve on their own in a few days. In addition, antibiotics can have adverse effects, which may include vomiting, diarrhea, upset stomach, skin rash, allergic reactions, yeast infections, and development of resistant bacteria (that make future infections more difficult to treat).

at least 10 days during which the patient is asymptomatic. Some experts require at least 4 episodes in a calendar year to fulfill the criteria for this condition. Chronic sinusitis is manifest as 90 or more uninterrupted days of respiratory symptoms, such as cough, nasal discharge, or nasal obstruction.

Children with RABS should be evaluated for underlying allergies, particularly allergic rhinitis; quantitative and functional immunologic defect(s), chiefly immunoglobulin A and immunoglobulin G deficiency; cystic fibrosis; gastroesophageal reflux disease; or dysmotile cilia syndrome.[101] Anatomic abnormalities obstructing one or more sinus ostia may be present. These include septal deviation, nasal polyps, or concha bullosa (pneumatization of the middle turbinate); atypical ethmoid cells with compromised drainage; a lateralized middle turbinate; and intrinsic ostiomeatal anomalies.[102] Contrast-enhanced CT, MRI, or endoscopy or all 3 should be performed for detection of obstructive conditions, particularly in children with genetic or acquired craniofacial abnormalities.

The microbiology of RABS is similar to that of isolated episodes of acute bacterial sinusitis and warrants the same treatment.[72] It should be recognized that closely spaced sequential courses of antimicrobial therapy may foster the emergence of antibiotic-resistant bacterial species as the causative agent in recurrent episodes. There are no systematically evaluated options for prevention of RABS in children. In general, the use of prolonged prophylactic antimicrobial therapy should be avoided and is not usually recommended for children with recurrent acute otitis media. However, when there are no recognizable predisposing conditions to remedy in children with RABS, prophylactic antimicrobial agents may be used for several months during the respiratory season. Enthusiasm for this strategy is tempered by concerns regarding the encouragement of bacterial resistance. Accordingly, prophylaxis should only be considered in carefully selected children whose infections have been thoroughly documented.

Influenza vaccine should be administered annually, and PCV-13 should be administered at the recommended ages for all children, including those with RABS. Intranasal steroids and nonsedating antihistamines can be helpful for children with allergic rhinitis, as can antireflux medications for those with gastroesophageal reflux disease. Children with anatomic abnormalities may require endoscopic surgery for removal of or reduction in ostiomeatal obstruction.

The pathogenesis of chronic sinusitis is poorly understood and appears to be multifactorial; however, many of the conditions associated with RABS

TABLE 4 Management of Worsening or Lack of Improvement at 72 Hours

Initial Management	Worse in 72 Hours	Lack of Improvement in 72 Hours
Observation	Initiate amoxicillin with or without clavulanate	Additional observation or initiate antibiotic based on shared decision-making
Amoxicillin	High-dose amoxicillin-clavulanate	Additional observation or high-dose amoxicillin-clavulanate based on shared decision-making
High-dose amoxicillin-clavulanate	Clindamycin[a] and cefixime OR linezolid and cefixime OR levofloxacin	Continued high-dose amoxicillin-clavulanate OR clindamycin[a] and cefixime OR linezolid and cefixime OR levofloxacin

[a] Clindamycin is recommended to cover penicillin-resistant *S pneumoniae*. Some communities have high levels of clindamycin-resistant *S pneumoniae*. In these communities, linezolid is preferred.

have also been implicated in chronic sinusitis, and it is clear that there is an overlap between the 2 syndromes.[101,102] In some cases, there may be episodes of acute bacterial sinusitis superimposed on a chronic sinusitis, warranting antimicrobial therapy to hasten resolution of the acute infection.

Complications of Acute Bacterial Sinusitis

Complications of acute bacterial sinusitis should be diagnosed when the patient develops signs or symptoms of orbital and/or central nervous system (intracranial) involvement. Rarely, complicated acute bacterial sinusitis can result in permanent blindness, other neurologic sequelae, or death if not treated promptly and appropriately. Orbital complications have been classified by Chandler et al.[32] Intracranial complications include epidural or subdural abscess, brain abscess, venous thrombosis, and meningitis.

Periorbital and intraorbital inflammation and infection are the most common complications of acute sinusitis and most often are secondary to acute ethmoiditis in otherwise healthy young children. These disorders are commonly classified in relation to the orbital septum; periorbital or preseptal inflammation involves only the eyelid, whereas postseptal (intraorbital) inflammation involves structures of the orbit. Mild cases of preseptal cellulitis (eyelid <50% closed) may be treated on an outpatient basis with appropriate oral antibiotic therapy (high-dose amoxicillin-clavulanate for comprehensive coverage) for acute bacterial sinusitis and daily follow-up until definite improvement is noted. If the patient does not improve within 24 to 48 hours or if the infection is progressive, it is appropriate to admit the patient to the hospital for antimicrobial therapy. Similarly, if proptosis, impaired visual acuity, or impaired and/or painful extraocular mobility is present on examination, the patient should be hospitalized, and a contrast-enhanced CT should be performed. Consultation with an otolaryngologist, an ophthalmologist, and an infectious disease expert is appropriate for guidance regarding the need for surgical intervention and the selection of antimicrobial agents.

Intracranial complications are most frequently encountered in previously healthy adolescent males with frontal sinusitis.[33,34] In patients with altered mental status, severe headache, or Pott's puffy tumor (osteomyelitis of the frontal bone), neurosurgical consultation should be obtained. A contrast-enhanced CT scan (preferably coronal thin cut) of the head, orbits, and sinuses is essential to confirm intracranial or intraorbital suppurative complications; in such cases, intravenous antibiotics should be started immediately. Alternatively, an MRI may also be desirable in some cases of intracranial abnormality. Appropriate antimicrobial therapy for intraorbital complications include vancomycin (to cover possible methicillin-resistant *S aureus* or penicillin-resistant *S pneumoniae*) and either ceftriaxone, ampicillin-sulbactam, or piperacillin-tazobactam.[103] Given the polymicrobial nature of sinogenic abscesses, coverage for anaerobes (ie, metronidazole) should also be considered for intraorbital complications and should be started in all cases of intracranial complications if ceftriaxone is prescribed.

Patients with small orbital, subperiosteal, or epidural abscesses and minimal ocular and neurologic abnormalities may be managed with intravenous antibiotic treatment for 24 to 48 hours while performing frequent visual and mental status checks.[104] In patients who develop progressive signs and symptoms, such as impaired visual acuity, ophthalmoplegia, elevated intraocular pressure (>20 mm), severe proptosis (>5 mm), altered mental status, headache, or vomiting, as well as those who fail to improve within 24 to 48 hours while receiving antibiotics, prompt surgical intervention and drainage of the abscess should be undertaken.[104] Antibiotics can be tailored to the results of culture and sensitivity studies when they become available.

AREAS FOR FUTURE RESEARCH

Since the publication of the original guideline in 2001, only a small number of high-quality studies of the diagnosis and treatment of acute bacterial sinusitis in children have been published.[5] Ironically, the number of published guidelines on the topic (5) exceeds the number of prospective,

placebo-controlled clinical trials of either antibiotics or ancillary treatments of acute bacterial sinusitis. Thus, as was the case in 2001, there are scant data on which to base recommendations. Accordingly, areas for future research include the following:

Etiology

1. Reexamine the microbiology of acute sinusitis in children in the postpneumococcal conjugate vaccine era and determine the value of using newer polymerase chain reaction–based respiratory testing to document viral, bacterial, and polymicrobial disease.
2. Correlate cultures obtained from the middle meatus of the maxillary sinus of infected children with cultures obtained from the maxillary sinus by puncture of the antrum.
3. Conduct more and larger studies to more clearly define and correlate the clinical findings with the various available diagnostic criteria of acute bacterial sinusitis (eg, sinus aspiration and treatment outcome).
4. Develop noninvasive strategies to accurately diagnose acute bacterial sinusitis in children.
5. Develop imaging technology that differentiates bacterial infection from viral infection or allergic inflammation, preferably without radiation.

Treatment

1. Determine the optimal duration of antimicrobial therapy for children with acute bacterial sinusitis.
2. Evaluate a "wait-and-see prescription" strategy for children with persistent symptom presentation of acute sinusitis.
3. Determine the optimal antimicrobial agent for children with acute bacterial sinusitis, balancing the incentives of choosing narrow-spectrum agents against the known microbiology of the disease and resistance patterns of likely pathogens.
4. Determine the causes and treatment of subacute, recurrent acute, and chronic bacterial sinusitis.
5. Determine the efficacy of prophylaxis with antimicrobial agents to prevent RABS.
6. Determine the effects of bacterial resistance among *S pneumoniae*, *H influenzae*, and *M catarrhalis* on outcome of treatment with antibiotics by the performance of randomized, double-blind, placebo-controlled studies in well-defined populations of patients.
7. Determine the role of adjuvant therapies (antihistamines, nasal corticosteroids, mucolytics, decongestants, nasal irrigation, etc) in patients with acute bacterial sinusitis by the performance of prospective, randomized clinical trials.
8. Determine whether early treatment of acute bacterial sinusitis prevents orbital or central nervous system complications.
9. Determine the role of complementary and alternative medicine strategies in patients with acute bacterial sinusitis by performing systematic, prospective, randomized clinical trials.
10. Develop new bacterial and viral vaccines to reduce the incidence of acute bacterial sinusitis.

SUBCOMMITTEE ON ACUTE SINUSITIS

Ellen R. Wald, MD, FAAP (Chair, Pediatric Infectious Disease Physician: no financial conflicts; published research related to sinusitis)
Kimberly E. Applegate, MD, MS, FAAP (Radiologist, AAP Section on Radiology: no conflicts)
Clay Bordley, MD, MPH, FAAP (Pediatric Emergency and Hospitalist Medicine physician: no conflicts)
David H. Darrow, MD, FAAP (Otolaryngologist, AAP Section on Otolaryngology–Head and Neck Surgery: no conflicts)
Mary P. Glode, MD, FAAP (Pediatric Infectious Disease Physician, AAP Committee on Infectious Disease: no conflicts)
S. Michael Marcy, MD, FAAP (General Pediatrician with Infectious Disease Expertise, AAP Section on Infectious Diseases: no conflicts)
Nader Shaikh, MD, FAAP (General Academic Pediatrician: no financial conflicts; published research related to sinusitis)
Michael J. Smith, MD, MSCE, FAAP (Epidemiologist, Pediatric Infectious Disease Physician: research funding for vaccine clinical trials from Sanofi Pasteur and Novartis)
Paul V. Williams, MD, FAAP (Allergist, AAP Section on Allergy, Asthma, and Immunology: no conflicts)
Stuart T. Weinberg, MD, FAAP (PPI Informatician, General Academic Pediatrician: no conflicts)
Carrie E. Nelson, MD, MS (Family Physician, American Academy of Family Physicians: employed by McKesson Health Solutions)
Richard M. Rosenfeld, MD, MPH, FAAP (Otolaryngologist, AAP Section on Otolaryngology–Head and Neck Surgery, American Academy of Otolaryngology–Head and Neck Surgery: no financial conflicts; published research related to sinusitis)

CONSULTANT

Richard N. Shiffman, MD, FAAP (Informatician, Guideline Methodologist, General Academic Pediatrician: no conflicts)

Sinusitis Clinical Practice Guideline Quick Reference Tools

- Action Statement Summary
  — Clinical Practice Guideline for the Diagnosis and Management of Acute Bacterial Sinusitis in Children Aged 1 to 18 Years
- *ICD-10-CM* Coding Quick Reference for Sinusitis
- AAP Patient Education Handout
  — *Sinusitis and Your Child*

Action Statement Summary

Clinical Practice Guideline for the Diagnosis and Management of Acute Bacterial Sinusitis in Children Aged 1 to 18 Years

Key Action Statement 1

Clinicians should make a presumptive diagnosis of acute bacterial sinusitis when a child with an acute URI presents with the following:

- Persistent illness, ie, nasal discharge (of any quality) or daytime cough or both lasting more than 10 days without improvement;

OR

- Worsening course, ie, worsening or new onset of nasal discharge, daytime cough, or fever after initial improvement;

OR

- Severe onset, ie, concurrent fever (temperature ≥39°C/102.2°F) and purulent nasal discharge for at least 3 consecutive days (Evidence Quality: B; Recommendation).

Key Action Statement 2A

Clinicians should not obtain imaging studies (plain films, contrast-enhanced computed tomography [CT], MRI, or ultrasonography) to distinguish acute bacterial sinusitis from viral URI (Evidence Quality: B; Strong Recommendation).

Key Action Statement 2B

Clinicians should obtain a contrast-enhanced CT scan of the paranasal sinuses and/or an MRI with contrast whenever a child is suspected of having orbital or central nervous system complications of acute bacterial sinusitis (Evidence Quality: B; Strong Recommendation).

Key Action Statement 3

Initial Management of Acute Bacterial Sinusitis

3A: "Severe onset and worsening course" acute bacterial sinusitis. The clinician should prescribe antibiotic therapy for acute bacterial sinusitis in children with severe onset or worsening course (signs, symptoms, or both) (Evidence Quality: B; Strong Recommendation).

3B: "Persistent illness." The clinician should either prescribe antibiotic therapy OR offer additional outpatient observation for 3 days to children with persistent illness (nasal discharge of any quality or cough or both for at least 10 days without evidence of improvement) (Evidence Quality: B; Recommendation).

Key Action Statement 4

Clinicians should prescribe amoxicillin with or without clavulanate as first-line treatment when a decision has been made to initiate antibiotic treatment of acute bacterial sinusitis (Evidence Quality: B; Recommendation).

Key Action Statement 5A

Clinicians should reassess initial management if there is either a caregiver report of worsening (progression of initial signs/symptoms or appearance of new signs/symptoms) OR failure to improve (lack of reduction in all presenting signs/symptoms) within 72 hours of initial management (Evidence Quality: C; Recommendation).

Key Action Statement 5B

If the diagnosis of acute bacterial sinusitis is confirmed in a child with worsening symptoms or failure to improve in 72 hours, then clinicians may change the antibiotic therapy for the child initially managed with antibiotic OR initiate antibiotic treatment of the child initially managed with observation (Evidence Quality: D; Option based on expert opinion, case reports, and reasoning from first principles).

Sinusitis and Your Child

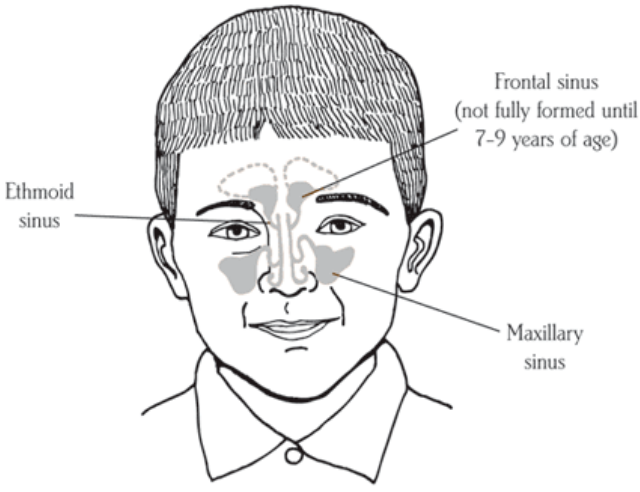
Sinusitis is an inflammation of the lining of the nose and sinuses. It is a very common infection in children.

Viral sinusitis usually accompanies a cold. Allergic sinusitis may accompany allergies such as hay fever. Bacterial sinusitis is a secondary infection caused by the trapping of bacteria in the sinuses during the course of a cold or allergy.

Fluid inside the sinuses

When your child has a viral cold or hay fever, the linings of the nose and sinus cavities swell up and produce more fluid than usual. This is why the nose gets congested and is "runny" during a cold.

Most of the time the swelling disappears by itself as the cold or allergy goes away. However, if the swelling does not go away, the openings that normally allow the sinuses to drain into the back of the nose get blocked and the sinuses fill with fluid. Because the sinuses are blocked and cannot drain properly, bacteria are trapped inside and grow there, causing a secondary infection. Although nose blowing and sniffing may be natural responses to this blockage, when excessive they can make the situation worse by pushing bacteria from the back of the nose into the sinuses.



The linings of the sinuses and the nose always produce some fluid (secretions). This fluid keeps the nose and sinus cavities from becoming too dry and adds moisture to the air that you breathe.

Is it a cold or bacterial sinusitis?

It is often difficult to tell if an illness is just a viral cold or if it is complicated by a bacterial infection of the sinuses.

Generally viral colds have the following characteristics:

- Colds usually last only 5 to 10 days.
- Colds typically start with clear, watery nasal discharge. After a day or 2, it is normal for the nasal discharge to become thicker and white, yellow, or green. After several days, the discharge becomes clear again and dries.
- Colds include a daytime cough that often gets worse at night.
- If a fever is present, it is usually at the beginning of the cold and is generally low grade, lasting for 1 or 2 days.
- Cold symptoms usually peak in severity at 3 or 5 days, then improve and disappear over the next 7 to 10 days.

Signs and symptoms that your child may have bacterial sinusitis include:

- Cold symptoms (nasal discharge, daytime cough, or both) lasting more than 10 days *without improving*
- Thick yellow nasal discharge *and* a fever for at least 3 or 4 days in a row
- A severe headache behind or around the eyes that gets worse when bending over
- Swelling and dark circles around the eyes, especially in the morning
- Persistent bad breath along with cold symptoms (However, this also could be from a sore throat or a sign that your child is not brushing his teeth!)

In very rare cases, a bacterial sinus infection may spread to the eye or the central nervous system (the brain). If your child has the following symptoms, call your pediatrician immediately:

- Swelling and/or redness around the eyes, not just in the morning but all day
- Severe headache and/or pain in the back of the neck
- Persistent vomiting
- Sensitivity to light
- Increasing irritability

Diagnosing bacterial sinusitis

It may be difficult to tell a sinus infection from an uncomplicated cold, especially in the first few days of the illness. Your pediatrician will most likely be able to tell if your child has bacterial sinusitis after examining your child and hearing about the progression of symptoms. In older children, when the diagnosis is uncertain, your pediatrician may order computed tomographic (CT) scans to confirm the diagnosis.

Treating bacterial sinusitis

If your child has bacterial sinusitis, your pediatrician may prescribe an antibiotic for at least 10 days. Once your child is on the medication, symptoms should start to go away over the next 2 to 3 days—the nasal discharge will clear and the cough will improve. *Even though your child may seem better, continue to give the antibiotics for the prescribed length of time. Ending the medications too early could cause the infection to return.*

When a diagnosis of sinusitis is made in children with cold symptoms lasting more than 10 days without improving, some doctors may choose to continue observation for another few days. If your child's symptoms worsen during this time or do not improve after 3 days, antibiotics should be started.

If your child's symptoms show no improvement 2 to 3 days after starting the antibiotics, talk with your pediatrician. Your child might need a different medication or need to be re-examined.

Treating related symptoms of bacterial sinusitis

Headache or sinus pain. To treat headache or sinus pain, try placing a warm washcloth on your child's face for a few minutes at a time. Pain medications such as acetaminophen or ibuprofen may also help. (However, do not give your child aspirin. It has been associated with a rare but potentially fatal disease called Reye syndrome.)

Nasal congestion. If the secretions in your child's nose are especially thick, your pediatrician may recommend that you help drain them with saline nose drops. These are available without a prescription or can be made at home by adding 1/4 teaspoon of table salt to an 8-ounce cup of water. Unless advised by your pediatrician, do not use nose drops that contain medications because they can be absorbed in amounts that can cause side effects.

Placing a cool-mist humidifier in your child's room may help keep your child more comfortable. Clean and dry the humidifier daily to prevent bacteria or mold from growing in it (follow the instructions that came with the humidifier). Hot water vaporizers are not recommended because they can cause scalds or burns.

Remember

If your child has symptoms of a bacterial sinus infection, see your pediatrician. Your pediatrician can properly diagnose and treat the infection and recommend ways to help alleviate the discomfort from some of the symptoms.

From your doctor

Diagnosis and Management of Childhood Obstructive Sleep Apnea Syndrome

- *Clinical Practice Guideline*

CLINICAL PRACTICE GUIDELINE

Diagnosis and Management of Childhood Obstructive Sleep Apnea Syndrome

abstract

FREE

OBJECTIVES: This revised clinical practice guideline, intended for use by primary care clinicians, provides recommendations for the diagnosis and management of the obstructive sleep apnea syndrome (OSAS) in children and adolescents. This practice guideline focuses on uncomplicated childhood OSAS, that is, OSAS associated with adenotonsillar hypertrophy and/or obesity in an otherwise healthy child who is being treated in the primary care setting.

METHODS: Of 3166 articles from 1999–2010, 350 provided relevant data. Most articles were level II–IV. The resulting evidence report was used to formulate recommendations.

RESULTS AND CONCLUSIONS: The following recommendations are made. (1) All children/adolescents should be screened for snoring. (2) Polysomnography should be performed in children/adolescents with snoring and symptoms/signs of OSAS; if polysomnography is not available, then alternative diagnostic tests or referral to a specialist for more extensive evaluation may be considered. (3) Adenotonsillectomy is recommended as the first-line treatment of patients with adenotonsillar hypertrophy. (4) High-risk patients should be monitored as inpatients postoperatively. (5) Patients should be reevaluated postoperatively to determine whether further treatment is required. Objective testing should be performed in patients who are high risk or have persistent symptoms/signs of OSAS after therapy. (6) Continuous positive airway pressure is recommended as treatment if adenotonsillectomy is not performed or if OSAS persists postoperatively. (7) Weight loss is recommended in addition to other therapy in patients who are overweight or obese. (8) Intranasal corticosteroids are an option for children with mild OSAS in whom adenotonsillectomy is contraindicated or for mild postoperative OSAS. *Pediatrics* 2012;130:576–584

INTRODUCTION

Obstructive sleep apnea syndrome (OSAS) is a common condition in childhood and can result in severe complications if left untreated. In 2002, the American Academy of Pediatrics (AAP) published a practice guideline for the diagnosis and management of childhood OSAS.[1] Since that time, there has been a considerable increase in publications and research on the topic; thus, the guidelines have been revised.

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

The purposes of this revised clinical practice guideline are to (1) increase the recognition of OSAS by primary care clinicians to minimize delay in diagnosis and avoid serious sequelae of OSAS; (2) evaluate diagnostic techniques; (3) describe treatment options; (4) provide guidelines for follow-up; and (5) discuss areas requiring further research. The recommendations in this statement do not indicate an exclusive course of treatment. Variations, taking into account individual circumstances, may be appropriate.

This practice guideline focuses on uncomplicated childhood OSAS—that is, the OSAS associated with adenotonsillar hypertrophy and/or obesity in an otherwise healthy child who is being treated in the primary care setting. This guideline specifically excludes infants younger than 1 year of age, patients with central apnea or hypoventilation syndromes, and patients with OSAS associated with other medical disorders, including but not limited to Down syndrome, craniofacial anomalies, neuromuscular disease (including cerebral palsy), chronic lung disease, sickle cell disease, metabolic disease, or laryngomalacia. These important patient populations are too complex to discuss within the scope of this article and require consultation with a pediatric subspecialist.

Additional information providing justification for the key action statements and a detailed review of the literature are provided in the accompanying technical report available online.[2]

METHODS OF GUIDELINE DEVELOPMENT

Details of the methods of guideline development are included in the accompanying technical report.[2] The AAP selected a subcommittee composed of pediatricians and other experts in the fields of sleep medicine, pulmonology, and otolaryngology, as well as experts from epidemiology and pediatric practice to develop an evidence base of literature on this topic. The committee included liaison members from the AAP Section on Otolaryngology-Head and Neck Surgery, American Thoracic Society, American Academy of Sleep Medicine, American College of Chest Physicians, and the National Sleep Foundation. Committee members signed forms disclosing conflicts of interest.

An automated search of the literature on childhood OSAS from 1999 to 2008 was performed by using 5 scientific literature search engines.[2] The medical subject heading terms that were used in all fields were snoring, apnea, sleep-disordered breathing, sleep-related breathing disorders, upper airway resistance, polysomnography, sleep study, adenoidectomy, tonsillectomy, continuous positive airway pressure, obesity, adiposity, hypopnea, hypoventilation, cognition, behavior, and neuropsychology. Reviews, case reports, letters to the editor, and abstracts were not included. Non–English-language articles, animal studies, and studies relating to infants younger than 1 year and to special populations (eg, children with craniofacial anomalies or sickle cell disease) were excluded. In several steps, a total of 3166 hits was reduced to 350 articles, which underwent detailed review.[2] Committee members selectively updated this literature search for articles published from 2008 to 2011 specific to guideline categories. Details of the literature grading system are available in the accompanying technical report.

Since publication of the previous guidelines, there has been an improvement in the quality of OSAS studies in the literature; however, there remain few randomized, blinded, controlled studies. Most studies were questionnaire or polysomnography based. Many studies used standard definitions for pediatric polysomnography scoring, but the interpretation of polysomnography (eg, the apnea hypopnea index [AHI] criterion used for diagnosis or to determine treatment) varied widely. The guideline notes the quality of evidence for each key action statement. Additional details are available in the technical report.

The evidence-based approach to guideline development requires that the evidence in support of each key action statement be identified, appraised, and summarized and that an explicit link between evidence and recommendations be defined. Evidence-based recommendations reflect the quality of evidence and the balance of benefit and harm that is anticipated when the recommendation is followed. The AAP policy statement, "Classifying Recommendations for Clinical Practice Guidelines,"[3] was followed in designating levels of recommendation (see Fig 1 and Table 1).

DEFINITION

This guideline defines OSAS in children as a "disorder of breathing during sleep characterized by prolonged partial upper airway obstruction and/or intermittent complete obstruction (obstructive apnea) that disrupts normal ventilation during sleep and normal sleep patterns,"[4] accompanied by symptoms or signs, as listed in Table 2. Prevalence rates based on level I and II studies range from 1.2% to 5.7%.[5–7] Symptoms include habitual snoring (often with intermittent pauses, snorts, or gasps), disturbed sleep, and daytime neurobehavioral problems. Daytime sleepiness may occur, but is uncommon in young children. OSAS is associated with neurocognitive impairment, behavioral problems, failure to thrive, hypertension, cardiac dysfunction, and systemic inflammation. Risk factors include adenotonsillar hypertrophy, obesity, craniofacial anomalies, and neuromuscular disorders. Only the first 2 risk factors are

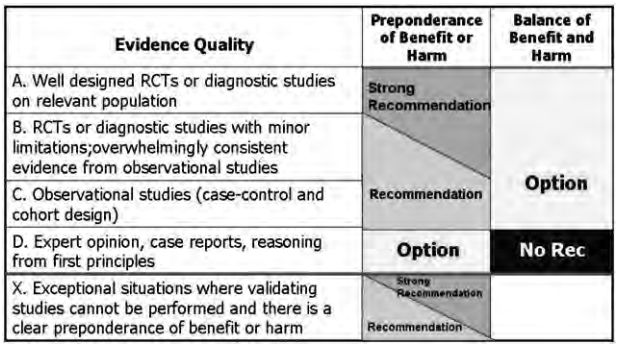

FIGURE 1

Evidence quality. Integrating evidence quality appraisal with an assessment of the anticipated balance between benefits and harms if a policy is carried out leads to designation of a policy as a strong recommendation, recommendation, option, or no recommendation. RCT, randomized controlled trial; Rec, recommendation.

discussed in this guideline. In this guideline, obesity is defined as a BMI >95th percentile for age and gender.[8]

KEY ACTION STATEMENTS

Key Action Statement 1: Screening for OSAS

As part of routine health maintenance visits, clinicians should inquire whether the child or adolescent snores. If the answer is affirmative or if a child or adolescent presents with signs or symptoms of OSAS (Table 2), clinicians should perform a more focused evaluation. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Evidence Profile KAS 1

- Aggregate evidence quality: B
- Benefit: Early identification of OSAS is desirable, because it is a high-prevalence condition, and identification and treatment can result in alleviation of current symptoms, improved quality of life, prevention of sequelae, education of parents, and decreased health care utilization.
- Harm: Provider time, patient and parent time.
- Benefits-harms assessment: Preponderance of benefit over harm.
- Value judgments: Panelists believe that identification of a serious medical condition outweighs the time expenditure necessary for screening.
- Role of patient preferences: None.
- Exclusions: None.
- Intentional vagueness: None.
- Strength: Recommendation.

Almost all children with OSAS snore,[9–11] although caregivers frequently do not volunteer this information at medical visits.[12] Thus, asking about snoring at each health maintenance visit (as well as at other appropriate times, such as when evaluating for tonsillitis) is a sensitive, albeit nonspecific, screening measure that is quick and easy to perform. Snoring is common in children and adolescents; however, OSAS is less common. Therefore, an affirmative answer should be followed by a detailed history and examination to determine whether further evaluation for OSAS is needed (Table 2); this clinical evaluation alone

TABLE 1 Definitions and Recommendation Implications

Statement	Definition	Implication
Strong recommendation	A strong recommendation in favor of a particular action is made when the anticipated benefits of the recommended intervention clearly exceed the harms (as a strong recommendation against an action is made when the anticipated harms clearly exceed the benefits) and the quality of the supporting evidence is excellent. In some clearly identified circumstances, strong recommendations may be made when high-quality evidence is impossible to obtain and the anticipated benefits strongly outweigh the harms.	Clinicians should follow a strong recommendation unless a clear and compelling rationale for an alternative approach is present.
Recommendation	A recommendation in favor of a particular action is made when the anticipated benefits exceed the harms but the quality of evidence is not as strong. Again, in some clearly identified circumstances, recommendations may be made when high-quality evidence is impossible to obtain but the anticipated benefits outweigh the harms.	It would be prudent for clinicians to follow a recommendation, but they should remain alert to new information and sensitive to patient preferences.
Option	Options define courses that may be taken when either the quality of evidence is suspect or carefully performed studies have shown little clear advantage to one approach over another.	Clinicians should consider the option in their decision-making, and patient preference may have a substantial role.
No recommendation	No recommendation indicates that there is a lack of pertinent published evidence and that the anticipated balance of benefits and harms is presently unclear.	Clinicians should be alert to new published evidence that clarifies the balance of benefit versus harm.

TABLE 2 Symptoms and Signs of OSAS

History
Frequent snoring (≥3 nights/wk)
Labored breathing during sleep
Gasps/snorting noises/observed episodes of apnea
Sleep enuresis (especially secondary enuresis)[a]
Sleeping in a seated position or with the neck hyperextended
Cyanosis
Headaches on awakening
Daytime sleepiness
Attention-deficit/hyperactivity disorder
Learning problems
Physical examination
Underweight or overweight
Tonsillar hypertrophy
Adenoidal facies
Micrognathia/retrognathia
High-arched palate
Failure to thrive
Hypertension

[a] Enuresis after at least 6 mo of continence.

does not establish the diagnosis (see technical report). Occasional snoring, for example, with an upper respiratory tract infection, is less of a concern than snoring that occurs at least 3 times a week and is associated with any of the symptoms or signs listed in Table 2.

Key Action Statement 2A: Polysomnography

If a child or adolescent snores on a regular basis and has any of the complaints or findings shown in Table 2, clinicians should either (1) obtain a polysomnogram (Evidence Quality A, Key Action strength: Recommendation) OR (2) refer the patient to a sleep specialist or otolaryngologist for a more extensive evaluation (Evidence quality D, Key Action strength: Option). (Evidence Quality: Grade A for polysomnography; Grade D for specialist referral, Recommendation Strength: Recommendation.)

Evidence Profile KAS 2A: Polysomnography

- Aggregate evidence quality: A
- Benefits: Establish diagnosis and determine severity of OSAS.
- Harm: Expense, time, anxiety/discomfort.
- Benefits-harms assessment: Preponderance of benefit over harm.
- Value judgments: Panelists weighed the value of establishing a diagnosis as more important than the minor potential harms listed.
- Role of patient preferences: Small because of preponderance of evidence that polysomnography is the most accurate way to make a diagnosis.
- Exclusions: See Key Action Statement 2B regarding lack of availability.
- Intentional vagueness: None.
- Strength: Recommendation.

Evidence Profile KAS 2A: Referral

- Aggregate evidence quality: D
- Benefits: Subspecialist may be better able to establish diagnosis and determine severity of OSAS.
- Harm: Expense, time, anxiety/discomfort.
- Benefits-harms assessment: Preponderance of benefit over harm.
- Value judgments: Panelists weighed the value of establishing a diagnosis as more important than the minor potential harms listed.
- Role of patient preferences: Large.
- Exclusions: None.
- Intentional vagueness: None.
- Strength: Option.

Although history and physical examination are useful to screen patients and determine which patients need further investigation for OSAS, the sensitivity and specificity of the history and physical examination are poor (see accompanying technical report). Physical examination when the child is awake may be normal, and the size of the tonsils cannot be used to predict the presence of OSAS in an individual child. Thus, objective testing is required. The gold standard test is overnight, attended, in-laboratory polysomnography (sleep study). This is a noninvasive test involving the measurement of a number of physiologic functions overnight, typically including EEG; pulse oximetry; oronasal airflow, abdominal and chest wall movements, partial pressure of carbon dioxide (P_{CO_2}); and video recording.[13] Specific pediatric measuring and scoring criteria should be used.[13] Polysomnography will demonstrate the presence or absence of OSAS. Polysomnography also demonstrates the severity of OSAS, which is helpful in planning treatment and in postoperative short- and long-term management.

Key Action Statement 2B: Alternative Testing

If polysomnography is not available, then clinicians may order alternative diagnostic tests, such as nocturnal video recording, nocturnal oximetry, daytime nap polysomnography, or ambulatory polysomnography. (Evidence Quality: Grade C, Recommendation Strength: Option.)

Evidence Profile KAS 2B

- Aggregate evidence quality: C
- Benefit: Varying positive and negative predictive values for establishing diagnosis.
- Harm: False-negative and false-positive results may underestimate or overestimate severity, expense, time, anxiety/discomfort.
- Benefits-harms assessment: Equilibrium of benefits and harms.
- Value judgments: Opinion of the panel that some objective testing is better than none. Pragmatic decision based on current shortage of pediatric polysomnography facilities (this may change over time).
- Role of patient preferences: Small, if choices are limited by availability;

families may choose to travel to centers where more extensive facilities are available.

- Exclusions: None.
- Intentional vagueness: None.
- Strength: Option.

Although polysomnography is the gold standard for diagnosis of OSAS, there is a shortage of sleep laboratories with pediatric expertise. Hence, polysomnography may not be readily available in certain regions of the country. Alternative diagnostic tests have been shown to have weaker positive and negative predictive values than polysomnography, but nevertheless, objective testing is preferable to clinical evaluation alone. If an alternative test fails to demonstrate OSAS in a patient with a high pretest probability, full polysomnography should be sought.

Key Action Statement 3: Adenotonsillectomy

If a child is determined to have OSAS, has a clinical examination consistent with adenotonsillar hypertrophy, and does not have a contraindication to surgery (see Table 3), the clinician should recommend adenotonsillectomy as the first line of treatment. If the child has OSAS but does not have adenotonsillar hypertrophy, other treatment should be considered (see Key Action Statement 6). Clinical judgment is required to determine the benefits of adenotonsillectomy compared with other treatments in obese children with varying degrees of adenotonsillar hypertrophy. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Evidence Profile KAS 3

- Aggregate evidence quality: B
- Benefit: Improve OSAS and accompanying symptoms and sequelae.
- Harm: Pain, anxiety, dehydration, anesthetic complications, hemorrhage, infection, postoperative respiratory difficulties, velopharyngeal incompetence, nasopharyngeal stenosis, death.
- Benefits-harms assessment: Preponderance of benefit over harm.
- Value judgments: The panel sees the benefits of treating OSAS as more beneficial than the low risk of serious consequences.
- Role of patient preferences: Low; continuous positive airway pressure (CPAP) is an option but involves prolonged, long-term treatment as compared with a single, relatively low-risk surgical procedure.
- Exclusions: See Table 3.
- Intentional vagueness: None.
- Strength: Recommendation.

Adenotonsillectomy is very effective in treating OSAS. Adenoidectomy or tonsillectomy alone may not be sufficient, because residual lymphoid tissue may contribute to persistent obstruction. In otherwise healthy children with adenotonsillar hypertrophy, adenotonsillectomy is associated with improvements in symptoms and sequelae of OSAS. Postoperative polysomnography typically shows a major decrease in the number of obstructive events, although some obstructions may still be present. Although obese children may have less satisfactory results, many will be adequately treated with adenotonsillectomy; however, further research is needed to determine which obese children are most likely to benefit from surgery. In this population, the benefits of a 1-time surgical procedure, with a small but real risk of complications, need to be weighed against long-term treatment with CPAP, which is associated with discomfort, disruption of family lifestyle, and risks of poor adherence. Potential complications of adenotonsillectomy are shown in Table 4. Although serious complications (including death) may occur, the rate of these complications is low, and the risks of complications need to be weighed against the consequences of untreated OSAS. In general, a 1-time only procedure with a relatively low morbidity is preferable to lifelong treatment with CPAP; furthermore, the efficacy of CPAP is limited by generally suboptimal adherence. Other treatment options, such as anti-inflammatory medications, weight loss, or tracheostomy, are less effective, are difficult to achieve, or have higher morbidity, respectively.

TABLE 3 Contraindications for Adenotonsillectomy

Absolute contraindications
No adenotonsillar tissue (tissue has been surgically removed)
Relative contraindications
Very small tonsils/adenoid
Morbid obesity and small tonsils/adenoid
Bleeding disorder refractory to treatment
Submucus cleft palate
Other medical conditions making patient medically unstable for surgery

Key Action Statement 4: High-Risk Patients Undergoing Adenotonsillectomy

Clinicians should monitor high-risk patients (Table 5) undergoing adenotonsillectomy as inpatients postoperatively. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

TABLE 4 Risks of Adenotonsillectomy

Minor
Pain
Dehydration attributable to postoperative nausea/vomiting and poor oral intake
Major
Anesthetic complications
Acute upper airway obstruction during induction or emergence from anesthesia
Postoperative respiratory compromise
Hemorrhage
Velopharyngeal incompetence
Nasopharyngeal stenosis
Death

TABLE 5 Risk Factors for Postoperative Respiratory Complications in Children With OSAS Undergoing Adenotonsillectomy

Younger than 3 y of age
Severe OSAS on polysomnography[a]
Cardiac complications of OSAS
Failure to thrive
Obesity
Craniofacial anomalies[b]
Neuromuscular disorders[b]
Current respiratory infection

[a] It is difficult to provide exact polysomnographic criteria for severity, because these criteria will vary depending on the age of the child; additional comorbidities, such as obesity, asthma, or cardiac complications of OSAS; and other polysomnographic criteria that have not been evaluated in the literature, such as the level of hypercapnia and the frequency of desaturation (as compared with lowest oxygen saturation). Nevertheless, on the basis of published studies (primarily Level III, see Technical Report), it is recommended that all patients with a lowest oxygen saturation <80% (either on preoperative polysomnography or during observation in the recovery room postoperatively) or an AHI ≥24/h be observed as inpatients postoperatively as they are at increased risk for postoperative respiratory compromise. Additionally, on the basis of expert consensus, it is recommended that patients with significant hypercapnia on polysomnography (peak P_{CO_2} ≥60 mm Hg) be admitted postoperatively. The committee noted that that most published studies were retrospective and not comprehensive, and therefore these recommendations may change if higher-level studies are published. Clinicians may decide to admit patients with less severe polysomnographic abnormalities based on a constellation of risk factors (age, comorbidities, and additional polysomnographic factors) for a particular individual.

[b] Not discussed in these guidelines.

Evidence Profile KAS 4

- Aggregate evidence quality: B
- Benefit: Effectively manage severe respiratory compromise and avoid death.
- Harm: Expense, time, anxiety.
- Benefits-harms assessment: Preponderance of benefit over harm.
- Value judgments: The panel believes that early recognition of any serious adverse events is critically important.
- Role of patient preferences: Minimal; this is an important safety issue.
- Exclusions: None.
- Intentional vagueness: None.
- Strength: Recommendation.

Patients with OSAS may develop respiratory complications, such as worsening of OSAS or pulmonary edema, in the immediate postoperative period. Death attributable to respiratory complications in the immediate postoperative period has been reported in patients with severe OSAS. Identified risk factors are shown in Table 5. High-risk patients should undergo surgery in a center capable of treating complex pediatric patients. They should be hospitalized overnight for close monitoring postoperatively. Children with an acute respiratory infection on the day of surgery, as documented by fever, cough, and/or wheezing, are at increased risk of postoperative complications and, therefore, should be rescheduled or monitored closely postoperatively. Clinicians should decide on an individual basis whether these patients should be rescheduled, taking into consideration the severity of OSAS in the particular patient and keeping in mind that many children with adenotonsillar hypertrophy have chronic rhinorrhea and nasal congestion, even in the absence of viral infections.

Key Action Statement 5: Reevaluation

Clinicians should clinically reassess all patients with OSAS for persisting signs and symptoms after therapy to determine whether further treatment is required. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Evidence Profile KAS 5A

- Aggregate evidence quality: B
- Benefit: Determine effects of treatment.
- Harm: Expense, time.
- Benefits-harms assessment: Preponderance of benefit over harm.
- Value judgments: Data show that a significant proportion of children continue to have abnormalities postoperatively; therefore, the panel determined that the benefits of follow-up outweigh the minor inconveniences.
- Role of patient preferences: Minimal; follow-up is good clinical practice.
- Exclusions: None.
- Intentional vagueness: None.
- Strength: Recommendation.

Clinicians should reassess OSAS-related symptoms and signs (Table 2) after 6 to 8 weeks of therapy to determine whether further evaluation and treatment are indicated. Objective data regarding the timing of the postoperative evaluation are not available. Most clinicians recommend reevaluation 6 to 8 weeks after treatment to allow for healing of the operative site and to allow time for upper airway, cardiac, and central nervous system recovery. Patients who remain symptomatic should undergo objective testing (see Key Action Statement 2) or be referred to a sleep specialist for further evaluation.

Key Action Statement 5B: Reevaluation of High-Risk Patients

Clinicians should reevaluate high-risk patients for persistent OSAS after adenotonsillectomy, including those who had a significantly abnormal baseline polysomnogram, have sequelae of OSAS, are obese, or remain symptomatic after treatment, with an objective test (see Key Action Statement 2) or refer such patients to a sleep specialist. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Evidence Profile KAS 5B

- Aggregate evidence quality: B
- Benefit: Determine effects of treatment.
- Harm: Expense, time, anxiety/discomfort.
- Benefits-harms assessment: Preponderance of benefit over harm.

- Value judgments: Given the panel's concerns about the consequences of OSAS and the frequency of postoperative persistence in high-risk groups, the panel believes that the follow-up costs are outweighed by benefits of recognition of persistent OSAS. A minority of panelists believed that all children with OSAS should have follow-up polysomnography because of the high prevalence of persistent postoperative abnormalities on polysomnography, but most panelists believed that persistent polysomnographic abnormalities in uncomplicated children with mild OSAS were usually mild in patients who were asymptomatic after surgery.
- Role of patient preferences: Minimal. Further evaluation is needed to determine the need for further treatment.
- Exclusions: None.
- Intentional vagueness: None.
- Strength: Recommendation.

Numerous studies have shown that a large proportion of children at high risk continue to have some degree of OSAS postoperatively[10,13,14]; thus, objective evidence is required to determine whether further treatment is necessary.

Key Action Statement 6: CPAP

Clinicians should refer patients for CPAP management if symptoms/signs (Table 2) or objective evidence of OSAS persists after adenotonsillectomy or if adenotonsillectomy is not performed. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Evidence Profile KAS 6

- Aggregate evidence quality: B
- Benefit: Improve OSAS and accompanying symptoms and sequelae.
- Harm: Expense, time, anxiety; parental sleep disruption; nasal and skin adverse effects; possible midface remodeling; extremely rare serious pressure-related complications, such as pneumothorax; poor adherence.
- Benefits-harms assessment: Preponderance of benefit over harm.
- Value judgments: Panelists believe that CPAP is the most effective treatment of OSAS that persists postoperatively and that the benefits of treatment outweigh the adverse effects. Other treatments (eg, rapid maxillary expansion) may be effective in specially selected patients.
- Role of patient preferences: Other treatments may be effective in specially selected patients.
- Exclusions: Rare patients at increased risk of severe pressure complications.
- Intentional vagueness: None.
- Policy level: Recommendation.

CPAP therapy is delivered by using an electronic device that delivers air at positive pressure via a nasal mask, leading to mechanical stenting of the airway and improved functional residual capacity in the lungs. There is no clear advantage of using bilevel pressure over CPAP.[15] CPAP should be managed by an experienced and skilled clinician with expertise in its use in children. CPAP pressure requirements vary among individuals and change over time; thus, CPAP must be titrated in the sleep laboratory before prescribing the device and periodically readjusted thereafter. Behavioral modification therapy may be required, especially for young children or those with developmental delays. Objective monitoring of adherence, by using the equipment software, is important. If adherence is suboptimal, the clinician should institute measures to improve adherence (such as behavioral modification, or treating side effects of CPAP) and institute alternative treatments if these measures are ineffective.

Key Action Statement 7: Weight Loss

Clinicians should recommend weight loss in addition to other therapy if a child/adolescent with OSAS is overweight or obese. (Evidence Quality: Grade C, Recommendation Strength: Recommendation.)

Evidence Profile KAS 7

- Aggregate evidence quality: C
- Benefit: Improve OSAS and accompanying symptoms and sequelae; non–OSAS-related benefits of weight loss.
- Harm: Hard to achieve and maintain weight loss.
- Benefits-harms assessment: Preponderance of benefit over harm.
- Value judgments: The panel agreed that weight loss is beneficial for both OSAS and other health issues, but clinical experience suggests that weight loss is difficult to achieve and maintain, and even effective weight loss regimens take time; therefore, additional treatment is required in the interim.
- Role of patient preferences: Strong role for patient and family preference regarding nutrition and exercise.
- Exclusions: None.
- Intentional vagueness: None.
- Strength: Recommendation.

Weight loss has been shown to improve OSAS,[16,17] although the degree of weight loss required has not been determined. Because weight loss is a slow and unreliable process, other treatment modalities (such as adenotonsillectomy or CPAP therapy) should be instituted until sufficient weight loss has been achieved and maintained.

Key Action Statement 8: Intranasal Corticosteroids

Clinicians may prescribe topical intranasal corticosteroids for children with mild OSAS in whom adenotonsillectomy is contraindicated or for children with mild postoperative OSAS. (Evidence Quality: Grade B, Recommendation Strength: Option.)

Evidence Profile KAS 8

- Aggregate evidence quality: B
- Benefit: Improves mild OSAS and accompanying symptoms and sequelae.
- Harm: Some subjects may not have an adequate response. It is not known whether therapeutic effect persists long-term; therefore, long-term observation is required. Low risk of steroid-related adverse effects.
- Benefits-harms assessment: Preponderance of benefit over harm.
- Value judgments: The panel agreed that intranasal steroids provide a less invasive treatment than surgery or CPAP and, therefore, may be preferred in some cases despite lower efficacy and lack of data on long-term efficacy.
- Role of patient preferences: Moderate role for patient and family preference if OSAS is mild.
- Exclusions: None.
- Intentional vagueness: None.
- Strength: Option.

Mild OSAS is defined, for this indication, as an AHI <5 per hour, on the basis of studies on intranasal corticosteroids described in the accompanying technical report.[2] Several studies have shown that the use of intranasal steroids decreases the degree of OSAS; however, although OSAS improves, residual OSAS may remain. Furthermore, there is individual variability in response to treatment, and long-term studies have not been performed to determine the duration of improvement. Therefore, nasal steroids are not recommended as a first-line therapy. The response to treatment should be measured objectively after a course of treatment of approximately 6 weeks. Because the long-term effect of this treatment is unknown, the clinician should continue to observe the patient for symptoms of recurrence and adverse effects of corticosteroids.

AREAS FOR FUTURE RESEARCH

A detailed list of research recommendations is provided in the accompanying technical report.[2] There is a great need for further research into the prevalence of OSAS, sequelae of OSAS, best treatment methods, and the role of obesity. In particular, well-controlled, blinded studies, including randomized controlled trials of treatment, are needed to determine the best care for children and adolescents with OSAS.

SUBCOMMITTEE ON OBSTRUCTIVE SLEEP APNEA SYNDROME*

Carole L. Marcus, MBBCh, Chairperson (Sleep Medicine, Pediatric Pulmonologist; Liaison, American Academy of Sleep Medicine; Research Support from Philips Respironics; Affiliated with an academic sleep center; Published research related to OSAS)

Lee J. Brooks, MD (Sleep Medicine, Pediatric Pulmonologist; Liaison, American College of Chest Physicians; No financial conflicts; Affiliated with an academic sleep center; Published research related to OSAS)

Sally Davidson Ward, MD (Sleep Medicine, Pediatric Pulmonologist; No financial conflicts; Affiliated with an academic sleep center; Published research related to OSAS)

Kari A. Draper, MD (General Pediatrician; No conflicts)

David Gozal, MD (Sleep Medicine, Pediatric Pulmonologist; Research support from AstraZeneca; Speaker for Merck Company; Affiliated with an academic sleep center; Published research related to OSAS)

Ann C. Halbower, MD (Sleep Medicine, Pediatric Pulmonologist; Liaison, American Thoracic Society; Research Funding from Resmed; Affiliated with an academic sleep center; Published research related to OSAS)

Sleep Apnea Clinical Practice Guideline Quick Reference Tools

- Action Statement Summary
  — Diagnosis and Management of Childhood Obstructive Sleep Apnea Syndrome
- *ICD-10-CM* Coding Quick Reference for Sleep Apnea
- AAP Patient Education Handout
  — *Sleep Apnea and Your Child*

Action Statement Summary

Diagnosis and Management of Childhood Obstructive Sleep Apnea Syndrome

Key Action Statement 1: Screening for OSAS

As part of routine health maintenance visits, clinicians should inquire whether the child or adolescent snores. If the answer is affirmative or if a child or adolescent presents with signs or symptoms of OSAS (Table 2), clinicians should perform a more focused evaluation. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Key Action Statement 2A: Polysomnography

If a child or adolescent snores on a regular basis and has any of the complaints or findings shown in Table 2, clinicians should either (1) obtain a polysomnogram (Evidence Quality A, Key Action strength: Recommendation) OR (2) refer the patient to a sleep specialist or otolaryngologist for a more extensive evaluation (Evidence quality D, Key Action strength: Option). (Evidence Quality: Grade A for polysomnography; Grade D for specialist referral, Recommendation Strength: Recommendation.)

Key Action Statement 2B: Alternative Testing

If polysomnography is not available, then clinicians may order alternative diagnostic tests, such as nocturnal video recording, nocturnal oximetry, daytime nap polysomnography, or ambulatory polysomnography. (Evidence Quality: Grade C, Recommendation Strength: Option.)

Key Action Statement 3: Adenotonsillectomy

If a child is determined to have OSAS, has a clinical examination consistent with adenotonsillar hypertrophy, and does not have a contraindication to surgery (see Table 3), the clinician should recommend adenotonsillectomy as the first line of treatment. If the child has OSAS but does not have adenotonsillar hypertrophy, other treatment should be considered (see Key Action Statement 6). Clinical judgment is required to determine the benefits of adenotonsillectomy compared with other treatments in obese children with varying degrees of adenotonsillar hypertrophy. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Key Action Statement 4: High-Risk Patients Undergoing Adenotonsillectomy

Clinicians should monitor high-risk patients (Table 5) undergoing adenotonsillectomy as inpatients postoperatively. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Key Action Statement 5: Reevaluation

Clinicians should clinically reassess all patients with OSAS for persisting signs and symptoms after therapy to determine whether further treatment is required. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Key Action Statement 5B: Reevaluation of High-Risk Patients

Clinicians should reevaluate high-risk patients for persistent OSAS after adenotonsillectomy, including those who had a significantly abnormal baseline polysomnogram, have sequelae of OSAS, are obese, or remain symptomatic after treatment, with an objective test (see Key Action Statement 2) or refer such patients to a sleep specialist. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Key Action Statement 6: CPAP

Clinicians should refer patients for CPAP management if symptoms/signs (Table 2) or objective evidence of OSAS persists after adenotonsillectomy or if adenotonsillectomy is not performed. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Key Action Statement 7: Weight Loss

Clinicians should recommend weight loss in addition to other therapy if a child/adolescent with OSAS is overweight or obese. (Evidence Quality: Grade C, Recommendation Strength: Recommendation.)

Key Action Statement 8: Intranasal Corticosteroids

Clinicians may prescribe topical intranasal corticosteroids for children with mild OSAS in whom adenotonsillectomy is contraindicated or for children with mild postoperative OSAS. (Evidence Quality: Grade B, Recommendation Strength: Option.)

Coding Quick Reference for Sleep Apnea	
ICD-10-CM	
G47.30	Sleep apnea, unspecified
G47.31	Primary central sleep apnea
G47.33	Obstructive sleep apnea (adult) (pediatric) _____(Code additional underlying conditions.)
J35.3	Hypertrophy of tonsils with hypertrophy of adenoids
E66.01	Morbid (severe) obesity due to excess calories
E66.09	Other obesity due to excess calories
E66.3	Overweight
E66.8	Other obesity
E66.9	Obesity, unspecified
P28.3	Primary sleep apnea of newborn
P28.4	Other apnea of newborn

Sleep Apnea and Your Child

Does your child snore a lot? Does he sleep restlessly? Does he have difficulty breathing, or does he gasp or choke, while he sleeps?

If your child has these symptoms, he may have a condition known as sleep apnea.

Sleep apnea is a common problem that affects an estimated 2% of all children, including many who are undiagnosed.

If not treated, sleep apnea can lead to a variety of problems. These include heart, behavior, learning, and growth problems.

How do I know if my child has sleep apnea?

Symptoms of sleep apnea include

- Frequent snoring
- Problems breathing during the night
- Sleepiness during the day
- Difficulty paying attention
- Behavior problems

If you notice any of these symptoms, let your pediatrician know as soon as possible. Your pediatrician may recommend an overnight sleep study called a *polysomnogram.* Overnight polysomnograms are conducted at hospitals and major medical centers. During the study, medical staff will watch your child sleep. Several sensors will be attached to your child to monitor breathing, oxygenation, and brain waves. An electroencephalogram (EEG) is a test that measures brain waves.

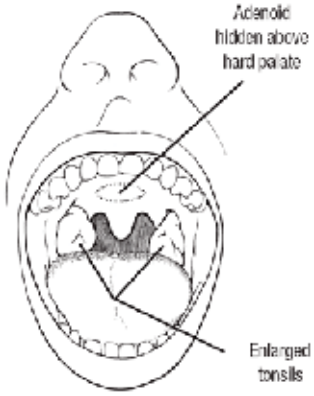
The results of the study will show whether your child suffers from sleep apnea. Other specialists, such as pediatric pulmonologists, otolaryngologists, neurologists, and pediatricians with specialty training in sleep disorders, may help your pediatrician make the diagnosis.

What causes sleep apnea?

Many children with sleep apnea have larger tonsils and adenoids.

Tonsils are the round, reddish masses on each side of your child's throat. They help fight infections in the body. You can only see the adenoid with an x-ray or special mirror. It lies in the space between the nose and throat.

Large tonsils and adenoid may block a child's airway while she sleeps. This causes her to snore and wake up often during the night. However, not every child with large tonsils and adenoid has sleep apnea. A sleep study can tell your doctor whether your child has sleep apnea or if she is simply snoring.



Children born with other medical conditions, such as Down syndrome, cerebral palsy, or craniofacial (skull and face) abnormalities, are at higher risk for sleep apnea. Overweight children are also more likely to suffer from sleep apnea.

How is sleep apnea treated?

The most common way to treat sleep apnea is to remove your child's tonsils and adenoid. This surgery is called a tonsillectomy and adenoidectomy. It is highly effective in treating sleep apnea.

Another effective treatment is nasal continuous positive airway pressure (CPAP), which requires the child to wear a mask while he sleeps. The mask delivers steady air pressure through the child's nose, allowing him to breathe comfortably. Continuous positive airway pressure is usually used in children who do not improve after tonsillectomy and adenoidectomy, or who are not candidates for tonsillectomy and adenoidectomy.

Children who may need additional treatment include children who are overweight or suffering from another complicating condition. Overweight children will improve if they lose weight, but may need to use CPAP until the weight is lost.

Remember

A good night's sleep is important to good health. If your child suffers from the symptoms of sleep apnea, talk with your pediatrician. A proper diagnosis and treatment can mean restful nights and restful days for your child and your family.

From your doctor

Reaffirmation of AAP Clinical Practice Guideline: The Diagnosis and Management of the Initial Urinary Tract Infection in Febrile Infants and Young Children 2–24 Months of Age

SUBCOMMITTEE ON URINARY TRACT INFECTION

FREE

It is the policy of the American Academy of Pediatrics to reassess clinical practice guidelines (CPGs) every 5 years and retire, revise, or reaffirm them. The members of the urinary tract infection (UTI) subcommittee who developed the 2011 UTI CPG[1] have reviewed the literature published since 2011 along with unpublished manuscripts and the status of some clinical trials still in progress. With this article, we reaffirm the 2011 UTI CPG and provide an updated review of the supporting evidence. For the convenience of the reader, we reiterate the 7 Key Action Statements here to obviate the need to consult the 2011 UTI CPG, although interested readers may want to review the text of the guideline[1] and/or its accompanying technical report.[2]

To cite: AAP SUBCOMMITTEE ON URINARY TRACT INFECTION. Reaffirmation of AAP Clinical Practice Guideline: The Diagnosis and Management of the Initial Urinary Tract Infection in Febrile Infants and Young Children 2–24 Months of Age. *Pediatrics.* 2016;138(6):e20163026

ACTION STATEMENT 1

If a clinician decides that a febrile infant with no apparent source for the fever requires antimicrobial therapy to be administered because of ill appearance or another pressing reason, the clinician should ensure that a urine specimen is obtained for both culture and urinalysis before an antimicrobial is administered; the specimen needs to be obtained through catheterization or suprapubic aspiration (SPA), because the diagnosis of UTI cannot be established reliably through culture of urine collected in a bag (evidence quality: A; strong recommendation).

Comment

A key to an accurate diagnosis of UTI is obtaining a sample of urine for culture with minimal contamination before starting antimicrobial

agents. Urine collected in a bag or via a clean catch method is suitable for urinalysis (see Action Statement 2, Option 2), but such specimens (especially urine collected in a bag) are less appropriate for culture. If a culture obtained by bag is positive, the likelihood of a false positive is extremely high, so the result must be confirmed by culturing urine obtained by a more reliable method; if an antimicrobial agent is present in the urine, the opportunity for confirmation is likely to be lost.

Although samples of urine obtained by transurethral catheterization may be contaminated by urethral flora, meticulous technique can reduce this possibility. To avoid contamination, 2 practical steps should be implemented: (1) the first few milliliters obtained by catheter should be discarded (allowed to fall outside of the sterile collecting vessel) and only the subsequent urine cultured; and (2) if the attempt at catheterization is unsuccessful, a new, clean catheter should be used (aided, in girls, by leaving the initial catheter in place as a marker).

ACTION STATEMENT 2

If a clinician assesses a febrile infant with no apparent source for the fever as not being so ill as to require immediate antimicrobial therapy, then the clinician should assess the likelihood of UTI.

Action Statement 2a. If the clinician determines the febrile infant to have a low likelihood of UTI (see text), then clinical follow-up monitoring without testing is sufficient (evidence quality: A; strong recommendation).

Action Statement 2b. If the clinician determines that the febrile infant is not in a low-risk group (see below), then there are 2 choices (evidence quality: A; strong recommendation).

Option 1 is to obtain a urine specimen through catheterization or SPA for culture and urinalysis.

Option 2 is to obtain a urine specimen through the most convenient means and to perform a urinalysis. If the urinalysis results suggest a UTI (positive leukocyte esterase test results or nitrite test or microscopic analysis results for leukocytes or bacteria), then a urine specimen should be obtained through catheterization or SPA and cultured; if urinalysis of fresh (less than 1 hour since void) urine yields negative leukocyte esterase and nitrite results, then it is reasonable to monitor the clinical course without initiating antimicrobial therapy, recognizing that a negative urinalysis does not rule out a UTI with certainty.

Comment

When the patient's degree of illness does not warrant immediate antimicrobial treatment and the risk of UTI is extremely low, the patient may be observed without assessing the urine. (The risk assessment tables in the 2011 UTI CPG have been simplified into algorithm form.[3]) If there is a low but real risk of infection, then either the best possible specimen should be obtained for urinalysis and culture, or a sample of urine obtained by a convenient method and a judgment made about culturing the urine dependent on the findings of the urinalysis or dipstick. A positive urinalysis provides sufficient concern to mandate a properly obtained urine specimen. This 2-step process (Option 2) is not only suitable for office practice but has been demonstrated to be feasible and beneficial in a busy pediatric emergency department, with the catheterization rate decreasing from 63% to fewer than 30% without increasing length of stay or missing UTIs.[4]

ACTION STATEMENT 3

To establish the diagnosis of UTI, clinicians should require both urinalysis results that suggest infection (pyuria and/or bacteriuria) and the presence of at least 50 000 colony-forming units (cfu) per milliliter of a uropathogen cultured from a urine specimen obtained through transurethral catheterization or SPA (evidence quality: C; recommendation).

Comment

The thrust of this key action statement is that the diagnosis of UTI in febrile infants is signaled by the presence of both bacteriuria and pyuria. In general, pyuria without bacteriuria is insufficient to make a diagnosis of UTI because it is nonspecific and occurs in the absence of infection (eg, Kawasaki disease, chemical urethritis, streptococcal infections). Likewise, bacteriuria, without pyuria is attributable to external contamination, asymptomatic bacteriuria, or, rarely, very early infection (before the onset of inflammation). Non–*Escherichia coli* isolates are less frequently associated with pyuria than *E coli*,[5] but the significance of this association is not clear at present. Non–*E coli* uropathogens are of concern because they are more likely to result in scarring than *E coli*,[6] but animal studies demonstrate the host inflammatory response to be what causes scarring rather than the presence of organisms.[7] Moreover, the rate of asymptomatic bacteriuria is sufficient to account for the lack of association with pyuria.

The remaining question is what constitutes "significant" bacteriuria and "significant" pyuria. In 1994,

by using single versus multiple organisms to distinguish true UTI from contamination, 50 000 cfu/mL was proposed as the appropriate threshold for specimens obtained by catheterization,[8] recommended in the 2011 UTI CPG and implemented in the Randomized Intervention for Children with Vesicoureteral Reflux (RIVUR) trial.[9] Lower colony counts are sufficient if the urine specimen is obtained by SPA and, thus, less likely to be contaminated, but most (80%) cases of UTI documented with urine obtained by SPA have 10^5 cfu/mL or more. Colony counts lower than 50 000 cfu/mL are currently being considered for the diagnosis of UTI.[10] If 10 000 cfu/mL coupled with symptoms (eg, fever) and evidence of inflammation (pyuria) proves both sensitive and specific, this threshold would be of particular assistance to clinicians who use laboratories that do not specify colony counts between 10 000 and 100 000 cfu/mL and, thereby, make the criterion of 50 000 cfu/mL difficult to use.

Significant pyuria is ≥10 white blood cells/mm^3 on an "enhanced urinalysis" or ≥5 white blood cells per high power field on a centrifuged specimen of urine or any leukocyte esterase on a dipstick.

ACTION STATEMENT 4

Action Statement 4a. When initiating treatment, the clinician should base the choice of route of administration on practical considerations: initiating treatment orally or parenterally is equally efficacious. The clinician should base the choice of agent on local antimicrobial sensitivity patterns (if available) and should adjust the choice according to sensitivity testing of the isolated uropathogen (evidence quality: A; strong recommendation).

Action Statement 4b. The clinician should choose 7 to 14 days as the duration of antimicrobial therapy (evidence quality B; recommendation).

Comment

Basing the choice of an initial antimicrobial agent on local sensitivity patterns can be difficult because applicable information may not be available. Whether the child has received antimicrobial therapy in the recent past should be considered. This exposure constitutes a risk factor for resistance to the recently prescribed antimicrobial. Further delineation of treatment duration has not been forthcoming, but a randomized controlled trial is currently under way comparing the effectiveness of 5 days versus 10 days of treatment.[11]

Note: The dose of ceftriaxone in Table 2 should be 50 mg/kg, every 24 h.

ACTION STATEMENT 5

Febrile infants with UTIs should undergo renal and bladder ultrasonography (RBUS) (evidence quality: C; recommendation).

Comment

As noted in the 2011 CPG, it is important that the study be a renal and bladder ultrasonogram, not a limited renal ultrasonogram. Ideally, the patient should be well-hydrated for the examination and the bladder should be evaluated while distended. Concern has been raised that RBUS is not effective to detect vesicoureteral reflux (VUR), as it is frequently normal in infants with low-grade VUR and even in some who have high-grade VUR. Moreover, nonspecific RBUS findings, such as mild renal pelvic or ureteral distention, are common and are not necessarily associated with reflux. However, low-grade VUR is generally not considered of concern for renal damage, and most studies (other than the RIVUR trial[9]) have demonstrated continuous antimicrobial prophylaxis (CAP) to lack benefit in this group.[1,2] Although RBUS is not invariably abnormal in infants with grades IV and V VUR, it does identify most, and, of particular importance, an abnormal RBUS is a major risk factor for scarring.[6]

ACTION STATEMENT 6

Action Statement 6a. Voiding cystourethrography (VCUG) should not be performed routinely after the first febrile UTI; VCUG is indicated if RBUS reveals hydronephrosis, scarring, or other findings that would suggest either high-grade VUR or obstructive uropathy, as well as in other atypical or complex clinical circumstances (evidence quality B; recommendation).

Action Statement 6b. Further evaluation should be conducted if there is a recurrence of febrile UTI (evidence quality: X; recommendation).

Comment

For decades, UTIs in infants were considered harbingers of underlying anatomic and/or physiologic abnormalities, so RBUS and VCUG were recommended to be performed routinely. VUR was a particular concern; CAP was assumed to be effective in preventing UTI and became standard practice when VUR was discovered. In the years leading up to the 2011 guideline, randomized controlled trials of CAP were performed. Authors of the 6 studies published in 2006-2010 graciously provided data to the guideline committee, permitting a meta-analysis of data specifically targeting febrile infants 2 to 24 months of age. CAP was not demonstrated to be effective, so the need to identify VUR by routine voiding cystourethrography was discouraged.[1,2] A recent large trial in the United States, the RIVUR trial,

concluded that CAP was of benefit, but, to prevent 1 UTI recurrence required 5840 doses of antimicrobial and did not reduce the rate of renal scarring.[9]

Since the publication of the 2011 guideline, multiple studies have demonstrated that abnormalities are missed by the selective imaging recommended in the guideline; however, there is no evidence that identifying these missed abnormalities is of sufficient clinical benefit to offset the cost, discomfort, and radiation.[12] Compared with performing the full array of imaging tests, the radiation burden incurred with the application of the guideline has been calculated to be reduced by 93%.[13] Moreover, in population studies, the significance of VUR and the value of treating VUR have been questioned.[14,15]

The authors of the RIVUR trial and its companion study, Careful Urinary Tract Infection Evaluation, have called attention to bowel/bladder dysfunction (BBD) as a major risk factor for UTI recurrences and recognize that, in children who have a UTI recurrence, evaluation for BBD (ie, constipation), rather than for VUR, can be performed by nonspecialists and does not incur high cost, cause discomfort, or require radiation.[16] BBD has long been underappreciated and deserves greater consideration.

ACTION STATEMENT 7

After confirmation of UTI, the clinician should instruct parents or guardians to seek prompt medical evaluation (ideally within 48 hours) for future febrile illnesses to ensure that recurrent infections can be detected and treated promptly (evidence quality: C; recommendation).

Comment

Prompt treatment is of clinical benefit to the child with the acute infection. What has been controversial is the definition of "prompt" and the relationship to renal scarring. A recent study identified that the median time to treatment was shorter in infants who did not incur a scar than in those who did (48 vs 72 hours). The study also noted that the rate of scarring increased minimally between days 1 and 2 and between days 2 and 3 but was much higher thereafter.[17]

abstract

FREE

OBJECTIVE: To revise the American Academy of Pediatrics practice parameter regarding the diagnosis and management of initial urinary tract infections (UTIs) in febrile infants and young children.

METHODS: Analysis of the medical literature published since the last version of the guideline was supplemented by analysis of data provided by authors of recent publications. The strength of evidence supporting each recommendation and the strength of the recommendation were assessed and graded.

RESULTS: Diagnosis is made on the basis of the presence of both pyuria and at least 50 000 colonies per mL of a single uropathogenic organism in an appropriately collected specimen of urine. After 7 to 14 days of antimicrobial treatment, close clinical follow-up monitoring should be maintained to permit prompt diagnosis and treatment of recurrent infections. Ultrasonography of the kidneys and bladder should be performed to detect anatomic abnormalities. Data from the most recent 6 studies do not support the use of antimicrobial prophylaxis to prevent febrile recurrent UTI in infants without vesicoureteral reflux (VUR) or with grade I to IV VUR. Therefore, a voiding cystourethrography (VCUG) is not recommended routinely after the first UTI; VCUG is indicated if renal and bladder ultrasonography reveals hydronephrosis, scarring, or other findings that would suggest either high-grade VUR or obstructive uropathy and in other atypical or complex clinical circumstances. VCUG should also be performed if there is a recurrence of a febrile UTI. The recommendations in this guideline do not indicate an exclusive course of treatment or serve as a standard of care; variations may be appropriate. Recommendations about antimicrobial prophylaxis and implications for performance of VCUG are based on currently available evidence. As with all American Academy of Pediatrics clinical guidelines, the recommendations will be reviewed routinely and incorporate new evidence, such as data from the Randomized Intervention for Children With Vesicoureteral Reflux (RIVUR) study.

CONCLUSIONS: Changes in this revision include criteria for the diagnosis of UTI and recommendations for imaging. *Pediatrics* 2011;128:595–610

INTRODUCTION

Since the early 1970s, occult bacteremia has been the major focus of concern for clinicians evaluating febrile infants who have no recognizable source of infection. With the introduction of effective conjugate vaccines against *Haemophilus influenzae* type b and *Streptococcus pneumoniae* (which have resulted in dramatic decreases in bacteremia and meningitis), there has been increasing appreciation of the urinary tract as the most frequent site of occult and serious bacterial infections. Because the clinical presentation tends to be nonspecific in infants and reliable urine specimens for culture cannot be obtained without invasive methods (urethral catheterization or suprapubic aspiration [SPA]), diagnosis and treatment may be delayed. Most experimental and clinical data support the concept that delays in the institution of appropriate treatment of pyelonephritis increase the risk of renal damage.[1,2]

This clinical practice guideline is a revision of the practice parameter published by the American Academy of Pediatrics (AAP) in 1999.[3] It was developed by a subcommittee of the Steering Committee on Quality Improvement and Management that included physicians with expertise in the fields of academic general pediatrics, epidemiology and informatics, pediatric infectious diseases, pediatric nephrology, pediatric practice, pediatric radiology, and pediatric urology. The AAP funded the development of this guideline; none of the participants had any financial conflicts of interest. The guideline was reviewed by multiple groups within the AAP (7 committees, 1 council, and 9 sections) and 5 external organizations in the United States and Canada. The guideline will be reviewed and/or revised in 5 years, unless new evidence emerges that warrants revision sooner. The guideline is intended for use in a variety of clinical settings (eg, office, emergency department, or hospital) by clinicians who treat infants and young children. This text is a summary of the analysis. The data on which the recommendations are based are included in a companion technical report.[4]

Like the 1999 practice parameter, this revision focuses on the diagnosis and management of initial urinary tract infections (UTIs) in febrile infants and young children (2–24 months of age) who have no obvious neurologic or anatomic abnormalities known to be associated with recurrent UTI or renal damage. (For simplicity, in the remainder of this guideline the phrase "febrile infants" is used to indicate febrile infants and young children 2–24 months of age.) The lower and upper age limits were selected because studies on infants with unexplained fever generally have used these age limits and have documented that the prevalence of UTI is high (~5%) in this age group. In those studies, fever was defined as temperature of at least 38.0°C (≥100.4°F); accordingly, this definition of fever is used in this guideline. Neonates and infants less than 2 months of age are excluded, because there are special considerations in this age group that may limit the application of evidence derived from the studies of 2- to 24-month-old children. Data are insufficient to determine whether the evidence generated from studies of infants 2 to 24 months of age applies to children more than 24 months of age.

METHODS

To provide evidence for the guideline, 2 literature searches were conducted, that is, a surveillance of Medline-listed literature over the past 10 years for significant changes since the guideline was published and a systematic review of the literature on the effectiveness of prophylactic antimicrobial therapy to prevent recurrence of febrile UTI/pyelonephritis in children with vesicoureteral reflux (VUR). The latter was based on the new and growing body of evidence questioning the effectiveness of antimicrobial prophylaxis to prevent recurrent febrile UTI in children with VUR. To explore this particular issue, the literature search was expanded to include trials published since 1993 in which antimicrobial prophylaxis was compared with no treatment or placebo treatment for children with VUR. Because all except 1 of the recent randomized controlled trials (RCTs) of the effectiveness of prophylaxis included children more than 24 months of age and some did not provide specific data according to grade of VUR, the authors of the 6 RCTs were contacted; all provided raw data from their studies specifically addressing infants 2 to 24 months of age, according to grade of VUR. Meta-analysis of these data was performed.

Results from the literature searches and meta-analyses were provided to committee members. Issues were raised and discussed until consensus was reached regarding recommendations. The quality of evidence supporting each recommendation and the strength of the recommendation were assessed by the committee member most experienced in informatics and epidemiology and were graded according to AAP policy[5] (Fig 1).

The subcommittee formulated 7 recommendations, which are presented in the text in the order in which a clinician would use them when evaluating and treating a febrile infant, as well as in algorithm form in the Appendix. This clinical practice guideline is not intended to be a sole source of guidance for the treatment of febrile infants with UTIs. Rather, it is intended to assist clinicians in decision-making. It is not intended to replace clinical judgment or to

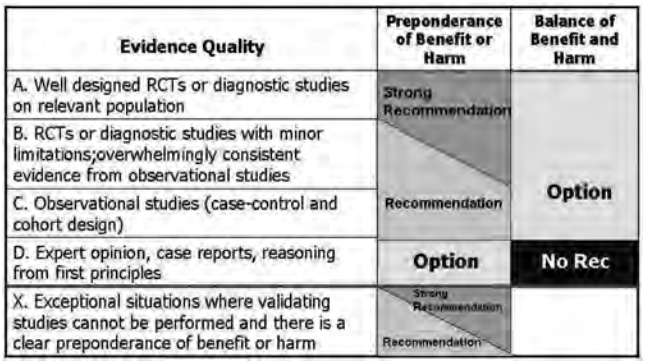

FIGURE 1
AAP evidence strengths.

establish an exclusive protocol for the care of all children with this condition.

DIAGNOSIS

Action Statement 1

If a clinician decides that a febrile infant with no apparent source for the fever requires antimicrobial therapy to be administered because of ill appearance or another pressing reason, the clinician should ensure that a urine specimen is obtained for both culture and urinalysis before an antimicrobial agent is administered; the specimen needs to be obtained through catheterization or SPA, because the diagnosis of UTI cannot be established reliably through culture of urine collected in a bag (evidence quality: A; strong recommendation).

When evaluating febrile infants, clinicians make a subjective assessment of the degree of illness or toxicity, in addition to seeking an explanation for the fever. This clinical assessment determines whether antimicrobial therapy should be initiated promptly and affects the diagnostic process regarding UTI. If the clinician determines that the degree of illness warrants immediate antimicrobial therapy, then a urine specimen suitable for culture should be obtained through catheterization or SPA before antimicrobial agents are administered, because the antimicrobial agents commonly prescribed in such situations would almost certainly obscure the diagnosis of UTI.

SPA has been considered the standard method for obtaining urine that is uncontaminated by perineal flora. Variable success rates for obtaining urine have been reported (23%–90%).[6–8] When ultrasonographic guidance is used, success rates improve.[9,10] The technique has limited risks, but technical expertise and experience are required, and many parents and physicians perceive the procedure as unacceptably invasive, compared with catheterization. However, there may be no acceptable alternative to SPA for boys with moderate or severe phimosis or girls with tight labial adhesions.

Urine obtained through catheterization for culture has a sensitivity of 95% and a specificity of 99%, compared with that obtained through SPA.[7,11,12] The techniques required for catheterization and SPA are well described.[13] When catheterization or SPA is being attempted, the clinician should have a sterile container ready to collect a urine specimen, because the preparation for the procedure may stimulate the child to void. Whether the urine is obtained through catheterization or is voided, the first few drops should be allowed to fall outside the sterile container, because they may be contaminated by bacteria in the distal urethra.

Cultures of urine specimens collected in a bag applied to the perineum have an unacceptably high false-positive rate and are valid only when they yield negative results.[6,14–16] With a prevalence of UTI of 5% and a high rate of false-positive results (specificity: ~63%), a "positive" culture result for urine collected in a bag would be a false-positive result 88% of the time. For febrile boys, with a prevalence of UTI of 2%, the rate of false-positive results is 95%; for circumcised boys, with a prevalence of UTI of 0.2%, the rate of false-positive results is 99%. Therefore, in cases in which antimicrobial therapy will be initiated, catheterization or SPA is required to establish the diagnosis of UTI.

- Aggregate quality of evidence: A (diagnostic studies on relevant populations).
- Benefits: A missed diagnosis of UTI can lead to renal scarring if left untreated; overdiagnosis of UTI can lead to overtreatment and unnecessary and expensive imaging. Once antimicrobial therapy is initiated, the opportunity to make a definitive diagnosis is lost; multiple studies of antimicrobial therapy have shown that the urine may be rapidly sterilized.
- Harms/risks/costs: Catheterization is invasive.
- Benefit-harms assessment: Preponderance of benefit over harm.
- Value judgments: Once antimicrobial therapy has begun, the opportunity to make a definitive diagnosis is lost. Therefore, it is important to have the most-accurate test for UTI performed initially.
- Role of patient preferences: There is no evidence regarding patient preferences for bag versus catheterized urine. However, bladder tap has

been shown to be more painful than urethral catheterization.

- Exclusions: None.
- Intentional vagueness: The basis of the determination that antimicrobial therapy is needed urgently is not specified, because variability in clinical judgment is expected; considerations for individual patients, such as availability of follow-up care, may enter into the decision, and the literature provides only general guidance.
- Policy level: Strong recommendation.

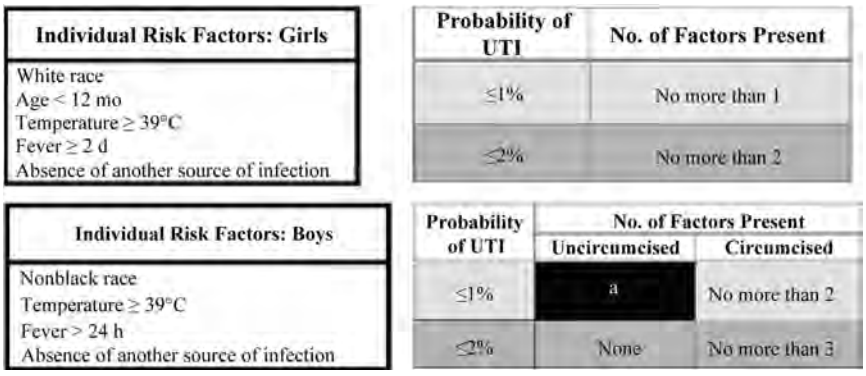

FIGURE 2

Probability of UTI Among Febrile Infant Girls[28] and Infant Boys[30] According to Number of Findings Present. [a]Probability of UTI exceeds 1% even with no risk factors other than being uncircumcised.

Action Statement 2

If a clinician assesses a febrile infant with no apparent source for the fever as not being so ill as to require immediate antimicrobial therapy, then the clinician should assess the likelihood of UTI (see below for how to assess likelihood).

Action Statement 2a

If the clinician determines the febrile infant to have a low likelihood of UTI (see text), then clinical follow-up monitoring without testing is sufficient (evidence quality: A; strong recommendation).

Action Statement 2b

If the clinician determines that the febrile infant is not in a low-risk group (see below), then there are 2 choices (evidence quality: A; strong recommendation). Option 1 is to obtain a urine specimen through catheterization or SPA for culture and urinalysis. Option 2 is to obtain a urine specimen through the most convenient means and to perform a urinalysis. If the urinalysis results suggest a UTI (positive leukocyte esterase test results or nitrite test or microscopic analysis results positive for leukocytes or bacteria), then a urine specimen should be obtained through catheterization or SPA and cultured; if urinalysis of fresh (<1 hour since void) urine yields negative leukocyte esterase and nitrite test results, then it is reasonable to monitor the clinical course without initiating antimicrobial therapy, recognizing that negative urinalysis results do not rule out a UTI with certainty.

If the clinician determines that the degree of illness does not require immediate antimicrobial therapy, then the likelihood of UTI should be assessed. As noted previously, the overall prevalence of UTI in febrile infants who have no source for their fever evident on the basis of history or physical examination results is approximately 5%,[17,18] but it is possible to identify groups with higher-than-average likelihood and some with lower-than-average likelihood. The prevalence of UTI among febrile infant girls is more than twice that among febrile infant boys (relative risk: 2.27). The rate for uncircumcised boys is 4 to 20 times higher than that for circumcised boys, whose rate of UTI is only 0.2% to 0.4%.[19–24] The presence of another, clinically obvious source of infection reduces the likelihood of UTI by one-half.[25]

In a survey asking, "What yield is required to warrant urine culture in febrile infants?," the threshold was less than 1% for 10.4% of academicians and 11.7% for practitioners[26]; when the threshold was increased to 1% to 3%, 67.5% of academicians and 45.7% of practitioners considered the yield sufficiently high to warrant urine culture. Therefore, attempting to operationalize "low likelihood" (ie, below a threshold that warrants a urine culture) does not produce an absolute percentage; clinicians will choose a threshold depending on factors such as their confidence that contact will be maintained through the illness (so that a specimen can be obtained at a later time) and comfort with diagnostic uncertainty. Fig 2 indicates the number of risk factors associated with threshold probabilities of UTI of at least 1% and at least 2%.

In a series of studies, Gorelick, Shaw, and colleagues[27–29] derived and validated a prediction rule for febrile infant girls on the basis of 5 risk factors, namely, white race, age less than 12 months, temperature of at least 39°C, fever for at least 2 days, and absence of another source of infection. This prediction rule, with sensitivity of 88% and specificity of 30%, permits some infant girls to be considered in a low-likelihood group (Fig 2). For example, of girls with no identifiable source of infection, those who are nonwhite and more than 12 months of age with a recent onset (<2 days) of low-

grade fever (<39°C) have less than a 1% probability of UTI; each additional risk factor increases the probability. It should be noted, however, that some of the factors (eg, duration of fever) may change during the course of the illness, excluding the infant from a low-likelihood designation and prompting testing as described in action statement 2a.

As demonstrated in Fig 2, the major risk factor for febrile infant boys is whether they are circumcised. The probability of UTI can be estimated on the basis of 4 risk factors, namely, nonblack race, temperature of at least 39°C, fever for more than 24 hours, and absence of another source of infection.[4,30]

If the clinician determines that the infant does not require immediate antimicrobial therapy and a urine specimen is desired, then often a urine collection bag affixed to the perineum is used. Many clinicians think that this collection technique has a low contamination rate under the following circumstances: the patient's perineum is properly cleansed and rinsed before application of the collection bag, the urine bag is removed promptly after urine is voided into the bag, and the specimen is refrigerated or processed immediately. Even if contamination from the perineal skin is minimized, however, there may be significant contamination from the vagina in girls or the prepuce in uncircumcised boys, the 2 groups at highest risk of UTI. A "positive" culture result from a specimen collected in a bag cannot be used to document a UTI; confirmation requires culture of a specimen collected through catheterization or SPA. Because there may be substantial delay waiting for the infant to void and a second specimen, obtained through catheterization, may be necessary if the urinalysis suggests the possibility of UTI, many clinicians prefer to obtain a definitive urine specimen through catheterization initially.

- Aggregate quality of evidence: A (diagnostic studies on relevant populations).
- Benefits: Accurate diagnosis of UTI can prevent the spread of infection and renal scarring; avoiding overdiagnosis of UTI can prevent overtreatment and unnecessary and expensive imaging.
- Harms/risks/costs: A small proportion of febrile infants, considered at low likelihood of UTI, will not receive timely identification and treatment of their UTIs.
- Benefit-harms assessment: Preponderance of benefit over harm.
- Value judgments: There is a risk of UTI sufficiently low to forestall further evaluation.
- Role of patient preferences: The choice of option 1 or option 2 and the threshold risk of UTI warranting obtaining a urine specimen may be influenced by parents' preference to avoid urethral catheterization (if a bag urine sample yields negative urinalysis results) versus timely evaluation (obtaining a definitive specimen through catheterization).
- Exclusions: Because it depends on a range of patient- and physician-specific considerations, the precise threshold risk of UTI warranting obtaining a urine specimen is left to the clinician but is below 3%.
- Intentional vagueness: None.
- Policy level: Strong recommendation.

TABLE 1 Sensitivity and Specificity of Components of Urinalysis, Alone and in Combination

Test	Sensitivity (Range), %	Specificity (Range), %
Leukocyte esterase test	83 (67–94)	78 (64–92)
Nitrite test	53 (15–82)	98 (90–100)
Leukocyte esterase or nitrite test positive	93 (90–100)	72 (58–91)
Microscopy, WBCs	73 (32–100)	81 (45–98)
Microscopy, bacteria	81 (16–99)	83 (11–100)
Leukocyte esterase test, nitrite test, or microscopy positive	99.8 (99–100)	70 (60–92)

Action Statement 3

To establish the diagnosis of UTI, clinicians should require *both* urinalysis results that suggest infection (pyuria and/or bacteriuria) *and* the presence of at least 50 000 colony-forming units (CFUs) per mL of a uropathogen cultured from a urine specimen obtained through catheterization or SPA (evidence quality: C; recommendation).

Urinalysis

General Considerations

Urinalysis cannot substitute for urine culture to document the presence of UTI but needs to be used in conjunction with culture. Because urine culture results are not available for at least 24 hours, there is considerable interest in tests that may predict the results of the urine culture and enable presumptive therapy to be initiated at the first encounter. Urinalysis can be performed on any specimen, including one collected from a bag applied to the perineum. However, the specimen must be fresh (<1 hour after voiding with maintenance at room temperature or <4 hours after voiding with refrigeration), to ensure sensitivity and specificity of the urinalysis. The tests that have received the most attention are biochemical analyses of leukocyte esterase and nitrite through a rapid dipstick method and urine microscopic examination for white blood cells (WBCs) and bacteria (Table 1).

Urine dipsticks are appealing, because they provide rapid results, do not require microscopy, and are eligible for a waiver under the Clinical Laboratory Improvement Amendments. They indicate the presence of leukocyte esterase (as a surrogate marker for pyuria) and urinary nitrite (which is converted from dietary nitrates in the presence of most Gram-negative enteric bacteria in the urine). The conversion of dietary nitrates to nitrites by bacteria requires approximately 4 hours in the bladder.[31] The performance characteristics of both leukocyte esterase and nitrite tests vary according to the definition used for positive urine culture results, the age and symptoms of the population being studied, and the method of urine collection.

Nitrite Test

A nitrite test is not a sensitive marker for children, particularly infants, who empty their bladders frequently. Therefore, negative nitrite test results have little value in ruling out UTI. Moreover, not all urinary pathogens reduce nitrate to nitrite. The test is helpful when the result is positive, however, because it is highly specific (ie, there are few false-positive results).[32]

Leukocyte Esterase Test

The sensitivity of the leukocyte esterase test is 94% when it used in the context of clinically suspected UTI. Overall, the reported sensitivity in various studies is lower (83%), because the results of leukocyte esterase tests were related to culture results without exclusion of individuals with asymptomatic bacteriuria. The absence of leukocyte esterase in the urine of individuals with asymptomatic bacteriuria is an advantage of the test, rather than a limitation, because it distinguishes individuals with asymptomatic bacteriuria from those with true UTI.

The specificity of the leukocyte esterase test (average: 72% [range: 64%–92%]) generally is not as good as the sensitivity, which reflects the nonspecificity of pyuria in general. Accordingly, positive leukocyte esterase test results should be interpreted with caution, because false-positive results are common. With numerous conditions other than UTI, including fever resulting from other conditions (eg, streptococcal infections or Kawasaki disease), and after vigorous exercise, WBCs may be found in the urine. Therefore, a finding of pyuria by no means confirms that an infection of the urinary tract is present.

The absence of pyuria in children with true UTIs is rare, however. It is theoretically possible if a febrile child is assessed before the inflammatory response has developed, but the inflammatory response to a UTI produces both fever and pyuria; therefore, children who are being evaluated because of fever should already have WBCs in their urine. More likely explanations for significant bacteriuria in culture in the absence of pyuria include contaminated specimens, insensitive criteria for pyuria, and asymptomatic bacteriuria. In most cases, when true UTI has been reported to occur in the absence of pyuria, the definition of pyuria has been at fault. The standard method of assessing pyuria has been centrifugation of the urine and microscopic analysis, with a threshold of 5 WBCs per high-power field (~25 WBCs per μL). If a counting chamber is used, however, the finding of at least 10 WBCs per μL in uncentrifuged urine has been demonstrated to be more sensitive[33] and performs well in clinical situations in which the standard method does not, such as with very young infants.[34]

An important cause of bacteriuria in the absence of pyuria is asymptomatic bacteriuria. Asymptomatic bacteriuria often is associated with school-aged and older girls,[35] but it can be present during infancy. In a study of infants 2 to 24 months of age, 0.7% of afebrile girls had 3 successive urine cultures with 10^5 CFUs per mL of a single uropathogen.[26] Asymptomatic bacteriuria can be easily confused with true UTI in a febrile infant but needs to be distinguished, because studies suggest that antimicrobial treatment may do more harm than good.[36] The key to distinguishing true UTI from asymptomatic bacteriuria is the presence of pyuria.

Microscopic Analysis for Bacteriuria

The presence of bacteria in a fresh, Gram-stained specimen of uncentrifuged urine correlates with 10^5 CFUs per mL in culture.[37] An "enhanced urinalysis," combining the counting chamber assessment of pyuria noted previously with Gram staining of drops of uncentrifuged urine, with a threshold of at least 1 Gram-negative rod in 10 oil immersion fields, has greater sensitivity, specificity, and positive predictive value than does the standard urinalysis[33] and is the preferred method of urinalysis when appropriate equipment and personnel are available.

Automated Urinalysis

Automated methods to perform urinalysis are now being used in many hospitals and laboratories. Image-based systems use flow imaging analysis technology and software to classify particles in uncentrifuged urine specimens rapidly.[38] Results correlate well with manual methods, especially for red blood cells, WBCs, and squamous epithelial cells. In the future, this may be the most common method by which urinalysis is performed in laboratories.

Culture

The diagnosis of UTI is made on the basis of quantitative urine culture results in addition to evidence of pyuria and/or bacteriuria. Urine specimens should be processed as expediently as

possible. If the specimen is not processed promptly, then it should be refrigerated to prevent the growth of organisms that can occur in urine at room temperature; for the same reason, specimens that require transportation to another site for processing should be transported on ice. A properly collected urine specimen should be inoculated on culture medium that will allow identification of urinary tract pathogens.

Urine culture results are considered positive or negative on the basis of the number of CFUs that grow on the culture medium.[36] Definition of significant colony counts with regard to the method of collection considers that the distal urethra and periurethral area are commonly colonized by the same bacteria that may cause UTI; therefore, a low colony count may be present in a specimen obtained through voiding or catheterization when bacteria are not present in bladder urine. Definitions of positive and negative culture results are operational and not absolute. The time the urine resides in the bladder (bladder incubation time) is an important determinant of the magnitude of the colony count. The concept that more than 100 000 CFUs per mL indicates a UTI was based on morning collections of urine from adult women, with comparison of specimens from women without symptoms and women considered clinically to have pyelonephritis; the transition range, in which the proportion of women with pyelonephritis exceeded the proportion of women without symptoms, was 10 000 to 100 000 CFUs per mL.[39] In most instances, an appropriate threshold to consider bacteriuria "significant" in infants and children is the presence of at least 50 000 CFUs per mL of a single urinary pathogen.[40] (Organisms such as *Lactobacillus* spp, coagulase-negative staphylococci, and *Corynebacterium* spp are not considered clinically relevant urine isolates for otherwise healthy, 2- to 24-month-old children.) Reducing the threshold from 100 000 CFUs per mL to 50 000 CFUs per mL would seem to increase the sensitivity of culture at the expense of decreased specificity; however, because the proposed criteria for UTI now include evidence of pyuria in addition to positive culture results, infants with "positive" culture results alone will be recognized as having asymptomatic bacteriuria rather than a true UTI. Some laboratories report growth only in the following categories: 0 to 1000, 1000 to 10 000, 10 000 to 100 000, and more than 100 000 CFUs per mL. In such cases, results in the 10 000 to 100 000 CFUs per mL range need to be evaluated in context, such as whether the urinalysis findings support the diagnosis of UTI and whether the organism is a recognized uropathogen.

Alternative culture methods, such as dipslides, may have a place in the office setting; sensitivity is reported to be in the range of 87% to 100%, and specificity is reported to be 92% to 98%, but dipslides cannot specify the organism or antimicrobial sensitivities.[41] Practices that use dipslides should do so in collaboration with a certified laboratory for identification and sensitivity testing or, in the absence of such results, may need to perform "test of cure" cultures after 24 hours of treatment.

- Aggregate quality of evidence: C (observational studies).
- Benefits: Accurate diagnosis of UTI can prevent the spread of infection and renal scarring; avoiding overdiagnosis of UTI can prevent overtreatment and unnecessary and expensive imaging. These criteria reduce the likelihood of overdiagnosis of UTI in infants with asymptomatic bacteriuria or contaminated specimens.
- Harms/risks/costs: Stringent diagnostic criteria may miss a small number of UTIs.
- Benefit-harms assessment: Preponderance of benefit over harm.
- Value judgments: Treatment of asymptomatic bacteriuria may be harmful.
- Role of patient preferences: We assume that parents prefer no action in the absence of a UTI (avoiding false-positive results) over a very small chance of missing a UTI.
- Exclusions: None.
- Intentional vagueness: None.
- Policy level: Recommendation.

MANAGEMENT

Action Statement 4

Action Statement 4a

When initiating treatment, the clinician should base the choice of route of administration on practical considerations. Initiating treatment orally or parenterally is equally efficacious. The clinician should base the choice of agent on local antimicrobial sensitivity patterns (if available) and should adjust the choice according to sensitivity testing of the isolated uropathogen (evidence quality: A; strong recommendation).

Action Statement 4b

The clinician should choose 7 to 14 days as the duration of antimicrobial therapy (evidence quality: B; recommendation).

The goals of treatment of acute UTI are to eliminate the acute infection, to prevent complications, and to reduce the likelihood of renal damage. Most children can be treated orally.[42–44] Patients whom clinicians judge to be "toxic" or who are unable to retain oral intake (including medications) should receive an antimicrobial agent parenter-

TABLE 2 Some Empiric Antimicrobial Agents for Parenteral Treatment of UTI

Antimicrobial Agent	Dosage
Ceftriaxone	75 mg/kg, every 24 h
Cefotaxime	150 mg/kg per d, divided every 6–8 h
Ceftazidime	100–150 mg/kg per d, divided every 8 h
Gentamicin	7.5 mg/kg per d, divided every 8 h
Tobramycin	5 mg/kg per d, divided every 8 h
Piperacillin	300 mg/kg per d, divided every 6–8 h

TABLE 3 Some Empiric Antimicrobial Agents for Oral Treatment of UTI

Antimicrobial Agent	Dosage
Amoxicillin-clavulanate	20–40 mg/kg per d in 3 doses
Sulfonamide	
Trimethoprim-sulfamethoxazole	6–12 mg/kg trimethoprim and 30-60 mg/kg sulfamethoxazole per d in 2 doses
Sulfisoxazole	120–150 mg/kg per d in 4 doses
Cephalosporin	
Cefixime	8 mg/kg per d in 1 dose
Cefpodoxime	10 mg/kg per d in 2 doses
Cefprozil	30 mg/kg per d in 2 doses
Cefuroxime axetil	20–30 mg/kg per d in 2 doses
Cephalexin	50–100 mg/kg per d in 4 doses

ally (Table 2) until they exhibit clinical improvement, generally within 24 to 48 hours, and are able to retain orally administered fluids and medications. In a study of 309 febrile infants with UTIs, only 3 (1%) were deemed too ill to be assigned randomly to either parenteral or oral treatment.[42] Parenteral administration of an antimicrobial agent also should be considered when compliance with obtaining an antimicrobial agent and/or administering it orally is uncertain. The usual choices for oral treatment of UTIs include a cephalosporin, amoxicillin plus clavulanic acid, or trimethoprim-sulfamethoxazole (Table 3). It is essential to know local patterns of susceptibility of coliforms to antimicrobial agents, particularly trimethoprim-sulfamethoxazole and cephalexin, because there is substantial geographic variability that needs to be taken into account during selection of an antimicrobial agent before sensitivity results are available. Agents that are excreted in the urine but do not achieve therapeutic concentrations in the bloodstream, such as nitrofurantoin, should not be used to treat febrile infants with UTIs, because parenchymal and serum antimicrobial concentrations may be insufficient to treat pyelonephritis or urosepsis.

Whether the initial route of administration of the antimicrobial agent is oral or parenteral (then changed to oral), the total course of therapy should be 7 to 14 days. The committee attempted to identify a single, preferred, evidence-based duration, rather than a range, but data comparing 7, 10, and 14 days directly were not found. There is evidence that 1- to 3-day courses for febrile UTIs are inferior to courses in the recommended range; therefore, the minimal duration selected should be 7 days.

- Aggregate quality of evidence: A/B (RCTs).
- Benefits: Adequate treatment of UTI can prevent the spread of infection and renal scarring. Outcomes of short courses (1–3 d) are inferior to those of 7- to 14-d courses.
- Harms/risks/costs: There are minimal harm and minor cost effects of antimicrobial choice and duration of therapy.
- Benefit-harms assessment: Preponderance of benefit over harm.
- Value judgments: Adjusting antimicrobial choice on the basis of available data and treating according to best evidence will minimize cost and consequences of failed or unnecessary treatment.
- Role of patient preferences: It is assumed that parents prefer the most-effective treatment and the least amount of medication that ensures effective treatment.
- Exclusions: None.
- Intentional vagueness: No evidence distinguishes the benefit of treating 7 vs 10 vs 14 days, and the range is allowable.
- Policy level: Strong recommendation/recommendation.

Action Statement 5

Febrile infants with UTIs should undergo renal and bladder ultrasonography (RBUS) (evidence quality: C; recommendation).

The purpose of RBUS is to detect anatomic abnormalities that require further evaluation, such as additional imaging or urologic consultation. RBUS also provides an evaluation of the renal parenchyma and an assessment of renal size that can be used to monitor renal growth. The yield of actionable findings is relatively low.[45,46] Widespread application of prenatal ultrasonography clearly has reduced the prevalence of previously unsuspected obstructive uropathy in infants, but the consequences of prenatal screening with respect to the risk of renal abnormalities in infants with UTIs have not yet been well defined. There is considerable variability in the timing and quality of prenatal ultrasonograms, and the report of "normal" ultrasonographic results cannot necessarily be relied on to dismiss completely the possibility of a structural abnormality unless the study was a detailed anatomic survey (with measurements), was performed during the third tri-

mester, and was performed and interpreted by qualified individuals.[47]

The timing of RBUS depends on the clinical situation. RBUS is recommended during the first 2 days of treatment to identify serious complications, such as renal or perirenal abscesses or pyonephrosis associated with obstructive uropathy when the clinical illness is unusually severe or substantial clinical improvement is not occurring. For febrile infants with UTIs who demonstrate substantial clinical improvement, however, imaging does not need to occur early during the acute infection and can even be misleading; animal studies demonstrate that *Escherichia coli* endotoxin can produce dilation during acute infection, which could be confused with hydronephrosis, pyonephrosis, or obstruction.[48] Changes in the size and shape of the kidneys and the echogenicity of renal parenchyma attributable to edema also are common during acute infection. The presence of these abnormalities makes it inappropriate to consider RBUS performed early during acute infection to be a true baseline study for later comparisons in the assessment of renal growth.

Nuclear scanning with technetium-labeled dimercaptosuccinic acid has greater sensitivity for detection of acute pyelonephritis and later scarring than does either RBUS or voiding cystourethrography (VCUG). The scanning is useful in research, because it ensures that all subjects in a study have pyelonephritis to start with and it permits assessment of later renal scarring as an outcome measure. The findings on nuclear scans rarely affect acute clinical management, however, and are not recommended as part of routine evaluation of infants with their first febrile UTI. The radiation dose to the patient during dimercaptosuccinic acid scanning is generally low (~1 mSv),[49] although it may be increased in children with reduced renal function. The radiation dose from dimercaptosuccinic acid is additive with that of VCUG when both studies are performed.[50] The radiation dose from VCUG depends on the equipment that is used (conventional versus pulsed digital fluoroscopy) and is related directly to the total fluoroscopy time. Moreover, the total exposure for the child will be increased when both acute and follow-up studies are obtained. The lack of exposure to radiation is a major advantage of RBUS, even with recognition of the limitations of this modality that were described previously.

- Aggregate quality of evidence: C (observational studies).
- Benefits: RBUS in this population will yield abnormal results in ~15% of cases, and 1% to 2% will have abnormalities that would lead to action (eg, additional evaluation, referral, or surgery).
- Harms/risks/costs: Between 2% and 3% will be false-positive results, leading to unnecessary and invasive evaluations.
- Benefit-harms assessment: Preponderance of benefit over harm.
- Value judgments: The seriousness of the potentially correctable abnormalities in 1% to 2%, coupled with the absence of physical harm, was judged sufficiently important to tip the scales in favor of testing.
- Role of patient preferences: Because ultrasonography is noninvasive and poses minimal risk, we assume that parents will prefer RBUS over taking even a small risk of missing a serious and correctable condition.
- Exclusions: None.
- Intentional vagueness: None.
- Policy level: Recommendation.

Action Statement 6

Action Statement 6a

VCUG should not be performed routinely after the first febrile UTI; VCUG is indicated if RBUS reveals hydronephrosis, scarring, or other findings that would suggest either high-grade VUR or obstructive uropathy, as well as in other atypical or complex clinical circumstances (evidence quality B; recommendation).

Action Statement 6b

Further evaluation should be conducted if there is a recurrence of febrile UTI (evidence quality: X; recommendation).

For the past 4 decades, the strategy to protect the kidneys from further damage after an initial UTI has been to detect childhood genitourinary abnormalities in which recurrent UTI could increase renal damage. The most common of these is VUR, and VCUG is used to detect this. Management included continuous antimicrobial administration as prophylaxis and surgical intervention if VUR was persistent or recurrences of infection were not prevented with an antimicrobial prophylaxis regimen; some have advocated surgical intervention to correct high-grade reflux even when infection has not recurred. However, it is clear that there are a significant number of infants who develop pyelonephritis in whom VUR cannot be demonstrated, and the effectiveness of antimicrobial prophylaxis for patients who have VUR has been challenged in the past decade. Several studies have suggested that prophylaxis does not confer the desired benefit of preventing recurrent febrile UTI.[51–55] If prophylaxis is, in fact, not beneficial and VUR is not required for development of pyelonephritis, then the rationale for performing VCUG routinely after an initial febrile UTI must be questioned.

RCTs of the effectiveness of prophylaxis performed to date generally included children more than 24 months of age, and some did not provide complete data according to grade of VUR. These 2 factors have compromised meta-analyses. To ensure direct comparisons, the committee contacted the 6 researchers who had conducted the most recent RCTs and requested raw data from their studies.[51–56] All complied, which permitted the creation of a data set with data for 1091 infants 2 to 24 months of age according to grade of VUR. A χ^2 analysis (2-tailed) and a formal meta-analysis did not detect a statistically significant benefit of prophylaxis in preventing recurrence of febrile UTI/pyelonephritis in infants without reflux or those with grades I, II, III, or IV VUR (Table 4 and Fig 3). Only 5 infants with grade V VUR were included in the RCTs; therefore, data for those infants are not included in Table 4 or Fig 3.

The proportion of infants with high-grade VUR among all infants with febrile UTIs is small. Data adapted from current studies (Table 5) indicate that, of a hypothetical cohort of 100 infants with febrile UTIs, only 1 has grade V VUR; 99 do not. With a practice of waiting for a second UTI to perform VCUG, only 10 of the 100 would need to undergo the procedure and the 1 with grade V VUR would be identified. (It also is possible that the 1 infant with grade V VUR might have been identified after the first UTI on the basis of abnormal RBUS results that prompted VCUG to be performed.) Data to quantify additional potential harm to an infant who is not revealed to have high-grade VUR until a second UTI are not precise but suggest that the increment is insufficient to justify routinely subjecting all infants with an initial febrile UTI to VCUG (Fig 4). To minimize any harm incurred by that infant, attempts have been made to identify, at the time of the initial UTI, those who have the greatest likelihood of having high-grade VUR. Unfortunately, there are no clinical or laboratory indicators that have been demonstrated to identify infants with high-grade VUR. Indications for VCUG have been proposed on the basis of consensus in the absence of data[57]; the predictive value of any of the indications for VCUG proposed in this manner is not known.

TABLE 4 Recurrences of Febrile UTI/Pyelonephritis in Infants 2 to 24 Months of Age With and Without Antimicrobial Prophylaxis, According to Grade of VUR

Reflux Grade	Prophylaxis		No Prophylaxis		*P*
	No. of Recurrences	Total *N*	No. of Recurrences	Total *N*	
None	7	210	11	163	.15
I	2	37	2	35	1.00
II	11	133	10	124	.95
III	31	140	40	145	.29
IV	16	55	21	49	.14

The level of evidence supporting routine imaging with VCUG was deemed insufficient at the time of the 1999 practice parameter to receive a recommendation, but the consensus of the subcommittee was to "strongly encourage" imaging studies. The position of the current subcommittee reflects the new evidence demonstrating antimicrobial prophylaxis not to be effective as presumed previously. Moreover, prompt diagnosis and effective treatment of a febrile UTI recurrence may be of greater importance regardless of whether VUR is present or the child is receiving antimicrobial prophylaxis. A national study (the Randomized Intervention for Children With Vesicoureteral Reflux study) is currently in progress to identify the effects of a prophylactic antimicrobial regimen for children 2 months to 6 years of age who have experienced a UTI, and it is anticipated to provide additional important data[58] (see Areas for Research).

Action Statement 6a

- Aggregate quality of evidence: B (RCTs).
- Benefits: This avoids, for the vast majority of febrile infants with UTIs, radiation exposure (of particular concern near the ovaries in girls), expense, and discomfort.
- Harms/risks/costs: Detection of a small number of cases of high-grade reflux and correctable abnormalities is delayed.
- Benefit-harms assessment: Preponderance of benefit over harm.
- Value judgments: The risks associated with radiation (plus the expense and discomfort of the procedure) for the vast majority of infants outweigh the risk of delaying the detection of the few with correctable abnormalities until their second UTI.
- Role of patient preferences: The judgment of parents may come into play, because VCUG is an uncomfortable procedure involving radiation exposure. In some cases, parents may prefer to subject their children to the procedure even when the chance of benefit is both small and uncertain. Antimicrobial prophylaxis seems to be ineffective in preventing recurrence of febrile UTI/pyelonephritis for the vast majority of infants. Some parents may want to avoid VCUG even after the second UTI. Because the benefit of identifying high-grade reflux is still in some doubt, these preferences should be considered. It is the judgment of the committee that VCUG is indicated after the second UTI.
- Exclusions: None.

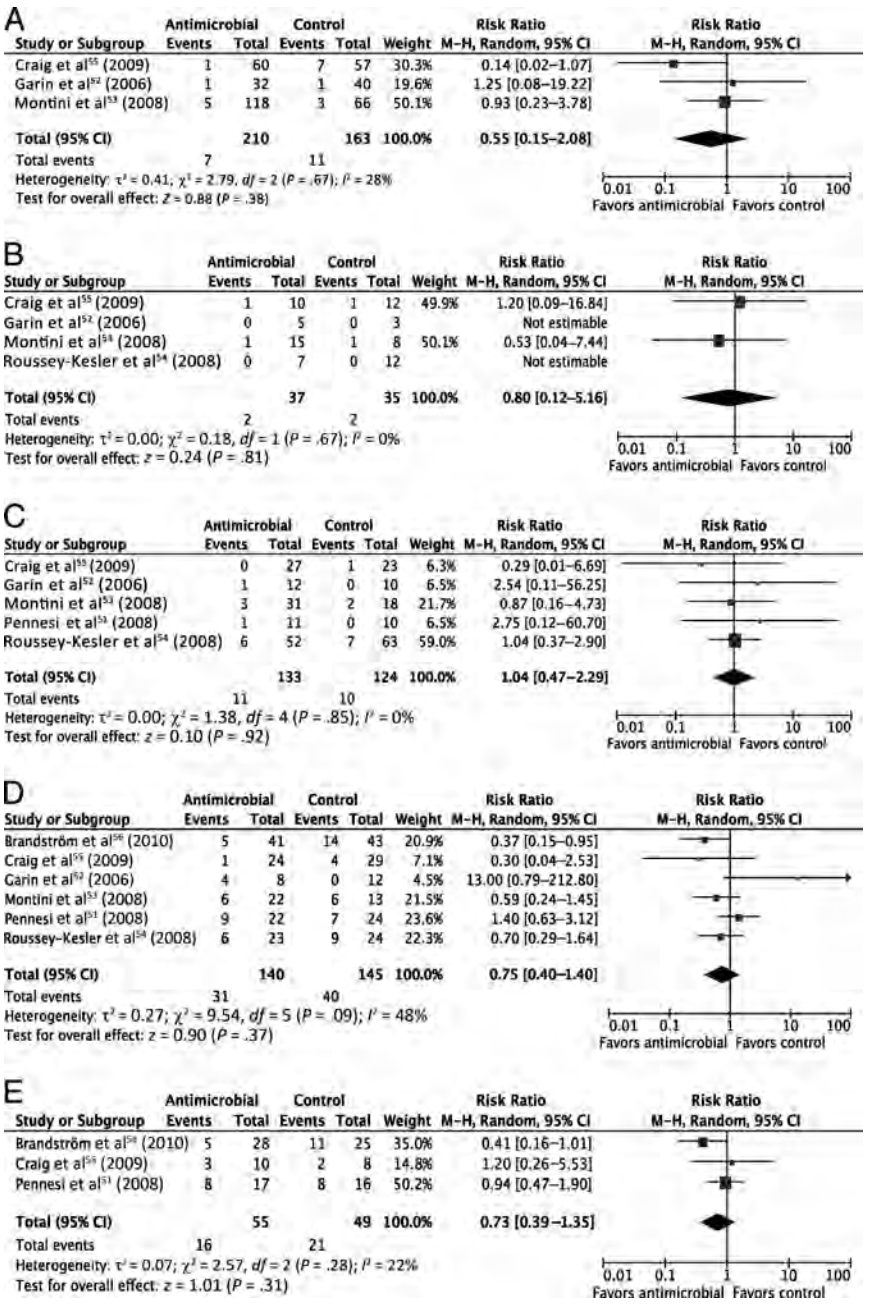

FIGURE 3

A, Recurrences of febrile UTI/pyelonephritis in 373 infants 2 to 24 months of age without VUR, with and without antimicrobial prophylaxis (based on 3 studies; data provided by Drs Craig, Garin, and Montini). B, Recurrences of febrile UTI/pyelonephritis in 72 infants 2 to 24 months of age with grade I VUR, with and without antimicrobial prophylaxis (based on 4 studies; data provided by Drs Craig, Garin, Montini, and Roussey-Kesler). C, Recurrences of febrile UTI/pyelonephritis in 257 infants 2 to 24 months of age with grade II VUR, with and without antimicrobial prophylaxis (based on 5 studies; data provided by Drs Craig, Garin, Montini, Pennesi, and Roussey-Kesler). D, Recurrences of febrile UTI/pyelonephritis in 285 infants 2 to 24 months of age with grade III VUR, with and without antimicrobial prophylaxis (based on 6 studies; data provided by Drs Brandström, Craig, Garin, Montini, Pennesi, and Roussey-Kesler). E, Recurrences of febrile UTI/pyelonephritis in 104 infants 2 to 24 months of age with grade IV VUR, with and without antimicrobial prophylaxis (based on 3 studies; data provided by Drs Brandström, Craig, and Pennesi). M-H indicates Mantel-Haenszel; CI, confidence interval.

TABLE 5 Rates of VUR According to Grade in Hypothetical Cohort of Infants After First UTI and After Recurrence

	Rate, %	
	After First UTI ($N = 100$)	After Recurrence ($N = 10$)
No VUR	65	26
Grades I–III VUR	29	56
Grade IV VUR	5	12
Grade V VUR	1	6

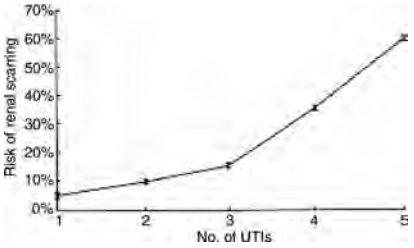

FIGURE 4

Relationship between renal scarring and number of bouts of pyelonephritis. Adapted from Jodal.[59]

- Intentional vagueness: None.
- Policy level: Recommendation.

Action Statement 6b

- Aggregate quality of evidence: X (exceptional situation).
- Benefits: VCUG after a second UTI should identify infants with very high-grade reflux.
- Harms/risks/costs: VCUG is an uncomfortable, costly procedure that involves radiation, including to the ovaries of girls.
- Benefit-harms assessment: Preponderance of benefit over harm.
- Value judgments: The committee judged that patients with high-grade reflux and other abnormalities may benefit from interventions to prevent further scarring. Further studies of treatment for grade V VUR are not underway and are unlikely in the near future, because the condition is uncommon and randomization of treatment in this group generally has been considered unethical.

- Role of patient preferences: As mentioned previously, the judgment of parents may come into play, because VCUG is an uncomfortable procedure involving radiation exposure. In some cases, parents may prefer to subject their children to the procedure even when the chance of benefit is both small and uncertain. The benefits of treatment of VUR remain unproven, but the point estimates suggest a small potential benefit. Similarly, parents may want to avoid VCUG even after the second UTI. Because the benefit of identifying high-grade reflux is still in some doubt, these preferences should be considered. It is the judgment of the committee that VCUG is indicated after the second UTI.
- Exclusions: None.
- Intentional vagueness: Further evaluation will likely start with VCUG but may entail additional studies depending on the findings. The details of further evaluation are beyond the scope of this guideline.
- Policy level: Recommendation.

Action Statement 7

After confirmation of UTI, the clinician should instruct parents or guardians to seek prompt medical evaluation (ideally within 48 hours) for future febrile illnesses, to ensure that recurrent infections can be detected and treated promptly (evidence quality: C; recommendation).

Early treatment limits renal damage better than late treatment,[1,2] and the risk of renal scarring increases as the number of recurrences increase (Fig 4).[59] For these reasons, all infants who have sustained a febrile UTI should have a urine specimen obtained at the onset of subsequent febrile illnesses, so that a UTI can be diagnosed and treated promptly.

- Aggregate quality of evidence: C (observational studies).
- Benefits: Studies suggest that early treatment of UTI reduces the risk of renal scarring.
- Harms/risks/costs: There may be additional costs and inconvenience to parents with more-frequent visits to the clinician for evaluation of fever.
- Benefit-harms assessment: Preponderance of benefit over harm.
- Value judgments: None.
- Role of patient preferences: Parents will ultimately make the judgment to seek medical care.
- Exclusions: None.
- Intentional vagueness: None.
- Policy level: Recommendation.

CONCLUSIONS

The committee formulated 7 key action statements for the diagnosis and treatment of infants and young children 2 to 24 months of age with UTI and unexplained fever. Strategies for diagnosis and treatment depend on whether the clinician determines that antimicrobial therapy is warranted immediately or can be delayed safely until urine culture and urinalysis results are available. Diagnosis is based on the presence of pyuria and at least 50 000 CFUs per mL of a single uropathogen in an appropriately collected specimen of urine; urinalysis alone does not provide a definitive diagnosis. After 7 to 14 days of antimicrobial treatment, close clinical follow-up monitoring should be maintained, with evaluation of the urine during subsequent febrile episodes to permit prompt diagnosis and treatment of recurrent infections. Ultrasonography of the kidneys and bladder should be performed to detect anatomic abnormalities that require further evaluation (eg, additional imaging or urologic consultation). Routine VCUG after the first UTI is not recommended; VCUG is indicated if RBUS reveals hydronephrosis, scarring, or other findings that would suggest either high-grade VUR or obstructive uropathy, as well as in other atypical or complex clinical circumstances. VCUG also should be performed if there is a recurrence of febrile UTI.

AREAS FOR RESEARCH

One of the major values of a comprehensive literature review is the identification of areas in which evidence is lacking. The following 8 areas are presented in an order that parallels the previous discussion.

1. The relationship between UTIs in infants and young children and reduced renal function in adults has been established but is not well characterized in quantitative terms. The ideal prospective cohort study from birth to 40 to 50 years of age has not been conducted and is unlikely to be conducted. Therefore, estimates of undesirable outcomes in adulthood, such as hypertension and end-stage renal disease, are based on the mathematical product of probabilities at several steps, each of which is subject to bias and error. Other attempts at decision analysis and thoughtful literature review have recognized the same limitations. Until recently, imaging tools available for assessment of the effects of UTIs have been insensitive. With the imaging techniques now available, it may be possible to identify the relationship of scarring to renal impairment and hypertension.
2. The development of techniques that would permit an alternative to invasive sampling and culture would be valuable for general use. Special attention should be given to infant girls and uncircumcised boys, because urethral catheterization may

be difficult and can produce contaminated specimens and SPA now is not commonly performed. Incubation time, which is inherent in the culture process, results in delayed treatment or presumptive treatment on the basis of tests that lack the desired sensitivity and specificity to replace culture.

3. The role of VUR (and therefore of VCUG) is incompletely understood. It is recognized that pyelonephritis (defined through cortical scintigraphy) can occur in the absence of VUR (defined through VCUG) and that progressive renal scarring (defined through cortical scintigraphy) can occur in the absence of demonstrated VUR.[52,53] The presumption that antimicrobial prophylaxis is of benefit for individuals with VUR to prevent recurrences of UTI or the development of renal scars is not supported by the aggregate of data from recent studies and currently is the subject of the Randomized Intervention for Children With Vesicoureteral Reflux study.[58]
4. Although the effectiveness of antimicrobial prophylaxis for the prevention of UTI has not been demonstrated, the concept has biological plausibility. Virtually all antimicrobial agents used to treat or to prevent infections of the urinary tract are excreted in the urine in high concentrations. Barriers to the effectiveness of antimicrobial prophylaxis are adherence to a daily regimen, adverse effects associated with the various agents, and the potential for emergence of antimicrobial resistance. To overcome these issues, evidence of effectiveness with a well-tolerated, safe product would be required, and parents would need sufficient education to understand the value and importance of adherence. A urinary antiseptic, rather than an antimicrobial agent, would be particularly desirable, because it could be taken indefinitely without concern that bacteria would develop resistance. Another possible strategy might be the use of probiotics.
5. Better understanding of the genome (human and bacterial) may provide insight into risk factors (VUR and others) that lead to increased scarring. Blood specimens will be retained from children enrolled in the Randomized Intervention for Children With Vesicoureteral Reflux study, for future examination of genetic determinants of VUR, recurrent UTI, and renal scarring.[58] VUR is recognized to "run in families,"[60,61] and multiple investigators are currently engaged in research to identify a genetic basis for VUR. Studies may also be able to distinguish the contribution of congenital dysplasia from acquired scarring attributable to UTI.
6. One of the factors used to assess the likelihood of UTI in febrile infants is race. Data regarding rates among Hispanic individuals are limited and would be useful for prediction rules.
7. This guideline is limited to the initial management of the first UTI in febrile infants 2 to 24 months of age. Some of the infants will have recurrent UTIs; some will be identified as having VUR or other abnormalities. Further research addressing the optimal course of management in specific situations would be valuable.
8. The optimal duration of antimicrobial treatment has not been determined. RCTs of head-to-head comparisons of various duration would be valuable, enabling clinicians to limit antimicrobial exposure to what is needed to eradicate the offending uropathogen.

OVERSIGHT BY THE STEERING COMMITTEE ON QUALITY IMPROVEMENT AND MANAGEMENT, 2009–2011

STAFF
Caryn Davidson, MA

ACKNOWLEDGMENTS

The committee gratefully acknowledges the generosity of the researchers who graciously shared their data to permit the data set with data for 1091 infants aged 2 to 24 months according to grade of VUR to be compiled, that is, Drs Per Brandström, Jonathan Craig, Eduardo Garin, Giovanni Montini, Marco Pennesi, and Gwenaelle Roussey-Kesler.

Urinary Tract Infection Clinical Practice Guideline Quick Reference Tools

- Action Statement Summary
  — Urinary Tract Infection: Clinical Practice Guideline for the Diagnosis and Management of the Initial UTI in Febrile Infants and Children 2 to 24 Months
- *ICD-10-CM* Coding Quick Reference for Urinary Tract Infection
- AAP Patient Education Handout
  — *Urinary Tract Infections in Young Children*

Action Statement Summary

Urinary Tract Infection: Clinical Practice Guideline for the Diagnosis and Management of the Initial UTI in Febrile Infants and Children 2 to 24 Months

Action Statement 1

If a clinician decides that a febrile infant with no apparent source for the fever requires antimicrobial therapy to be administered because of ill appearance or another pressing reason, the clinician should ensure that a urine specimen is obtained for both culture and urinalysis before an antimicrobial agent is administered; the specimen needs to be obtained through catheterization or SPA, because the diagnosis of UTI cannot be established reliably through culture of urine collected in a bag (evidence quality: A; strong recommendation).

Action Statement 2

If a clinician assesses a febrile infant with no apparent source for the fever as not being so ill as to require immediate antimicrobial therapy, then the clinician should assess the likelihood of UTI (see below for how to assess likelihood).

Action Statement 2a

If the clinician determines the febrile infant to have a low likelihood of UTI (see text), then clinical follow-up monitoring without testing is sufficient (evidence quality: A; strong recommendation).

Action Statement 2b

If the clinician determines that the febrile infant is not in a low-risk group (see below), then there are 2 choices (evidence quality: A; strong recommendation). Option 1 is to obtain a urine specimen through catheterization or SPA for culture and urinalysis. Option 2 is to obtain a urine specimen through the most convenient means and to perform a urinalysis. If the urinalysis results suggest a UTI (positive leukocyte esterase test results or nitrite test or microscopic analysis results positive for leukocytes or bacteria), then a urine specimen should be obtained through catheterization or SPA and cultured; if urinalysis of fresh (<1 hour since void) urine yields negative leukocyte esterase and nitrite test results, then it is reasonable to monitor the clinical course without initiating antimicrobial therapy, recognizing that negative urinalysis results do not rule out a UTI with certainty.

Action Statement 3

To establish the diagnosis of UTI, clinicians should require *both* urinalysis results that suggest infection (pyuria and/or bacteriuria) *and* the presence of at least 50 000 colony-forming units (CFUs) per mL of a uropathogen cultured from a urine specimen obtained through catheterization or SPA (evidence quality: C; recommendation).

Action Statement 4a

When initiating treatment, the clinician should base the choice of route of administration on practical considerations. Initiating treatment orally or parenterally is equally efficacious. The clinician should base the choice of agent on local antimicrobial sensitivity patterns (if available) and should adjust the choice according to sensitivity testing of the isolated uropathogen (evidence quality: A; strong recommendation).

Action Statement 4b

The clinician should choose 7 to 14 days as the duration of antimicrobial therapy (evidence quality: B; recommendation).

Action Statement 5

Febrile infants with UTIs should undergo renal and bladder ultrasonography (RBUS) (evidence quality: C; recommendation).

Action Statement 6a

VCUG should not be performed routinely after the first febrile UTI; VCUG is indicated if RBUS reveals hydronephrosis, scarring, or other findings that would suggest either high-grade VUR or obstructive uropathy, as well as in other atypical or complex clinical circumstances (evidence quality B; recommendation).

Action Statement 6b

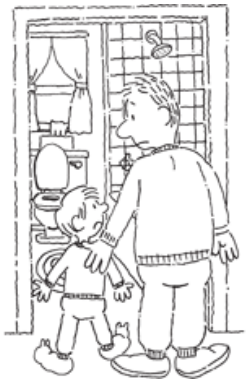
Further evaluation should be conducted if there is a recurrence of febrile UTI (evidence quality: X; recommendation).

Action Statement 7

After confirmation of UTI, the clinician should instruct parents or guardians to seek prompt medical evaluation (ideally within 48 hours) for future febrile illnesses, to ensure that recurrent infections can be detected and treated promptly (evidence quality: C; recommendation).

Coding Quick Reference for Urinary Tract Infection
ICD-10-CM
N39.0 Urinary tract infection, site not specified
P39.3 Neonatal urinary tract infection

Urinary Tract Infections in Young Children



Urinary tract infections (UTIs) are common in young children. These infections can lead to serious health problems. UTIs may go untreated because the symptoms may not be obvious to the child or the parents. The following is information from the American Academy of Pediatrics about UTIs—what they are, how children get them, and how they are treated.

The urinary tract

The urinary tract makes and stores urine. It is made up of the kidneys, ureters, bladder, and urethra (see illustration on the next page). The kidneys produce urine. Urine travels from the kidneys down 2 narrow tubes called the ureters to the bladder. The bladder is a thin muscular bag that stores urine until it is time to empty urine out of the body. When it is time to empty the bladder, a muscle at the bottom of the bladder relaxes. Urine then flows out of the body through a tube called the urethra. The opening of the urethra is at the end of the penis in boys and above the vaginal opening in girls.

Urinary tract infections

Normal urine has no germs (bacteria). However, bacteria can get into the urinary tract from 2 sources: (1) the skin around the rectum and genitals and (2) the bloodstream from other parts of the body. Bacteria may cause infections in any or all parts of the urinary tract, including the following:

- Urethra (called urethritis)
- Bladder (called cystitis)
- Kidneys (called pyelonephritis)

UTIs are common in infants and young children. The frequency of UTIs in girls is much greater than in boys. About 3% of girls and 1% of boys will have a UTI by 11 years of age. A young child with a high fever and no other symptoms has a 1 in 20 chance of having a UTI. Uncircumcised boys have more UTIs than those who have been circumcised.

Symptoms

Symptoms of UTIs may include the following:

- Fever
- Pain or burning during urination
- Need to urinate more often, or difficulty getting urine out
- Urgent need to urinate, or wetting of underwear or bedding by a child who knows how to use the toilet
- Vomiting, refusal to eat
- Abdominal pain
- Side or back pain
- Foul-smelling urine
- Cloudy or bloody urine
- Unexplained and persistent irritability in an infant
- Poor growth in an infant

Diagnosis

If your child has symptoms of a UTI, your child's doctor will do the following:

- Ask about your child's symptoms.
- Ask about any family history of urinary tract problems.
- Ask about what your child has been eating and drinking.
- Examine your child.
- Get a urine sample from your child.

Your child's doctor will need to test your child's urine to see if there are bacteria or other abnormalities.

Ways urine is collected

Urine must be collected and analyzed to determine if there is a bacterial infection. Older children are asked to urinate into a container.

There are 3 ways to collect urine from a young child:

1. The preferred method is to place a small tube, called a catheter, through the urethra into the bladder. Urine flows through the tube into a special urine container.
2. Another method is to insert a needle through the skin of the lower abdomen to draw urine from the bladder. This is called needle aspiration.
3. If your child is very young or not yet toilet trained, the child's doctor may place a plastic bag over the genitals to collect the urine. Since bacteria on the skin can contaminate the urine and give a false test result, this method is used only to screen for infection. If an infection seems to be present, the doctor will need to collect urine through 1 of the first 2 methods in order to determine if bacteria are present.

Your child's doctor will discuss with you the best way to collect your child's urine.

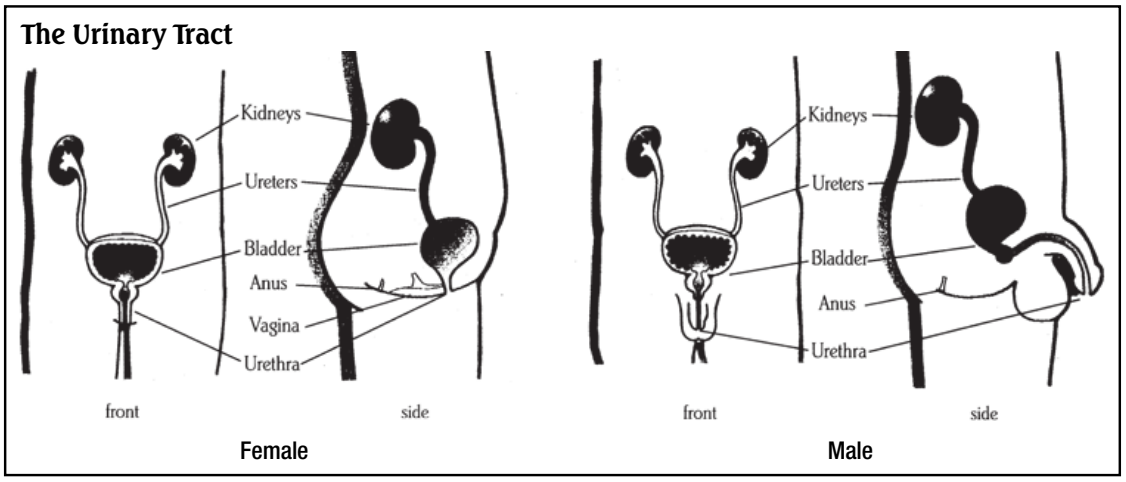
Treatment

UTIs are treated with antibiotics. The way your child receives the antibiotic depends on the severity and type of infection. Antibiotics are usually given by mouth, as liquid or pills. If your child has a fever or is vomiting and is unable to keep fluids down, the antibiotics may be put directly into a vein or injected into a muscle.

UTIs need to be treated right away to

- Get rid of the infection.
- Prevent the spread of the infection outside of the urinary tract.
- Reduce the chances of kidney damage.

Infants and young children with UTIs usually need to take antibiotics for 7 to 14 days, sometimes longer. Make sure your child takes all the medicine your child's doctor prescribes. Do not stop giving your child the medicine until the child's doctor says the treatment is finished, even if your child feels better. UTIs can return if not fully treated.



Follow-up

If the UTI occurs early in life, your child's doctor will probably want to make sure the urinary tract is normal with a kidney and bladder ultrasound. This test uses sound waves to examine the bladder and kidneys.

In addition, your child's doctor may want to make sure that the urinary tract is functioning normally and is free of any damage. Several tests are available to do this, including the following:

Voiding cystourethrogram (VCUG). A catheter is placed into the urethra and the bladder is filled with a liquid that can be seen on x-rays. This test shows whether the urine is flowing back from the bladder toward the kidneys instead of all of it coming out through the urethra as it should.

Nuclear scans. Radioactive material is injected into a vein to see if the kidneys are normal. There are many kinds of nuclear scans, each giving different information about the kidneys and bladder. The radioactive material gives no more radiation than any other kind of x-ray.

Remember

UTIs are common and most are easy to treat. Early diagnosis and prompt treatment are important because untreated or repeated infections can cause long-term medical problems. Children who have had one UTI are more likely to have another. Be sure to see your child's doctor early if your child has had a UTI in the past and has fever. Talk with your child's doctor if you suspect that your child might have a UTI.

From your doctor

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

The American Academy of Pediatrics is an organization of 66,000 primary care pediatricians, pediatric medical subspecialists, and pediatric surgical specialists dedicated to the health, safety, and well-being of infants, children, adolescents, and young adults.

American Academy of Pediatrics
Web site — www.HealthyChildren.org

SECTION 2

Endorsed Clinical Practice Guidelines

The American Academy of Pediatrics endorses and accepts as its policy the following guidelines from other organizations.

AUTISM SPECTRUM DISORDER

Screening and Diagnosis of Autism

Quality Standards Subcommittee of the American Academy of Neurology and the Child Neurology Society

ABSTRACT. Autism is a common disorder of childhood, affecting 1 in 500 children. Yet, it often remains unrecognized and undiagnosed until or after late preschool age because appropriate tools for routine developmental screening and screening specifically for autism have not been available. Early identification of children with autism and intensive, early intervention during the toddler and preschool years improves outcome for most young children with autism. This practice parameter reviews the available empirical evidence and gives specific recommendations for the identification of children with autism. This approach requires a dual process: (1) routine developmental surveillance and screening specifically for autism to be performed on all children to first identify those at risk for any type of atypical development, and to identify those specifically at risk for autism; and (2) to diagnose and evaluate autism, to differentiate autism from other developmental disorders. (8/00, reaffirmed 10/03, 7/06, 7/10, 8/14)

CARDIOVASCULAR HEALTH

Expert Panel on Integrated Guidelines for Cardiovascular Health and Risk Reduction in Children and Adolescents: Summary Report

National Heart, Lung, and Blood Institute

INTRODUCTION (EXCERPT). Atherosclerotic cardiovascular disease (CVD) remains the leading cause of death in North Americans, but manifest disease in childhood and adolescence is rare. By contrast, risk factors and risk behaviors that accelerate the development of atherosclerosis begin in childhood, and there is increasing evidence that risk reduction delays progression toward clinical disease. In response, the former director of the National Heart, Lung, and Blood Institute (NHLBI), Dr Elizabeth Nabel, initiated development of cardiovascular health guidelines for pediatric care providers based on a formal evidence review of the science with an integrated format addressing all the major cardiovascular risk factors simultaneously. An expert panel was appointed to develop the guidelines in the fall of 2006. (10/12)

CEREBRAL PALSY

Diagnostic Assessment of the Child With Cerebral Palsy

Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of the Child Neurology Society

ABSTRACT. ***Objective.*** The Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of the Child Neurology Society develop practice parameters as strategies for patient management based on analysis of evidence. For this parameter the authors reviewed available evidence on the assessment of a child suspected of having cerebral palsy (CP), a nonprogressive disorder of posture or movement due to a lesion of the developing brain.

Methods. Relevant literature was reviewed, abstracted, and classified. Recommendations were based on a four-tiered scheme of evidence classification.

Results. CP is a common problem, occurring in about 2 to 2.5 per 1,000 live births. In order to establish that a brain abnormality exists in children with CP that may, in turn, suggest an etiology and prognosis, neuroimaging is recommended with MRI preferred to CT (Level A). Metabolic and genetic studies should not be routinely obtained in the evaluation of the child with CP (Level B). If the clinical history or findings on neuroimaging do not determine a specific structural abnormality or if there are additional and atypical features in the history or clinical examination, metabolic and genetic testing should be considered (Level C). Detection of a brain malformation in a child with CP warrants consideration of an underlying genetic or metabolic etiology. Because the incidence of cerebral infarction is high in children with hemiplegic CP, diagnostic testing for coagulation disorders should be considered (Level B). However, there is insufficient evidence at present to be precise as to what studies should be ordered. An EEG is not recommended unless there are features suggestive of epilepsy or a specific epileptic syndrome (Level A). Because children with CP may have associated deficits of mental retardation, ophthalmologic and hearing impairments, speech and language disorders, and oral-motor dysfunction, screening for these conditions should be part of the initial assessment (Level A).

Conclusions. Neuroimaging results in children with CP are commonly abnormal and may help determine the etiology. Screening for associated conditions is warranted as part of the initial evaluation. (3/04, reaffirmed 7/07)

CERUMEN IMPACTION

Cerumen Impaction

American Academy of Otolaryngology—Head and Neck Surgery Foundation

ABSTRACT. This update of the 2008 American Academy of Otolaryngology—Head and Neck Surgery Foundation cerumen impaction clinical practice guideline provides evidence-based recommendations on managing cerumen impaction. Cerumen impaction is defined as an accumulation of cerumen that causes symptoms, prevents assessment of the ear, or both. Changes from the prior guideline include

- a consumer added to the development group;
- new evidence (3 guidelines, 5 systematic reviews, and 6 randomized controlled trials);
- enhanced information on patient education and counseling;
- a new algorithm to clarify action statement relationships;
- expanded action statement profiles to explicitly state quality improvement opportunities, confidence in the evidence, intentional vagueness, and differences of opinion;
- an enhanced external review process to include public comment and journal peer review; and
- new key action statements on managing cerumen impaction that focus on primary prevention, contraindicated intervention, and referral and coordination of care. (1/17)

CONGENITAL MUSCULAR DYSTROPHY

Evidence-based Guideline Summary: Evaluation, Diagnosis, and Management of Congenital Muscular Dystrophy. Report of the Guideline Development Subcommittee of the American Academy of Neurology and the Practice Issues Review Panel of the American Association of Neuromuscular & Electrodiagnostic Medicine

American Academy of Neurology and American Association of Neuromuscular & Electrodiagnostic Medicine

ABSTRACT. ***Objective.*** To delineate optimal diagnostic and therapeutic approaches to congenital muscular dystrophy (CMD) through a systematic review and analysis of the currently available literature.

Methods. Relevant, peer-reviewed research articles were identified using a literature search of the MEDLINE, EMBASE, and Scopus databases. Diagnostic and therapeutic data from these articles were extracted and analyzed in accordance with the American Academy of Neurology classification of evidence schemes for diagnostic, prognostic, and therapeutic studies. Recommendations were linked to the strength of the evidence, other related literature, and general principles of care.

Results. The geographic and ethnic backgrounds, clinical features, brain imaging studies, muscle imaging studies, and muscle biopsies of children with suspected CMD help predict subtype-specific diagnoses. Genetic testing can confirm some subtype-specific diagnoses, but not all causative genes for CMD have been described. Seizures and respiratory complications occur in specific subtypes. There is insufficient evidence to determine the efficacy of various treatment interventions to optimize respiratory, orthopedic, and nutritional outcomes, and more data are needed regarding complications.

Recommendations. Multidisciplinary care by experienced teams is important for diagnosing and promoting the health of children with CMD. Accurate assessment of clinical presentations and genetic data will help in identifying the correct subtype-specific diagnosis in many cases. Multiorgan system complications occur frequently; surveillance and prompt interventions are likely to be beneficial for affected children. More research is needed to fill gaps in knowledge regarding this category of muscular dystrophies. (3/15, reaffirmed 7/18)

DEPRESSION

Guidelines for Adolescent Depression in Primary Care (GLAD-PC): Part I. Practice Preparation, Identification, Assessment, and Initial Management

Rachel A. Zuckerbrot, MD; Amy Cheung, MD; Peter S. Jensen, MD; Ruth E.K. Stein, MD; Danielle Laraque, MD; and GLAD-PC Steering Group

ABSTRACT. ***Objectives***. To update clinical practice guidelines to assist primary care (PC) clinicians in the management of adolescent depression. This part of the updated guidelines is used to address practice preparation, identification, assessment, and initial management of adolescent depression in PC settings.

Methods. By using a combination of evidence- and consensus-based methodologies, guidelines were developed by an expert steering committee in 2 phases as informed by (1) current scientific evidence (published and unpublished) and (2) draft revision and iteration among the steering committee, which included experts, clinicians, and youth and families with lived experience.

Results. Guidelines were updated for youth aged 10 to 21 years and correspond to initial phases of adolescent depression management in PC, including the identification of at-risk youth, assessment and diagnosis, and initial management. The strength of each recommendation and its evidence base are summarized. The practice preparation, identification, assessment, and initial management section of the guidelines include recommendations for (1) the preparation of the PC practice for improved care of adolescents with depression; (2) annual universal screening of youth 12 and over at health maintenance visits; (3) the identification of depression in youth who are at high risk; (4) systematic assessment procedures by using reliable depression scales, patient and caregiver interviews, and *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* criteria; (5) patient and family psychoeducation; (6) the establishment of relevant links in the community; and (7) the establishment of a safety plan.

Conclusions. This part of the guidelines is intended to assist PC clinicians in the identification and initial management of adolescents with depression in an era of great clinical need and shortage of mental health specialists, but they cannot replace clinical judgment; these guidelines are not meant to be the sole source of guidance for depression management in adolescents. Additional research that addresses the identification and initial management of youth with depression in PC is needed, including empirical testing of these guidelines. (2/18)

Guidelines for Adolescent Depression in Primary Care (GLAD-PC): Part II. Treatment and Ongoing Management

Amy H. Cheung, MD; Rachel A. Zuckerbrot, MD; Peter S. Jensen, MD; Danielle Laraque, MD; Ruth E.K. Stein, MD; and GLAD-PC Steering Group

ABSTRACT. ***Objectives***. To update clinical practice guidelines to assist primary care (PC) in the screening and assessment of depression. In this second part of the updated guidelines, we address treatment and ongoing management of adolescent depression in the PC setting.

Methods. By using a combination of evidence- and consensus-based methodologies, the guidelines were updated in 2 phases as informed by (1) current scientific evidence (published and unpublished) and (2) revision and iteration among the steering committee, including youth and families with lived experience.

Results. These updated guidelines are targeted for youth aged 10 to 21 years and offer recommendations for the management of adolescent depression in PC, including (1) active monitoring of mildly depressed youth, (2) treatment with evidence-based medication and psychotherapeutic approaches in cases of moderate and/or severe depression, (3) close monitoring of side effects, (4) consultation and comanagement of care with mental health specialists, (5) ongoing tracking of outcomes, and (6) specific steps to be taken in instances of partial or no improvement after an initial treatment has begun. The strength of each recommendation and the grade of its evidence base are summarized.

Conclusions. The Guidelines for Adolescent Depression in Primary Care cannot replace clinical judgment, and they should not be the sole source of guidance for adolescent depression management. Nonetheless, the guidelines may assist PC clinicians in the management of depressed adolescents in an era of great clinical need and a shortage of mental health specialists. Additional research concerning the management of depressed youth in PC is needed, including the usability, feasibility, and sustainability of guidelines, and determination of the extent to which the guidelines actually improve outcomes of depressed youth. (2/18)

DUCHENNE MUSCULAR DYSTROPHY

Practice Guideline Update Summary: Corticosteroid Treatment of Duchenne Muscular Dystrophy

David Gloss, MD, MPH&TM; Richard T. Moxley III, MD; Stephen Ashwal, MD; and Maryam Oskoui, MD, for the American Academy of Neurology Guideline Development Subcommittee

ABSTRACT. ***Objective.*** To update the 2005 American Academy of Neurology (AAN) guideline on corticosteroid treatment of Duchenne muscular dystrophy (DMD).

Methods. We systematically reviewed the literature from January 2004 to July 2014 using the AAN classification scheme for therapeutic articles and predicated recommendations on the strength of the evidence.

Results. Thirty-four studies met inclusion criteria.

Recommendations. In children with DMD, prednisone should be offered for improving strength (Level B) and pulmonary function (Level B). Prednisone may be offered for improving timed motor function (Level C), reducing the need for scoliosis surgery (Level C), and delaying cardiomyopathy onset by 18 years of age (Level C). Deflazacort may be offered for improving strength and timed motor function and delaying age at loss of ambulation by 1.4–2.5 years (Level C). Deflazacort may be offered for improving pulmonary function, reducing the need for scoliosis surgery, delaying cardiomyopathy onset, and increasing survival at 5–15 years of follow-up (Level C for each). Deflazacort and prednisone may be equivalent in improving motor function (Level C). Prednisone may be associated with greater weight gain in the first years of treatment than deflazacort (Level C).

Deflazacort may be associated with a greater risk of cataracts than prednisone (Level C). The preferred dosing regimen of prednisone is 0.75 mg/kg/d (Level B). Over 12 months, prednisone 10 mg/kg/weekend is equally effective (Level B), with no long-term data available. Prednisone 0.75 mg/kg/d is associated with significant risk of weight gain, hirsutism, and cushingoid appearance (Level B). *Neurology*® 2016;86:465–472 (2/16, reaffirmed 1/19)

DYSPLASIA OF THE HIP

Guideline on Detection and Nonoperative Management of Pediatric Developmental Dysplasia of the Hip in Infants up to Six Months of Age: Evidence-based Clinical Practice Guideline
American Academy of Orthopaedic Surgeons

OVERVIEW. This clinical practice guideline is based upon a systematic review of published articles related to the detection and early management of hip instability and dysplasia in typically developing children less than 6 months of age. This guideline provides practice recommendations for the early screening and detection of hip instability and dysplasia and also highlights gaps in the published literature that should stimulate additional research. This guideline is intended towards appropriately trained practitioners involved in the early examination and assessment of typically developing children for hip instability and dysplasia. (9/14)

FOOD ALLERGY

Guidelines for the Diagnosis and Management of Food Allergy in the United States: Report of the NIAID-Sponsored Expert Panel
National Institute of Allergy and Infectious Diseases

ABSTRACT. Food allergy is an important public health problem that affects children and adults and may be increasing in prevalence. Despite the risk of severe allergic reactions and even death, there is no current treatment for food allergy: the disease can only be managed by allergen avoidance or treatment of symptoms. The diagnosis and management of food allergy also may vary from one clinical practice setting to another. Finally, because patients frequently confuse nonallergic food reactions, such as food intolerance, with food allergies, there is an unfounded belief among the public that food allergy prevalence is higher than it truly is. In response to these concerns, the National Institute of Allergy and Infectious Diseases, working with 34 professional organizations, federal agencies, and patient advocacy groups, led the development of clinical guidelines for the diagnosis and management of food allergy. These Guidelines are intended for use by a wide variety of health care professionals, including family practice physicians, clinical specialists, and nurse practitioners. The Guidelines include a consensus definition for food allergy, discuss comorbid conditions often associated with food allergy, and focus on both IgE-mediated and non-IgE-mediated reactions to food. Topics addressed include the epidemiology, natural history, diagnosis, and management of food allergy, as well as the management of severe symptoms and anaphylaxis. These Guidelines provide 43 concise clinical recommendations and additional guidance on points of current controversy in patient management. They also identify gaps in the current scientific knowledge to be addressed through future research. (12/10)

HEMORRHAGE

An Evidence-based Prehospital Guideline for External Hemorrhage Control
American College of Surgeons Committee on Trauma

ABSTRACT. This report describes the development of an evidence-based guideline for external hemorrhage control in the prehospital setting. This project included a systematic review of the literature regarding the use of tourniquets and hemostatic agents for management of life-threatening extremity and junctional hemorrhage. Using the GRADE methodology to define the key clinical questions, an expert panel then reviewed the results of the literature review, established the quality of the evidence and made recommendations for EMS care. A clinical care guideline is proposed for adoption by EMS systems. (3/14)

HIV

Guidelines for the Prevention and Treatment of Opportunistic Infections in HIV-Exposed and HIV-Infected Children
US Department of Health and Human Services

SUMMARY. This report updates the last version of the Guidelines for the Prevention and Treatment of Opportunistic Infections (OIs) in HIV-Exposed and HIV-Infected Children, published in 2009. These guidelines are intended for use by clinicians and other health-care workers providing medical care for HIV-exposed and HIV-infected children in the United States. The guidelines discuss opportunistic pathogens that occur in the United States and ones that might be acquired during international travel, such as malaria. Topic areas covered for each OI include a brief description of the epidemiology, clinical presentation, and diagnosis of the OI in children; prevention of exposure; prevention of first episode of disease; discontinuation of primary prophylaxis after immune reconstitution; treatment of disease; monitoring for adverse effects during treatment, including immune reconstitution inflammatory syndrome (IRIS); management of treatment failure; prevention of disease recurrence; and discontinuation of secondary prophylaxis after immune reconstitution. A separate document providing recommendations for prevention and treatment of OIs among HIV-infected adults and post-pubertal adolescents (*Guidelines for the Prevention and Treatment of Opportunistic Infections in HIV-Infected Adults and Adolescents*) was prepared by a panel of adult HIV and infectious disease specialists (see http://aidsinfo.nih.gov/guidelines).

These guidelines were developed by a panel of specialists in pediatric HIV infection and infectious diseases (the Panel on Opportunistic Infections in HIV-Exposed and HIV-Infected Children) from the U.S. government and academic institutions. For each OI, one or more pediatric specialists with subject-matter expertise reviewed the literature for new information since the last guidelines were published and then proposed revised recommendations for review by the full Panel. After these reviews and discussions, the guidelines underwent further revision, with review and approval by the Panel, and final endorsement by the National Institutes of Health (NIH), Centers for Disease Control and Prevention (CDC), the HIV Medicine Association (HIVMA) of the Infectious Diseases Society of America (IDSA), the Pediatric Infectious Disease Society (PIDS), and the American Academy of Pediatrics (AAP). So that readers can ascertain how best to apply the recommendations in their practice environments, the recommendations are rated by a letter that indicates the strength of the recommendation, a Roman numeral that indicates the quality of the evidence supporting the recommendation, and where applicable, a * notation that signifies a hybrid of higher-quality adult study evidence and consistent but lower-quality pediatric study evidence.

More detailed methodologic considerations are listed in Appendix 1 (Important Guidelines Considerations), including a description of the make-up and organizational structure of the Panel, definition of financial disclosure and management of conflict of interest, funding sources for the guidelines, methods of collecting and synthesizing evidence and formulating recommendations, public commentary, and plans for updating the guidelines. The names and financial disclosures for each of the Panel members are listed in Appendices 2 and 3, respectively.

An important mode of childhood acquisition of OIs and HIV infection is from infected mothers. HIV-infected women may be more likely to have coinfections with opportunistic pathogens (e.g., hepatitis C) and more likely than women who are not HIV-infected to transmit these infections to their infants. In addition, HIV-infected women or HIV-infected family members coinfected with certain opportunistic pathogens may be more likely to transmit these infections horizontally to their children, resulting in increased likelihood of primary acquisition of such infections in young children. Furthermore, transplacental transfer of antibodies that protect infants against serious infections may be lower in HIV-infected women than in women who are HIV-uninfected. Therefore, infections with opportunistic pathogens may affect not just HIV-infected infants but also HIV-exposed, uninfected infants. These guidelines for treating OIs in children, therefore, consider treatment of infections in all children—HIV-infected and HIV-uninfected—born to HIV-infected women.

In addition, HIV infection increasingly is seen in adolescents with perinatal infection who are now surviving into their teens and in youth with behaviorally acquired HIV infection. Guidelines for postpubertal adolescents can be found in the adult OI guidelines, but drug pharmacokinetics (PK) and response to treatment may differ in younger prepubertal or pubertal adolescents. Therefore, these guidelines also apply to treatment of HIV-infected youth who have not yet completed pubertal development.

Major changes in the guidelines from the previous version in 2009 include:

- Greater emphasis on the importance of antiretroviral therapy (ART) for prevention and treatment of OIs, especially those OIs for which no specific therapy exists;
- Increased information about diagnosis and management of IRIS;
- Information about managing ART in children with OIs, including potential drug-drug interactions;
- Updated immunization recommendations for HIV-exposed and HIV-infected children, including pneumococcal, human papillomavirus, meningococcal, and rotavirus vaccines;
- Addition of sections on influenza, giardiasis, and isosporiasis;
- Elimination of sections on aspergillosis, bartonellosis, and HHV-6 and HHV-7 infections; and
- Updated recommendations on discontinuation of OI prophylaxis after immune reconstitution in children.

The most important recommendations are highlighted in boxed major recommendations preceding each section, and a table of dosing recommendations appears at the end of each section. The guidelines conclude with summary tables that display dosing recommendations for all of the conditions, drug toxicities and drug interactions, and 2 figures describing immunization recommendations for children aged 0 to 6 years and 7 to 18 years.

The terminology for describing use of antiretroviral (ARV) drugs for treatment of HIV infection has been standardized to ensure consistency within the sections of these guidelines and with the *Guidelines for the Use of Antiretroviral Agents in Pediatric HIV Infection.* Combination antiretroviral therapy (cART) indicates use of multiple (generally 3 or more) ARV drugs as part of an HIV treatment regimen that is designed to achieve virologic suppression; highly active antiretroviral therapy (HAART), synonymous with cART, is no longer used and has been replaced by cART; the term ART has been used when referring to use of ARV drugs for HIV treatment more generally, including (mostly historical) use of one- or two-agent ARV regimens that do not meet criteria for cART.

Because treatment of OIs is an evolving science, and availability of new agents or clinical data on existing agents may change therapeutic options and preferences, these recommendations will be periodically updated and will be available at http://AIDSinfo.nih.gov. (11/13, updated 11/18)

INFANTILE SPASMS

Evidence-based Guideline Update: Medical Treatment of Infantile Spasms

American Academy of Neurology and Child Neurology Society

ABSTRACT. ***Objective.*** To update the 2004 American Academy of Neurology/Child Neurology Society practice parameter on treatment of infantile spasms in children.

Methods. MEDLINE and EMBASE were searched from 2002 to 2011 and searches of reference lists of retrieved articles were performed. Sixty-eight articles were selected for detailed review; 26 were included in the analysis. Recommendations were based on a 4-tiered classification scheme combining pre-2002 evidence and more recent evidence.

Results. There is insufficient evidence to determine whether other forms of corticosteroids are as effective as adrenocorticotropic hormone (ACTH) for short-term treatment of infantile spasms. However, low-dose ACTH is probably as effective as high-dose ACTH. ACTH is more effective than vigabatrin (VGB) for short-term treatment of children with infantile spasms (excluding those with tuberous sclerosis complex). There is insufficient evidence to show that other agents and combination therapy are effective for short-term treatment of infantile spasms. Short lag time to treatment leads to better long-term developmental outcome. Successful short-term treatment of cryptogenic infantile spasms with ACTH or prednisolone leads to better long-term developmental outcome than treatment with VGB.

Recommendations. Low-dose ACTH should be considered for treatment of infantile spasms. ACTH or VGB may be useful for short-term treatment of infantile spasms, with ACTH considered preferentially over VGB. Hormonal therapy (ACTH or prednisolone) may be considered for use in preference to VGB in infants with cryptogenic infantile spasms, to possibly improve developmental outcome. A shorter lag time to treatment of infantile spasms with either hormonal therapy or VGB possibly improves long-term developmental outcomes. (6/12, reaffirmed 1/18)

INTRAVASCULAR CATHETER-RELATED INFECTIONS

Guidelines for the Prevention of Intravascular Catheter-Related Infections

Society of Critical Care Medicine, Infectious Diseases Society of America, Society for Healthcare Epidemiology of America, Surgical Infection Society, American College of Chest Physicians, American Thoracic Society, American Society of Critical Care Anesthesiologists, Association for Professionals in Infection Control and Epidemiology, Infusion Nurses Society, Oncology Nursing Society, Society of Cardiovascular and Interventional Radiology, American Academy of Pediatrics, and the Healthcare Infection Control Practices Advisory Committee of the Centers for Disease Control and Prevention

ABSTRACT. These guidelines have been developed for practitioners who insert catheters and for persons responsible for surveillance and control of infections in hospital, outpatient, and home health-care settings. This report was prepared by a working group comprising members from professional organizations representing the disciplines of critical care medicine, infectious diseases, health-care infection control, surgery, anesthesiology, interventional radiology, pulmonary medicine, pediatric medicine, and nursing. The working group was led by the Society of Critical Care Medicine (SCCM), in collaboration

with the Infectious Disease Society of America (IDSA), Society for Healthcare Epidemiology of America (SHEA), Surgical Infection Society (SIS), American College of Chest Physicians (ACCP), American Thoracic Society (ATS), American Society of Critical Care Anesthesiologists (ASCCA), Association for Professionals in Infection Control and Epidemiology (APIC), Infusion Nurses Society (INS), Oncology Nursing Society (ONS), Society of Cardiovascular and Interventional Radiology (SCVIR), American Academy of Pediatrics (AAP), and the Healthcare Infection Control Practices Advisory Committee (HICPAC) of the Centers for Disease Control and Prevention (CDC) and is intended to replace the *Guideline for Prevention of Intravascular Device-Related Infections* published in 1996. These guidelines are intended to provide evidence-based recommendations for preventing catheter-related infections. Major areas of emphasis include (1) educating and training health-care providers who insert and maintain catheters; (2) using maximal sterile barrier precautions during central venous catheter insertion; (3) using a 2% chlorhexidine preparation for skin antisepsis; (4) avoiding routine replacement of central venous catheters as a strategy to prevent infection; and (5) using antiseptic/antibiotic impregnated short-term central venous catheters if the rate of infection is high despite adherence to other strategies (ie, education and training, maximal sterile barrier precautions, and 2% chlorhexidine for skin antisepsis). These guidelines also identify performance indicators that can be used locally by health-care institutions or organizations to monitor their success in implementing these evidence-based recommendations. (11/02)

MEDULLARY THYROID CARCINOMA

Revised American Thyroid Association Guidelines for the Management of Medullary Thyroid Carcinoma

American Thyroid Association Guidelines Task Force on Medullary Thyroid Carcinoma

ABSTRACT. ***Introduction.*** The American Thyroid Association appointed a Task Force of experts to revise the original Medullary Thyroid Carcinoma: Management Guidelines of the American Thyroid Association.

Methods. The Task Force identified relevant articles using a systematic PubMed search, supplemented with additional published materials, and then created evidence-based recommendations, which were set in categories using criteria adapted from the United States Preventive Services Task Force Agency for Healthcare Research and Quality. The original guidelines provided abundant source material and an excellent organizational structure that served as the basis for the current revised document.

Results. The revised guidelines are focused primarily on the diagnosis and treatment of patients with sporadic medullary thyroid carcinoma (MTC) and hereditary MTC.

Conclusions. The Task Force developed 67 evidence-based recommendations to assist clinicians in the care of patients with MTC. The Task Force considers the recommendations to represent current, rational, and optimal medical practice. (6/15)

MIGRAINE HEADACHE

Practice Guideline Update: Acute Treatment of Migraine in Children and Adolescents. Report of the Guideline Development, Dissemination, and Implementation Subcommittee of the American Academy of Neurology and the American Headache Society

Maryam Oskoui, MD, MSc; Tamara Pringsheim, MD; Yolanda Holler-Managan, MD; Sonja Potrebic, MD, PhD; Lori Billinghurst, MD, MSc; David Gloss, MD; Andrew D. Hershey, MD, PhD; Nicole Licking, DO; Michael Sowell, MD; M. Cristina Victorio, MD; Elaine M. Gersz; Emily Leininger; Heather Zanitsch; Marcy Yonker, MD; and Kenneth Mack, MD, PhD

ABSTRACT. ***Objective.*** To provide evidence-based recommendations for the acute symptomatic treatment of children and adolescents with migraine.

Methods. We performed a systematic review of the literature and rated risk of bias of included studies according to the American Academy of Neurology classification of evidence criteria. A multidisciplinary panel developed practice recommendations, integrating findings from the systematic review and following an Institute of Medicine–compliant process to ensure transparency and patient engagement. Recommendations were supported by structured rationales, integrating evidence from the systematic review, related evidence, principles of care, and inferences from evidence.

Results. There is evidence to support the efficacy of the use of ibuprofen, acetaminophen (in children and adolescents), and triptans (mainly in adolescents) for the relief of migraine pain, although confidence in the evidence varies between agents. There is high confidence in the evidence that adolescents receiving oral sumatriptan/naproxen and zolmitriptan nasal spray are more likely to be headache-free at 2 hours than those receiving placebo. No acute treatments were effective for migraine-related nausea or vomiting; some triptans were effective for migraine-related phonophobia and photophobia.

Recommendations. Recommendations for the treatment of acute migraine in children and adolescents focus on the importance of early treatment, choosing the route of administration best suited to the characteristics of the individual migraine attack, and providing counseling on lifestyle factors that can exacerbate migraine, including trigger avoidance and medication overuse. (8/19)

Practice Guideline Update: Pharmacologic Treatment for Pediatric Migraine Prevention. Report of the Guideline Development, Dissemination, and Implementation Subcommittee of the American Academy of Neurology and the American Headache Society

Maryam Oskoui, MD, MSc; Tamara Pringsheim, MD; Lori Billinghurst, MD; Sonja Potrebic, MD, PhD; Elaine M. Gersz; David Gloss, MD, MPH&TM; Yolanda Holler-Managan, MD; Emily Leininger; Nicole Licking, DO; Kenneth Mack, MD, PhD; Scott W. Powers, PhD, ABPP; Michael Sowell, MD; M. Cristina Victorio, MD; Marcy Yonker; Heather Zanitsch; and Andrew D. Hershey, MD, PhD

ABSTRACT. ***Objective.*** To provide updated evidence-based recommendations for migraine prevention using pharmacologic treatment with or without cognitive behavioral therapy in the pediatric population.

Methods. The authors systematically reviewed literature from January 2003 to August 2017 and developed practice recommendations using the American Academy of Neurology 2011 process, as amended.

Results. Fifteen Class I–III studies on migraine prevention in children and adolescents met inclusion criteria. There is insufficient evidence to determine if children and adolescents receiving divalproex, onabotulinumtoxinA, amitriptyline, nimodipine, or flunarizine are more or less likely than those receiving placebo to have a reduction in headache frequency. Children with migraine receiving propranolol are possibly more likely than those receiving placebo to have an at least 50% reduction in headache frequency. Children and adolescents receiving topiramate and cinnarizine are probably more likely than those receiving placebo to have a decrease in headache frequency. Children with migraine receiving amitriptyline plus cognitive behavioral therapy are more likely than those receiving amitriptyline plus headache education to have a reduction in headache frequency.

Recommendations. The majority of randomized controlled trials studying the efficacy of preventive medications for pediatric migraine fail to demonstrate superiority to placebo. Recommendations for the prevention of migraine in children include counseling on lifestyle and behavioral factors that influence headache frequency and assessment and management of comorbid disorders associated with headache persistence. Clinicians should engage in shared decision-making with patients and caregivers regarding the use of preventive treatments for migraine, including discussion of the limitations in the evidence to support pharmacologic treatments. (8/19)

NOSEBLEED (EPISTAXIS)

Clinical Practice Guideline: Nosebleed (Epistaxis)

David E. Tunkel, MD; Samantha Anne, MD, MS; Spencer C. Payne, MD; Stacey L. Ishman, MD, MPH; Richard M. Rosenfeld, MD, MPH, MBA; Peter J. Abramson, MD; Jacqueline D. Alikhaani; Margo McKenna Benoit, MD; Rachel S. Bercovitz, MD, MS; Michael D. Brown, MD, MSc; Boris Chernobilsky, MD; David A. Feldstein, MD; Jesse M. Hackell, MD; Eric H. Holbrook, MD; Sarah M. Holdsworth, MSN, APRN; Kenneth W. Lin, MD, MPH; Meredith Merz Lind, MD; David M. Poetker, MD, MA; Charles A. Riley, MD; John S. Schneider, MD, MA; Michael D. Seidman, MD; Venu Vadlamudi, MD; Tulio A. Valdez, MD; Lorraine C. Nnacheta, MPH, DrPH; Taskin M. Monjur

ABSTRACT. **Objective.** Nosebleed, also known as epistaxis, is a common problem that occurs at some point in at least 60% of people in the United States. While the majority of nosebleeds are limited in severity and duration, about 6% of people who experience nosebleeds will seek medical attention. For the purposes of this guideline, we define the target patient with a nosebleed as a patient with bleeding from the nostril, nasal cavity, or nasopharynx that is sufficient to warrant medical advice or care. This includes bleeding that is severe, persistent, and/or recurrent, as well as bleeding that impacts a patient's quality of life. Interventions for nosebleeds range from self-treatment and home remedies to more intensive procedural interventions in medical offices, emergency departments, hospitals, and operating rooms. Epistaxis has been estimated to account for 0.5% of all emergency department visits and up to one-third of all otolaryngology-related emergency department encounters. Inpatient hospitalization for aggressive treatment of severe nosebleeds has been reported in 0.2% of patients with nosebleeds.

Purpose. The primary purpose of this multidisciplinary guideline is to identify quality improvement opportunities in the management of nosebleeds and to create clear and actionable recommendations to implement these opportunities in clinical practice. Specific goals of this guideline are to promote best practices, reduce unjustified variations in care of patients with nosebleeds, improve health outcomes, and minimize the potential harms of nosebleeds or interventions to treat nosebleeds.

The target patient for the guideline is any individual aged ≥3 years with a nosebleed or history of nosebleed who needs medical treatment or seeks medical advice. The target audience of this guideline is clinicians who evaluate and treat patients with nosebleed. This includes primary care providers such as family medicine physicians, internists, pediatricians, physician assistants, and nurse practitioners. It also includes specialists such as emergency medicine providers, otolaryngologists, interventional radiologists/neuroradiologists and neurointerventionalists, hematologists, and cardiologists. The setting for this guideline includes any site of evaluation and treatment for a patient with nosebleed, including ambulatory medical sites, the emergency department, the inpatient hospital, and even remote outpatient encounters with phone calls and telemedicine. Outcomes to be considered for patients with nosebleed include control of acute bleeding, prevention of recurrent episodes of nasal bleeding, complications of treatment modalities, and accuracy of diagnostic measures.

This guideline addresses the diagnosis, treatment, and prevention of nosebleed. It focuses on nosebleeds that commonly present to clinicians via phone calls, office visits, and emergency room encounters. This guideline discusses first-line treatments such as nasal compression, application of vasoconstrictors, nasal packing, and nasal cautery. It also addresses more complex epistaxis management, which includes the use of endoscopic arterial ligation and interventional radiology procedures. Management options for 2 special groups of patients—patients with hereditary hemorrhagic telangiectasia syndrome and patients taking medications that inhibit coagulation and/or platelet function—are included in this guideline.

This guideline is intended to focus on evidence-based quality improvement opportunities judged most important by the guideline development group. It is not intended to be a comprehensive, general guide for managing patients with nosebleed. In this context, the purpose is to define useful actions for clinicians, generalists, and specialists from a variety of disciplines to improve quality of care. Conversely, the statements in this guideline are not intended to limit or restrict care provided by clinicians based on their experience and assessment of individual patients. (1/20)

PALLIATIVE CARE

Clinical Practice Guidelines for Quality Palliative Care, 4th Edition
National Consensus Project for Quality Palliative Care (2018)

POSITIONAL PLAGIOCEPHALY

Systematic Review and Evidence-based Guidelines for the Management of Patients With Positional Plagiocephaly
Congress of Neurologic Surgeons

ABSTRACT. *Background.* Positional plagiocephaly is a common problem seen by pediatricians, pediatric neurologists, and pediatric neurosurgeons. Currently, there are no evidence-based guidelines on the management of positional plagiocephaly. The topics addressed in subsequent chapters of this guideline include: diagnosis, repositioning, physical therapy, and orthotic devices.

Objective. To evaluate topics relevant to the diagnosis and management of patients with positional plagiocephaly. The rigorous systematic process in which this guideline was created is presented in this chapter.

Methods. This guideline was prepared by the Plagiocephaly Guideline Task Force, a multidisciplinary team comprised of physician volunteers (clinical experts), medical librarians, and clinical guidelines specialists. The task force conducted a series of systematic literature searches of the National Library of Medicine and the Cochrane Library, according to standard protocols described below, for each topic addressed in subsequent chapters of this guideline.

Results. The systematic literature searches returned 396 abstracts relative to the 4 main topics addressed in this guideline. The results were analyzed and are described in detail in each subsequent chapter included in this guideline.

Conclusion. Evidence-based guidelines for the management of infants with positional plagiocephaly will help practitioners manage this common disorder. (11/16)

RHINOPLASTY

Improving Nasal Form and Function after Rhinoplasty
American Academy of Otolaryngology—Head and Neck Surgery Foundation

ABSTRACT. Rhinoplasty, a surgical procedure that alters the shape or appearance of the nose while preserving or enhancing

the nasal airway, ranks among the most commonly performed cosmetic procedures in the United States, with >200,000 procedures reported in 2014. While it is difficult to calculate the exact economic burden incurred by rhinoplasty patients following surgery with or without complications, the average rhinoplasty procedure typically exceeds $4000. The costs incurred due to complications, infections, or revision surgery may include the cost of long-term antibiotics, hospitalization, or lost revenue from hours/days of missed work.

The resultant psychological impact of rhinoplasty can also be significant. Furthermore, the health care burden from psychological pressures of nasal deformities/aesthetic shortcomings, surgical infections, surgical pain, side effects from antibiotics, and nasal packing materials must also be considered for these patients. Prior to this guideline, limited literature existed on standard care considerations for pre- and postsurgical management and for standard surgical practice to ensure optimal outcomes for patients undergoing rhinoplasty. The impetus for this guideline is to utilize current evidence-based medicine practices and data to build unanimity regarding the peri- and postoperative strategies to maximize patient safety and to optimize surgical results for patients. (2/17)

SEIZURE

Treatment of the Child With a First Unprovoked Seizure

Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of the Child Neurology Society

ABSTRACT. The Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of the Child Neurology Society develop practice parameters as strategies for patient management based on analysis of evidence regarding risks and benefits. This parameter reviews published literature relevant to the decision to begin treatment after a child or adolescent experiences a first unprovoked seizure and presents evidence-based practice recommendations. Reasons why treatment may be considered are discussed. Evidence is reviewed concerning risk of recurrence as well as effect of treatment on prevention of recurrence and development of chronic epilepsy. Studies of side effects of anticonvulsants commonly used to treat seizures in children are also reviewed. Relevant articles are classified according to the Quality Standards Subcommittee classification scheme. Treatment after a first unprovoked seizure appears to decrease the risk of a second seizure, but there are few data from studies involving only children. There appears to be no benefit of treatment with regard to the prognosis for long-term seizure remission. Antiepileptic drugs (AED) carry risks of side effects that are particularly important in children. The decision as to whether or not to treat children and adolescents who have experienced a first unprovoked seizure must be based on a risk–benefit assessment that weighs the risk of having another seizure against the risk of chronic AED therapy. The decision should be individualized and take into account both medical issues and patient and family preference. (1/03, reaffirmed 7/06, 7/10, 7/13, 1/16, 10/18)

SEPTIC SHOCK AND SEPSIS-ASSOCIATED ORGAN DYSFUNCTION

Surviving Sepsis Campaign International Guidelines for the Management of Septic Shock and Sepsis-Associated Organ Dysfunction in Children

Scott L. Weiss, MD, MSCE, FCCM (Co-Vice Chair); Mark J. Peters, MD, PhD (Co-Vice Chair); Waleed Alhazzani, MD, MSc, FRCPC (Methodology Chair); Michael S. D. Agus, MD, FCCM, FAAP; Heidi R. ABSTRACT. ***Objectives.*** To develop evidence-based recommendations for clinicians caring for children (including infants, school-aged children, and adolescents) with septic shock and other sepsis-associated organ dysfunction.

Design. A panel of 49 international experts, representing 12 international organizations, as well as three methodologists and three public members was convened. Panel members assembled at key international meetings (for those panel members attending the conference), and a stand-alone meeting was held for all panel members in November 2018. A formal conflict-of-interest policy was developed at the onset of the process and enforced throughout. Teleconferences and electronic-based discussion among the chairs, co-chairs, methodologists, and group heads, as well as within subgroups, served as an integral part of the guideline development process.

Methods. The panel consisted of six subgroups: recognition and management of infection, hemodynamics and resuscitation, ventilation, endocrine and metabolic therapies, adjunctive therapies, and research priorities. We conducted a systematic review for each Population, Intervention, Control, and Outcomes question to identify the best available evidence, statistically summarized the evidence, and then assessed the quality of evidence using the Grading of Recommendations Assessment, Development, and Evaluation approach. We used the evidence-to-decision framework to formulate recommendations as strong or weak, or as a best practice statement. In addition, "in our practice" statements were included when evidence was inconclusive to issue a recommendation, but the panel felt that some guidance based on practice patterns may be appropriate.

Results. The panel provided 77 statements on the management and resuscitation of children with septic shock and other sepsis-associated organ dysfunction. Overall, six were strong recommendations, 52 were weak recommendations, and nine were best-practice statements. For 13 questions, no recommendations could be made; but, for 10 of these, "in our practice" statements were provided. In addition, 49 research priorities were identified.

Conclusions. A large cohort of international experts was able to achieve consensus regarding many recommendations for the best care of children with sepsis, acknowledging that most aspects of care had relatively low quality of evidence resulting in the frequent issuance of weak recommendations. Despite this challenge, these recommendations regarding the management of children with septic shock and other sepsis-associated organ dysfunction provide a foundation for consistent care to improve outcomes and inform future research. (2/20)

STATUS EPILEPTICUS

Diagnostic Assessment of the Child With Status Epilepticus (An Evidence-based Review)

Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of the Child Neurology Society

ABSTRACT. ***Objective.*** To review evidence on the assessment of the child with status epilepticus (SE).

Methods. Relevant literature were reviewed, abstracted, and classified. When data were missing, a minimum diagnostic yield was calculated. Recommendations were based on a four-tiered scheme of evidence classification.

Results. Laboratory studies (Na^{++} or other electrolytes, Ca^{++}, glucose) were abnormal in approximately 6% and are generally ordered as routine practice. When blood or spinal fluid cultures were done on these children, blood cultures were abnormal in at least 2.5% and a CNS infection was found in at least 12.8%. When antiepileptic drug (AED) levels were ordered in known epileptic children already taking AEDs, the levels were low in 32%. A total of 3.6% of children had evidence of ingestion. When studies for inborn errors of metabolism were done, an abnormality was found in 4.2%. Epileptiform abnormalities occurred in 43% of EEGs of children with SE and helped determine the nature and location of precipitating electroconvulsive events (8% generalized, 16% focal, and 19% both). Abnormalities on neuroimaging studies that may explain the etiology of SE were found in at least 8% of children.

Recommendations. Although common clinical practice is that blood cultures and lumbar puncture are obtained if there is a clinical suspicion of a systemic or CNS infection, there are insufficient data to support or refute recommendations as to whether blood cultures or lumbar puncture should be done on a routine basis in children in whom there is no clinical suspicion of a systemic or CNS infection (Level U). AED levels should be considered when a child with treated epilepsy develops SE (Level B). Toxicology studies and metabolic studies for inborn errors of metabolism may be considered in children with SE when there are clinical indicators for concern or when the initial evaluation reveals no etiology (Level C). An EEG may be considered in a child with SE as it may be helpful in determining whether there are focal or generalized epileptiform abnormalities that may guide further testing for the etiology of SE, when there is a suspicion of pseudostatus epilepticus (nonepileptic SE), or nonconvulsive SE, and may guide treatment (Level C). Neuroimaging may be considered after the child with SE has been stabilized if there are clinical indications or if the etiology is unknown (Level C). There is insufficient evidence to support or refute routine neuroimaging in a child presenting with SE (Level U). (11/06, Reaffirmed 7/10, 7/13, 7/16, 1/19)

TELEHEALTH

Operating Procedures for Pediatric Telehealth

American Telemedicine Association

INTRODUCTION. Children represent one of our most vulnerable populations, and, as such, require special considerations when participating in telehealth encounters. Some services provided to adult patients by telehealth may not be easily adapted to or appropriate for pediatric patients due to physical factors (patient size), legal factors (consent, confidentiality), the ability to communicate and provide a history, developmental stage, unique pediatric conditions, and age-specific differences in both normal and disease states (AHRQ, n.d.; Alverson, 2008). These operating procedures for pediatric telehealth aim to improve the overall telehealth experience for pediatric patients, providers, and patient families. Telehealth holds particular promise in facilitating the management and coordination of care for medically complex children and those with chronic conditions, such as asthma, chronic lung disease, autism, diabetes, and behavioral health conditions.

Through the use of telehealth, providers can provide appointment flexibility, increase access, promote continuity of care, and improve quality, either as a part of or as a complement to care delivered through the patient-centered medical home (PCMH). Whether telehealth services are delivered through the PCMH or as a complement to it, telehealth providers **should** routinely communicate with a patient's primary care provider and any relevant specialists regarding a telehealth encounter. Telehealth providers **shall** have a standard mechanism in place to share secure documentation of the encounter with the PCMH (AAP, 2015) in a timely manner.

These operating procedures do reference general telehealth operating principles that apply beyond pediatrics and that warrant particular emphasis, but they are not meant to serve as a comprehensive stand-alone guide to the development and operation of a telemedicine service. ATA has developed and published core standards for telehealth operations that provide overarching guidance for clinical, technical and administrative standards (ATA, 2014a). The Pediatric Operating Procedures complement existing professional organization guidance from the American Academy of Pediatrics, the American Psychological Association, the American Association of Family Physicians and the Society of Adolescent Health and Medicine. THYROID NODULES AND DIFFERENTIATED THYROID CANCER

Management Guidelines for Children With Thyroid Nodules and Differentiated Thyroid Cancer

American Thyroid Association Guidelines Task Force on Pediatric Thyroid Cancer

ABSTRACT. ***Background.*** Previous guidelines for the management of thyroid nodules and cancers were geared toward adults. Compared with thyroid neoplasms in adults, however, those in the pediatric population exhibit differences in pathophysiology, clinical presentation, and long-term outcomes. Furthermore, therapy that may be recommended for an adult may not be appropriate for a child who is at low risk for death but at higher risk for long-term harm from overly aggressive treatment. For these reasons, unique guidelines for children and adolescents with thyroid tumors are needed.

Methods. A task force commissioned by the American Thyroid Association (ATA) developed a series of clinically relevant questions pertaining to the management of children with thyroid nodules and differentiated thyroid cancer (DTC). Using an extensive literature search, primarily focused on studies that included subjects ≤18 years of age, the task force identified and reviewed relevant articles through April 2014. Recommendations were made based upon scientific evidence and expert opinion and were graded using a modified schema from the United States Preventive Services Task Force.

Results. These inaugural guidelines provide recommendations for the evaluation and management of thyroid nodules in children and adolescents, including the role and interpretation of

ultrasound, fine-needle aspiration cytology, and the management of benign nodules. Recommendations for the evaluation, treatment, and follow-up of children and adolescents with DTC are outlined and include preoperative staging, surgical management, postoperative staging, the role of radioactive iodine therapy, and goals for thyrotropin suppression. Management algorithms are proposed and separate recommendations for papillary and follicular thyroid cancers are provided.

Conclusions. In response to our charge as an independent task force appointed by the ATA, we developed recommendations based on scientific evidence and expert opinion for the management of thyroid nodules and DTC in children and adolescents. In our opinion, these represent the current optimal care for children and adolescents with these conditions. (7/15)

TOBACCO USE

Treating Tobacco Use and Dependence: 2008 Update
US Department of Health and Human Services

ABSTRACT. *Treating Tobacco Use and Dependence: 2008 Update,* a Public Health Service-sponsored Clinical Practice Guideline, is a product of the Tobacco Use and Dependence Guideline Panel ("the Panel"), consortium representatives, consultants, and staff. These 37 individuals were charged with the responsibility of identifying effective, experimentally validated tobacco dependence treatments and practices. The updated Guideline was sponsored by a consortium of eight Federal Government and nonprofit organizations: the Agency for Healthcare Research and Quality (AHRQ); Centers for Disease Control and Prevention (CDC); National Cancer Institute (NCI); National Heart, Lung, and Blood Institute (NHLBI); National Institute on Drug Abuse (NIDA); American Legacy Foundation; Robert Wood Johnson Foundation (RWJF); and University of Wisconsin School of Medicine and Public Health's Center for Tobacco Research and Intervention (UW-CTRI). This Guideline is an updated version of the 2000 *Treating Tobacco Use and Dependence: Clinical Practice Guideline* that was sponsored by the U.S. Public Health Service, U. S. Department of Health and Human Services.

An impetus for this Guideline update was the expanding literature on tobacco dependence and its treatment. The original 1996 Guideline was based on some 3,000 articles on tobacco treatment published between 1975 and 1994. The 2000 Guideline entailed the collection and screening of an additional 3,000 articles published between 1995 and 1999. The 2008 Guideline update screened an additional 2,700 articles; thus, the present Guideline update reflects the distillation of a literature base of more than 8,700 research articles. Of course, this body of research was further reviewed to identify a much smaller group of articles that served as the basis for focused Guideline data analyses and review.

This Guideline contains strategies and recommendations designed to assist clinicians; tobacco dependence treatment specialists; and health care administrators, insurers, and purchasers in delivering and supporting effective treatments for tobacco use and dependence. The recommendations were made as a result of a systematic review and meta-analysis of 11 specific topics identified by the Panel (proactive quitlines; combining counseling and medication relative to either counseling or medication alone; varenicline; various medication combinations; long-term medications; cessation interventions for individuals with low socioeconomic status/limited formal education; cessation interventions for adolescent smokers; cessation interventions for pregnant smokers; cessation interventions for individuals with psychiatric disorders, including substance use disorders; providing cessation interventions as a health benefit; and systems interventions, including provider training and the combination of training and systems interventions). The strength of evidence that served as the basis for each recommendation is indicated clearly in the Guideline update. A draft of the Guideline update was peer reviewed prior to publication, and the input of 81 external reviewers was considered by the Panel prior to preparing the final document. In addition, the public had an opportunity to comment through a *Federal Register* review process. The key recommendations of the updated Guideline, *Treating Tobacco Use and Dependence: 2008 Update,* based on the literature review and expert Panel opinion, are as follows:

Ten Key Guideline Recommendations

The overarching goal of these recommendations is that clinicians strongly recommend the use of effective tobacco dependence counseling and medication treatments to their patients who use tobacco, and that health systems, insurers, and purchasers assist clinicians in making such effective treatments available.

1. Tobacco dependence is a chronic disease that often requires repeated intervention and multiple attempts to quit. Effective treatments exist, however, that can significantly increase rates of long-term abstinence.
2. It is essential that clinicians and health care delivery systems consistently identify and document tobacco use status and treat every tobacco user seen in a health care setting.
3. Tobacco dependence treatments are effective across a broad range of populations. Clinicians should encourage every patient willing to make a quit attempt to use the counseling treatments and medications recommended in this Guideline.
4. Brief tobacco dependence treatment is effective. Clinicians should offer every patient who uses tobacco at least the brief treatments shown to be effective in this Guideline.
5. Individual, group, and telephone counseling are effective, and their effectiveness increases with treatment intensity. Two components of counseling are especially effective, and clinicians should use these when counseling patients making a quit attempt:
   - Practical counseling (problem solving/skills training)
   - Social support delivered as part of treatment
6. Numerous effective medications are available for tobacco dependence, and clinicians should encourage their use by all patients attempting to quit smoking—except when medically contraindicated or with specific populations for which there is insufficient evidence of effectiveness (i.e., pregnant women, smokeless tobacco users, light smokers, and adolescents).
   - Seven first-line medications (5 nicotine and 2 non-nicotine) reliably increase long-term smoking abstinence rates:
     - Bupropion SR
     - Nicotine gum
     - Nicotine inhaler
     - Nicotine lozenge
     - Nicotine nasal spray
     - Nicotine patch
     - Varenicline
     - Clinicians also should consider the use of certain combinations of medications identified as effective in this Guideline.
7. Counseling and medication are effective when used by themselves for treating tobacco dependence. The combination of counseling and medication, however, is more effective than either alone. Thus, clinicians should encourage all individuals making a quit attempt to use both counseling and medication.

8. Telephone quitline counseling is effective with diverse populations and has broad reach. Therefore, both clinicians and health care delivery systems should ensure patient access to quitlines and promote quitline use.
9. If a tobacco user currently is unwilling to make a quit attempt, clinicians should use the motivational treatments shown in this Guideline to be effective in increasing future quit attempts.
10. Tobacco dependence treatments are both clinically effective and highly cost-effective relative to interventions for other clinical disorders. Providing coverage for these treatments increases quit rates. Insurers and purchasers should ensure that all insurance plans include the counseling and medication identified as effective in this Guideline as covered benefits.

The updated Guideline is divided into seven chapters that provide an overview, including methods (Chapter 1); information on the assessment of tobacco use (Chapter 2); clinical interventions, both for patients willing and unwilling to make a quit attempt at this time (Chapter 3); intensive interventions (Chapter 4); systems interventions for health care administrators, insurers, and purchasers (Chapter 5); the scientific evidence supporting the Guideline recommendations (Chapter 6); and information relevant to specific populations and other topics (Chapter 7).

A comparison of the findings of the updated Guideline with the 2000 Guideline reveals the considerable progress made in tobacco research over the brief period separating these two publications. Tobacco dependence increasingly is recognized as a chronic disease, one that typically requires ongoing assessment and repeated intervention. In addition, the updated Guideline offers the clinician many more effective treatment strategies than were identified in the original Guideline. There now are seven different first-line effective agents in the smoking cessation pharmacopoeia, allowing the clinician and patient many different medication options. In addition, recent evidence provides even stronger support for counseling (both when used alone and with other treatments) as an effective tobacco cessation strategy; counseling adds to the effectiveness of tobacco cessation medications, quitline counseling is an effective intervention with a broad reach, and counseling increases tobacco cessation among adolescent smokers.

Finally, there is increasing evidence that the success of any tobacco dependence treatment strategy cannot be divorced from the health care system in which it is embedded. The updated Guideline contains new evidence that health care policies significantly affect the likelihood that smokers will receive effective tobacco dependence treatment and successfully stop tobacco use. For instance, making tobacco dependence treatment a covered benefit of insurance plans increases the likelihood that a tobacco user will receive treatment and quit successfully. Data strongly indicate that effective tobacco interventions require coordinated interventions. Just as the clinician must intervene with his or her patient, so must the health care administrator, insurer, and purchaser foster and support tobacco intervention as an integral element of health care delivery. Health care administrators and insurers should ensure that clinicians have the training and support to deliver consistent, effective intervention to tobacco users. One important conclusion of this Guideline update is that the most effective way to move clinicians to intervene is to provide them with information regarding multiple effective treatment options and to ensure that they have ample institutional support to use these options. Joint actions by clinicians, administrators, insurers, and purchasers can encourage a culture of health care in which failure to intervene with a tobacco user is inconsistent with standards of care. TURNER SYNDROME

Clinical Practice Guidelines for the Care of Girls and Women With Turner Syndrome: Proceedings From the 2016 Cincinnati International Turner Syndrome Meeting

Claus H. Gravholt; Niels H. Andersen; Gerard S. Conway; Olaf M. Dekkers; Mitchell E. Geffner; Karen O. Klein; Angela E. Lin; Nelly Mauras; Charmian A. Quigley; Karen Rubin; David E. Sandberg; Theo C. J. Sas; Michael Silberbach; Viveca Söderström-Anttila; Kirstine Stochholm; Janielle A. van Alfen-van derVelden; Joachim Woelfle; and Philippe F. Backeljauw (on behalf of the International Turner Syndrome Consensus Group)

ABSTRACT. Turner syndrome affects 25–50 per 100,000 females and can involve multiple organs through all stages of life, necessitating multidisciplinary approach to care. Previous guidelines have highlighted this, but numerous important advances have been noted recently. These advances cover all specialty fields involved in the care of girls and women with TS. This paper is based on an international effort that started with exploratory meetings in 2014 in both Europe and the USA, and culminated with a Consensus Meeting held in Cincinnati, Ohio, USA in July 2016. Prior to this meeting, five groups each addressed important areas in TS care: 1) diagnostic and genetic issues, 2) growth and development during childhood and adolescence, 3) congenital and acquired cardiovascular disease, 4) transition and adult care, and 5) other comorbidities and neurocognitive issues. These groups produced proposals for the present guidelines. Additionally, four pertinent questions were submitted for formal GRADE (Grading of Recommendations, Assessment, Development and Evaluation) evaluation with a separate systematic review of the literature. These four questions related to the efficacy and most optimal treatment of short stature, infertility, hypertension, and hormonal replacement therapy. The guidelines project was initiated by the European Society of Endocrinology and the Pediatric Endocrine Society, in collaboration with the European Society for Paediatric Endocrinology, the Endocrine Society, the European Society of Human Reproduction and Embryology, the American Heart Association, the Society for Endocrinology, and the European Society of Cardiology. The guideline has been formally endorsed by the European Society of Endocrinology, the Pediatric Endocrine Society, the European Society for Paediatric Endocrinology, the European Society of Human Reproduction and Embryology and the Endocrine Society. Advocacy groups appointed representatives who participated in pre-meeting discussions and in the consensus meeting. (9/17)

Includes policy statements, clinical reports, and technical reports published between January 1, 2020, and December 31, 2020

INTRODUCTION

This section of ***Pediatric Clinical Practice Guidelines & Policies: A Compendium of Evidence-based Research for Pediatric Practice*** is composed of policy statements, clinical reports, and technical reports issued by the American Academy of Pediatrics (AAP) and is designed as a quick reference tool for AAP members, AAP staff, and other interested parties. Section 3 includes the full text of all AAP policies published in 2020. Section 4 is a compilation of all active AAP policies (through December 31, 2020) arranged alphabetically, with abstracts where applicable. A subject index is also available. These materials should help answer questions that arise about the AAP position on child health care issues. **However, remember that AAP policy statements, clinical reports, and technical reports do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.**

Policy statements have been written by AAP committees, councils, task forces, or sections and approved by the AAP Board of Directors. Most of these statements have appeared previously in ***Pediatrics*** or ***AAP News***.

This section does not contain all AAP policies. It does not include

- Press releases.
- Motions and resolutions that were approved by the Board of Directors. These can be found in the Board of Directors' minutes.
- Policies in manuals, pamphlets, booklets, or other AAP publications. These items can be ordered through the AAP. To order, visit http://shop.aap.org/books or call 866/843-2271.
- Testimony before Congress or government agencies.

All policy statements, clinical reports, and technical reports from the American Academy of Pediatrics automatically expire 5 years after publication unless reaffirmed, revised, or retired at or before that time. Please check the American Academy of Pediatrics website at www.aap.org for up-to-date reaffirmations, revisions, and retirements.

2020 Recommendations for Preventive Pediatric Health Care

- *Policy Statement*

POLICY STATEMENT Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

American Academy of Pediatrics

DEDICATED TO THE HEALTH OF ALL CHILDREN™

2020 Recommendations for Preventive Pediatric Health Care

COMMITTEE ON PRACTICE AND AMBULATORY MEDICINE, BRIGHT FUTURES PERIODICITY SCHEDULE WORKGROUP

The 2020 Recommendations for Preventive Pediatric Health Care (Periodicity Schedule) have been approved by the American Academy of Pediatrics (AAP) and represents a consensus of the AAP and the Bright Futures Periodicity Schedule Workgroup. Each child and family is unique; therefore, these recommendations are designed for the care of children who are receiving competent parenting, have no manifestations of any important health problems, and are growing and developing in a satisfactory fashion. Developmental, psychosocial, and chronic disease issues for children and adolescents may require frequent counseling and treatment visits separate from preventive care visits. Additional visits also may become necessary if circumstances suggest variations from the normal.

The AAP continues to emphasize the great importance of continuity of care in comprehensive health supervision and the need to avoid fragmentation of care.[1]

The Periodicity Schedule will not be published in *Pediatrics*. Readers are referred to the AAP website (www.aap.org/periodicityschedule) for the most recent version of the Periodicity Schedule and the full set of footnotes. This process will ensure that health care professionals have the most current recommendations. The Periodicity Schedule will be reviewed and revised annually to reflect current recommendations.

The following is the change made to the Periodicity Schedule since it was last published in March 2019.

MATERNAL DEPRESSION

Footnote 16 has been updated to read, "Screening should occur per 'Incorporating Recognition and Management of Perinatal Depression Into Pediatric Practice' (https://pediatrics.aappublications.org/content/143/1/e20183259)."

Abusive Head Trauma in Infants and Children

Sandeep K. Narang, MD, JD, FAAP,[a] Amanda Fingarson, DO, FAAP,[a] James Lukefahr, MD, FAAP,[b] COUNCIL ON CHILD ABUSE AND NEGLECT

Abusive head trauma (AHT) remains a significant cause of morbidity and mortality in the pediatric population, especially in young infants. In the past decade, advancements in research have refined medical understanding of the epidemiological, clinical, biomechanical, and pathologic factors comprising the diagnosis, thereby enhancing clinical detection of a challenging diagnostic entity. Failure to recognize AHT and respond appropriately at any step in the process, from medical diagnosis to child protection and legal decision-making, can place children at risk. The American Academy of Pediatrics revises the 2009 policy statement on AHT to incorporate the growing body of knowledge on the topic. Although this statement incorporates some of that growing body of knowledge, it is not a comprehensive exposition of the science. This statement aims to provide pediatric practitioners with general guidance on a complex subject. The Academy recommends that pediatric practitioners remain vigilant for the signs and symptoms of AHT, conduct thorough medical evaluations, consult with pediatric medical subspecialists when necessary, and embrace the challenges and need for strong advocacy on the subject.

HISTORY

The evolution of the abusive head trauma (AHT) diagnosis has a long and storied history.[1–3] Earlier nomenclature included whiplash shaken infant syndrome, shaken impact syndrome, inflicted childhood neurotrauma, and shaken baby syndrome. The current term, AHT, was adopted by the American Academy of Pediatrics (AAP) in 2009 in recognition of the fact that inflicted head injury of children can involve a variety of biomechanical forces, including shaking. That change in terminology (from shaken baby syndrome), however, was misinterpreted by some in the legal and medical communities as an indication of some doubt in or invalidation of the diagnosis and the mechanism of shaking as a cause of injury. The AAP continues to affirm the dangers and harms of shaking infants, continues to embrace the "shaken baby syndrome" diagnosis as a valid subset of the AHT diagnosis, and encourages pediatric practitioners to educate

community stakeholders when necessary.

PRESENTATION AND EVALUATION

AHT has an estimated incidence of 32 to 38 cases per 100 000 children per year in the first year of life and is fatal in nearly one-quarter of cases.[4,5] AHT presents with a wide spectrum of signs and symptoms. The clinical manifestations of AHT can be subtle (such as vomiting and fussiness) and are often missed. Sheets et al[6] found that more than one-quarter of children with severe physical abuse had previous sentinel injuries missed by physicians, and over 80% of those sentinel injuries were bruises. Bruising in infants should alert the physician to the possibility of abuse. Particular attention should be given to "TEN-4" bruising (bruising of the torso, ears, and neck in children younger than 4 years or any bruising in an infant younger than 4 months).[7] Oral injuries in infants, such as frenulum tears, may also accompany or precede AHT and should prompt consideration of abuse.[8] Thus, it is crucial for the pediatric practitioner to maintain high vigilance for subtle findings that can indicate AHT and perform a careful evaluation as dictated by the clinical presentation.

AHT is on the differential of common presenting complaints of infants and young children, such as fussiness, vomiting, or altered mental status. Medical diseases that can mimic the findings commonly seen in AHT are increasingly recognized, and screening is performed when indicated. A comprehensive medical evaluation, including a thorough skin examination, skeletal survey, head imaging, and a timely ophthalmology consultation, remains the cornerstone of AHT assessments.[9] As with all medical diagnoses, caregiver histories are important, and careful documentation of the reported history is needed.

Children with suspected intracranial injury should have a cranial computed tomography and/or MRI scan.[9,10] MRI of the spine should also be considered to assess for ligamentous injuries or spinal subdural hemorrhage.[10,11] Cranial ultrasonography is diagnostically insensitive for detecting AHT and should not be considered a sufficient diagnostic neuroimaging modality in cases of suspected AHT.[10] Although many cases of AHT do not demonstrate osseous injury, a complete skeletal survey should be performed in children younger than 2 years with concerns for AHT because occult fractures can occur in up to 42% of cases.[4] It is important that skeletal surveys conform to established guidelines of multiple views of the axial and appendicular skeleton.[10] A skeletal survey should be performed by technicians and read by radiologists who are experienced in these specialized imaging studies; otherwise, findings can be missed or misread, which can place both the pediatric practitioner at medicolegal risk and the patient at risk for further physical harm. Limited imaging, such as "babygrams," diminishes the diagnostic sensitivity of skeletal findings.[10]

Pediatric practitioners often find it helpful to consult a subspecialist in the field of child abuse pediatrics to ensure that the medical evaluation has been complete and that the diagnosis is accurate. Subspecialists in radiology, ophthalmology, neurosurgery, neurology, general pediatric surgery, and other fields should also be consulted when necessary to ensure a complete and accurate evaluation.

DIAGNOSIS AND OUTCOMES

Advancements in technology, research, and clinical experience have improved our current understanding of the etiologies, clinical features, and outcomes of AHT. Several recent systematic reviews have assisted in identifying clinical features more suggestive of abusive than accidental injury.[11–13] Features such as apnea, retinal hemorrhages, and "TEN-4" bruising are much more common in abusive than accidental injury.[7,12] Additionally, advancements in our clinical understanding of retinal hemorrhages have revealed that certain patterns of retinal hemorrhages (specifically too numerous to count in one or both eyes, present in all layers of the retina, and extending into the retinal periphery) are far more common in AHT than in accidental head injury.[13] Finally, traumatic retinoschisis (blood accumulating in the macula beneath the internal limiting membrane or deeper retinal layers, with or without surrounding circumlinear paramacular retinal folds) is highly suggestive of abusive trauma.[14]

Although there is not a particular pattern of cranial injury unique to AHT, certain findings, such as a subdural hemorrhage in certain locations (multiple, along the convexities, or interhemispheric), cerebral ischemia, cerebral edema, and skull fractures (co-occurring with intracranial injury), are more common in AHT than in accidental injury.[11] Additionally, recent studies have revealed spinal subdural hemorrhage to be more common in children with abusive (versus accidental) head trauma.[15]

Short falls (often defined as less than 1.5 m, or 5 ft)[16] continue to be a common historical explanation for injuries often seen in AHT. Although a few isolated case reports have identified the potential mortality of some short-fall events, numerous lines of clinical research have clarified the extreme rarity of short falls as a cause of severe neurologic injury or death in young infants. In a comprehensive review of short-fall literature, the estimated mortality rate of short falls affecting infants and

young children is <0.48 deaths per 1 million young children per year.[16] Because short falls may be proffered in courts as a likely medical explanation for the findings commonly seen in AHT,[17] pediatric practitioners should be prepared to educate multidisciplinary colleagues on the relative improbability of serious injuries or death as a result of short falls.

Clinical prediction tools have been developed to determine the probability of AHT given specific combinations of physical examination and clinical, laboratory, and radiographic findings.[18,19] Additionally, early work using serum biomarkers to identify acute intracranial hemorrhage has shown promise in identifying infants with nonspecific clinical symptoms who warrant neuroimaging.[20] Although these diagnostic advancements show significant promise, their application to current-day pediatric practice is premature.

It is important for pediatric practitioners to recognize the significant morbidity and mortality that accompany AHT. Secondary brain injury from hypoxia, ischemia, and metabolic or inflammatory cascades contribute to poor outcomes.[21,22] Almost 70% of survivors of AHT have some degree of lasting neurologic impairment, including static encephalopathy, intellectual disability, cerebral palsy, cortical blindness, seizure disorders, behavior problems, and learning disabilities.[23,24] Endocrine dysfunction is common in survivors of AHT and may manifest years after injury.[25] Survivors of AHT should be referred at hospital discharge to medical homes where pediatricians can provide ongoing follow-up and prompt referral to pediatric medical subspecialists when indicated.[25]

BIOMECHANICS

The biomechanics of AHT is a complex topic. For obvious ethical reasons, scientific studies of the topic depend on the development and use of biofidelic models, either physical or computer generated. Throughout decades of clinical and laboratory research on infant head trauma, a number of biomechanical models have been used to assess the impact of various force parameters on the infant head and spine. Some early biomechanical models raised concerns about the ability of shaking events alone to generate sufficient forces to induce a variety of infant brain injuries, inferring that impact was a necessary prerequisite to induce infant head injury.[26] However, subsequent studies have highlighted the biofidelic limitations of that earlier work and have validated shaking alone as a mechanism for inducing infant brain injury.[27,28]

Additionally, in clinical studies, researchers continue to emphasize the importance of shaking as an injurious mechanism in many cases of AHT. In a study examining 112 cases of perpetrator admissions to AHT in court, shaking was a commonly reported mechanism of injury, with the shaking being described as violent in 100% of cases and being separate, repetitive incidents in 55% of the cases (with a mean repetitive incidence of 10 times).[29]

Some authors have postulated that evidence of significant cervical spine injury was a necessary finding before infant brain injury could be attributed to exclusive shaking events.[30] Although improvements in radiologic imaging have led to increased detection rates of ligamentous and other cervical spine injury in AHT cases, the biomechanical literature does not support the contention that bony, soft-tissue, or spinal cord injury must always be present in cases of AHT.[30]

All biomechanical models, whether physical or computer generated, have limitations and fall short of a precise representation of the complex pathophysiology of the human infant.[31] Clinicians and researchers acknowledge that although precise mechanisms for all abusive injuries remain incompletely understood, sound evidence-based literature supports the conclusion that both inflicted rotational and contact forces to the head can cause brain injury, intracranial hemorrhage, spinal hemorrhage and/or injury, and retinal hemorrhage.[31] Biomechanical research forms an important adjunct to the growing body of knowledge on pediatric traumatic brain injury. However, pediatric practitioners may need to educate multidisciplinary partners on the benefits and limitations of biomechanical literature in AHT.

PREVENTION

Prevention strategies to curtail the incidence of AHT have been developed and researched, and some states have mandated “shaken baby syndrome” education for parents of all newborn infants. Some hospital-based programs have shown success in some settings. Dias et al[32] demonstrated a decrease in AHT in a region of New York using written and video content about the dangers of shaking in addition to asking parents to voluntarily sign a commitment statement acknowledging and affirming receipt and understanding of the information. Their findings were replicated in another part of New York, but larger implementation across the state of Pennsylvania failed to demonstrate a reduction in AHT.[33,34] The Period of PURPLE Crying is a multifaceted program that aims to educate parents about infant sleeping, crying, and soothing behaviors. It involves an in-hospital postpartum implementation phase in which, in addition to the written and DVD education that parents receive, there is later education from public

health nurses and annual community education. This program revealed a decrease in AHT incidence after implementation in British Columbia, but implementation in the state of North Carolina did not demonstrate a decrease in the incidence of AHT.[35,36]

Although it has been difficult to consistently demonstrate a decrease in AHT rates with educational interventions, some prevention programs have found other worthwhile results, including parental reports of improved understanding of infant crying, parental reports of improved emotional self-regulation, and an increase in parental knowledge of AHT.[37] Similarly, although the Nurse-Family Partnership, an in-home visitation program, has not demonstrated an effect on AHT rates specifically, the program has demonstrated a long-term decrease in child maltreatment and may be a useful approach in addressing AHT.[38] Providing economic support for families may be another prevention approach. Studies evaluating the impact of paid family leave and the earned income tax credit in California have demonstrated a reduction in AHT rates, although further research about generalizability is needed.[39,40] The AAP supports prevention efforts aimed at reducing the frequency of AHT and has called for continued research in this area.

LEGAL IMPACT

Few pediatric diagnoses have engendered as much debate in medicolegal circles as AHT. Because the diagnosis may result in children being removed from their homes and adults being imprisoned for their actions, the existence of a debate is understandable. However, the debate is a philosophical one, not a scientific one.

The debate arises from the legal requirement of physicians to subsequently express in court their degree of certainty of the AHT diagnosis (ie, to a "reasonable medical certainty"). Some authors have clarified that "reasonable medical certainty" is a pro forma legal expression required of physicians to assure courts that the opinions expressed are reasonable and nonspeculative.[41] Pediatric practitioners should understand that legal burdens of proof (ie, beyond a reasonable doubt) are not required for the diagnosis. Diagnosing AHT requires the same meticulousness, thoughtfulness, and comprehensiveness as any other medical diagnosis, no more and no less.

Because civil and criminal justice systems are often involved in cases of AHT, debates related to mechanism and causation of injury often are transferred to the courtroom. On occasion, a pediatric practitioner may be called on to testify in AHT hearings. The court may allow extraneous or pseudoscientific theories to be considered as explanations for findings of AHT, and a pediatrician who is called to testify should be sufficiently versed in these extraneous theories and in the scientific literature girding the AHT diagnosis so that he or she can present responsible, ethical testimony to the court.[17] In preparing for testimony, reviewing the literature with a child abuse pediatrician can be helpful.

The term "shaken baby syndrome" has become synonymous in public discourse with AHT in all its forms.[42] The term is sometimes used inaccurately to describe infants with impact injury alone or with multiple mechanisms of head and brain injury and is focused on a specific mechanism of injury rather than the abusive event that was perpetrated against a helpless victim. Legal challenges to the term "shaken baby syndrome" can distract from the more important questions of accountability of the perpetrator and/or the safety of the victim. The pediatric practitioner should be prepared to "use the term 'abusive head trauma' rather than a term that implies a single injury mechanism, such as shaken baby syndrome, in their diagnosis and medical communications."[43]

THE ROLE OF THE PEDIATRICIAN

The diagnosis of child abuse has enormous social, psychological, and legal implications for families. The role of the pediatric practitioner is not to apportion blame or investigate potential criminal activity but to identify the medical problem, evaluate and treat the child's injuries, and offer honest medical information to parents, families, investigators, and attorneys and/or judges. When child protective services or law enforcement are involved in an investigation, the pediatric practitioner is often called on to interpret and communicate medical information for nonmedical professionals in an understandable manner that accurately reflects the medical data.

Pediatricians are mandated reporters, which means they are required to report suspected abuse and neglect to state child protective services, regardless of whether a definitive diagnosis of maltreatment has been made. As mandated reporters of suspected child abuse and neglect, pediatric practitioners carry the burden of recognizing and responding to medical manifestations of AHT. The diagnosis is sometimes obvious but can be missed by practitioners, particularly when infants present with subtle signs and symptoms.[4] Additionally, pediatric practitioners do not always report injuries that are highly suspicious for abuse to child welfare agencies, putting children at

further risk for injury.[44,45] To protect infants who are abused and prevent future severe neurologic injury, pediatric practitioners must remain vigilant for the possibility of AHT in infants who present with both subtle and overt neurologic symptoms and take seriously the ethical and legal mandates to report suspected child abuse to child protective agencies for investigation.

As with any other diagnosis, pediatric practitioners have a responsibility to formulate a thorough differential diagnosis when presented with a patient with findings suggestive of AHT and to consider the possibility of abuse early in that process, with the understanding that a final medical diagnosis of AHT is made only after consideration of all the available clinical data.

On some occasions, the diagnosis is apparent early in the course of the evaluation because some infants and children have injuries to multiple organ systems that could only be the result of inflicted trauma. On other occasions, the diagnosis is less certain. In these less certain circumstances, the pediatric practitioner should carefully balance, both in verbal expression and written documentation, the need for child protection with ongoing medical evaluations. Pediatric practitioners should be cautious to not overstate the significance of particular medical findings, yet they should still effectively communicate the need for child safety when indicated. Because verbal and written communications with collaborative investigative agencies can be challenging, early consultation with a child abuse pediatrician may be prudent.

Providing a medical home for survivors of AHT is an important role for pediatricians because both short- and long-term complications can occur. Frequent monitoring and prompt referral to subspecialists when needed are key to achieving the best possible outcomes.

Finally, pediatric practitioners can work to prevent AHT by supporting prevention efforts in their clinical practices. Pediatric practitioners may help prevent AHT by carefully assessing for psychosocial risk factors often associated with abuse,[46] by providing anticipatory guidance to new parents about the dangers of shaking and impact, by providing methods for dealing with the frustration of a crying infant, and by providing access to prevention resources and supports. They can also stress the importance of leaving a young infant or toddler in the care of adults whom the parents trust will not harm their child and has been educated on the topic of AHT. Lastly, pediatric practitioners can work to advance evidence-based prevention efforts through research.

RECOMMENDATIONS

The AAP recommends the following:

1. Pediatric practitioners should remain vigilant for the signs, symptoms, and head injury patterns associated with AHT.
2. Pediatric practitioners should perform a thorough and objective medical evaluation of infants and children who present to medical care with signs and symptoms of potential AHT. Consultants in radiology, ophthalmology, neurosurgery, general pediatric surgery, and other subspecialties are important partners in the medical evaluation and can assist in interpreting data and reaching a diagnosis.
3. Pediatric practitioners should consider consulting a subspecialist in the field of child abuse pediatrics to ensure that the medical evaluation of the patient has been complete and that the diagnosis is accurate.
4. Pediatric practitioners should continue to use the term "abusive head trauma" rather than a term that implies a single injury mechanism, such as shaken baby syndrome, in their diagnosis and medical communications.
5. Pediatric practitioners should report cases to child protective services when there is reasonable suspicion or reasonable cause to believe AHT has occurred and be prepared to educate investigative agencies on the medical information that forms the basis of the suspicion.
6. Pediatric practices should provide medical homes for survivors of AHT or refer them to medical homes to help achieve optimal rehabilitation and long-term monitoring for complications.
7. Pediatric practitioners who are called on to interact with legal and child protective agencies should be versed in the science underpinning AHT and be prepared to educate these stakeholders on both supported and unsupported theories of causation commonly proffered in court.
8. Pediatric practitioners should educate parents and caregivers about safe approaches to soothing an infant and coping with crying infants and about the dangers of shaking an infant, striking an infant, or impacting an infant's head against a surface.

Advocacy and Collaborative Health Care for Justice-Involved Youth

Mikah C. Owen, MD, MPH, FAAP,[a] Stephenie B. Wallace, MD, MSPH, FAAP,[b] COMMITTEE ON ADOLESCENCE

Children and adolescents who become involved with the justice system often do so with complex medical, mental health, developmental, social, and legal needs. Most have been exposed to childhood trauma or adversity, which both contribute to their involvement with the justice system and negatively impact their health and well-being. Whether youth are held in confinement or in their home communities, pediatricians play a critical role in promoting the health and well-being of justice-involved youth. Having a working knowledge of the juvenile justice system and common issues facing justice-involved youth may help pediatricians enhance their clinical care and advocacy efforts. This policy statement is a revision of the 2011 policy "Health Care for Youth in the Juvenile Justice System." It provides an overview of the juvenile justice system, describes racial bias and overrepresentation of youth of color in the justice system, reviews the health and mental health status of justice-involved youth, and identifies advocacy opportunities for juvenile justice reform.

INTRODUCTION

In 2017, approximately 809 700 persons under the age of 18 were arrested in the United States,[1] a number that has steadily declined from the peak of nearly 2.7 million in 1996.[2] Decreases in juvenile arrests coincide with concomitant decreases in the number of confined youth. In 2017, approximately 202 900 delinquency cases involved detention,[3] a 50% decrease from the peak of 405 700 in 2005.[3] Whether detained pending the resolution of their legal case or committed to a correctional facility by a judge, most youth quickly return to their home communities. In 2017, the median time in placement was 68 days (23 days for detained youth versus 114 days for committed youth).[4] Thus, pediatricians, whether practicing in juvenile correctional facilities or in communities, may have the opportunity to care for youth involved in the justice system.

Despite improving trends in juvenile arrests and confinement, justice-involved youth continue to experience significant barriers to reaching their full potential. Barriers such as racial and ethnic bias, exposure to

adverse childhood experiences (ACEs), and unmet physical and mental health needs continue to interfere with the optimal health and development of youth involved with the justice system. Ideally, contact with the juvenile justice system would serve as an opportunity to improve the health and developmental trajectory of youth by identifying precipitants to involvement with the justice system and implementing services to address the young person's needs. Unfortunately, for many youth, involvement with the justice system serves as nothing more than another traumatic experience. Pediatricians, as trusted child advocates, are uniquely positioned to identify and respond to the needs of justice-involved youth and their families. Whether through the provision of clinical care, participation in advocacy activities aimed at reforming the juvenile justice system, or by addressing the root causes of juvenile delinquency, pediatricians have a critical role in improving outcomes for youth involved with the justice system.

OVERVIEW OF THE JUVENILE JUSTICE SYSTEM

In the United States, most children and adolescents suspected of committing a crime are typically placed under the jurisdiction of the juvenile justice system, which is separate from the criminal (adult) justice system. Although each state, and the District of Columbia, have a unique juvenile justice system with different structures and processes, the way a delinquency case progresses through the juvenile justice system is similar among most jurisdictions.[5,6] Law enforcement and non–law enforcement sources (parents, victims, schools) may refer youth under the age of 18 to the juvenile justice system. At the time of arrest, law enforcement agencies may refer the youth for further processing within the juvenile justice system or divert the case to an alternative program outside the system, known as diversion. At or around the time of arrest, adolescents may be held in facilities pending the resolution of their case (detention). If the legal agency refers a case to juvenile court, an intake officer reviews the case and decides whether to dismiss the case, handle the case informally, or proceed to formal processing in juvenile court (petition). Formal cases in juvenile court proceed to an adjudicatory hearing (trial) in which a judge may find a young person not guilty or adjudicated delinquent (guilty). In the case of adjudication, the case progresses to a disposition hearing (sentencing) in which a juvenile court judge orders the disposition (sanctions). Juvenile court judges have a wide range of disposition options, starting with less severe options such as community service and counseling, progressing to more severe options such as intensive probation or residential placement. Residential placement is the out-of-home placement of adjudicated delinquent youth and may include group homes, residential treatment facilities, and long-term secure facilities.

Not all minors accused of breaking the law progress through the juvenile justice system. The maximum age of juvenile court jurisdiction varies between states: 45 states have a maximum age of 17 and 5 states have a maximum age of 16.[7] Additionally, all states have transfer laws that remove youth from the jurisdiction of juvenile court and place them in the jurisdiction of criminal (adult) court in certain circumstances. Transfer laws and processes vary by state and are discussed in the section of this statement on juvenile transfer laws.

States and local jurisdictions mostly administer juvenile justice systems; however, the federal government has established guidelines for minimum protections of youth involved with the justice system. The Juvenile Justice Delinquency and Prevention Act (JJDPA), first enacted in 1974[8] and reauthorized by the Juvenile Justice Reform Act of 2018,[9] maintains 4 core protections for youth involved with the justice system:

- deinstitutionalization of status offenders: juveniles who have committed an offense that would not be a crime if committed by an adult (eg, curfew violation or running away) and juveniles who are not charged with any crimes may not be placed in secure detention facilities;
- removal from adult jail: with a few exceptions, juveniles should not be held in adult jails or lockups (this provision was strengthened in 2018, and states have 3 years to comply);
- sight and sound separation: juveniles held in adult facilities should be separated from incarcerated adults by both sight and sound; and
- racial and ethnic disparities: states must implement policy, practice, and system improvement strategies to identify and reduce racial and ethnic disparities among youth who come into contact with the juvenile justice system.

States that do not comply with these core protections are not eligible to receive federal grant funding provided through the JJDPA.

YOUTH INVOLVED WITH THE JUSTICE SYSTEM

Racial and Ethnic Disparities

Despite decreases in youth arrest and confinement rates, there remain significant racial and ethnic disparities throughout the juvenile justice system. As seen in Table 1, racial and ethnic disparities exist at virtually every decision point in the juvenile justice system.

TABLE 1 Racial and/or Ethnic Disparities in the Juvenile Justice System (All Data From 2018, Unless Otherwise Specified)

	White	African American	Hispanic	AIAN	AHPI
US population <18 y,[10] %	50	14	26	1	5
Juvenile arrest relative rate (RR)[11,a]	—	2.6	Not reported[b]	1.3	0.3
Cases referred to juvenile court RR[12]	—	2.9	0.9	1.2	0.2
Cases diverted RR[12]	—	0.6	0.8	0.8	1.0
Cases detained RR[12]	—	1.4	1.5	1.3	1.2
Cases adjudicated delinquent RR[12]	—	0.9	1.1	1.1	1.0
Adjudicated cases resulting in secure confinement RR[12]	—	1.4	1.4	1.2	0.9
Cases judicially waived to criminal court[12]	—	1.6	1.0	0.9	0.9
Juvenile residential placement RR[13]	—	4.6	1.4	2.8	0.2
Decrease juveniles in residential placement 2006–2015,[14] %	54	46	45	51	65
Decline in juvenile court delinquency cases 2005–2015,[15] %	53	44	38	40	57

AIAN, American Indian or Alaskan native; AHPI, Asian American, Hawaiian, or Pacific Islander; —, not applicable.

[a] Relative rates relative to white youth.

[b] Not all agencies provide ethnicity data; thus, arrest rates for Hispanic juveniles are not reported.

Empirical explanations for racial and ethnic disparities within the justice system are commonly grouped into 2 broad conceptual frameworks: differential treatment and differential offending.[16–18] The differential treatment hypothesis[16–18] attributes racial and ethnic disparities to "inequities—intended or unintended—in justice system practices."[18] Multiple studies have demonstrated racial bias against youth of color at all decision points in the juvenile justice system (arrest, referral to court, diversion, detention, petition, adjudication, probation, secure confinement, and transfer to criminal court).[16,19] Authors of a 2018 review article[19] examined official processing of youth of color at various juvenile justice decision points from January 2001 to December 2014. The authors of that review found that 79% of studies showed that status as a person of color had some disadvantaging effect for youth processed in the juvenile justice system. The negative impact of race was especially prominent at earlier decision points in the juvenile justice system (eg, arrest, referral to court, and preadjudication detention). Conversely, the differential offending hypothesis attributes racial and ethnic disparities within the juvenile justice system to "differences in the incidence, seriousness, and persistence of engagement in delinquent and criminal behavior."[18] The differential offending hypothesis does not ascribe differences in delinquent behavior to biological or genetic differences between races or ethnicities. Instead, the hypothesis posits youth of color are more likely to experience a variety of risk factors for delinquency (poverty, low-performing schools, harsh discipline practices in schools, increased police presence in communities, exposure to violence, incarcerated parents, toxic stress, etc) and thus more likely to commit certain types of crimes.[17] Much of the research supporting this hypothesis relies on the use of official records such as arrest rates, confinement rates, and/or conviction rates. Citing empirical data from official records, which are influenced by inequities in justice system practices (eg, overpolicing of historically disenfranchised neighborhoods, racial profiling, disparate sentencing of youth of color, differential treatment in the plea-bargaining process, implicit and/or explicit bias against youth of color), may overestimate the differences in delinquent and/or criminal behaviors between racial and ethnic groups and perpetuate bias within the literature. Furthermore, more research is needed to identify how social factors more commonly experienced by youth of color mediate racial and/or ethnic disparities in the juvenile justice system.

Although helpful as conceptual frameworks, the differential treatment and differential offending hypotheses represent an oversimplification of the causes of racial and ethnic disparities within the juvenile justice system. Racial and ethnic disparities within the juvenile justice system exist within the broader context of disparities in child health and well-being. Collectively, the sources of these disparities are rooted in inequities in the social and environmental determinants of health (eg, poverty, racism) and the failure of public policies to adequately address them. Key policy statements from the American Academy of Pediatrics (AAP), "The Impact of Racism on Child and Adolescent Health,"[20] "Poverty and Child Health in the United States"[21] and "Health Equity and Children's Rights"[22] provide insight on how these inequities impact the health and development of children and adolescents and how pediatricians can respond to mitigate their impact.

Children and Adolescents Exposed to ACEs

Research has established the significant impact of childhood trauma, adversity, or ACEs on the health and well-being of children and adolescents.[23] Multiple studies have documented high prevalence rates of childhood trauma among justice-involved youth, with many studies finding that over 90% of youth in the justice system have experienced at least one form of childhood trauma.[24–26] The National Child Traumatic Stress Network found justice-involved youth experience an

average of 5 different forms of childhood trauma.[27] Sixty-two percent of youth in the National Center for Child Traumatic Stress study experienced trauma within the first 5 years of life; Table 2 identifies the different types of trauma justice-involved youth experienced in this study.

Aware of the high prevalence of trauma and cognizant that incarceration itself represents a traumatic experience, advocates have called for the implementation of trauma-informed policies, procedures, and standards across the spectrum of juvenile justice settings. In 2015, the National Child Traumatic Stress Network published the *Essential Elements of a Trauma-Informed Juvenile Justice System*,[28] a guide that educates programs working with justice-involved youth to recognize and respond to the needs of youth who have experienced trauma. A 2012 report by the US Department of Justice provides recommendations on how to incorporate trauma-informed care practices throughout the spectrum of the juvenile justice system.[29] Recommendations include the following:

- make trauma-informed screening, assessment, and care the standard in juvenile justice services;
- abandon juvenile justice correctional practices that traumatize children;
- provide juvenile justice services appropriate to children's ethnocultural background;
- provide care and services to address the special circumstances and needs of girls in the juvenile justice system;
- provide care and services to address the special circumstances and needs of lesbian, gay, bisexual, transgender, and queer and/or questioning (LGBTQ) youth in the juvenile justice system;
- develop and implement policies in every school system that aim to keep children in school rather than policies that lead to suspension and expulsion;
- guarantee that all violence-exposed children accused of a crime have legal representation;
- help, do not punish, child victims of sex trafficking; and
- whenever possible, prosecute young offenders in the juvenile justice system.

For justice-involved youth receiving care in the community, the AAP Resilience Project (https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/resilience/Pages/Resilience-Project.aspx) is a great resource to educate pediatricians to incorporate trauma-informed care into their practice.

TABLE 2 Prevalence of Trauma Types Among Justice-Involved Youth[27]

Trauma Type	Percentage of Youth	
	Male	Female
Traumatic loss or bereavement	59	65
Domestic violence	51	56
Impaired caregiver	48	57
Emotional abuse	46	54
Community violence	41	30
Neglect	31	30
Physical maltreatment and/or abuse	39	41
Physical assault	27	24
School violence	23	23
Serious injury or unintentional injury	20	19
Sexual maltreatment and/or abuse	16	32
Sexual assault and/or rape	9	39

Female Youth

Because of larger relative declines in the arrest rates of male youth, the proportion of justice-involved girls and young women has increased.[30] Recent data reveal that female youth accounted for 29% of youth arrests[31] and 15% of youth residential placement.[32]

Available literature suggests that in comparison with male youth, justice-involved female youth experience higher rates of trauma exposure, sexual and physical abuse victimization, and mental illness[25] and are more likely to have been involved with the child welfare system.[33]

In 2015, the Office of Juvenile Justice and Delinquency Prevention issued policy guidance aimed at improving system and programmatic responses for justice-involved female youth.[34] Key recommendations from the report include the following:

- prohibition of placement of minor sex trafficking victims in the juvenile justice system;
- development of alternatives to detention and incarceration for female youth; and
- competency of all programs and services to serve girls and young women in, or at risk of entering, the juvenile justice system.

LGBTQ Youth

Studies report LGBTQ youth compose 13% to 15% of youth in the juvenile justice system,[35–37] but this may be an underestimate because many jurisdictions do not collect information on sexual orientation or gender identity, and youth may not disclose this information because of fear of mistreatment.[35] Most research on LGBTQ youth in the juvenile justice system is focused on sexual orientation and does not include data on transgender or gender-diverse

youth. Like youth from historically disenfranchised racial and/or ethnic groups, LGBTQ youth experience more risk factors for involvement with the juvenile justice system and differential treatment within the system. LGBTQ youth experience higher rates of physical and sexual violence, familial rejection, bullying, mental health problems, and other risk factors that increase the likelihood of system involvement.[36,37] Literature suggests LGBTQ youth face bias and maltreatment across the spectrum of juvenile justice settings. One study found that LGBTQ and gender-diverse youth were more likely to be detained for truancy, warrants, probation violations, running away, and child sex trafficking.[38] Another study found LGBTQ youth reported youth-on-youth sexual victimization at a rate of nearly 7 times that of heterosexual youth (10.3% vs 1.5%).[39] Multiple reports have found LGBTQ youth in detention facilities experience increased rates of emotional abuse, physical abuse, and time in isolation.[36,37,40] The Prison Rape Elimination Act of the Juvenile Facility Standards of 2003[41] includes provisions to keep LGBTQ youth safe in detention facilities and include, but are not limited to, the following:

- staff must receive training on how to communicate effectively with LGBTQ and gender-nonconforming youth;
- facilities are required to ascertain whether youth are (or are perceived to be) lesbian, bisexual, gay, and/or transgender or gender nonconforming;
- the use of isolation and/or solitary confinement is limited; and
- case-by-case housing decisions are required for transgender and intersex adolescents.

Although the Prison Rape Elimination Act standards provide basic protections for detained LGBTQ youth, they do not set comprehensive standards that promote the overall well-being of confined LGBTQ youth. The Annie E. Casey Foundation[37] and The Equity Project provide best practices and guidance for the development and implementation of more comprehensive standards.[42]

Medical Care for Transgender Youth

Medical care for transgender youth in confinement, including access to hormone therapy, is variable. In a 2015 article, authors analyzed state statutes and department of corrections policies regarding medical services and treatment of transgender inmates and found that 13 states allow for the initiation of hormone treatment and 21 states allow for the continuation of hormone treatment; the authors were unable to identify relevant policies or statues in 10 states.[43] The 2015 National Commission on Correctional Health Care (NCCHC) position statement "Transgender, Transsexual, and Gender Nonconforming Health Care in Correctional Settings"[44] makes recommendations for the health management of transgender patients held in confinement. Recommendations include the following:

- health staff should manage transgender patients in a manner that respects their biomedical and psychosocial needs;
- the management of medical or surgical transgender care should follow accepted standards developed by professionals with expertise in transgender health;
- there should be no blanket administrative or other policies that restrict specific medical treatments; and
- transgender patients who received hormone therapy with or without a prescription before incarceration should have therapy continued without interruption.

Youth Involved With the Child Welfare System

Youth with current or past involvement with the child welfare system, often referred to as crossover or dual-status youth, are overrepresented in the juvenile justice system. Although national data are lacking and estimates vary by jurisdiction, studies reveal the prevalence of dual-status youth in the juvenile justice system commonly exceeds 50%.[45,46] When compared with youth who are not involved in both systems, dual-status youth are younger at the time of first arrest, detained more often, and have more significant mental health and educational needs.[33] The JJDPA requires states to establish polices and systems to incorporate child welfare records into juvenile justice records to establish and implement treatment plans of justice-involved youth.

MEDICAL AND MENTAL HEALTH CARE FOR CONFINED YOUTH

Confined youth have a constitutional right to adequate medical and mental health care[47,48]; however, because of the lack of clearly defined federal standards and differences in state laws regarding the provision of health care for confined youth, on-site medical and mental health care services vary widely between jurisdictions and correctional facilities.[49] States, counties, or private contractors may provide health care services for confined youth.[50] Federal law prohibits the use of Medicaid funds for inmates of a public institution,[50] and local governments (states, counties, cities) are responsible for funding health care services for confined youth.

In addition to state laws governing the provision of health care for confined youth, detention facilities may seek voluntary accreditation from the NCCHC. The NCCHC published "Standards for Health

Services in Juvenile Detention and Confinement Facilities" and provides accreditation for health services in juvenile detention facilities.[51] The AAP, American Academy of Child and Adolescent Psychiatry (AACAP), American College of Obstetricians and Gynecologists (ACOG), and the American Public Health Association support the NCCHC standards, which address 9 general areas: health care services and support, patient care and treatment, special needs and services, governance and administration, safety, personnel and training, health records, health promotion, and medical legal issues.[51] The NCCHC recommends physical, mental, and oral health screenings after admission, a comprehensive health assessment within 7 days of admission, and appropriate follow-up care. Although NCCHC accreditation is voluntary, it is important for providers in confinement facilities to be aware of these standards and juvenile correctional facilities to adopt and comply with the standards.

The 2011 AAP policy statement "Health Care for Youth in the Juvenile Justice System"[52] provided a detailed overview of the physical and mental health needs of confined youth and the provision of health care services for youth in correctional facilities. Since the 2011 policy statement, there have been few additional nationally representative studies on the health status of justice-involved youth published. The Survey of Youth in Residential Placement (SYRP) of 2010[53] remains the most comprehensive nationally representative examination of the health needs of confined youth. The SYRP found 69% of confined youth reported an unmet health care need, including injury, problems with vision or hearing, dental needs, or "other illness." The SYRP did not inquire about specific illnesses or injuries. Common health concerns for these youth include traumatic injuries, oral health needs, sexually transmitted infections (STIs), and reproductive health needs.[53,54]

Few studies have been used to examine chronic illness in incarcerated youth, and incarcerated youth may have difficulty accessing care before confinement.[52] Quality coordinated care within the justice and medical systems can identify and manage chronic illnesses during confinement. The NCCHC recommends that systems identify and enroll youth with chronic illnesses in a chronic disease management plan.[51]

Reproductive and/or Sexual Health

The 1991 NCCHC study[55] remains the only nationally representative sample evaluating the history of sexual activity and contraceptive use among confined youth. Confined youth reported higher rates of sexual activity, increased likelihood of 4 or more lifetime sexual partners, and lower rates of contraception or condom use during their most recent sexual intercourse. Multiple smaller studies have revealed similar results,[56–59] and these behaviors place justice-involved youth at risk for unintended pregnancy as well as STIs and HIV infections. It is important for adolescents to receive counseling on safe sex practices, which include barrier methods, hormonal contraception, long-acting reversible contraception, and emergency contraception, and receive timely and appropriate reproductive health care during confinement. Reproductive health care includes assessment of youth's self-reported sexual behaviors and practices, STI and HIV testing and treatment, trauma counseling, necessary emergency contraception, and counseling on all other forms of contraception as recommended by the AAP.[60] The NCCHC recommends evaluating all youth assigned female sex at birth for pregnancy risk after admission. Early pregnancy identification allows youth to consider options regarding their pregnancy and parenthood.

The 2010 SYRP revealed 13% of confined male and 5% of female youth were expecting children.[53] ACOG recommends incarcerated pregnant adolescents receive the same pregnancy care (pregnancy counseling, prenatal and perinatal care, and abortion services) as nonincarcerated adolescents.[61] A unique challenge for pregnant incarcerated women and adolescents is the use of mechanical restraints, commonly known as shackling. ACOG[62] notes that shackling interferes with the ability of the health care clinician to assess and evaluate the health of the woman and fetus and may put the health of both at risk (increased risk of falls, increased risk of venous thrombosis due to limited mobility, interference with normal labor and delivery, and interference with mother-child bonding).[61] ACOG, the American Medical Association, and many other professional organizations have called for prohibiting, or severely restricting, the use of shackles to restrain pregnant women.[62] The Juvenile Justice Reform Act of 2018 prohibits the use of restraints on pregnant women and adolescents during labor, delivery, and postpartum recovery unless there is an immediate threat of harm to self or others (states have 2 years to phase out the use of restraints).[9]

Infections

It is important for health care clinicians to give special attention to screening, immunization, and treatment of specific infections among justice-involved youth.

Tuberculosis

The NCCHC recommends screening all youth for tuberculosis after entry into the justice system unless the local health department determines the community's prevalence does not warrant screening.[51] The 2018 AAP

Red Book: 2018 Report of the Committee on Infectious Diseases outlines methods for assessing risk and screening youth for exposure.[63] The Centers for Disease Control and Prevention also provides recommendations for prevention and control of tuberculosis in detention facilities.[64]

STIs and/or HIV

Data from the Center for Disease Control and Prevention's *Sexually Transmitted Disease Surveillance 2011*[65] found confined youth have elevated rates of STIs (Table 3).

Although HIV prevalence data for confined youth are not available, the same risk factors for STIs place them at risk for HIV infection. In 2017, youth aged 13 to 24 made up 21% of all new HIV diagnoses in the United States.[66]

Routine screening, education (including safe sex practices; abstinence; and barrier, hormonal, long-acting reversible contraception; and emergency contraception), and treatment of STIs and/or HIV among confined youth may decrease the overall disease burden and improve sexual and relationship health. The NCCHC recommends STI testing (chlamydia, gonorrhea, HIV, and syphilis, of which there is significant prevalence) be offered to all youth within 48 hours of arrival.[51]

Immunizations

There is a lack of nationally representative data regarding the immunization status of confined youth, but facility-level data suggest they have significantly lower immunization coverage rates. In a study of one juvenile detention facility in California, authors found only 3% of adolescents had received all recommended immunizations before their first detention.[67] Barriers to full immunization coverage among justice-involved youth may include poor access to health care and lack of a medical home before confinement.[67]

Although immunization requirements for confined youth vary between jurisdictions, confinement may be an opportunity for justice-involved youth to receive immunizations. Studies have revealed that detention and/or secure placement of youth may be associated with higher immunization coverage rates.[67,68] Implementing routine immunization policies in juvenile detention facilities may increase immunization coverage for confined youth. Use of state immunization registries can help determine necessary immunizations.

Mental Health Disorders

Although estimates vary, the prevalence of mental health disorders among justice-involved youth commonly ranges from 50% to 80%.[69–73] Common mental health disorders include depressive disorders, anxiety disorders, disruptive behavior, attention-deficit/hyperactivity disorder, posttraumatic stress disorder, and substance use disorders.[69]

The variable data on the prevalence of mental health disorders among juvenile justice-involved youth are indicative of the limitations of the studies in the literature (use of nonstandardized measures, different diagnostic tools, measurement at different levels of the juvenile justice system, and data specific to individual facility or state). Furthermore, the high prevalence of mental health disorders is interconnected with the high prevalence of trauma and ACEs found in this population.[74,75] Most justice-involved youth experience trauma and polyvictimization from a young age. These experiences, and resulting toxic stress response, may result in maladaptive behaviors such as increased stress reactivity, impulsivity, hyperarousal, and decreased ability to self-regulate.[76] Youth who have experienced multiple traumatic events are at increased risk of delinquency, contact with law enforcement, involvement with the juvenile justice system, school suspension and dropout, volatile relationships, and substance use.[77] Polyvictimized youth are also more likely to receive diagnoses of externalizing disorders such as conduct disorders, oppositional defiant disorder, and antisocial behaviors.[72,78] There is increasing recognition that for many youth, these diagnoses may be rooted in complex trauma and polyvictimization.[79,80]

Substance Use

As illustrated in Table 4, the prevalence of substance use in confined youth exceeds that of the general adolescent population. However, it is important to consider that for many justice-involved youth, substance use may be the instigating factor of their arrest or confinement.

Recognizing the high prevalence of mental health disorders and substance use among justice-involved youth and the lack of appropriate care in many juvenile facilities, many jurisdictions have implemented programs (ie, mental health courts, substance abuse courts) aimed at providing community-based alternatives to detention for those with mental health and/or substance use disorders.[33] Several diversion programs are effective at decreasing recidivism and/or improving

TABLE 3 STI Rates Among Adolescents Aged 12–18 Years in Juvenile Correction Facilities, 2011 (Last Year Data From Juvenile Correctional Facilities Were Included)

Disease	Overall Positivity, %	
	Female	Male
Chlamydia	15.7	7.4
Gonorrhea	4.4	1.2

TABLE 4 Prevalence of Substance Use Among Confined Youth and the General Adolescent Population

Substance	Lifetime Prevalence Among Confined Youth,[53,a] %	Lifetime Prevalence at Grade 12, General Population, 2018,[81,b] %
Alcohol	74	59
Marijuana or hashish	84	44
Cocaine/crack	30	4/1.5
Ecstasy	26	4
Methamphetamine	22	0.7
Acid/LSD	19	5
Heroin	7	0.8
Any illegal drug (excluding marijuana)	50	19

LSD, lysergic acid diethylamide.

[b] Self-reported data from the Monitoring the Future National Survey on Drug Use.

behavioral health outcomes in justice-involved youth[82]; however, there is significant variability in the design and implementation of these programs, leading to limitations in studying their collective impact.[82] Further studies to identify eligible youth and effective diversion services and programs may improve outcomes in justice-involved youth.

Screening and Assessment for Mental Health and Substance Use Disorders

NCCHC standards recommend screening all confined youth for current or past mental illness and legal and illegal drug use at the time of arrival to the facility.[51] A 2014 survey[83] of juvenile facilities across the United States found 88% of facilities screened all or some youth for substance use and 99% of facilities reported screening all or some youth for mental health needs. Generally, mental health screening involves nonclinical staff using a standardized screening tool.

On-site Psychiatric Care and Psychotropic Medications

The decision to initiate or change medical treatment of psychiatric disorders in confined youth is challenging. The AACAP published recommendations for mental health assessment and treatment of youth in the correctional system.[84] The AACAP recommends psychotropic medications only be used as part of an individually developed comprehensive treatment plan. To ensure treatment can proceed in a safe and supervised fashion, AACAP guidance recommends determining the youth's legal disposition and placement before initiating or changing medication regimens.[85]

National data are lacking on the use of psychotropic medications for justice-involved youth; however, state- and facility-level data suggest these youth receive psychotropic medications at a higher rate than the general adolescent population. In an analysis of juvenile facilities in 55 California counties, authors found the average proportion of youth receiving psychoactive medication was 17%.[86] In a study of 668 youth in 3 detention facilities in 1 state, authors found that 10% had psychotropic medication dispensed within 1 month of intake.[87] In comparison, from 2005 to 2010, 6% of adolescents reported use of psychotropic medication within the past month.[88]

Suicide and Suicidality

Studies consistently demonstrate justice-involved youth are at increased risk for suicidal thoughts and behaviors. In a longitudinal study of 1829 youth detained at 1 facility over a 3-year period, authors found 36% had ever felt like life was hopeless, 10% had thought about killing themselves in the past 6 months, and 11% had attempted suicide in the past.[89] In a 2015 literature review, authors found that 19% to 32% of justice-involved youth had suicidal ideations in the past year and 12% to 16% had attempted suicide in the past year.[90]

The 2014 Juvenile Residential Facility Census (JRFC) found that suicide was the most common cause of death for youth in residential placement.[83] From 2000 to 2014, there was an average of 7 suicides per year in juvenile detention facilities across the United States.

The JRFC report found that 93% of reporting facilities screened some or all youth for suicide risk. Available studies indicate facilities with annual suicide prevention training and suicide risk screening shortly after admission reported lower suicide rates.[91,92] Only one-fifth of facilities had the 7 key components deemed necessary for suicide prevention.[91,93] These components include written protocols, intake screening, suicide prevention training, safe housing, observation, mortality review, and cardiopulmonary resuscitation and certification.

Informed Consent and the Right to Refuse Care

According to NCCHC standards, "all examinations, treatments, and procedures are governed by informed consent practices for juvenile care that are applicable in the jurisdiction. A juvenile may refuse specific health evaluations and treatments in accordance with the laws in the jurisdiction."[51] NCCHC standards also state that youth may not be punished for refusing medical or mental health treatment.[51]

Continuity of Care

It is ideal for justice-involved youth to receive comprehensive and coordinated physical and mental health care during confinement and in their communities. Barriers to such

care include lack of preventive care in the community, lack of an established medical home, and disruptions in Medicaid or Children's Health Insurance Program coverage. Federal law prohibits the use of Medicaid funds for inmates of a public institution.[94] As a result, many jurisdictions terminate Medicaid eligibility at the time of entry into secure detention facilities.[94] In 2018, Congress passed legislation prohibiting states from terminating Medicaid eligibility for incarcerated juveniles.[95] States may suspend Medicaid coverage during incarceration, but before release, they must conduct a redetermination of eligibility and restore coverage, if eligible. States remain prohibited from using Medicaid to cover incarcerated juveniles.

Identifying and connecting youth with a medical home before release may have long-term benefits to their overall health and well-being. Winkelman et al[96] showed that youth with any justice involvement (detained, paroled, probation, or arrest) were more likely to have an emergency department (ED) visit in the last year compared with youth not involved with the justice system. Similarly, justice-involved youth are more likely to be hospitalized than their peers, and their use of the ED and inpatient services, as measured in person-years, is significantly higher than that of youth not involved with the justice system.[96] Use of the ED and increased hospitalization days by justice-involved youth may contribute to increased health care costs and represents an opportunity to improve the continuity of care for these youth once they return to their communities. It is ideal for these youth to be connected to medical homes and pediatricians who are prepared to address their needs.

Continuity of care starts at the time of admission to the facility. If the youth already has a primary care provider (PCP), it is crucial for the medical staff to contact the PCP to verify previous diagnoses and treatment(s).[97] For cases in which the youth does not have a PCP, medical staff can provide resources to establish primary care. Providing summaries of medical care for the PCP, appropriate subspecialists, or mental health specialists at the time of release to the community is also important. Additionally, detention facilities and jurisdictions can establish policies and procedures that ensure eligible uninsured youth are enrolled in Medicaid or the Children's Health Insurance Program before release from detention and have access to health care coverage as they reenter their home communities.[98,99]

DEVELOPMENTALLY APPROPRIATE CONFINEMENT FACILITIES

Conditions of Confinement

Youth may be confined in a variety of confinement facilities (short-term detention facilities, long-term secure facilities, camps, residential treatment facilities, etc); however, most are confined in locked facilities, many of which resemble adult jails and prisons in form and function (restricted by gates, fences and locked doors, regular use of restraints such as handcuffs and shackles, locking youth in their room for sleep and/or punishment, use of punitive discipline strategies, etc). For youth with a history of trauma, confinement in such facilities may exacerbate symptomatology related to trauma.[100] The trauma of confinement extends beyond the physical environment. Since 2000, systemic abuses of confined youth have been documented in 29 states.[101] Thirty-eight percent of confined youth fear being physically attacked, 50% report detention staff applies punishments without cause, and 33% report the use of unnecessary force.[101] In 2017, the National Council of Juvenile and Family Court Judges passed a resolution urging states to establish independent monitoring systems (independent bodies responsible for receiving and investigating complaints) for confined youth, with a special focus on the use of isolation, use of mechanical restraints, use of force, access to programming, levels of violence, and access to families.[102] Several jurisdictions have implemented independent monitoring systems for confined youth.[103] The Annie E. Casey Foundation's Juvenile Detention Alternatives Initiative provides guidance and technical assistance for jurisdictions interested in monitoring and improving conditions of confinement.[104]

Isolation and Solitary Confinement

Solitary confinement is "the involuntary placement of a youth alone in a cell, room, or other area for any reason other than as a temporary response to behavior that threatens immediate harm to the youth or others."[105] While in isolation, youth may be denied access to educational material, detention facility programming, recreational activities, and contact with family.[106]

Nationally representative data suggest the use of isolation and solitary confinement is common in juvenile detention facilities. The JRFC found 47% of juvenile detention centers reported locking youth in a room for 4 or more hours within the previous month.[83] The SYRP found 35% of youth reported being held in isolation or solitary confinement.[53] Of those held in isolation, 55% reported being held for more than 24 hours.[53] These reports may understate the use of juvenile isolation and solitary confinement because they do not include youth in adult facilities.

The negative effects of solitary confinement on adults are well documented and may include anxiety, depression, impaired memory, hallucinations, suicidal thoughts, anger, psychosis, paranoia, heart

palpitations, headaches, abdominal pain, and insomnia.[107] The 2009 "Juvenile Suicide in Confinement: A National Survey" highlights this vulnerability.[108] In this report, the authors examined 110 juvenile suicides occurring between 1995 and 1999 and found 62% of suicide victims had a history of room confinement, and 51% were on room confinement status at the time of their death.

In 2016, the US Department of Justice issued guiding principles on the use of isolation and solitary confinement and recommended against the use of isolation and solitary confinement in juveniles, stating, "In very rare situations, a juvenile may be separated from others as a temporary response to behavior that poses a serious and immediate risk of physical harm to any person. Even in such cases, the placement should be brief, designed as a 'cool down' period, and done only in consultation with a mental health professional."[109] In 2018, Congress passed legislation prohibiting the use of room confinement (except as a temporary response for juveniles who pose a serious and immediate risk to themselves or others) for youth in federal facilities.[110] There are few juveniles in federal detention centers, and nonfederal detention centers are not obligated to adhere to these principles.

Many states have passed legislation aimed at restricting or eliminating juvenile isolation. A 2016 analysis by the Lowenstein Center for the Public Interest found that 29 states or jurisdictions prohibit the use of punitive solitary confinement in juvenile detention facilities, 15 states impose time limits on the use of punitive solitary confinement, and 7 states place no limits to the use of solitary confinement.[111] In 2016, the AAP endorsed the United Nations position and the AACAP policy statement on solitary confinement of juvenile offenders and opposed the use of solitary confinement for juveniles in correctional facilities.

Many organizations have developed tools to reduce the use of isolation in juvenile confinement. The Council of Juvenile Correctional Administrators published a tool kit[112] outlining steps to reduce the use of isolation and recommendations to use alternative behavior management options and responses. These options may include cognitive behavioral therapy, dialectical behavior therapy, collaborative problem solving and trauma-informed care, and de-escalation training for juvenile correctional employees, workers, and/or officers.

Educational Needs

Youth involved with the justice system often present with significant educational challenges. The SYRP[53] found that 24% of youth reported they were not enrolled in school at the time they entered custody, 61% had been expelled or suspended, and 48% reported being below the level expected for their age. Learning disabilities are more common among youth in custody, with reported rates as high as 30%.[53]

Despite increased educational need, available data suggest confined youth receive inadequate educational support. A 2016 report from the US Department of Education Office for Civil Rights[113] found the number of hours and days of educational programming varies widely between facilities, teachers working in confinement facilities are more likely to be absent, and confinement facilities are less likely to offer essential math and science courses. The US Department of Education and Department of Justice developed guiding principles for the provision of high-quality education in juvenile justice secure settings.[114]

In multiple studies, authors have documented that youth with intellectual and developmental disabilities are overrepresented in the juvenile justice system. Although there is variance between sites, the estimated national average prevalence of intellectual and developmental disabilities in confined youth is 33%.[115] Confined youth with intellectual and developmental disabilities have the same rights under the Individuals with Disabilities Education Act as nonconfined youth and are entitled to individualized education programs and special education services.[115] The National Center on Criminal Justice and Disability provides recommendations for preventing involvement of adolescents with intellectual and developmental disabilities in the justice system and improving the delivery of special education services for confined youth.[116]

JUVENILE JUSTICE REFORM AND OPPORTUNITIES FOR ADVOCACY

Community-Based Interventions and Alternatives to Youth Confinement

Over the last 2 decades, advances in social, developmental, and neurologic sciences have transformed our understanding of health and well-being across the life course. It is recognized that trauma, adversity, and ACEs are associated with a maladaptive stress response, changes in brain architecture, and poor physical, mental, and behavioral health outcomes.[23,26] Advances in neuroscience and neuroimaging have demonstrated numerous structural and functional changes in the brain occur during the period of adolescence.[117] These changes may be associated with impulsive, risk-taking, and reward-seeking behaviors that may make adolescents more likely to interact with the justice system.

This evolving knowledge has contributed to the development and

implementation of community-based alternatives to incarceration that are more appropriate for the unique developmental needs of justice-involved youth. Numerous reports have highlighted shortcomings associated with the incarceration of juveniles in the United States. The Annie E. Casey Foundation's *No Place For Kids: The Case for Reducing Juvenile Incarceration* argues that juvenile incarceration is dangerous (documented cases of physical and sexual abuse), ineffective (does not decrease involvement in delinquent behaviors), unnecessary (only 26% of youth confined in residential facilities committed a violent offense), obsolete (community-based alternatives have been demonstrated to reduce recidivism), wasteful (in 2008, an estimated $5 billion was spent on juvenile incarceration), and inadequate (deficient in mental health treatment, substance use treatment, educational programming, and transitional support and often retraumatizes youth).[118]

Many jurisdictions responded to these concerns by implementing reforms (diversion programs, mentor programs, implementation of the Juvenile Detention Alternatives Initiative, etc)[118,119] aimed at reducing the rate of juvenile incarceration and improving outcomes for justice-involved youth. The Juvenile Detention Alternatives Initiative is one available resource and tool that provides training and technical assistance to jurisdictions interested in reforming their juvenile justice systems. Examples of community-based alternatives to detention and secure confinement include day and evening reporting centers (providing youth with supervision and programming during the day and/or evening), electronic monitoring, home- or community-based detention, and intensive family treatment models such as multisystemic therapy, functional family therapy, and multidimensional foster care.[118,119]

The Office of Juvenile Justice and Delinquency Prevention[120] advocates for a comprehensive strategy of supporting the adolescent's family and engaging core institutions, such as schools, businesses, and religious organizations, to help develop mature and responsible youth. The strategy of delinquency prevention is the most effective approach while recognizing the need for graduated sanctions to protect the community. The best prevention involves targeting risk factors for delinquency, such as ACEs, childhood trauma, drugs and firearms in the community, family conflict, abuse and neglect, poor commitment to school, and negative peer influences, while focusing on protective factors such as a resilient individual temperament; close relationships with family, teachers, other adults, and peers; and promoting school success and avoidance of drugs and crime.[17,29,118–120]

Overall, there is growing evidence that for many youth, community-based alternatives to incarceration are more effective options than confinement.[118,119] This evidence and overall reductions in youth crime have contributed to significant decreases in the rate of juvenile confinement in the United States.

Juvenile Transfer Laws

Juvenile transfer laws govern the relocation of juvenile cases to adult court. Current juvenile transfer laws were created largely as a result of state legislative actions during the 1980s and 1990s, triggered by a rise in youth crime and intense media focus on juvenile crime during that period.[121] States responded by enacting legislation that automatically placed juveniles in the jurisdiction of the adult court for certain offenses or gave prosecutors discretion to place juveniles in adult court. Although juvenile crime rates have steadily decreased since the mid-1990s, many of the juvenile transfer laws of this era remain in effect.[121]

Although legislators enacted these laws as a deterrent to juvenile crime, evidence suggests that juvenile transfer laws have little or no effect on general juvenile crime rates.[122] Additionally, compared with youth in the juvenile court system, recidivism rates were higher for juveniles with cases in adult criminal court. Recidivism rates were higher particularly for violent offenders.[122] Proposed explanations for increased recidivism rates among youth tried in criminal court include the stigma of having a felony criminal record, less focus on rehabilitation in the adult criminal justice system, and sense of resentment among youth tried and punished as adults.[122]

Currently, all states have transfer laws that allow juvenile offenders to be prosecuted in adult court. The 4 types of transfer laws[7] are as follows:

- statutory exclusion: specific crimes are automatically transferred to adult court;
- judicially controlled transfer: all juvenile cases begin in juvenile court and must be transferred to adult court by the juvenile court;
- prosecutorial discretion: also known as "direct file," prosecutors may choose to file in adult or juvenile court; and
- once an adult, always an adult: once a juvenile has been prosecuted in adult court, all future cases go to adult court.

Juveniles prosecuted in adult court may be confined in adult detention facilities. Juveniles in adult prisons report learning more criminal behavior from adult inmates, fear of victimization, and being least likely to say they would not reoffend. Juveniles in adult facilities, compared with those in juvenile facilities, have an eightfold increase in suicide, fivefold increase in being sexually assaulted,

and twofold increase in likelihood of being attacked with a weapon by other inmates or beaten by staff.[123]

Reform efforts have focused on changing the ways in which juveniles may be transferred to adult court. Advocates argue that statutory exclusion and prosecutorial discretion may limit the juvenile court's ability to provide the most appropriate sanctions for youth. There is also concern that prosecutors may use the threat of adult sanctions to coerce youth to accept plea bargains to avoid longer sentences. Several states have successfully enacted legislation limiting the transfer of juveniles to adult court.[123] For example, in 2012, Colorado enacted legislation limiting juvenile transfer to adult court, allowing for judicial review for all juvenile cases and adding juvenile sentencing provisions to convictions in adult court. In the 5 years after this legislation, Colorado saw a 78% reduction in direct file cases and a 99% reduction in adult jailing of juveniles.[124]

Life Without Parole and Death Penalty

Over the last 15 years, the US Supreme Court issued several decisions limiting extreme sentences for juvenile offenders declaring unconstitutional capital punishment of individuals who committed crimes as a juvenile (under age 18)[125] and abolishing mandatory life without parole sentences for crimes committed as a juvenile; however, it is still permissible to impose life without parole sentences for juveniles after judicial consideration of individual case circumstances.[126] The United States is the only country in the world that sentences juveniles to life without the possibility of parole.[127] Extensive advocacy efforts, including litigation, media campaigns, and legislative advocacy are underway with goals of abolishing juvenile sentences of life without parole in the United States.[128]

Minimum Age of Juvenile Court Jurisdiction

The minimum age of juvenile court jurisdiction is the youngest age at which a child may be referred to a juvenile court for a delinquent act. At the time this policy was written, only 21 states had a minimum age standard, varying from 6 to 11 years of age.[129] In 2017, approximately 29 779 children younger than 12 years were referred to juvenile court, and 3375 were held in detention.[130] Article 40 of the United Nations Convention on the Rights of the Child decrees governments establish "a minimum age below which children shall be presumed not to have the capacity to infringe the penal law"[131] and specified that this age be no younger than 12 years.[132] Many advocates have called for the establishment of state and/or federal laws that set the minimum age of criminal responsibility at no younger than 12 years.[133]

Fines and Fees in the Juvenile Justice System

Juvenile courts throughout the country regularly impose costs that may include court costs, fees for a public defender, probation supervision fees, child support to the state, cost of Global Positioning System monitoring, cost for participation in diversion programs, health care costs, and fines.[134] Low socioeconomic status is a well-established risk factor for involvement with the juvenile justice system, and imposition of such costs may place an undue burden on justice-involved youth and their families.[17] Furthermore, inability or failure to pay these costs may lead to significant consequences for justice-involved youth, including civil judgment, extension of probation, violation of probation, incarceration, suspension of driver's license, ineligibility for expungement, and imposition of additional fees.[135]

Access to Legal Representation

Children and adolescents accused of crimes have a constitutional right to legal counsel regardless of their ability to pay.[136] However, youth may encounter many barriers to obtaining adequate legal representation. An analysis by the National Juvenile Defender Center[137] found the following:

- only 11 states have a presumption that youth are automatically eligible for an attorney irrespective of financial status;
- no states guarantee lawyers for youth during interrogation; and
- 43 states allow youth to waive their right to a lawyer without first consulting a lawyer.

Youth without adequate access to legal representation throughout their involvement in the justice system may not fully understand their rights and may be influenced to make decisions that are not in their best interest. Recommendations made by the National Juvenile Defender Center[137] include making all youth eligible for a publicly funded juvenile defender, appointing youth a lawyer before interrogation and well in advance of the first court hearing, and prohibiting waiver of counsel until youth have the chance to consult with a lawyer.

Empowerment of Justice-Involved Youth

Decades of research have been conducted on risk factors for juvenile delinquency, protective factors, and outcomes for justice-involved youth; however, until recently, the voices of justice-involved youth have been largely absent from juvenile justice research and policy.[138] Justice-involved youth are the experts of their lived experience and have unique insight into the strengths and weaknesses of the juvenile justice system. Justice-involved youth have

demonstrated that when given the opportunity, they can provide both insight into the root causes of juvenile delinquency and offer recommendations for improvement of the juvenile justice system.[138,139]

RECOMMENDATIONS

The following recommendations are provided for caring and advocating for justice-involved youth and their families.

Delivery of Care

- Confined youth should receive the same level and standards of medical, oral, mental health, and substance use care as nonconfined youth accessing care in their communities. Pediatricians should ensure that confidential health care is practiced in accordance with state and local laws, even in correction health clinics.
- All juvenile correctional facilities should adopt and comply with the NCCHC's "Standards for Health Services in Juvenile Detention and Confinement Facilities."
- Facilities should provide youth who are confined for more than 1 week comprehensive preventive services, including a comprehensive history and physical examination; mental health and substance use screening; dental screening; vision screening; pregnancy screening with options counseling; the full range of contraception, including emergency contraception; vaccines; STI and/or HIV testing; adequate pregnancy care; and management of chronic health conditions. Care should be affirming and appropriate for all youth, including those who identify as LGBTQ.
- Consistent with NCCHC recommendations, transgender youth who received hormone therapy before incarceration should have therapy continued without interruption, absent urgent medical reasons to cease treatment.
- All juvenile facilities should implement a comprehensive suicide prevention program that includes ongoing suicide risk assessment.
- Whenever possible, the pediatrician from the medical home should be notified when an adolescent is admitted and discharged from a detention facility. In cases in which confined youth do not have a pediatrician, efforts should be made to establish care in a medical home.
- Strict limits should be placed on the use of restraints for pregnant and hospitalized adolescents.
- Incarcerated youth should maintain eligibility for their existing health insurance benefits. If insurance eligibility is terminated or suspended during confinement, it should be reinstated before release. Eligible uninsured youth should be enrolled in Medicaid while incarcerated.
- Legislation repealing the Medicaid inmate exclusion policy should be supported, thus allowing Medicaid coverage for incarcerated children and adolescents.

Developmentally Appropriate Confinement Facilities

- Children and adolescents should be detained or incarcerated only in facilities with developmentally appropriate programs with staff who are trained to deal with their unique mental health, social, educational, recreational, and supervisory needs and should not be detained in adult facilities.
- Detention facilities and juvenile justice systems should implement a trauma-informed approach that responds to the needs of justice-involved youth and their families.
- Consistent with recommendations of the US Department of Education and Department of Justice, education in confinement facilities should be provided in "a safe, healthy facility-wide climate that prioritizes education, provides the conditions for learning, and encourages the necessary behavioral and social support services that address the individual needs of all youths, including those with disabilities and English learners."[114]
- Use of isolation and solitary confinement for children and adolescents should be prohibited.
- Because of documented cases of systemic and recurring maltreatment of confined youth, jurisdictions should establish independent oversight entities for youth confinement facilities.
- Confinement facilities should recognize and respond to the unique needs of justice-involved female youth, LGBTQ youth, and youth with chronic medical, mental health, and developmental needs.

Advocacy and Juvenile Justice Reform

Many opportunities exist for pediatricians to advocate for juvenile justice reform. Pediatricians can work with the AAP chapter in their state, justice-involved youth and their families, the juvenile justice sections of their state judiciary and bar, state and local governmental officials, detention facilities, and community organizations serving justice-involved youth. Although key issues may vary between jurisdictions, priority targets for juvenile justice reform may include the following recommendations:

- Incarceration of adolescents is a last resort and only for offenders who have committed serious crimes and cannot be safely placed in a community-based program.
- Support research and advocacy efforts aimed at eliminating racial and ethnic disparities within the justice system. Research and

advocacy efforts should include an examination of racial and/or ethnic bias throughout the justice system and focus on delinquency prevention by mitigating the impact of interpersonal and structural racism.

- Support legislation that establishes a minimum age of (at least) 12 years for criminal responsibility under which a person may not be charged with a crime.
- Support legislation abolishing sentencing of adolescents to life without the possibility of parole.
- Support legislation reducing and/or eliminating the imposition of fees and fines for justice-involved youth and their families.
- Support legislation ensuring all justice-involved youth receive adequate and timely legal representation.
- Advocate for adolescents to be prosecuted in the juvenile justice system. Transfer to the adult court should occur only after judicial review. A youth's mental health status and exposure to trauma, adversity, and ACEs should be considered as mitigating factors.
- Advocate for research to identify risk factors for involvement with the justice system, protective factors, outcomes for incarcerated youth, and effectiveness of community-based alternatives to incarceration and use resulting data to make evidence-based juvenile justice policy reforms.
- Engage justice-involved youth and families as advocates for juvenile delinquency prevention and juvenile justice reform.

Barrier Protection Use by Adolescents During Sexual Activity

- *Policy Statement*

POLICY STATEMENT Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

American Academy of Pediatrics

DEDICATED TO THE HEALTH OF ALL CHILDREN®

Barrier Protection Use by Adolescents During Sexual Activity

Laura K. Grubb, MD, MPH, FAAP, COMMITTEE ON ADOLESCENCE

abstract

Rates of sexual activity, pregnancies, and births among adolescents have continued to decline during the past decade to historic lows. Despite these positive trends, many adolescents remain at risk for unintended pregnancy and sexually transmitted infections (STIs). When used consistently and correctly, latex and synthetic barrier methods reduce the risk of many STIs, including HIV, and pregnancy. This update of the 2013 policy statement is intended to assist pediatricians in understanding and supporting the use of barrier methods by their patients to prevent unintended pregnancies and STIs and address obstacles to their use.

Departments of Pediatrics and Public Health and Community Medicine, Floating Hospital for Children at Tufts Medical Center, Boston, Massachusetts

Policy statements from the American Academy of Pediatrics benefit from expertise and resources of liaisons and internal (AAP) and external reviewers. However, policy statements from the American Academy of Pediatrics may not reflect the views of the liaisons or the organizations or government agencies that they represent.

Dr Grubb, along with the Committee on Adolescence, researched, conceived of, designed, analyzed and interpreted data for, drafted, and revised this policy statement and approved the final manuscript as submitted.

The guidance in this statement does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

All policy statements from the American Academy of Pediatrics automatically expire 5 years after publication unless reaffirmed, revised, or retired at or before that time.

The Society for Adolescent Health and Medicine has endorsed this policy statement.

INTRODUCTION

This policy statement updates the 2013 American Academy of Pediatrics (AAP) statement on condom use.[1] Sexually transmitted infections (STIs), including new HIV infections, and unintended pregnancies among adolescents remain significant public health problems. Although abstinence from sexual activity is the most effective way to reduce pregnancy and STIs, it is important for young people to be prepared for the time when they will become sexually active. The prevention of STIs in adolescents involves abstinence or safer sexual practices by those who are not abstinent. The accompanying technical report[2] provides new information concerning adolescent pregnancy, STIs and HIV, and minority youth to emphasize the need for comprehensive barrier method counseling and education for all youth, regardless of stated sexual orientation, behaviors, gender, or intellectual and/or physical differences. For this statement, the age range for adolescent visits, as defined in the AAP's *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents, Fourth Edition*, is 11 to 21 years of age.[3] Detailed information forming the basis of the recommendations in this policy statement is found in the technical report.[2]

BARRIER METHODS

Preventing HIV, STIs, or pregnancy involves more than traditional condoms, and sexual practices of adolescents consist of more than penile-

vaginal penetration. Therefore, this policy statement has been expanded to include all barrier methods and multiple types of sexual activity.[4] Adolescents and young adults may use a variety of barrier methods to reduce the transmission of STIs or prevent pregnancy by reducing or preventing the transmission of bodily fluids, skin-to-skin contact, or skin-to-mucous membrane contact. The external condom, commonly known as the male condom, is a latex, synthetic, or natural material shield designed to fit over the male penis and is available over the counter. The internal condom (formerly the female condom) is a loose-fitting polyurethane (nitrile) sheath with 2 flexible polyurethane rings and is the only US Food and Drug Administration–approved nonpenile barrier method for STI prevention currently available in the United States. Users may place it inside the anus, vagina, or mouth. The internal condom is only available in the United States with a prescription. Another over the counter barrier method is a dental dam, or a latex, synthetic (nitrile or polyurethane) sheet (usually square shaped) that users may place over the penis, vulva, vagina, mouth, anus, or any part of the body. Although not evidence based or advised, adolescents may also improvise using plastic wrap or plastic bags to act as barriers.

THE ROLE OF PEDIATRICIANS IN PROMOTING SAFER SEX AND BARRIER METHOD USE

Pediatricians are encouraged to address adolescent sexual and reproductive health on a routine basis, including with youth who have developmental or physical disabilities,[5,6] by taking a sexual history, discussing healthy sexuality, performing an appropriate examination, providing patient-centered and age-appropriate anticipatory guidance, and delivering appropriate screenings and vaccinations.[7] The HEADSS (home, education and employment, activities, drugs, sexuality, and suicide and depression) interview provides an excellent structure for discussing a variety of issues that may affect sexual health and barrier use.[8] Key AAP publications provide a framework to assist pediatricians in incorporating various aspects of sexual and reproductive health care into their practices and provide guidance on overcoming obstacles to delivering this care routinely while maximizing opportunities for confidential health services delivery in their offices.[9,10] The AAP Adolescent Sexual Health Web site also provides significant resources (https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/adolescent-sexual-health/Pages/Assessing-the-Adolescent-Patient.aspx).

Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents, Fourth Edition, outlines how pediatricians and other providers can support parents and adolescents in promoting healthy sexual development and sexuality, including discussion of the use of barrier methods to protect against STIs, including HIV.[9] Multiple studies reviewed in the technical report[2] suggest increased efforts are needed by pediatricians, educators, and those in public health to encourage parents to talk about these issues. The implication for pediatricians is that providing parents with accurate information about adolescent sexual behavior, risks, and use and effectiveness of barrier methods can improve communication with their adolescents.

Pediatricians and other physicians may provide barrier education and free barrier methods within their offices and support efforts to increase availability within their communities. The World Health Organization offers instructions on proper external barrier method use (Table 1).[11] Table 2 provides a list of resources for pediatricians. In addition, the District of Columbia and the state of New York have condom distribution programs that may serve as models for health care providers and organizations.[12,13] Many states have Web sites that offer free mail delivery of barrier methods (Table 2).[14] Most

TABLE 1 World Health Organization Instructions for Proper Barrier Method Use

Use a new barrier method for each act of sexual intercourse.
Open the package carefully so the barrier does not tear.
Before any genital contact, place the condom on the tip of the erect penis with the rolled side out. Do not unroll the condom before putting it on. If not circumcised, pull the foreskin back. Squeeze the tip of the condom and put it on the end of the hard penis. Unroll the condom all the way to the base of the erect penis.
Always put the barrier on before entering partner or before genital, oral, or anal contact with partner.
Immediately after ejaculation, hold the rim of the condom and withdraw the penis while it is still erect (before it gets soft). Slide the condom off without spilling the liquid (semen) inside. Throw away or bury the used barrier or condom safely.
Do not use grease, oils, lotions, or petroleum jelly (Vaseline) to make barrier methods slippery. Only use a lubricant that does not have oil in it.[a]
Only use a barrier method once.
Store barrier methods in a cool, dry place.
Do not use barrier methods that are expired.

local or state public health departments offer low-cost or free barrier programs that pediatricians may contact for assistance. Additionally, to enhance safer sex and proper barrier usage, it is important for adolescents to receive comprehensive, evidence-based, medically accurate sexual education that includes barrier method instruction.

The AAP has published a policy statement on refusal to provide information or treatment based on claims conscience.[15] According to the policy, pediatricians and physicians have a duty to inform their patients about relevant, legally available treatment options to which they object and have a moral obligation to refer patients to other physicians who will provide and educate about those services.

CONCLUSIONS

When adolescents and young adults use barrier methods consistently and correctly, these methods are an excellent means to reduce the risk of many STIs, including HIV, and prevent pregnancy. Pediatricians are uniquely suited to provide screening and anticipatory guidance around sexual behaviors, prevention of adverse consequences, harm reduction, and availability and appropriate use of barrier methods. Pediatricians should advocate for increased education, availability, and reduced obstacles to barrier methods for adolescents in their practices and communities.

RECOMMENDATIONS

1. Discuss abstaining from sexual intercourse as the most effective way to prevent genital STIs, as well as HIV infection, and unintended pregnancy.
2. Support and encourage the consistent and correct use of barrier methods as well as other reliable contraception as part of anticipatory guidance during visits with adolescents who are sexually active or contemplating sexual activity, including emphasis on the responsibility of all genders in preventing unintended pregnancies and STIs.
3. Use the recommendations in *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents, Fourth Edition* promoting communication between parents and adolescents about healthy sexual development and sexuality and supporting education programs that help parents develop communications skills with their adolescents regarding the prevention of STIs and proper use of barrier methods.
4. Remove restrictions and obstacles to barrier method availability to encourage and promote barrier method use among adolescents. Beyond retail distribution of barrier methods, the provision of free or low-cost barrier methods is a priority for adolescent-friendly health services. Pediatricians and other clinicians are encouraged to provide barrier methods within their offices and support availability within their communities.
5. Advocate for barrier method availability programs through a collaborative community process and the provision of comprehensive sequential sexuality education. This is ideally part of a kindergarten-to-12th-grade health education program with parental involvement, counseling, coaching, and positive peer support.
6. Support school barrier method educational programs, especially because these programs reach large adolescent populations and may potentially provide a comprehensive array of related educational and health care resources.
7. Actively communicate to parents and communities that making barrier methods available to adolescents does not increase the onset or frequency of adolescent sexual activity and that use of barrier methods can help decrease rates of unintended pregnancy and acquisition of STIs.
8. Monitor adolescents who use preexposure prophylaxis or nonbarrier contraception, are bisexual or lesbian, and/or are in established relationships closely

for risk compensation (the adjustment of behavior in response to perceived level of risk) leading to decreased use of barrier methods. Pediatricians can assess risk during acute or routine visits to determine the need for additional counseling regarding barrier methods or STI testing. Engage and support additional research to identify strategies to increase continued barrier method use for populations that may engage in risk compensation.

9. Advocate for engagement and support of additional research regarding barrier use (and safer sex practices) for higher-risk youth and those living in areas with lack of access to barrier methods.

Barrier Protection Use by Adolescents During Sexual Activity

- *Technical Report*

TECHNICAL REPORT

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN®

Barrier Protection Use by Adolescents During Sexual Activity

Laura K. Grubb, MD, MPH, FAAP, COMMITTEE ON ADOLESCENCE

Rates of sexual activity, pregnancies, and births among adolescents have continued to decline during the past decade to historic lows. Despite these positive trends, many adolescents remain at risk for unintended pregnancy and sexually transmitted infections (STIs). This technical report discusses the new data and trends in adolescent sexual behavior and barrier protection use. Since 2017, STI rates have increased and use of barrier methods, specifically external condom use, has declined among adolescents and young adults. Interventions that increase availability of or accessibility to barrier methods are most efficacious when combined with additional individual, small-group, or community-level activities that include messages about safer sex. Continued research informs public health interventions for adolescents that increase the consistent and correct use of barrier methods and promote dual protection of barrier methods for STI prevention together with other effective methods of contraception.

TRENDS IN ADOLESCENT SEXUAL ACTIVITY AND CONSEQUENCES: THE AMERICAN ACADEMY OF PEDIATRICS BRIGHT FUTURES

Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents, Fourth Edition provides guidance for adolescent visits for ages 11 to 21 years, and in this report, we will provide information that includes this age range.[1] Despite recent data indicating sexual activity has declined among adolescents, the current rates of sexual activity and health consequences of sexually transmitted infections (STIs) and pregnancy indicate that these remain significant public health concerns. The Centers for Disease Control and Prevention (CDC), through its Youth Risk Behavior Surveillance System, reports sexual behaviors in a nationally representative sample of high school students surveyed biannually. In the most recently available Youth Risk Behavior Survey (YRBS) from 2017, 40% of high school students reported they had ever had sexual intercourse (defined as penile-vaginal penetration), 29% reported they were currently sexually active, and 10% had sexual intercourse with 4 or more partners in their lifetime.[2]

In 2017, the year for which the most recent data are available, 456 000 adolescent and young women younger than 20 years became pregnant; 448 000 of those pregnancies were among 15- to 19-year-olds, and 7400 were among those 14 years of age and younger.[3] In 2017, the US pregnancy rate among 15- to 19-year-olds was at its lowest point in at least 80 years[3]; however, the birth rate for US teenagers remains higher than that for other industrialized nations, with marked disparities by race and/or ethnicity and geographic area.[4]

New cases of STIs increased 31% in the United States from 2013 to 2017, with half of the 2.3 million new STIs reported each year among young people 15 to 24 years of age.[3,5,6] The CDC does not publish specific data on STI rates by modes of transmission. The rate of reported cases of chlamydia, gonorrhea, and syphilis increased for both sexes in both the adolescent (15–19 years of age) and young adult (20–24 years of age) age groups between 2012 and 2016. For chlamydia and gonorrhea, rates are consistently highest among adolescent and young women 15 to 24 years of age; however, the rate of reported chlamydia in male patients increased, whereas the rate in female patients decreased from 2012 to 2016.[3] Reported cases of syphilis have been consistently higher among adolescent and young adult men compared with women, and between 2012 and 2016, rates of reported syphilis cases increased substantially in both adolescent and young adult men and women.[6] Because trichomoniasis (*Trichomonas vaginalis* infection) is not a reportable disease, it is difficult to determine the prevalence among adolescents. In the United States, there are approximately 7 million new cases of trichomoniasis each year, and prevalence rates range from 3% in a nationally representative sample of women to 14% in adolescents.[7,8]

An estimated 50 900 youth had HIV infection in 2016, representing 4% of all people with HIV infection. Of those, an estimated 56% were aware of their infection, and people 15 to 24 years of age were the least likely to be aware of their infection compared with any other age group.[9] Young people (13–24 years of age) accounted for an estimated 21% of all new HIV diagnoses in the United States in 2018, totaling 7891 people, of whom 87% were natal male youth and 13% were natal female youth.[10] The CDC attributed 80% of new HIV diagnoses among youth to male-to-male sexual contact and 20% to other means (vaginal-penile sexual contact, intravenous drug use, dual male-to-male sexual contact, intravenous drug use, and other). Among young women who received an HIV diagnosis, the CDC attributed 85% of those infections to vaginal-penile contact and 15% to other transmission methods.[10] There is a paucity of data for transgender adolescents, but the results from the National HIV Surveillance System 2009–2014 revealed that youth 13 to 19 years of age accounted for 8% of new HIV diagnoses among transgender people.[10–12] The study also revealed that 25% of transgender women were living with HIV infection and that the percentage of transgender people who received a new HIV diagnosis was more than 3 times the national average in 2015.[13] In 2018, 1252 youth received a diagnosis of AIDS.[14]

In discussing barrier methods and risks, it is important to include information about youth living with HIV acquired through perinatal transmission (PHIV). The CDC does not report specific adolescent data, but at the end of 2016, 1814 children were living with PHIV, and 10 101 adults and adolescents (13 years of age and older) were living with PHIV.[15] Youth with HIV infection generally receive combination antiretroviral therapy (a combination of 3 or more drugs that stops the virus from making copies of itself in the body), and concern exists for extensive drug-resistant strains if these youth are not taking combination antiretroviral therapy consistently.[16] In a prospective cohort study of the reproductive health of sexually active female adolescents with PHIV, the cumulative incidence of pregnancy at 19 years of age was 21%, and incidence of STIs was 26%.[17,18] Several studies have revealed that adolescents with PHIV have higher rates of sexual activity, multiple partners, and unprotected penetrative intercourse compared with noninfected peers; more adolescents frequently tested positive for multidrug-resistant HIV and rarely disclosed their HIV status to partners.[19,20]

Adolescents with intellectual and physical disabilities are an overlooked group when it comes to sexual behavior, but they have similar rates of sexual behaviors when compared with their peers without disabilities.[20] These youth receive limited sexual education from their parents and pediatricians because many assume they will not engage in sexual behaviors.[21] The American Academy of Pediatrics clinical report "Sexuality of Children and Adolescents With Developmental Disabilities" provides additional information.[22]

This information concerning adolescent pregnancy, STIs and/or HIV, and minority youth is provided to emphasize the need for comprehensive barrier method counseling and education for all youth, regardless of stated sexual orientation, behaviors, gender, or intellectual and/or physical differences.

BARRIER METHOD USE

Recent Trends in Adolescent Barrier Method Use

The external condom remains the most popular contraceptive method

among adolescents. Most reported barrier method use data are for the external condom because there is a paucity of current available data for other barrier methods. The 2017 YRBS data refer to external condoms and vaginal-penile sexual activity.[23] Although overall sexual activity decreased among high school students, barrier method use (referred to as condom use in the YRBS) also declined among sexually active adolescents. Among sexually active high school students, 54% reported condom use during their last sexual encounter, a decline from 62% in 2007.[2] Among 12th-grade students, 57% reported ever being sexually active, but they had the lowest use of condoms among all grades.[23] The prevalence of having used a condom during the last sexual intercourse was higher among male than female students, and use rates were as follows: white male students, 62%; Black male students, 58%; Hispanic male students, 62%; white female students, 47%; Black female students, 46%; and Hispanic female students, 47%. Use rates declined with increasing grade level.[23] Among currently sexually active students, 56% of self-identified heterosexual students; 40% of self-identified gay, lesbian, and bisexual students; and 44% of questioning students used a condom during the last sexual intercourse.[23] The prevalence of having used a condom during the last sexual intercourse was higher among heterosexual (56%) than sexual-minority (40%) students. Among female students, the prevalence of having used a condom during the last sexual intercourse was higher among heterosexual students (50%) than lesbian and bisexual students (37%), and among male students, the prevalence was higher among heterosexual students (62%) than gay and bisexual students (53%). The prevalence of having used a condom at last sexual intercourse also was higher among heterosexual male students (62%) than heterosexual female students (50%).[23] In one study, approximately one-third of transgender female youth reported not using barrier methods consistently during receptive anal intercourse with casual and commercial partners; less than half consistently used them with a main partner.[24]

The National HIV Behavioral Surveillance interviewed individuals in 23 cities, and among HIV-negative males who have sex with males (MSM) 18 to 24 years of age, 10% reported having condomless vaginal sex with female partners, 3.5% reported having condomless anal sex with female partners (3.5%), and 73% reported having condomless anal sex with male partners. Among HIV-positive MSM, 7% reported having condomless vaginal sex with female partners, 3% reported having condomless anal sex with female partners, and 74% reported having condomless anal sex with male partners.[25] Rates of actual barrier method use in surveys also may be lower than reported because of the uncertain or questionable validity of self-report of this and other sexual behaviors that are prone to bias. For example, in a clinic-based sample of Black female participants 15 to 21 years of age in Atlanta, Georgia, 186 young women reported 100% condom use via an audio computer-assisted self-interviewing technique.[26] In these young women, 34% had a positive biological marker for unprotected vaginal sex (a Y chromosome polymerase chain reaction assay) in the past 14 days. As a possible explanation of these findings, participants may have used condoms inconsistently or incorrectly, or youth might have provided socially desirable answers.

The rate of barrier method use is significantly less for oral intercourse. Using data collected from 3816 cisgender female participants and 3520 cisgender male participants in the 2011–2015 National Survey of Family Growth, the authors found, for adolescents and young adults 15 to 24 years of age, that 58% of male participants and female participants reported having at least 1 oral opposite-sex partner in the last 12 months. Condom use at the last oral sex was 8% for female participants and 9% for male participants. Black male participants (adjusted odds ratio [aOR] 3.46), Black female participants (aOR 2.65), and female participants of other races and/or ethnicities (aOR 2.40) were more likely to use a condom at the last oral sex. Women 20 to 24 years of age (aOR 0.31), women whose mothers had a college education or more (aOR 0.43), and men and women who reported no intercourse experience were less likely to use a condom at the last oral sex (aORs 0.46 and 0.20, respectively).[27]

Factors That Influence Barrier Method Use

Several factors, including individual, family, cultural, sociodemographic, attitude, education, relationship, and partner-related factors, influence barrier method use[28] (Table 1). In the most current national study of male adolescents,[29] factors associated with greater consistency of barrier method use included Black race or ethnicity, more positive attitudes toward barrier methods, and more discussion of health topics with parents. Adolescents who did not have formal sex education were half as likely to use a barrier method at first intercourse and even less likely to use barrier methods consistently. A lower rate of barrier method use at first sexual intercourse was associated with older age, an older or casual first sexual partner, and a partner using another method of contraception. These factors were also associated with a lower rate of barrier method use at last sex, except for having a casual sexual partner, which was associated with a higher rate of barrier method use.[29] In a large study of rural adolescents,[30] authors found

TABLE 1 Factors Influencing Barrier Use Among Adolescents

Personal Factors	Environmental Factors	Behavioral Factors
Age	Parental communication	Barrier method use history
Barriers	Perceived social support	Sexual history
Sex	Social norms	Substance use
Goals		
Knowledge		
Personal standards		
Self-efficacy		
Self-esteem		
Worry		

that sexually active students who used barrier methods had significantly higher levels of knowledge about sexual risk, self-esteem, personal standards for barrier method use, self-efficacy (an individual's belief in his or her capacity to execute behaviors necessary to produce specific performance attainments) for barrier method use, self-efficacy for partner communication, self-efficacy for refusal of unwanted intercourse, barrier method use goals, and perceived norms and lower levels of worry about pregnancy compared with students who did not use barrier methods. Adolescents using barrier methods reported significantly higher levels of perceived support from their family, and the perceived level of support received from friends or from significant others did not differ between those who used barrier methods and those who did not.[30]

Relationship factors play an important role in barrier method use among adolescents. In the Toronto Relationship Study,[31] authors found that negative relationship dynamics (conflict, control, mistrust, jealousy, perceived partner inferiority) and positive qualities (love, enmeshment, salience, self-disclosure) were associated with consistent barrier method use. Teenagers who scored highly on both positive and negative qualities had the least consistent barrier method use. Conversely, teenagers in relationships with low positive and negative qualities had the most consistent barrier method use. Relationship duration was negatively associated with consistent barrier method use.[31] Another study revealed higher rates of barrier method use in youth who perceived their partners as wanting to use barrier methods and in those able to communicate their desire to use barrier methods with their partners.[32] Lack of barrier method use by adolescents is also associated with perceptions that barrier methods reduce sexual pleasure and/or that partners disapprove of barrier method use. This perception was supported by one large study that revealed that perceptions about how barrier methods reduce sexual pleasure were more strongly associated with not using a barrier method.[33] Other factors associated with increased barrier method use include receiving comprehensive sex and HIV education programs,[34] attending schools where barrier methods are available,[35,36] and perceived risk of getting STIs.[34]

In several studies, authors have examined the role of parent-adolescent communication about sexual risk and the association with increased adolescent use of barrier methods.[37–39] Parental communication about sexual risk and barrier method use is associated with increases in adolescents' use of barrier methods, especially at first intercourse. Timing of the discussion is important; in one study, the highest rates of barrier method use at first and last sex, as well as for regular use, were found among adolescent girls who communicated with their mothers about barrier method use before onset of sexual activity, as compared with after initiation.[40] In the most recent longitudinal study of parents and their children regarding the timing of parent and child communication about sexual behaviors, more than 40% of the children had intercourse before there were discussions about STI symptoms, barrier method use, birth control, or partner barrier method refusal.[41,42]

In a randomized clinical trial of Hispanic and Black mother-adolescent (11–14 years of age) dyads, mothers waiting in a pediatric clinic received a parent-based intervention. The intervention group demonstrated significantly reduced rates of transitioning to sexual activity and frequency of sexual intercourse, with decreases in oral sex nearly reaching statistical significance ($P < .054$), compared with controls. Specifically, sexual activity increased from 6% to 22% for adolescents in the standard of care control condition, although it remained at 6% among adolescents in the intervention condition at the 9-month follow-up.[42] The media also may influence adolescent sexual behavior.[43,44] Exposure to sexual content in music, movies, magazines, television, and the Internet may play an important role in adolescent sexual activity. Despite the increasingly sexually explicit material in media and programming, there are rare messages promoting responsible sexual activity, such as contraception use (including condom use).[35] In primetime television, 77% of programs have sexual content, but only 14% reference risks or responsibility of sexual behavior.[44]

Substance use also affects sexual behavior and barrier use. In studies of young adult and adolescent sexual behavior after use of alcohol, marijuana, or other illicit substances (including nonmedical use of

prescription drugs), authors found associated increases in risky sexual behavior and lower rates of barrier protection use.[45–47]

Barrier availability may significantly affect use among adolescents. External condoms, dental dams, and barrier sheets are available over the counter in all states but may still be difficult for adolescents to access. Many stores stock condoms in physically inaccessible places that require a store attendant to assist the customer.[48] Barrier methods can be expensive, and private insurance does not pay for them, but some states' Medicaid plans do.[49] Barrier methods are less available in poorer neighborhoods,[50] rural areas, American Indian or Alaska Native communities,[51,52] and certain faith-based communities or colleges or universities.[53]

Sexual-minority youth may have different patterns of barrier use, but there are limited data on their habits. Sexual-minority youth may not use barriers during sexual activity for similar reasons as their heteronormative peers, but they often have unique explanations. In a study of women who have sex with women (40% of participants were 24 years of age or younger), the percentage of women who reported never using barrier protection was significantly higher among those in monogamous relationships than among those in nonmonogamous relationships (78.6% vs 27.4%, respectively; $P < .01$).[54] Women who reported always using barrier protection were significantly more likely to be in nonmonogamous than monogamous relationships (14.3% vs 3.5%, respectively; $P < .01$). Of note, 27.7% of nonmonogamous women reported using barrier protection with their secondary partners only. Overall, most of the study population (83%–88%) reported never using barrier protection when performing and receiving digital sex or when performing and receiving oral sex. Barrier use was slightly more prevalent in the context of genital stimulation with a sex toy, with 62.1% and 63.4% of respondents reporting that they never used barrier protection when performing and receiving this type of stimulation, respectively.[54]

In a qualitative study of lesbian and bisexual female participants 14 to 18 years of age, reasons participants did not use latex barriers (external condom or dental dam) during sex with female partners included pleasure, risk perception based on sex of sexual partner, lack of knowledge of sexual risk or of barrier use for female-to-female sexual activities, and use of STI testing as a prevention tool.[55] One 17-year-old girl shared, "they [other girls] probably don't think [about barriers] since condoms are seen as a way to prevent pregnancy, and when two girls have sex they can't get pregnant so we forget that there's still a chance of STDs." Additionally, participants cited greater trust with female partners, no concern for pregnancy, lack of awareness of importance, and lack of inclusive sexuality education.

Among MSM, there are a variety of reasons for barrier use behaviors. In a survey of adolescent MSM,[56] most received sexual education from parents and school, but they lacked information on specific or explicit information concerning male-to-male sexual activity (eg, types of male-to-male sex, how to safely and comfortably have anal sex). For MSM, relationship to partner correlates with condom use. For HIV-negative MSM 18 to 24 years of age, 52% reported condomless anal sex with a main male partner, compared with 44% with casual male partners. In the same survey, 55% of HIV-positive MSM reported condomless anal sex with a main partner, compared with 41% with a casual partner.[25] In a large Internet study of adolescent MSM, participants reported increased likelihood of condom use with casual partners and first-time partners and associated higher perceived pleasure with condom use.[57] Participants' condom use was less likely if their partners did not ejaculate, when they had sex in a location other than a residence, or with higher levels of preintercourse arousal or erection difficulty. In a study of Black MSM, authors found that participants used perceived masculinity of potential partners to assess HIV-related risk, in which masculine men were presumed low risk and effeminate men were presumed high risk, thus contributing to condom use behavior.[58]

Dual Protection

Nonbarrier contraceptive methods offer pregnancy protection but no protection against STIs. Dual-method use, the use of barriers in combination with other contraceptive methods to protect against STIs and unwanted pregnancy, is the ideal contraceptive practice for adolescents. The 2017 YRBS revealed that 9% of all male and female high school students reported dual contraceptive use (defined as external condom use with another contraceptive method) with the last intercourse.[23] The overall percentage of dual usage increased with age, up to 10% among 12th-graders, and was highest among white (12%), Black (6%), and Hispanic (4%) students. Studies have revealed beliefs that positively correlate with dual contraceptive use, including perceived benefits of protected sex, positive attitudes about birth control, and higher perceived risk of STI and pregnancy consequences.[59] Additionally, predictors of dual-method use are similar to predictors of adolescent barrier use (Table 1). Younger age at first coitus, older partner age, history of sexual abuse, lower self-esteem, and obesity are predictive of inconsistent use and nonuse of barrier methods. Longer relationship duration is also predictive of lower barrier-only or

dual-method use but not of overall contraceptive use, even after controlling for age.[60] Adolescents with main and regular partners tend to discontinue use of barriers quickly, especially if they are using other pregnancy prevention methods.

Because adolescents have increased their use of long-acting reversible contraceptive (LARC) methods, there are concerns about their effects on adolescent use of barrier protection. LARCs are considered the best form of contraception for adolescents wishing to avoid pregnancy, but they offer no protection against STIs. An analysis of YRBS cross-sectional data revealed that among 2288 sexually active female participants, 2% used LARCs; 6% used depot medroxyprogesterone acetate injection, the ethinyl estradiol and norelgestromin patch, or the etonogestrel and ethinyl estradiol vaginal ring; 22% used oral contraceptives; 41% used condoms; 12% used withdrawal or another method; 16% used no contraceptive method; and 2% were not sure.[61] LARC users were approximately 60% less likely to use barriers compared with oral contraceptive users. Authors did not find significant differences in condom use between LARC users and depot injection, patch, or ring users, but LARC users were more than twice as likely to have 2 or more recent sexual partners compared with oral contraceptive, depot injection, patch, or ring users.[61] In a secondary analysis of the Contraceptive Choice Project, authors found that LARC use was associated with increased acquisition of an STI within the first 12 months after placement compared with no use of LARCs.[62] These findings suggest that adolescents using other contraceptive methods besides barriers may be engaging in risk compensation, the adjustment of behavior in response to perceived level of risk.

Preexposure Prophylactic Therapy and Barrier Use

For individuals at increased risk for HIV acquisition (sexually active MSM, individuals with an HIV-positive partner, those engaging in anal intercourse, those engaging in frequent sex without a barrier, or those with a high number of sexual partners), the CDC recommends preexposure prophylaxis (PrEP) to reduce HIV acquisition and transmission.[63] The US Food and Drug Administration (FDA) has approved both emtricitabine and tenofovir disoproxil fumarate and emtricitabine and tenofovir alafenamide for PrEP in adults and adolescents who weigh at least 35 kg.[64] The CDC Web site provides HIV risk behavior assessment, PrEP clinical practice guidelines, patient and provider education, and tool kits.[65–68] PrEP can reduce the risk of HIV acquisition by 90% when people use it consistently. With the increase in PrEP use, researchers have documented significant declines in barrier use[69–71] and increases in STIs among MSM (cisgender males and transgender females), suggesting that PrEP users may be engaging in risk compensation.

EFFECTIVENESS OF BARRIER METHOD USE

Most studies of barrier method effectiveness involve external condoms. External condoms consist of 3 types of materials: most (>80%) are latex (natural rubber), a small percentage (less than 5%) are natural membrane (lamb cecum), and approximately 15% are synthetic (eg, polyurethane).[72] The CDC only recommends latex and synthetic condoms for prevention of STIs and HIV because natural-membrane condoms contain small pores that may allow for passage of viruses, including HIV, hepatitis B virus, and herpes simplex virus.[73] In a recent Cochrane review, authors concluded that nonlatex synthetic condoms were linked with higher rates of clinical breakage than their latex counterparts.[74] The synthetic (AT-10 resin, polyisoprene, polyethylene, or polyurethane) condoms still provide an acceptable alternative for individuals with allergies, sensitivities, or preferences that might prevent the consistent use of latex condoms. The polyurethane condom is not as effective as the latex external condom for pregnancy prevention.[75] Synthetic barrier methods are compatible with both oil- and water-based lubricants, and although not extensively studied, synthetic external condoms are believed to provide STI protection similar to external latex condoms; however, FDA labeling currently restricts their recommended use to latex-sensitive or latex-allergic people.[76] In the United States, the FDA regulates external condoms and barrier methods (dental dams) marketed to prevent STIs as medical devices, and stringent manufacturing standards exist to ensure testing of each barrier for holes or weak spots before sale.[77,78]

External condoms can be effective against unintended pregnancy when used consistently and correctly. External condom failure rates have declined significantly since 1995, from 18% to 13% with typical use, according to the National Survey of Family Growth (2006–2010).[79] Researchers estimate that the failure rate of the external condom for pregnancy is 2% in 12 months of perfect use (ie, 2 pregnancies per 100 woman-years).[79] The most important noncontraceptive benefit of external condom use is the additional protection against acquisition and transmission of STIs, including HIV. If the user places the external condom on the penis before genital, oral, anal, or skin contact and uses it throughout activity, this should prevent contact with semen, vaginal secretions,

saliva, blood, skin and mucosal lesions, and infectious secretions. External condoms greatly reduce the risk of STI transmission to or from the penile urethra, including gonorrhea, chlamydia, trichomoniasis, hepatitis B virus, and HIV.[80–88] Barrier methods also provide protection against STIs transmitted via skin-to-skin contact or contact with mucosal surfaces in those covered areas, including genital herpes simplex virus, human papillomavirus, syphilis, and chancroid; all published studies refer to the external condom.[89–91] The latex condom effectively blocked passage of the smallest sexually transmitted pathogen, hepatitis B virus, according to in vitro studies.[91] In most studies on external condom effectiveness, vaginal-penile sexual activity is evaluated. Adolescents can also use either a latex or synthetic barrier during anogenital and orogenital intercourse to reduce the risk of STIs.

Well-designed epidemiological studies and those of couples with discordant HIV infection status have revealed that external condoms are highly effective against transmission of HIV. Researchers conducted a meta-analysis of studies comparing seroconversion rates among couples who regularly used external condoms and those who used them inconsistently to determine their use and/or effectiveness in preventing HIV transmission. Results of the analysis revealed that external condoms were 90% to 95% effective in preventing HIV transmission when opposite- and same-sex partners used them consistently.[80]

Given the coital-dependent nature of barrier methods, the degrees of consistency and correctness of use influence effectiveness against both unintended pregnancy and STIs. Factors associated with decreased effectiveness include failure to use a barrier with every act of intercourse, incomplete use (late application and early removal), improper use, barrier breakage and slippage, not using a new barrier when switching from one form of sex to another, barrier method–associated erection problems (either during application or during intercourse), and problems with the fit or feel of barriers, including problems related to the size or shape of the barrier or discomfort or interference with sensation.[92,93]

The internal condom (formerly female condom) is a loose-fitting polyurethane (nitrile) sheath with 2 flexible polyurethane rings and is the only FDA-approved nonpenile barrier method for STI prevention currently available in the United States.[94] The FDA regulates the internal condom as a level III product, on par with medical devices such as pacemakers, thus making manufacturing and distribution more challenging in the United States. The FDA approved the original device (brand name FC1) in 1993 and the revised product (brand name FC2) in 2009. In September 2018, the FDA petitioned to reclassify the female condom as a level II device and renamed it the internal condom.[95] This proposed change would increase access to internal barrier methods in the United States and broaden use, especially when it comes to the lesbian, gay, bisexual, transgender, and questioning community, because an increasing number of people have begun to use this method for nonvaginal intercourse. The FC2 device is the only internal condom available in the United States. Recently, the FC2 manufacturer, Veru, decided to take the FC2 off of pharmacy shelves and make it available exclusively through prescription with the rationale that by doing so, they would ensure that women with health insurance can access them free of charge under the Patient Protection and Affordable Care Act's mandate for contraceptive coverage.[96] There are no published data on the effects of this change.

Data regarding contraceptive effectiveness of FC1 internal condoms suggest that estimated rates of pregnancy during the first 12 months of perfect use and typical use are 5% and 21% respectively; these pregnancy rates are slightly higher than those of the external condom. Although available data suggest that internal condoms may provide similar degrees of protection against pregnancy and STIs as do latex external male condoms alone, this conclusion has not been demonstrated, and thus comparative research is needed.[61] Overall internal condom use accounts for less than 1% of US barrier use overall.[97]

Adolescents may also use dental dams, latex sheets, or improvised barriers to protect against STIs and pregnancy. Published data on the effectiveness of these barrier methods are unavailable, but the CDC does provide proper-use information on its Web site.[98]

EFFORTS AIMED AT INCREASING BARRIER METHOD USE

In a review of the literature, authors found contradicting evidence on the effectiveness of community- and behavioral-level barrier method promotion programs, highlighting the need for further evaluation of program effectiveness.[63,64,99,100] One large-scale review revealed concern that these programs might hasten the initiation of sex, but this concern appears unfounded.[65] In the 52 studies measuring timing of initiation of sex, 42% found that sexual initiation was significantly delayed for at least 6 months after participation in such a program, and 55% found no effect. There are few programs promoting enhanced sexual pleasure as a motivating factor, which

has led to increased uptake of barrier methods and safer sex behaviors.[101–103]

In 2017, the Society for Adolescent Health and Medicine published a position statement, "Condom Availability in Schools: A Practical Approach to the Prevention of Sexually Transmitted Infection/HIV and Unintended Pregnancy," recommending increased barrier method availability at schools.[35] The evidence on the impact of availability of barrier methods in schools is inconsistent.[104–107] In the most recent study of programs in Massachusetts high schools, adolescents attending schools where barrier methods were available were more likely to receive barrier method use instruction and less likely to report lifetime or recent sexual intercourse, and adolescents who were sexually active were twice as likely to use barrier methods at the most recent sexual encounter.[108] Studies have revealed that school condom programs do not increase sexual activity, the number of sexual partners, or risk behaviors.[109,110]

Likewise, clinic-based interventions have been effective in increasing barrier method use and decreasing STIs.[111,112] The CDC publishes a summary: "Compendium of Evidence-Based Interventions and Best Practices for HIV Prevention."[113]

In a recent meta-analysis of high-quality US and international studies of structural-level barrier method distribution interventions, authors found significant effects on increased barrier method use, increased barrier method acquisition, increased barrier method carrying, delayed sexual initiation of youth, and reduced incidence of STIs.[114] The interventions that increase availability of or accessibility to barrier methods are most efficacious when combined with additional individual, small-group, or community-level activities. The intervention effects were significant across target participant characteristics (youth, adults, commercial sex workers, STI clinic populations, or male participants). In a large systematic review of the literature, authors found that interventions using constructs of the information, motivation, and behavioral skills model were associated with significant increases in condom use or condom-use intentions.[115] Additionally, interventions that included modules to increase self-efficacy for condom use and that taught participants where to obtain condoms and how to negotiate condom use with partners or elicit positive associations (feelings) toward condoms were associated with increased condom use or intention to use condoms.

Social networks may promote barrier use as well. In a study of homeless youth, those who had a condom-using peers reported increased condom use and reduced risky behavior.[116] In a large review of network-based condom intervention strategies, authors of all studies reported substantial improvement in condom use for the intervention groups compared with the control groups.[117] Social media platforms also provide information and promote safer sexual practices, including barrier use.[118] Study authors reported small short-term gains in condom use or consumption but mixed long-term behavioral effectiveness.[117,119,120]

Availability of barrier methods in the pediatrician's office may reduce obstacles to use for adolescents, but a survey of primary care providers revealed that most do not distribute condoms in their practices.[121] Providers cited the following risks to distribution of condoms: potential for parent or caregiver disproval (66%), potential of upsetting or offending patients (28%), possibility of preventing adolescents from developing self-reliance (11%), and potential of promoting sexual activity (7%). Of those who did not distribute condoms, the most cited reasons included unsure and had not thought about it (45%), inconvenience (31%), and concern for parent or caregiver disproval (27%). Ninety percent of providers endorsed that they would or may be willing to consider office-based condom distribution if they had help with organizing and funding this service.

To enhance safer sex and proper barrier usage, it is important for adolescents to receive comprehensive, evidence-based, and medically accurate sexual education that includes barrier method instruction. A review of states' sexuality education programs revealed that 16 states require instruction on barrier methods or contraception with sexuality or HIV and/or STI education.[122] Additionally, adolescents need affordable access to barrier methods without discrimination or other barriers. Most barrier methods are sold over the counter in all 50 states and territories, but obstacles persist, including barriers displayed behind counters or in locked cabinets, store or pharmacy personnel refusing to sell to adolescents of certain ages, cost, and poor availability in some neighborhoods.

CONCLUSIONS

Recent trends in adolescent and young adult sexual behavior reveal that adolescents and young adults remain at risk for unintended pregnancies, STIs, and HIV. When adolescents and young adults use barrier methods consistently and correctly, these methods are excellent means to reduce the risk of many

STIs, including HIV, and prevent pregnancy.

Chemical-Biological Terrorism and Its Impact on Children

- *Policy Statement*

POLICY STATEMENT Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Chemical-Biological Terrorism and Its Impact on Children

Sarita Chung, MD, FAAP,[a] Carl R. Baum, MD, FACMT, FAAP,[b] Ann-Christine Nyquist, MD, MSPH, FAAP,[c] DISASTER PREPAREDNESS ADVISORY COUNCIL, COUNCIL ON ENVIRONMENTAL HEALTH, COMMITTEE ON INFECTIOUS DISEASES

abstract

Chemical and biological events (including infectious disease outbreaks) may affect children disproportionately, and the threat of a chemical or biological attack remains in the United States and worldwide. Although federal programs and funding support a broad range of federal initiatives for public health preparedness and response, funding at the state and local levels has been flat or is decreasing, potentially leaving communities vulnerable. Consequently, pediatricians need to prepare and be ready to care for children in their communities before, during, and after a chemical or biological event, including during long-term recovery. Some medical countermeasures for particular chemical and biological agents have not been adequately studied or approved for children. The American Academy of Pediatrics provides resources and education on disaster preparedness and response, including information on the pediatrician's role in disasters, pediatric medical countermeasures, and mental health after an event as well as individual and family preparedness. This policy statement addresses the steps that clinicians and policy makers can take to protect children and mitigate the effects of a chemical or biological attack.

INTRODUCTION

Children remain victims of chemical or biological terrorism; recent examples include the 2017–2018 chemical attacks by the Assad regime against civilians in Syria. Emerging biological outbreaks, such as the global 2013–2016 Ebola outbreaks originating in West Africa and the 2016–2018 Zika virus outbreak, offered opportunities to test response systems that would be needed in the case of biological terrorism. Consequently, pediatric health care providers, in collaboration with public health officials and emergency management personnel, must be prepared to respond to the needs of children before, during, and after a chemical or biological event. Pediatric health care providers can help by offering guidance to the local, state, and federal governmental and nongovernmental organizations that are charged with caring for children,

and they can be a valuable resource for first-responder training as well as community and hospital preparedness, response, and recovery. Involvement of pediatric health care providers in preparedness planning and training activities increases the likelihood that the needs of children will be considered and addressed.

STATEMENT OF THE PROBLEM

Pediatricians play a pivotal role in providing care in the medical home and supporting the community before, during, and after a chemical or biological event. To this end, pediatricians and their staff can proactively seek education and be prepared to promote and share information on readiness approaches, offer anticipatory guidance to families, report appearances of unusual disease clusters, and help guide families after events. The intent of this policy statement is to provide pediatricians and other professionals with an overview of the following:

1. children's vulnerabilities with respect to chemical and biological events;
2. chemical and biological agents of concern; and
3. roles of the pediatrician in the medical home and in collaboration with prehospital and hospital organizations and governmental agencies in preparation for, detection of, and response to chemical and biological events.

NEW INFORMATION

This revised policy statement and a new, accompanying technical report replace the 2006 policy statement "Chemical-Biological Terrorism and Its Impact on Children."

REVIEW OF EVIDENCE

Children's Vulnerabilities

Exposure to chemical and biological weapons may occur through a variety of routes, including airborne, waterborne, or foodborne routes. Compared with adults, children have greater risks of both exposure and harm because of key developmental, anatomic, and physiologic vulnerabilities. These risks include the following differences between children and adults: children inhale considerably more air on a per-kilogram basis; they breathe air from a breathing zone that is closer to the ground, where heavier-than-air substances concentrate; they have a proportionately greater body-surface area, which is important when it comes to agents that contact the skin; and they ingest considerably more fluid (particularly milk, which may be contaminated with chemicals, especially radioisotopes, or biological agents) and food on a per-kilogram basis.

Children are among those most at risk for psychological trauma and behavioral difficulties after chemical and biological terrorism. Children may suffer from a range of short- and long-term effects on their psychological functioning, emotional adjustment, and developmental trajectory. Persistent adjustment reactions can be anticipated in some children long after a chemical or biological event, particularly among those who have escaped countries where such attacks may have occurred, or even in children without direct exposure to these events. There may be a need for specific disaster plans in schools for these students. The American Academy of Pediatrics (AAP) offers recommendations for pediatricians and others to work with families to develop plans within its Family Readiness Kit[1] and the policy "Emergency Information Forms and Emergency Preparedness for Children With Special Health Care Needs."[2]

Agents of Concern

For the purposes of this policy statement, agents of concern (chemicals and biological agents that can be used in a terrorist attack) can be subdivided as follows: chemicals include nerve agents, blistering agents (vesicants), irritants (corrosives), choking agents, asphyxiants (cyanogens and carbon monoxide), and disabling (incapacitating) agents; biological agents include Centers for Disease Control and Prevention Category A agents (anthrax, botulism, plague, smallpox, tularemia, and the viral hemorrhagic fevers), which are considered the greatest public health threat. More details regarding these agents are in the accompanying technical report, "Chemical-Biological Terrorism and Its Impact on Children."[3]

Roles of the Pediatrician and Other Health Care Professionals

Comprehensive resources regarding presentation and management of illnesses due to chemical and biological agents are now accessible in different formats, such as apps or Web sites optimized for mobile devices, and have been developed to allow for just-in-time use in a disaster. The AAP continues to develop resources, including the accompanying technical report, to help all health care professionals to understand the needs of children in a disaster and provide specific guidance for chemical and biological threats. Additional information is provided in the AAP resource "Pediatric Disaster Preparedness and Response Topical Collection" (www.aap.org/disasters/manual).[4]

Pediatricians and other primary care providers are uniquely positioned to advance disaster preparedness and response: in their ability to care directly for patients, they can provide wisdom "from the field," coordinating with disaster response and public health authorities to guide rational preparedness and response efforts at local (including child care programs and schools), state, and federal levels. Because they understand the different developmental stages of children, pediatric health care providers can provide input on

planning for pediatric evacuation, triage, surge, and family reunification after disasters. In addition, pediatric health care providers may be the first to recognize and diagnose psychological trauma and behavioral difficulties after an event.

In recent years, these authorities have shifted their efforts to an "all-hazards approach," which establishes a single integrated model of disaster response that can be equally effective for chemical and biological agents. In a disaster, health care providers must be ready to provide care outside of their usual scope of practice. In addition, health care providers may be the first to encounter or report an outbreak. Recent pediatric research has demonstrated that educational efforts increase health care professionals' knowledge and confidence, which may improve their participation during an actual event.[5,6]

Syndromic surveillance (detection of health indicators that precede diagnosis) potentially signals early stages of a chemical release or an infectious disease outbreak and may serve to minimize consequences. Reports of unusual presentations from pediatricians and other clinicians are critical, but additional methods may inform rapid epidemic detection.[7] These methods include data gathered from automated monitoring of hospital emergency department diagnoses or individual Internet searches to crowd sourcing of social media applications on mobile devices. The latter technique was used after the 2017 sarin attacks in Syria, when researchers reviewed videos uploaded by civilians who documented clinical symptoms and gaps in clinical care.[8]

Prehospital and Hospital Organizations

Care of pediatric patients is becoming more regionalized, and definitive pediatric hospital care is becoming less available in the community.[9] Although recommendations to improve pediatric readiness in hospital emergency departments are available,[10] pediatric interhospital transfers are increasing, and more definitive pediatric hospital care is becoming gradually dependent on referral centers.[7] In addition, given that in 2013 only 46.8% of US hospitals reported having a disaster plan that included pediatric considerations, the care of children during a local chemical or biological attack can be impeded or delayed, which may lead to poor outcomes.[11] Recent ventilator research, for example, shows that there are few types of devices that are capable of supporting the ventilation of children of all ages.[12]

Hospital preparedness for patients with highly contagious infectious diseases has improved since the 2013–2016 Ebola outbreaks in West Africa. Federal agencies have established a regional treatment network for Ebola and other special pathogens, increasing the capacity to care for such patients, particularly children.[13] Because of this experience, protocols for donning and doffing personal protective equipment have improved to better protect the safety of health care professionals.

Hospital readiness plans are most often developed to accommodate surge capacity, or increased numbers of pediatric patients. These may include, for example, the ability to create additional bed spaces through cohorting or rapid discharge of inpatients. Hospital policies need to recognize the developmental and psychological needs of children, especially those with special health care needs, and the importance of using age-appropriate equipment and supplies.[14,15] Hospitals will want to prepare in advance to be able to track children who arrive without identification or parents or guardians and have plans for immediate family reunification.[16] Exercises and drills are an important part of preparedness, and resources are available to address pediatric preparedness and promote pediatrician involvement.[4,17,18]

Personal Protective Equipment and Decontamination

After exposure to a chemical or biological weapon, children may become covered by toxic material that can be absorbed, ingested, or inhaled and produce systemic toxicity. Although chemical exposures may cause immediate symptoms, infectious exposures may have an incubation period. Regardless, if an exposure is known, victims will need to undergo immediate decontamination to remove the contaminant and prevent additional sequelae.[19] To prepare for decontamination events, involved health care professionals need to be trained to don personal protective equipment to prevent secondary exposures. The decontamination process for victims includes removal of clothing followed by dry decontamination (absorbent or adsorbent materials) or wet decontamination (cleansed with soap and water or showers). For pediatric victims, the shower water should be warmed to avoid hypothermia and used at lower pressure to prevent additional skin damage. In cold climates, heat lamps, blankets, and other mechanisms may be needed to prevent hypothermia. Additional principles of decontamination are covered in the accompanying technical report.[3]

Poison Control Centers

In the event of a terrorist attack, the national network of state and regional poison control centers (1-800-222-1222) may be the first point of contact for health care providers and members of the public. These poison centers, staffed by certified specialists in poison information and backed by medical toxicologists, can triage disaster calls to appropriate local, state, and federal agencies.

Governmental Agencies

After the September 11, 2001, terrorist attacks and subsequent anthrax releases, the federal government expanded its emergency preparedness efforts. These include the establishment of the Department of Homeland Security in 2002 and, within the Department of Health and Human Services (DHHS), the Office of the Assistant Secretary for Preparedness and Response, in 2006. Other Department of Homeland Security and DHHS agencies, including the Federal Emergency Management Agency, the Centers for Disease Control and Prevention, the Food and Drug Administration, and the National Institutes of Health, have been reorganized to accommodate chemical and biological preparedness and response.

Although there have been some advances in pediatric medical countermeasures (MCMs), significant gaps remain.[20] The US Strategic National Stockpile, a part of DHHS, is the largest supply of potentially life-saving pharmaceuticals and medical supplies and is designed to support citizens in response to disasters that overwhelm state and local resources. As of 2013, only 40% of the medications in the Strategic National Stockpile have been approved for use in the pediatric population.[21] There continue to be ongoing efforts at the federal level to ensure pediatric treatments for all chemical and biological threats. For medications that are not approved for pediatric patients, the Food and Drug Administration can issue an emergency use authorization or investigational new drug application for their use. If the medication falls under the investigational new drug application, additional consent would be needed, which could be challenging to explain to frightened parents and could present challenges to MCM mass-distribution efforts during a public health emergency. In addition, the absence of dedicated pediatric autoinjectors for medications such as atropine hampers the ability of first responders to provide immediate care to younger children. Ongoing research and development is needed to ensure that all MCMs can be used safely in children, with attention being paid to appropriate dosing, formulations, and devices (eg, autoinjectors).[5]

SUMMARY AND RECOMMENDATIONS

The AAP provides supplemental details on many of the topics discussed in this policy in the accompanying technical report, "Chemical-Biological Terrorism and Its Impact on Children."[3] This technical report contains more specific details on the role of the pediatric provider, specific hospital and health care needs, decontamination processes, and mental health implications related to chemical and bioterrorism events. Because the threat of chemical and biological terrorism continues, and children are likely to be affected by such acts, the AAP offers recommendations for pediatricians and others.

Recommendations for Pediatricians

1. Pediatricians should be aware of agents of concern as well as the response systems (eg, poison control centers and local and state agencies) that evaluate and manage children and strive to minimize their physical and mental trauma.
2. Pediatricians should become, and remain, aware of principles of preparation and response to similar public health emergencies (eg, hazardous-materials incidents or emerging infectious diseases). Education on the all-hazards approach should occur as early in training as possible as well as in continuing education. Telemedicine and telementoring (for example, Extension for Community Healthcare Outcomes) with subject matter experts are potential solutions for just-in-time training).
3. Pediatricians need to be aware of pediatric decontamination strategies and appropriate use of personal protective equipment to protect health care staff.[22]
4. Pediatricians should participate, as need and opportunity arise, in local public health and community exercises, drills, and activities (such as with first responders, at hospitals, and in the medical home) in chemical and biological terrorism preparedness, response, and recovery.[5]
5. Pediatricians should work, when possible, with local early care and education (ie, Head Start, child care, early childhood, and/or preschool) programs and school systems to develop plans for rapid evacuation, relocation, family reunification, triage, and treatment protocols (including vaccination) if an act of chemical or biological terrorism occurs. Pediatricians also should work with local school systems, child care centers, or child-serving agencies as well as mental health providers to help support children after such an event with age-appropriate and developmentally appropriate interventions.
6. Pediatricians should recognize their role in syndromic surveillance and detection of health indicators and familiarize themselves with the related medical sequelae and potential behavioral and mental health effects because children who were exposed to chemical or biological agents during a terrorist attack may present to their pediatrician's office for follow-up and long-term care. Many more children beyond those who were exposed directly will experience significant distress, and pediatricians will need to recognize signs and symptoms of

distress and proactively encourage these children and their families to receive support for their emotional and behavioral needs.

Recommendations for the Health Care Sector

1. Response to chemical and biological attacks will start locally. First responders and local public health officials should be prepared and ready to care for acutely ill and injured children of all ages. Preparation efforts should have adequate resources to provide appropriate MCMs, facility-transfer protocols, and pediatric training for staff (especially appropriate use of personal and protective equipment and decontamination protocols).
2. In addition to medical care of victims of a chemical or biological attack, health care systems and hospitals will need to prepare for the unique needs of children and their families in all phases of readiness, response, and recovery.[7] This includes, but is not limited to, disease surveillance, decontamination of children, identification and tracking of unaccompanied children, family reunification, administration of MCMs to families, and mental health screening and services. Health system readiness for the needs of children and families during and after a disaster should be built on day-to-day pediatric emergency preparedness guidance.[10]
3. The needs of children and youth with special health care needs, including those of children with chronic health conditions, as well as a variety of physical and developmental disabilities must be incorporated into disaster planning.
4. Disaster exercises and drills involving the whole health care community should be conducted and include pediatric victims.

Recommendations for Government

1. Public health and emergency management agencies should work actively with pediatric health care providers to continue to provide assistance and resources to hospitals, pediatric offices, local AAP chapters, community health centers, and other health care facilities to ensure that workers in these facilities are prepared to respond to chemical or biological terrorist incidents that involve children.
2. The needs of children should always be included among the required deliverables and performance benchmarks in funding programs for emergency preparedness, response, and recovery. Furthermore, it is critical for this funding to include the ability to conduct research and collect data during disasters on the impact of the disaster on children (such as chemical or biological exposures) to develop or evaluate innovative solutions.
3. The federal government must ensure, through funding, research, and study trials, that all vaccines and MCMs can be used in children, which would include but not be limited to pediatric-friendly forms of administration, such as rapidly dissolvable formulations or appropriately dosed autoinjectors.
4. State and federal governments should support both funding and accreditation of continuing education on the topic of chemical and biological terrorism and ensure that mechanisms to address the needs of children are included. Maintenance of Certification credits are an important vehicle for the ongoing education of health care providers. Collaboration with the AAP on education is important because the AAP can assist with implementing Maintenance of Certification, quality-improvement projects, Extension for Community Healthcare Outcomes clinics and telementoring projects, and additional educational efforts.

abstract

Children are potential victims of chemical or biological terrorism. In recent years, children have been victims of terrorist acts such as the chemical attacks (2017–2018) in Syria. Consequently, it is necessary to prepare for and respond to the needs of children after a chemical or biological attack. A broad range of public health initiatives have occurred since the terrorist attacks of September 11, 2001. However, in many cases, these initiatives have not ensured the protection of children. Since 2001, public health preparedness has broadened to an all-hazards approach, in which response plans for terrorism are blended with those for unintentional disasters or outbreaks (eg, natural events such as earthquakes or pandemic influenza or man-made catastrophes such as a hazardous-materials spill). In response to new principles and programs that have evolved over the last decade, this technical report supports the accompanying update of the American Academy of Pediatrics 2006 policy statement "Chemical-Biological Terrorism and its Impact on Children." The roles of the pediatrician and public health agencies continue to evolve, and only their coordinated readiness and response efforts will ensure that the medical and mental health needs of children will be met successfully. In this document, we will address chemical and biological incidents. Radiation disasters are addressed separately.

BACKGROUND INFORMATION

In 2000, the American Academy of Pediatrics (AAP) published the policy statement "Chemical-Biological Terrorism and its Impact on Children." Preceding events such as the 1995 sarin attack in Tokyo, Japan, illustrate the reality that acts of domestic chemical terrorism can occur, with significant impact on the health of children. The subsequent 2006 policy statement highlighted the need for increased awareness and preparedness in response to additional acts of chemical and biological terrorism, including the release of anthrax spores through the US postal system, intentional toxic chemical contamination of food in Michigan and California, and the identification of ricin-laden letters in a post office in

South Carolina. Unfortunately, since the publication of the 2006 policy statement, there have been additional chemical attacks affecting children, such as the 2017 sarin[1] and 2018 chlorine attacks[2] in Syria. These attacks have led to significant pediatric morbidity and mortality. Emerging biological threats, such as Ebola and Zika viruses, have provided opportunities to test the systems of pediatric disaster preparedness nationally and internationally. In the same time frame, there continues to be substantial progress as new chemical and biological medical countermeasures (MCMs) are approved by the US Food and Drug Administration (FDA), additional methods for surveillance are in place, and advances in pediatric disaster preparedness and education are available to assist emergency responders with evidence-based best practices.

Since the September 11, 2001, terrorist attacks and subsequent anthrax releases in the United States, the AAP has recognized the need to strategically address the impact of terrorism (ie, an act designed to frighten, hurt, or kill people) on children at the national, state, and local level. This has led to the appointment of the AAP Disaster Preparedness Advisory Council, which collaborates with federal partners (including the Department of Health and Human Services [DHHS] Office of the Assistant Secretary for Preparedness and Response [ASPR], Centers for Disease Control and Prevention [CDC], Department of Homeland Security [DHS], FDA, Federal Emergency Management Agency, and the National Institute of Child Health and Human Development) as well as more than 70 AAP member disaster preparedness contacts in all AAP chapters who work with their local and state partners to address the needs of children throughout the disaster cycle. The federal government also created the National Commission on Children and Disasters, the National Advisory Committee on Children and Disasters, and the National Biodefense Science Board, all of which included pediatric subject matter experts. The AAP hosts a comprehensive Web site for pediatric health care providers with a page devoted to information on terrorism and its impact on children (www.aap.org/disasters/terrorism). Additional AAP activities to promote pediatric disaster awareness include publication of disaster policy statements such as "Ensuring the Health of Children in Disasters" and "Providing Psychosocial Support to Children and Families in the Aftermath of Disasters and Crises" along with education on specific chemical and biological threats in the AAP manual *Pediatric Environmental Health* (the "Green Book") and the AAP manual *Red Book: 2018 Report of the Committee on Infectious Diseases*.[3–6] The AAP has also promoted pediatric preparedness through implementation of a 2016 regional pediatric and public health tabletop exercise and a 2017 virtual tabletop exercise (www.aap.org/disasters/tabletop).[7]

The unfortunate continuing occurrence of chemical and biological terrorism demonstrates the ongoing need to improve public health and health care system preparedness in all respects, including the detection of covert events, establishment of comprehensive response protocols for children, and implementation of plans for rapid resource mobilization to care for children. At the governmental level, the passage of key federal legislation (Table 1) has facilitated these efforts. However, there remains a need for pediatric health care providers to be knowledgeable about the chemical and biological weapons that could be used against a population that includes children and to be able to provide care during the recovery period. Moreover, principles of the care of children after chemical and biological terrorism are evolving, and these approaches will continue to inform future work.

STATEMENT OF THE PROBLEM

Pediatricians play a pivotal role in providing care in the medical home and supporting the community before, during, and after a chemical or biological event. It is critical for pediatricians and others who care for children in all care settings to continue to educate themselves regarding the pediatric consequences of a chemical or biological attack. Readiness resources and approaches will vary depending on practice setting, such as community hospitals, pediatric hospitals, emergency departments, and office practices. The role of the pediatrician and others who care for children in ensuring the health of children in disasters has been described.[3,8] Specific to chemical and biological terrorism, pediatricians and their staff will need to be prepared to promote and share information on readiness approaches, advise on pediatric decontamination strategies, provide appropriate medical care, offer anticipatory guidance to families, report appearances of unusual disease clusters, and help guide families after events. This technical report summarizes relevant information and evidence. Although the focus of this document is geared toward the US health care system, principles of this technical report can be applied to international health care settings.

NEW INFORMATION

This technical report and its accompanying policy statement[9] replace the 2006 policy statement, with an added focus on identifying and resolving system issues that are paramount to minimizing morbidity and mortality in children after their

December 2016	Public Law 114-326	National Urban Search and Rescue Response System Act of 2016

exposure to a chemical or biological weapon.

REVIEW OF EVIDENCE

Exposure Sources for Chemical and Biological Weapons

Exposure to chemical and biological weapons can occur through several potential sources. Airborne releases of agents have remained the primary concern because large populations can be exposed by this route. Potential mechanisms of exposure include crop-dusting airplanes, tainted letters, and release of agents into confined spaces (eg, subway tunnels, office buildings, theaters). Contamination of the water supply is also a potential source for exposure, although dilution of chemical and biological agents in water is mitigating, and few chemical or biological agents are both water stable and resistant to water-purification techniques that decrease the risk. Finally, the contamination of food that is either unprocessed (eg, uncultivated grain) or processed (eg, a consumer product) is considered a potential means of exposure to chemical or biological weapons.

Specific Vulnerabilities in Children

After events of chemical or biological terrorism, children have a greater risk of both exposure and harm, the result of key developmental, anatomic, and physiologic vulnerabilities. Children have greater life expectancy than adults and, therefore, have more time in which to develop sequelae such as cancer from a variety of sources of exposure (air, water, or food) to chemical or biological weapons. For each source of exposure, children possess a significantly greater likelihood of exposure because of their intake patterns. Children inhale considerably more air on a per-weight basis than adults (400 vs 140 mL/kg per minute, respectively). Consequently, for any concentration of an airborne toxicant, a child will inhale more of the substance on a per-kilogram basis than an adult. Also, substances that are heavier than

air have their highest concentration near the ground, closer to the breathing zone of the child. Because of a proportionately greater body-surface area, children have both greater exposure and an increased likelihood of systemic toxicity to agents that contact their skin. Children have fluid and food intakes that differ significantly from adults. For example, children ingest approximately 100 mL/kg of water per day, whereas adults ingest 40 to 60 mL/kg per day. Children drink more milk than adults, placing them at risk for exposure to agents that can enter the milk supply through contamination of the grass on which cows feed. In the Chernobyl radiation disaster, cows grazed in contaminated pastures, leading to excess radioactivity in their milk. Children drinking this milk sustained significant exposure to radioisotopes, including iodine and strontium.[10] Finally, children not only eat more food on a per-kilogram basis but also have diets that are distinctly different from adults (eg, greater consumption of fruits). Once exposed to a chemical or biological agent, children have numerous physiologic vulnerabilities that could lead to a greater risk of harm. These vulnerabilities include undeveloped self-preservation skills that make them less able to flee danger; an immature immune system that makes them less able to contain infection (eg, plague); less fluid reserve, which can result in a greater risk of severe dehydration after exposure to agents that produce excess gastrointestinal fluid loss (eg, Ebola virus disease); and a greater risk of anxiety reactions and posttraumatic stress disorder after witnessing or being victim to a terrorist act.4 Additionally, with the advent of technology, there is increased availability of social media to children and adolescents, allowing for access to online terrorist information or suggestive material on how to terrorize.

Public Health Preparedness

The All-Hazards Approach

In past years, resources have been provided to public health authorities, including the network of state and regional poison control centers, and first responders (fire officials, police officers, and emergency medical services personnel) to create systems capable of responding to a possible chemical attack. Similarly, emerging and reemerging infections as well as highly contagious organisms such as Ebola have led to a massive public health effort to improve response capability to future acts of biological terrorism. The initiation of these response campaigns revealed large-scale weaknesses in state and local public health infrastructure. Moreover, it became evident that intense effort was being directed toward events that might never occur rather than toward public health threats of much greater likelihood (eg, an unintentional hazardous chemical release). Finally, it became clear that a fragmented and reactive public health response plan is more expensive and inefficient than a single, comprehensive plan. As a result, disaster response agencies and public health authorities have increasingly embraced the concept of the "all-hazards approach." Representing a dramatic paradigm shift in the preparation for chemical and biological terrorism, the all-hazards approach is designed to augment the public health infrastructure, using an integrated model of disaster response. The creation of all-hazards response systems has led to improvements in public health response capabilities. For example, an effective public health response protocol for a sarin release would be equally effective for a hazardous-materials (hazmat) release in the community, such as the 2017 chemical fires in Texas that followed massive flooding and power losses in the wake of Hurricane Harvey.[11] Similarly, the same protocol created to respond to the appearance of smallpox can be modified easily to contain an outbreak of severe acute respiratory syndrome. However, as threats increase and local and state budgets fluctuate, there will continue to be challenges to achieve adequate responses.

Pediatric Disaster Preparedness and Education

Several investigators have studied disaster preparedness and education specific to the needs of children. In 2008, Schobitz et al[12] conducted a study of pediatric and emergency medicine residents at a single institution to assess their baseline knowledge of management of pediatric victims of chemical and biological terrorism. Using an expert-developed, validated test, the investigators determined that the residents of this era were unprepared to manage these victims. The 2010 Pediatric Emergency Mass Critical Care Task Force concluded that mass events place unusual stresses on health care providers, many of whom must provide care outside of their scope of practice, and that education and educational resources can mitigate anxiety and chaos in these contexts.[13] Subsequent research in pediatric disaster triage has demonstrated that a multiple-simulation curriculum can improve prehospital care providers' assessment skills.[14] In addition, studies have revealed an increase in clinical staff's knowledge and confidence with pediatric disaster skills with short, topic-focused educational interventions.[15,16] There are also review articles of pediatric disaster courses to educate health care professionals.[15,17,18]

Agents of Concern

Chemicals

Three traditional assumptions specific to chemical terrorism have proven simplistic. These include the narrow concepts that (1) such weapons were intentionally and specifically manufactured as instruments of mass destruction; (2) chemical terrorism was dramatic and recognized immediately (eg, the sarin

incident in Tokyo); and (3) only well-organized, well-funded terrorist groups were capable of releasing chemical weapons after extensive planning. These concepts have been expanded to include the possibilities that (1) readily available, legitimate chemicals, such as chlorine, can be misused (ie, "weapons of opportunity"); (2) these acts can be covert, with delayed recognition; and (3) a motivated, "lone-wolf" individual with few resources can perpetrate significant releases.

Acts of chemical terrorism involving children illustrate these expanded concepts. In 1999, patrons of a restaurant in Fresno, California, developed severe gastroenteritis. An investigation by public health authorities discovered that the carbamate insecticide methomyl had been added maliciously to the salt. More than 100 adults and children became ill with nausea, vomiting, and diarrhea; a perpetrator was never identified.[19] In 2003, in Grand Rapids, Michigan, a disgruntled grocery store worker placed a nicotine-containing insecticide into ground beef, making it available for purchase by unsuspecting customers. It was not until widespread illness (nausea, mouth burning, vomiting) was reported and there was a recall and analysis of the meat, revealing the presence of nicotine, that this was recognized as an act of terrorism. Ultimately, more than 100 people became ill, including more than 40 children, in what is now considered the largest act of chemical terrorism in US history.[20]

Research in the past decade specific to chemical exposures has been focused on antidotes and resultant injury after exposure. For nerve-agent exposure, 3 classes of medication are used in the treatment of nerve-agent exposure: (1) anticholinergics, usually first-line atropine, to block excess acetylcholine at peripheral muscarinic receptors; (2) oximes, such as pralidoxime, to reactivate inhibited acetylcholinesterase; and (3) anticonvulsants[21] (please refer to the Nerve Agents section for further discussion of clinical effects). Some studies have explored the problem of antidote dosing in children, particularly with respect to prepackaged autoinjectors. Baker[22] noted that adult doses of atropine are well tolerated, even in young children, and recommended the use of the atropine (0.5 or 2 mg) autoinjector for children younger than 1 year after nerve-agent exposures when weight dosing is impractical or not possible to control excessive bronchorrhea and to prevent respiratory failure.[22] In a 2009 review of research on atropine dosing, Sandilands et al[23] considered pharmacokinetic data to balance sufficient and timely dosing of atropine versus the risk of overdose; the authors recommended relatively large initial doses of atropine in children, who are relatively resistant to its adverse effects. Droste et al[21] used a pharmacokinetic model to analyze current CDC and US Army treatment protocols and found that in general, oxime therapy alone was ineffective in alleviating symptoms.[19] The atropine and pralidoxime combination autoinjector can, in theory, be used in children older than 1 year; as of 2018, however, the combination autoinjector was not FDA approved for pediatric patients weighing less than 41 kg. However, authors of an extensive review of antidotes for a variety of chemical agents concluded that the strength of evidence supporting the use of these antidotes is generally weak and that more research is needed.[24]

Other investigators have studied injury related to chemical exposures. Custer et al[25] used an in vitro test lung to simulate pediatric lung injury; the goal was to assess the efficacy of transport and/or emergency ventilators in the setting of mass-casualty respiratory failure. These investigators found that few of the ventilators, chosen from a range of manufacturers, were capable of the minimum alarm and tidal volume function necessary to support the ventilation of pediatric victims.

Additional efforts have focused on improving access to information after chemical exposures. The ASPR, in cooperation with the National Library of Medicine, has developed a Web site that is intended to enable health care professionals to respond to mass-casualty events involving chemicals (https://chemm.nlm.nih.gov/). The resource can be downloaded to a computer or mobile device in advance of an event that might limit or interrupt Internet access.[26]

The analysis of a mass-casualty event may identify 1 or more specific chemicals. The World Health Organization considers the following 6 categories of chemicals to be the most likely threats: nerve agents, blistering agents (vesicants), irritants (corrosives), choking agents, asphyxiants (cyanogens and carbon monoxide), and disabling (incapacitating) agents, including lacrimators (Table 2).[27]

Nerve Agents

Nerve agents are well absorbed through intact skin and even through examination gloves used in clinical settings. All nerve agents act as acetylcholinesterase inhibitors, producing the same symptoms and signs associated with organophosphate poisoning. Manifestations can range from mild (miosis, nausea, diarrhea) to severe (muscle weakness, fasciculations, respiratory failure, coma, and seizures).

In the 1995 sarin episode in Tokyo, the most unanticipated sequela was the degree of injury to health care professionals.[28] Several hundred physicians, nurses, and other health care professionals became ill as a result of 2 factors: handling of sarin-contaminated victims without wearing personal protective equipment (PPE) and entry of contaminated victims into health care facilities, allowing sarin vapor to

enter the ventilation system.[27,29] This event firmly demonstrated the importance of using PPE to protect health care professionals, decontaminating victims before building entry to maintain office or hospital safety, and using environmental controls such as airborne infection isolation rooms (negative-pressure rooms).

Management of nerve-agent exposure includes supportive care and, when indicated, prompt administration of the antidotes atropine and pralidoxime (see the introduction to the previous section, Chemicals, for recent research regarding atropine, pralidoxime, and autoinjectors).[30] Autoinjectors are particularly important in mass-casualty incidents when there is a need to treat large numbers of victims as quickly and efficiently as possible. Until recently, the absence of pediatric autoinjectors complicated the rapid administration of atropine and pralidoxime to children; only the devices approved for adults, containing 2 mg of atropine and 600 mg of pralidoxime, were available. In 2003, the FDA approved new dosage forms of atropine sulfate, approved since 1973 for adults, for use in children and adolescents after nerve-agent exposure.[31] However, the continued absence of a combination pediatric autoinjector in the United States, which is critical to the successful treatment of central nervous system and muscular toxicity from nerve agents, leaves the use of standard, multidose vials as the only therapeutic option. To address this issue, consensus guidelines now recommend that children weighing 13 kg or more (2–3 years of age or older) receive a 600-mg dose of pralidoxime from an autoinjector because this pralidoxime dose falls within the range of safety for the drug.[32] Children weighing less than 13 kg can receive the customary weight-based (20–50 mg/kg) dose, administered from a multidose vial; if the multidose vial is unavailable, an autoinjector could be used. Repeat dosing of atropine may be necessary to mitigate secretions.

Other aspects of care to children who have been exposed to nerve agents are found in recent reviews.[29,33]

Blistering Agents (Vesicants)

Vesicants include sulfur mustard and lewisite, an arsenic-based blistering agent first used in World War I. British antilewisite (dimercaprol) was developed in subsequent years and mitigated the risk to allied soldiers in World War II; it remains useful today as an antidote in some cases of heavy-metal poisoning.[34] The vesicants, released as aerosols, produce erythema, burning, vesiculation, and then desquamation of the skin. Victims of blistering-agent exposure typically develop skin tingling, then burning; within 24 hours, skin sloughing begins to occur, with wounds having the appearance of partial-thickness burns. These agents -are also immunosuppressive, further increasing the risk of severe -infection. Treatment is largely supportive. Important principles of management include topical decontamination and PPE use to protect health care professionals.[35]

TABLE 2 Chemical Weapons of Concern

Agent Classification	Built Weapon	NATO Codes	Weapon of Opportunity
Nerve agents	Tabun	GA	Pesticides
	Sarin	GB	Nicotine
	Soman	GD	Organophosphates
	VX gas	VX	Carbamates
Blistering agents (vesicants)	Lewisite	L	—
	Mustard gas	HD	—
	Nitrogen mustard	—	—
Irritants (corrosives)	—	—	Ammonia
	—	—	Bromine
	—	—	Chlorine
Choking agents	Phosgene	CG	Perfluoroisobutylene (Teflon) and other chemical polymers
	Nitrogen oxides	NOx	Smoke, products of combustion
Asphyxiants	Hydrogen cyanide	AC	Industrial cyanide
	—	—	Sodium azide
	—	—	Carbon monoxide
Disabling agents (incapacitators)	3-quinuclidinyl benzilate	BZ	Anticholinergics
	Cannabinoids	—	—
	Barbiturates	—	—
	Fentanyl derivatives	—	—
	Lacrimators: Chloroacetophenone	CN	Lacrimators
	Chlorobenzylidene	CS	Capsaicin

AC, hydrogen cyanide; BZ, 3-quinuclidinyl benzilate; CG, phosgene; CN, chloroacetophenone; CS, chlorobenzylidene; GA, tabun; GB, sarin; GD, soman; HD, mustard gas; L, lewisite; NATO, North Atlantic Treaty Organization; NOx, nitrogen oxide; —, not applicable. Adapted from World Health Organization. Chemical weapons of concern. Available at: www.who.int/csr/delibepidemics/annex1.pdf. Accessed June 15, 2018. Adapted from Tuorinksy SD, ed. *Medical Aspects of Chemical Warfare.* Washington, DC: Office of the Surgeon General at TMM Publications; 2008: 292–293.

Irritants (Corrosives)

The irritants and corrosives include common chemicals such as ammonia, bromine, and chlorine, which can affect the skin, eyes, mucous membranes, gastrointestinal tract, and predominantly, the upper and lower respiratory tracts. Decontamination includes copious water irrigation of the skin and eyes; management is mainly supportive, but the risk of delayed pulmonary injury remains for 24 hours.[36] The Assad regime in Syria has used chlorine gas against civilians, causing at least 1 pediatric death.[2,37]

Choking Agents

Choking agents are created to produce, usually in delayed fashion, pulmonary injury: bronchospasm, pulmonary edema, and respiratory failure. Immediate symptoms include eye burning, tearing, and blepharospasm. The major agent of this group is phosgene; however, common industrial chemicals, including polytef (Teflon) and other chemical polymers, act as choking agents depending on their ambient concentration. Most choking agents are heavier than air, which could produce higher concentrations at the breathing level of the child. Treatment is supportive.

Asphyxiants (Cyanogens and Carbon Monoxide)

The asphyxiants include the cyanogens and carbon monoxide, often generated in fires. Victims of asphyxiant exposure must be recognized promptly to remove them from the source and to administer life-saving antidotes.

The cyanogens (cyanide salts and sodium azide) interrupt cellular use of oxygen, producing respiratory distress, coma, metabolic acidosis, and lactic acidosis. In the United States, the traditional cyanide antidote "kit" was amyl nitrite inhalation or sodium nitrite injection—which generates methemoglobin—followed by sodium thiosulfate, which reacts with methemoglobin and converts the potentially lethal cyanide ion to the stable thiocyanate ion. Hydroxocobalamin is a newer option that acts more rapidly than thiosulfate and avoids the additional hazard of the methemoglobin intermediate.[38]

Carbon monoxide, a potential weapon of opportunity, binds avidly to hemoglobin and other hemoproteins, interfering with oxygen transport and tissue delivery, and may lead to nonspecific symptoms that mimic viral infections. After immediate removal from carbon monoxide exposure, victims will benefit from receiving 100% oxygen administered via a nonrebreather mask. The degree of illness rather than specific carboxyhemoglobin levels can guide treatment; some experts recommend consultation with a hyperbaric oxygen facility for more severe cases.[39]

Disabling (Incapacitating) Agents

Disabling or incapacitating agents include several different chemical classes (eg, anticholinergic agents, hallucinogens, cannabinoids, and fentanyl derivatives). In the 2002 Russian theater hostage incident, a fentanyl-based disabling agent may have been released during the rescue effort. The agent, although successful in overwhelming the hostage-takers, also killed 127 hostages.[40]

Many disabling agents are weapons of opportunity, easily acquired pharmaceutical agents, or substances of abuse that are added surreptitiously to common sources of food or drink.

Included among disabling agents are lacrimators. Often referred to collectively as Mace or "tear gas," lacrimators include the chemicals chloroacetophenone and chlorobenzylidene as well as capsaicin ("pepper spray"). Lacrimators are designed to produce incapacitation from irritation of the eye and other mucous membranes. Exposure to lacrimators leads to eye burning, tearing, and blepharospasm; victims may become temporarily blind. Inhalation produces mouth pain, shortness of breath, and, in rare cases, laryngospasm. Because capsaicin is widely sold as a nonlethal weapon, episodes of capsaicin release into the ventilation system of schools and buildings are a relatively common prank, although such incidents meet the definition of terrorism.[41]

Biological Agents

Most of the biological agents that could be used as weapons are now discussed in the AAP *Red Book*,[6] although some agents (eg, ricin) are not discussed in detail. Ricin is discussed in a subsequent section of this report.

The biological agents of concern are listed in Table 3. These agents have been placed by the CDC into categories A, B, or C. Thirty-nine agents are included in these 3 categories.

Category A agents are considered the greatest public health threat because of their potential ease of dissemination, resulting high morbidity and mortality, and potential to cause public panic and need for special actions for public health preparedness. Currently, there are 6 agents in this group, including the pathogens that cause anthrax, botulism, plague, smallpox, tularemia, and the viral hemorrhagic fevers, specifically filoviruses (Ebola and Marburg viruses) and arenaviruses (Lassa and Machupo viruses). Detailed descriptions of these agents have been published in the AAP *Red Book* and elsewhere.[6,42] The second highest-priority agents (category B) are moderately easy to disseminate, with moderate morbidity and low mortality. Category B agents also require additional enhancements of

CDC diagnostic and surveillance capabilities (Table 3). Category C agents are of concern because of their future potential to be engineered for mass dissemination, with attendant major health impact with high morbidity and mortality. Mycotoxins are toxins produced by fungi. Agents of primary concern, trichothecenes and aflatoxins, have properties of both chemical weapons and biological weapons and could be used in chemical warfare (Tables 1 and 2).[43,44]

Smallpox (Variola)

Until the Ebola virus epidemic in 2013–2016, the most widely discussed category A agent was Variola major, the agent that causes smallpox. Initial CDC smallpox immunization efforts initiated in 2002 included a "ring immunization" (surveillance and containment) strategy in the United States.[45,46] Subsequently, the CDC recommended a 3-phase plan for smallpox immunization of health care professionals and other individuals, although the program met with only limited success in the first phase of vaccination of health care professionals in acute-care facilities.[42] A high rate of vaccine refusal by health care professionals, concerns about the safety of the vaccine, extensive contraindications to the vaccine, and the appearance of unrecognized adverse effects from the vaccine (eg, fatal cardiac disease)[47,48] hampered the program.[49,50] In 2015, the CDC and AAP published updated clinical guidance for use of the 3 smallpox vaccines in the US Strategic National Stockpile (SNS) for people at risk for smallpox infection after an intentional or accidental release of the virus.[43]

Ricin

Although it is a category B agent, ricin has become a major biological weapon of concern because it is 1 of the most toxic biological agents known. A plant-derived, heat-stable toxin, ricin is an extract of the castor bean (*Ricinus communis*). Ricin acts by inhibition of protein synthesis of cells, ultimately resulting in cell death. Rapidly dividing tissues, particularly the gastrointestinal epithelium, are most susceptible to ricin actions. With these effects, ricin produces severe morbidity and mortality.

Ricin is a versatile agent that can be administered by ingestion, inhalation, or injection. When ingested, it can produce a syndrome of severe gastrointestinal upset, vomiting, hemorrhagic gastroenteritis, shock, and cardiovascular collapse. After inhalation, respiratory distress with a necrotizing pneumonitis may occur. Injection produces rapid shock and cardiovascular collapse. Treatment is supportive. A vaccine against ricin is currently under development.

Ricin has been associated with terrorist activity in the United States on multiple occasions, particularly as an agent sent through the mail. In October 2003, 2 ricin-containing letters were found in the US postal system.[51] In a third incident, ricin was found in the mail sorter of a congressional post office in January 2004. In June 2006, the CDC developed a comprehensive guideline for public health and medical officials in response to a ricin incident.[52] As recently as 2013, the Federal Bureau of Investigation responded to reports of suspicious letters received at mail facilities that contained ricin.[53]

Syndromic Surveillance

Overt acts of chemical and biological terrorism such as the sarin release in Tokyo present the challenge of rapidly identifying the agent and mobilizing the proper interventions. However, acts of chemical and biological terrorism may also be covert. Examples include the cyanide contamination of Tylenol (1982),[54] the release of anthrax (2001), and the nicotine contamination of ground beef (2003).[18] Covert incidents pose a significantly greater public health challenge and are more likely to induce widespread fear than overt events. Mechanisms for early recognition of a covert chemical or biological event, therefore, are necessary to contain the incident and minimize its impact.

TABLE 3 Biological Weapons of Concern

Weapon Category
Category A
Anthrax (*Bacillus anthracis*)
Botulinum (*Clostridium botulinum* toxin)
Plague (*Yersinia pestis*)
Smallpox (*Variola major*)
Tularemia (*Francisella tularensis*)
Viral hemorrhagic fevers (filoviruses [eg, Ebola, Marburg] and arenaviruses [eg, Lassa, Machupo])
Category B
Brucellosis (*Brucella* species)
Epsilon toxin of *Clostridium perfringens*
Food-safety threats (eg, *Salmonella* species, *Escherichia coli* 0157:H7)
Glanders (*Burkholderia mallei*)
Melioidosis (*Burkholderia pseudomallei*)
Psittacosis (*Chlamydia psittaci*)
Q fever (*Coxiella burnetii*)
Ricin toxin from *Ricinus communis* (castor beans)
Staphylococcal enterotoxin B
Typhus (*Rickettsia prowazekii*)
Viral encephalitis (alphaviruses [VEE, EEE, WEE])
Water safety threats (eg, *Vibrio cholerae*, *Cryptosporidium parvum*)
Category C
Emerging threat agents (eg, Nipah virus, hantavirus)

EEE, eastern equine encephalomyelitis; VEE, Venezuelan equine encephalomyelitis; WEE, western equine encephalomyelitis.

Syndromic surveillance, a specialized type of outbreak detection, is a term used to describe mechanisms for monitoring health indices or events that reflect the early stages of a chemical release or of an infection or disease of public health importance to minimize consequences.[55,56] Syndromic surveillance is considered an important means of identifying public health emergencies in their initial stages. Syndromic surveillance techniques, summarized below, can be clinician based or automated. Many syndromic surveillance systems are based in hospital emergency departments.

Astute Clinician

The traditional mechanism of detection of an unusual occurrence has been the clinician who recognizes atypical patterns of symptoms, signs, or disease and reports them to public health authorities. The "astute clinician" principle places all health care professionals (including physicians, advanced practice providers, nurses, paramedics, emergency medical technicians, infection preventionists, laboratorians, pharmacists, epidemiologists, and health educators) in the role of sentinels for the appearance of disease clusters or other clinical abnormalities. It is important to identify and work with those who may already have a defined role in syndromic surveillance. For example, school nurses have an established or particular role in this area, and there are other professionals with these capabilities. The pivotal role of physicians and other health care professionals in surveillance, particularly for acts of terrorism, has led the CDC and other agencies to educate clinicians about chemical and biological weapons release and the diseases they produce. Clinical cues, case definitions, and syndromes for chemical weapons exposure have been published (Table 4) along with numerous resources to expand clinicians' ability to recognize covert terrorist incidents.[25,50,57]

To facilitate uniform reporting among local, state, and federal authorities after unintentional or intentional releases of chemical agents, the CDC has developed case definitions for illness.[51]

Automated Systems

Recently, there has been a rapid increase in the development of real-time, automated syndromic surveillance tools. Such automated decision support uses software to identify sentinel events such as an unusual amount of work or school absenteeism, changes in consumer purchase of over-the-counter products (eg, antipyretics or cough syrups), and changes in the chief-complaint profile among those who visit primary care physicians or hospital emergency departments.[58–60]

The CDC BioSense Platform (www.cdc.gov/nssp/biosense/index.html) is an integrated, national surveillance system that gathers data from diagnosis codes included in electronic medical records to enhance situational awareness for an all-hazards approach. The DHS BioWatch Program (www.dhs.gov/biowatch-program) provides early warning of a bioterrorist attack in more than 30 major metropolitan areas across the country.

A number of surveillance studies have attempted to use the massive volume of data on the Internet to inform rapid epidemic detection. Various surveillance tools, such as the Program for Monitoring Emerging Diseases–Mail (available at www.promedmail.org; International Society for Infectious Diseases) and HealthMap (available at www.healthmap.org; Boston Children's Hospital), which aggregates content from the Program for Monitoring Emerging Diseases–Mail and other sources, are capable of providing alleged outbreak signals ranging from days to months before official reports.[61,62]

Crowdsourcing

An unconventional and unplanned type of syndromic surveillance has arisen in recent years with the advent of mobile devices and social media applications. For example, in the 2013 intentional release of sarin gas near Damascus, Syria, many individuals recorded videos of the atrocity that killed 1400 civilians; Rosman et al[63] searched the YouTube Web site for videos that had been uploaded in the weeks after the release. Many of these videos documented significant clinical signs—including dyspnea, diaphoresis, and syncope—and also revealed problems with the use of PPE, decontamination strategies, and antidote administration. Nonclinicians contributed "crowdsourced" data, in effect, to syndromic surveillance. Although there were no chemical or biological releases at the 2013 Boston Marathon bombings, investigators were able to identify specific keywords that were posted within minutes of the explosions on the social media site Twitter before any reports were issued from public safety officials or traditional news media outlets.[64]

Governmental Roles in Emergency Preparedness

Although emergency preparedness legislation existed before 2001, the passage of additional rules has resulted in efforts by the federal government to improve public health readiness across the nation (Table 1) despite federal budgets remaining flat for more than a decade and state and local budgets declining for public health and emergency response. In contrast, there has been an escalating need to ensure the safety of all US citizens. Established in 2002, the DHS is the main federal agency that leads efforts to protect the US population against chemical, biological, and

TABLE 4 Clinical Syndromes Associated With Chemical and Biological Agents

Category	Clinical Syndrome	Potential Etiologies
Cellular hypoxia	Altered mental status, dyspnea, seizures, and/or metabolic acidosis	Cyanide, carbon monoxide, hydrogen sulfide, and/or sodium azide
Cholinergic crisis	Salivation, diarrhea, lacrimation, bronchorrhea, diaphoresis, miosis, fasciculation, weakness, bradycardia, altered mental status, and/or seizures	Nicotine, nerve agents, and/or organophosphates
Gastrointestinal illness	Abdominal pain, vomiting, profuse diarrhea, hypotension, and/or cardiovascular collapse	Ricin, staphylococcal enterotoxin E, arsenic, and/or Ebola
Lacrimation	Tearing, blepharospasm, and/or incapacitation	Lacrimators (Mace), ammonia, and/or halogens (chlorine, bromine)
Mucosal irritation	Tearing, nose and mouth burning, and/or sore throat	Ammonia and/or halogens
Muscle rigidity	Generalized muscle contractions, painful neck and/or limb spasm, and/or seizurelike activity	Strychnine
Muscle weakness	Generalized muscle weakness, ptosis, and/or respiratory embarrassment	Botulism
Peripheral neuropathy	Muscle weakness or atrophy, "stocking-glove" sensory loss, and/or depressed or absent deep tendon reflexes	Arsenic and/or thallium
Respiratory distress, acute onset	Cough, wheeze, shortness of breath, and/or generalized mucosal irritation	Ammonia and/or halogens
Respiratory distress, delayed	Cough, respiratory distress, wheeze, hypoxia, and/or pulmonary edema	Phosgene and/or sulfur mustard

radiation threats. Specifically, the DHS strives to secure the nation from many threats (eg, aviation, border security, cyber security, and emergency response). Mission areas include preventing terrorism and enhancing security, managing the US borders, administering immigration laws, securing cyberspace, and ensuring disaster resilience. Within the DHHS, the ASPR was established in 2006 to minimize the adverse health consequences from disasters. The ASPR has led the development of the National Health Security Strategy and oversees implementation of the National Biodefense Strategy.[65,66] The ASPR continuously identifies and addresses gaps in coordinating patient care and transportation in disasters, especially for coalitions and states. The ASPR also offers support in this area through the federally funded Hospital Preparedness Program, which is now focused on health care coalition preparedness efforts. The potential benefits of regional disaster health response systems are also being explored. The ASPR also leads the disaster medical assistance teams (DMATs), which provide medical assistance to regions after a large-scale disaster.[67] Although there are individuals on DMATs who have pediatric expertise, personnel on DMATs are trained to provide initial care for both adults and children. The Medical Reserve Corps, another federal effort designed to create community "medical strike teams," has no clearly established pediatric capability or standards (https://mrc.hhs.gov/HomePage).

Other DHHS agencies have undergone change; these include the CDC, FDA, and National Institutes of Health, all of which have reorganized practice, regulatory, and research priorities to include chemical and biological terrorism, along with other public health threats. In 2002, the CDC established the Coordinating Office for Terrorism Preparedness and Emergency Response (later referred to as the Office of Public Health Preparedness and Response and now renamed the Center for Preparedness and Response), and in 2012, the CDC launched the Children's Preparedness Unit to address children's needs in the context of infectious disease outbreaks and other public health emergencies. The CDC also integrated a children's health team into its Emergency Operations Center structure, beginning in 2009 with the H1N1 influenza pandemic and continuing through the responses to the Ebola virus epidemic (2013–2016); the Zika virus outbreak in 2016–2018; the Flint, Michigan, water contamination in 2016; Hurricanes Harvey, Irma, and Maria in 2017; and Hurricane Michael in 2018. At state and local levels, planning for chemical and biological terrorism is now coordinated by multiple agencies, including departments of health, emergency management agencies, poison control centers, and law enforcement authorities.[68] Because there is variability across states, pediatricians can inquire as to which agencies are in charge of planning for and responding to chemical and biological attacks in their local communities.

Poison Control Centers

The network of regional and state poison control centers, funded by federal, state, and local sources, may be the first point of contact for health care providers and members of the public concerned about possible terrorist attacks. Callers can reach poison centers 24 hours a day via a national toll-free number (800-222-1222), and call data are uploaded automatically in nearly real time (currently a median of 9.5 minutes to upload data from all centers) to the National Poison Data System, maintained at the American Association of Poison Control Centers.[69]

SNS and Pediatric MCMs

The SNS has become 1 of the most important initiatives in mass-casualty disaster response.[31] Designed to respond to disasters that overwhelm state and local resources, the SNS includes such capabilities as the delivery of medications and medical supplies to areas of need within a clinically relevant time frame. The SNS supplies include pediatric dosage forms and pediatric sizes of medical supplies as well as instructions for compounding certain tablets and capsules into liquid formulations for some but not all MCMs.[70] Unfortunately, not all MCMs are licensed for use in children, and not all MCMs are available in ideal formulations that are appropriate for younger children. According to the 2013 US Government Accountability Office, 40% of the MCMs in the SNS have not been approved for pediatric use. Of the 60% of MCMs that are approved for children, there are many instances when use is limited to people of specific ages. Currently, unapproved MCMs may be distributed under FDA emergency use authorization or investigational new drug application. If an MCM is considered under the investigational new drug application, additional consent would be needed, which would be challenging to explain to frightened parents and would likely prolong MCM mass distribution efforts during a public health emergency. Ongoing efforts continue within the ASPR to address the MCM needs of pediatric populations in relation to the current medications within the SNS and make prioritized recommendations for formulary additions or changes. The AAP has identified several concerns and recommendations in its policy, "Medical Countermeasures for Children in Public Health Emergencies, Disasters, or Terrorism."[71] Even with an increased awareness of the need, significant barriers remain to developing, testing, procuring, and distributing medications in doses and formulations appropriate for children.[62,72] In addition, state and local plans for medication distribution need to be developed in collaboration with pediatric experts and consider children's needs for maximum effectiveness and efficiency.

The Primary Care Provider and Community Response

Pediatricians play a pivotal role in providing care in the medical home and supporting the community before, during, and after a chemical or biological attack.[4] Most families will seek medical advice from a trusted source such as their pediatrician. Pediatricians can emphasize the need for family disaster preparedness planning before an event and provide resources such as the AAP Family Readiness Kit.[73] After an attack or outbreak, pediatricians and their staff will need to be knowledgeable about the medical course for the agent of concern and provide anticipatory guidance to the families. Although victims of a chemical or biological attack may be treated initially in hospital emergency department settings, victims may also seek care from the medical home. Thus, pediatricians will need to be prepared for a surge in communications with patients and families, have the appropriate PPE (and related training on how to use the equipment), and have developed isolation procedures. Pediatricians will also need to be prepared to help families care for the long-term physical and emotional sequelae. Additional information on the role of the pediatrician in disaster preparedness and response is available.[3,8]

Prehospital and Hospital Preparedness

Hospital protocols for pediatric victims of chemical or biological terrorism must be established in all hospitals. These disaster protocols require an integrated response from the emergency department, ICU, operating rooms, and other key clinical areas within the hospital. Response needs include having an adequate number of pediatric supplies and staff members trained in the care of ill children, including pediatric medication weight-based dosing (milligrams of medication per kilogram of body weight) to minimize morbidity and mortality.[3,31,74,75] The needs of children with chronic health conditions as well as physical and intellectual disabilities need to be considered in the disaster plan. All hospitals should have disaster protocols for pediatric patients, including mobilization of child-life specialists, volunteers, and others such as behavioral health professionals who can provide comfort to and minimize the stress of children, particularly if those children are separated from their parents. For hospitals that do not treat large numbers of children, telehealth and telementoring technologies offer access to information and to pediatric subspecialists to facilitate the care of children.[76] In addition, hospitals participating in a regional coalition may be asked to provide care for victims far away from the affected site.

To be fully prepared for chemical or biological terrorism, pediatric and general hospitals must also have an evacuation plan for times when the hospital environment becomes uninhabitable. Although protocols for "vertical evacuation" (ie, the removal of patients to other areas or floors within the same building) are well established in hospital-based disaster response, comprehensive plans for complete building evacuation are less well developed. Pediatric hospitals requiring full evacuation may have the additional challenge of transporting pediatric patients to health care facilities with relatively few pediatric resources. Nonetheless, memoranda of agreement with

nearby or affiliated institutions and regional alliances are a key part of a comprehensive pediatric hospital disaster plan.

Decontamination

Several investigators have focused on the logistics of prehospital and hospital preparedness. In a study of 2 mass decontamination field exercises, investigators in the United Kingdom used radio-frequency identification tags and detection mats to examine bottlenecks in the process. Computer analysis revealed that bottlenecks occurred at specific phases of the process (eg, the redressing or "rerobing" that followed decontamination showers), and subsequent simulations revealed that shortening the duration of showers and adding capacity in the rerobing area could improve throughput of casualties.[77]

After exposure to a chemical or biological weapon, children may become covered by toxic material that can produce skin injury or be absorbed, producing systemic toxicity. In the case of infectious material, the contamination of skin could be sufficient to represent a threat to health care professionals as well as the victim. When children are covered with unknown but potentially dangerous chemical or infectious material, immediate decontamination is required.[78] To minimize exposure to health care professionals and patients within the health care facility, the child should be disrobed outdoors—as per Occupational Safety and Health Administration regulations—before entering the ambulance or building, with attention to prevention of hypothermia, as noted below. Plans should address the collection of contaminated water. Disrobing alone accounts for more than 85% of topical decontamination and is an extremely effective means of ending exposure. In the Tokyo sarin experience, it was determined that removal of clothing can eliminate pockets of trapped gas.[79] When possible, the victim should disrobe himself or herself to minimize exposure to others. Health care professionals should not assist in disrobing unless they are wearing appropriate PPE.[68]

There is some debate about the merits of dry decontamination (removal of clothing, scraping, absorbent or adsorbent materials, vacuuming, pressurized air, provision of replacement clothing) alone versus wet decontamination, which adds showering to topical decontamination. The decision to use dry versus wet decontamination may depend, for example, on the presence of clearly visible contamination or evidence of a blistering agent.[66]

Showering further removes chemicals, microbes, and debris. As with disrobing, showering usually happens outdoors. However, some institutions may have specially designed indoor hazmat decontamination facilities. Protocols should include strategies for using warm water and low-pressure showers (to avoid trauma to the skin), etc, to prevent hypothermia in children, as well as methods for the collection of contaminated water. Principles of showering include the establishment of 3 management zones in the decontamination staging area (hot [maximum contamination], warm [less contamination]), and cold [no contamination] zones), use of water that has been warmed to a temperature of 100°F, a water pressure of 60 lb psi, and containment of the wastewater. If the toxic material is oily or firmly adherent to the child's skin, a mild soap or shampoo should be used; solutions such as mild bleach should not be used on children because of the risk of skin injury.[31] If an outdoor shower is not available, the child can be simply disrobed before being brought into the health care facility for further care. Decontamination can be a frightening procedure for children, exacerbated by the identity-concealing PPE that clinicians are wearing. Efforts can be made to keep parents nearby and families intact; when possible, parents should remain with their child to offer psychological support and assist with their child's decontamination.[80]

A number of studies have explored various materials—including water—for decontamination. One preliminary study of water-only decontamination of an oil-based, mock chemical-biological agent suggested that 100% of subjects could be decontaminated within 90 seconds.[81] Although proprietary agents are available for specific types of exposures, a review of corrosive dermal exposures found that water is efficacious, widely available, and inexpensive.[82] In specific, known exposures, other decontamination agents may be more effective: a study of the molecular tracer 4-cyanophenol found that decontamination efficiency from porcine skin was 54% with water, up to 70% with dry fuller's earth, and around 90% with a suspension of fuller's earth.[83] In terms of wet versus dry decontamination, another study of absorbent materials in an ex vivo model indicated that dry decontamination was superior to wet methods for removing liquid contaminants but was not effective against particulate matter.[84]

The consensus among investigators, however, is that time is the single most important factor in successful decontamination.[85] In most cases, decontamination is most successful if performed within minutes of exposure, which has the added benefit of mitigating the demand on health care facilities. This has introduced the concept of self-care decontamination and the mnemonic MADE: move and assist, disrobe and decontaminate, evaluate and evacuate.[86]

All health care professionals who assist in decontamination must protect themselves by wearing appropriate PPE.[87] Currently, there are 4 levels of PPE, ranging from level A, which is the highest level of protection, to level D, which consists of a simple gown, gloves, and surgical mask. Many exposed subjects self-present to health care facilities. For hospital personnel, level C PPE (a chemical-resistant suit and gloves, with an air-purifying respirator) is considered adequate for hospital-based management of most contaminated victims. Health care facilities can develop plans for rapid access to PPE equipment and train staff on its use. Other recently published principles of decontamination and PPE are outlined in Table 5.[88,89]

Isolation and Containment

In the current era, hospitals and health clinics need to develop protocols to be vigilant in screening, isolating, and starting treatment of patients with highly contagious emerging infectious diseases. Ideally, integrated communication systems will be in place to help clinicians identify pediatric patients with concerning travel history and possible exposures to an emerging infectious disease. Clinicians can become better prepared by knowing how to contact local and state public health officials if there is concern of a highly contagious pathogen, an emerging infection, or a cluster of illness. Preparation for the 2013–2016 Ebola virus outbreak has led to federally identified biocontainment treatment centers in each US region, including, in some cases, tertiary care pediatric hospitals. Institutions caring for a child with a high-consequence pathogen require policies that include and recognize the developmental and psychological needs of children as well as policies that address parental presence and the use of age-appropriate equipment and supplies.[90,91]

Surge Capacity

An effective response to large-scale chemical or biological terrorism (ie, an incident with more casualties than routine operations can accommodate) requires the creation of surge capacity protocols. Federal, state, and local public health authorities are essential in assisting health facilities during crises of large magnitude. Crisis standards of care have been reviewed and established at all levels.[92] Definitive care of pediatric patients is increasingly dependent on interhospital transfers and referral centers.[93] Lack of disaster planning for children in local health care facilities will impede and complicate the care of children. Because disasters happen locally, all health care systems must consult with pediatric experts and plan for the needs of children during a disaster. Plans for such an event might include (1) the creation of additional bed spaces through cohorting; (2) mechanisms for the rapid discharge of inpatients to increase capacity; (3) an inventory of all sites in the hospital where critical care can be provided; (4) establishment of a site for patient triage, ideally outside of the hospital; (5) identification of care sites for those whose injuries are minor; (6) mechanisms for labeling and tracking patients, particularly children who arrive without personal identification and may not be able to identify their parents; and (7) plans for maintaining hospital security by preventing the entry of contaminated victims and other unauthorized individuals.[94,95] For nonpediatric hospitals, surge capacity plans for a mass-casualty chemical or biological incident involving children can include mechanisms for mobilizing health care professionals with pediatric expertise, including telemedicine. Surge capacity principles are summarized in Table 6.

Pediatric Mental Health

Given that the primary intent of terrorist attacks is to cause psychological distress among victims, witnesses, and the general population, it is to be expected that adjustment reactions will be a major challenge—if not the primary challenge—after chemical and biological terrorism, for both children and adults. Children are among those most at risk for psychological trauma and behavioral difficulties after

TABLE 5 Principles of Decontamination

Principles
All decontamination should occur outside of the health care facility.
All health care professionals should wear appropriate PPE, as determined by their safety officer and occupational health specialist.
All levels of health care professionals should be trained to quickly access and use PPE, including physicians, nurses, clinical assistants, security, and environmental services.
Remove clothing from the victims as quickly as possible. Victims should disrobe themselves when possible.
Discarded clothing should be placed in a labeled plastic bag and stored for possible use by law enforcement.
Consider dry (removal of clothing, scraping, absorbent or adsorbent materials, vacuuming, pressurized air, and/or provision of replacement clothing) versus wet decontamination (addition of showers).
If showering is used, ensure the following:
The water should have a temperature of approximately 100°F and a pressure of 60 psi.
Water alone is used routinely. If the material is oily, a mild soap or shampoo should be added.
Victims should shower for 5 min unless specific alternative recommendations are given.
When possible, water effluent should be contained rather than placing it in the local wastewater stream.
Use heat lamps, blankets, and other mechanisms to prevent hypothermia.
Cover hands, feet, and other exposed areas of the victim if there is evidence of gross contamination.
If there are multiple victims, anticipate the need to perform out-of-hospital triage.

a disaster and will also be influenced by their parents' reactions and by coverage in social and public media. Children may experience short- and long-term effects on their psychological functioning, emotional adjustment, and developmental trajectory. Adjustment reactions may include anxiety, worries, or fears; sadness or depression; difficulties with concentration and learning; developmental or social regression; sleep or eating problems; substance abuse or other risk-taking behavior; posttraumatic reactions and disorders; bereavement when deaths have occurred; and somatization. These reactions may be seen even among children in the community who have had no direct or indirect exposure to the chemical or biological agents. These reactions may persist long after an event, which should be a consideration for those children who have escaped countries where such terrorist attacks are known or believed to have occurred in the past.

Emotional distress may interfere with accurate reporting of symptoms or instead mimic physical responses to the chemical or biological agents. Primary and subspecialty care pediatricians will often be the first to see children experiencing psychological distress in this setting, whether it presents as physical complaints, an adjustment reaction to the terrorist attack, or a combination. Given that virtually all children in a community affected by a terrorist attack are likely to experience some degree of emotional distress and anxiety, it is critical that pediatricians become comfortable in the assessment and acute management of adjustment reactions and mental health problems that may be seen. Pediatricians should be prepared to provide psychosocial support, psychological first aid, and psychoeducation in addition to evaluation and referral to mental health specialists when indicated and resources allow.[5]

TABLE 6 Surge Capacity Principles for Hospitals

Principles
Preparation
Obtain PPE, showers, and other emergency-response equipment
Stockpile pediatric supplies
Stockpile or plan for additional pediatric pharmaceuticals
Perform drills; consider tabletop exercises using pediatric victims
Familiarize with wt-based dosing (eg, milligrams of medication per kilogram of body wt) for pediatric emergency medicines
Response
Anticipate a 1:5:7 ratio of critically ill/urgently ill ("walking wounded")/well ("worried well") casualties[96,97]
Anticipate the "second-wave" phenomenon[98]
Reserve the emergency department for critically ill patients
Perform triage and decontamination outside of the hospital
Put protocols in place to prevent campus security from unauthorized intrusion
Identify and use alternate sites of care; identify transportation options

Pediatricians who live in communities affected by terrorist attacks are likely to be worried about the health of family, friends, and themselves. They may find the delivery of care exhausting and emotionally draining given the surge in health care needs (in most cases predominantly because of the large number of individuals with psychological distress), the uncertainty of providing care during an evolving crisis for which the pediatrician has limited information and experience, and the distress that results from delivering compassionate care and witnessing the suffering of children and their families, pediatric colleagues, and the pediatrician's own family and friends. Attention to self-care and support of professional colleagues is an important component of the response to the crisis throughout the long-term recovery period.[5]

CONCLUSIONS

The threat of a chemical or biological attack remains high. Children can be the intended target or part of the targeted group. Although advances have been made in surveillance, pediatric disaster education, decontamination, and awareness, there continue to be gaps in incorporating children into disaster planning, especially with respect to the use of pediatric MCMs. Pediatric health care providers will need to be knowledgeable of possible agents and sequelae to provide optimal medical and mental health management for children exposed to chemical or biological terrorism. Pediatric health care providers will need to be trained on pediatric decontamination strategies as well as the use of PPE. Pediatric health providers can also help their communities with chemical and biological preparedness and response activities.

Children Exposed to Maltreatment: Assessment and the Role of Psychotropic Medication

• *Clinical Report*

CLINICAL REPORT Guidance for the Clinician in Rendering Pediatric Care

American Academy of Pediatrics

DEDICATED TO THE HEALTH OF ALL CHILDREN™

Children Exposed to Maltreatment: Assessment and the Role of Psychotropic Medication

Brooks Keeshin, MD, FAAP,[a] Heather C. Forkey, MD, FAAP,[b] George Fouras, MD, DFAACAP,[c] Harriet L. MacMillan, CM, MD, MSc, FRCPC,[d] AMERICAN ACADEMY OF PEDIATRICS, COUNCIL ON CHILD ABUSE AND NEGLECT, COUNCIL ON FOSTER CARE, ADOPTION, AND KINSHIP CARE, AMERICAN ACADEMY OF CHILD AND ADOLESCENT PSYCHIATRY, COMMITTEE ON CHILD MALTREATMENT AND VIOLENCE, COMMITTEE ON ADOPTION AND FOSTER CARE

Pediatricians regularly care for children who have experienced child maltreatment. Child maltreatment is a risk factor for a broad range of mental health problems. Issues specific to child maltreatment make addressing emotional and behavioral challenges among maltreated children difficult. This clinical report focuses on 2 key issues necessary for the care of maltreated children and adolescents in pediatric settings: trauma-informed assessments and the role of pharmacotherapy in maltreated children and adolescents. Specific to assessment, current or past involvement of the child in the child welfare system can hinder obtaining necessary information or access to appropriate treatments. Furthermore, trauma-informed assessments can help identify the need for specific interventions. Finally, it is important to take both child welfare system and trauma-informed assessment approaches into account when considering the use of psychotropic agents because there are critical diagnostic and systemic issues that affect the prescribing and discontinuing of psychiatric medications among children with a history of child maltreatment.

INTRODUCTION

Child maltreatment includes physical, sexual, and psychological abuse as well as neglect experienced by children and adolescents. Approximately 700 000 children and adolescents are substantiated victims of maltreatment in the United States each year.[1] The actual number is likely higher because nationally reported child welfare statistics greatly underestimate the prevalence of child maltreatment.[2] Pediatric health care providers routinely care for maltreated children and adolescents, and a disproportionate number of children and adolescents with a history of

maltreatment are likely to experience emotional, behavioral, and developmental problems.[3,4]

Addressing mental health conditions in children and adolescents who have experienced maltreatment involves a comprehensive assessment that is used to guide the provision of follow-up care and treatment. When maltreated children receive treatment of emotional and behavioral problems, emphasis may be placed on pharmacotherapy rather than on a broad range of interventions, including psychotherapy.[5] Each child's case will have its own individual features, and there are situations in which medications are necessary; however, irrespective of mental health diagnosis, maltreated children and adolescents receive more psychotropic medications than comparable populations receiving psychiatric care, suggesting overtreatment.[6,7] Children and adolescents involved with the child welfare system are 2 to 3 times more likely to be treated with psychotropic medication compared with those without such involvement.[8,9] In addition, 33% of all foster children are prescribed a psychotropic medication. Among Medicaid-eligible children, foster children are approximately 4 times more likely to be prescribed a second-generation antipsychotic than children not in foster care,[10] with 10% of foster children receiving 3 or more psychotropic medications at any given time.[11]

The purpose of this clinical report is to provide guidance for pediatric health care providers on the assessment and treatment of mental health conditions commonly experienced by maltreated children and adolescents in both foster care and in-home placement with a particular focus on the appropriate use of psychotropic medication. The report reviews: (1) the potential impact of the child welfare system on mental health assessment and treatment; (2) methods for assessing children and adolescents for traumatic experiences, including trauma- and non–trauma-related symptoms; and (3) approaches to the use of psychotropic medication among maltreated children and adolescents. The latter will include principles and recommendations for the prescribing and discontinuing of psychotropic medications.

ASSESSMENT

Child Welfare System

Understanding key aspects of the child welfare system and how it serves children is important for the assessment of child maltreatment experiences and traumatic stress symptoms as well as treatment planning. Although there is variability among jurisdictions, many of the key decision points are consistent across systems. Contact with child protective services (CPS) begins with a report filed by a mandated reporter, a concerned citizen, or a family member. For substantiated cases with an identified safety or risk issue, a court petition may be filed, which may result in the child becoming a court dependent. In court-dependent cases, service plans or reunification requirements ordered by the court determine the services or "reasonable efforts" that CPS must provide to the family and caregivers of the child. Cases are reviewed periodically to check on the progress of the parents or caregivers as they work toward achieving service plan goals with the aim of eventual reunification of the dependent child with his or her family, if safe to do so.

In court proceedings, the concept of "best interests of the child" is typically used to guide decisions. In addition, the principles of least restrictive settings, maintenance of family or kinship relations, and permanency are important considerations. For children who cannot safely stay at home, placement with a foster or kinship family will be the next step. It is not uncommon in the foster care system for living circumstances to be disrupted and to experience multiple moves within the system. Half of children in foster care are moved to other homes or more restrictive settings while in foster care because of behavioral concerns.[12] After multiple failed placements or when specialized services are needed, children may be moved to residential or congregate care (ie, group homes).

Emotional, Behavioral, and Developmental Problems

A recent clinical report from the American Academy of Pediatrics (AAP), "Clinical Considerations Related to the Behavioral Manifestations of Child Maltreatment,"[13] recognizes that children and adolescents who have been exposed to one or more types of maltreatment may experience a broad range of emotional, behavioral, and developmental problems.[14–17] The clinical report provides a comprehensive overview of these signs and symptoms as well as some of the most commonly associated conditions, such as posttraumatic stress disorder (PTSD).[13] Young children are overrepresented in the maltreated population and may also have emotional and behavioral problems as a result of maltreatment. These clinical problems may include changes in mood, anxiety, sleep, eating or feeding, and behavioral patterns and require that the pediatric health care provider be vigilant for the changes, given developmental stage and limited verbal interactions.[18] Because pediatricians, child psychiatrists, and other health care professionals encounter children in their practices who have been abused and/or neglected, it is important for these pediatric providers to assist children and their families in addressing impairments associated with maltreatment.

Child maltreatment is an experience and not a symptom or disorder. A focused and trauma-informed assessment should be conducted before initiating treatment including referral of a child and/or family to a specific intervention and/or medication. The broad range of conditions and symptoms associated with different forms of child maltreatment show little specificity by type of experience.[2,19] Furthermore, children and adolescents are often exposed to more than one type of maltreatment,[20] and the effects of maltreatment can overlap or be comorbid with non–trauma-related conditions. When available, review of CPS court reports or court reports filed by an assigned court-appointed special advocate can provide valuable assessment information for the pediatric provider. Determination of which aspects of a child's emotional, behavioral, or developmental condition are directly related to specific episodes of child maltreatment versus chronic exposure to maltreatment or other biological, familial, and social factors can be difficult and is generally not possible in the pediatric setting.

Developing a comprehensive picture of a child's exposure to and effects from maltreatment is important because of the pervasive consequences that maltreatment can have on the developing child. Multiple domains of functioning can be affected, including attachment, cognition, self-image, emotional responses, social interactions, and behavior.[21] Affected children and adolescents and their families often interact with professionals from multiple service sectors, including health care, mental health, child welfare, law enforcement, education, and juvenile justice. A number of specific factors may be considered, including the type and timing of exposure to maltreatment as related to developmental stage, the range of symptoms, functional impairment including developmental delay, and how behaviors and symptoms may be related to triggers and reminders of the maltreatment.

Medical, Social, and Trauma Histories

Medical, social, and trauma histories are particularly important in determining the intervention needs of a child and family when history includes child maltreatment. Emphasis on history helps to change the conversation from "What is wrong with you?" to "What happened to you?" This trauma-informed approach is critical to destigmatize and validate the patient and family. The approach will differ depending on the child's living arrangements and access to caregivers. The goal is for the clinician to communicate to the child and family an openness to hearing about past and present events and convey the message that the information is important in formulating decisions about treatment in the present and future. Children and/or family do not necessarily have to provide all details about past injuries, traumas, social services involvement, or foster care placements because this information may be gathered from other sources. Child welfare, school, and previous medical records, when available, can be obtained to inform the history.

Pediatricians should obtain a comprehensive social history to inform a child's treatment needs after exposure to abuse and/or neglect.[22] They should attempt to determine the child's current living arrangements, including any contact with the biological family, foster care placement, residential treatment, or involvement with juvenile justice. The assessment of any ongoing violence, including exposure to intimate partner violence among caregivers, is not only the responsibility of CPS; the pediatrician should be alert to these issues as well as parental mental health problems, including substance use disorder. Pediatricians must emphasize safety as a paramount consideration. It should be made clear that if a child or family is unsafe at any time, an emergency report will be made to CPS.

Assessment of Current Trauma, Social Determinants of Health, and Resilience

Increasingly, pediatric literature supports the practice of being aware of and alert to children's traumatic experiences and social determinants of health because these are important considerations when making decisions about diagnoses and treatments. Traumatic events, including maltreatment, can have a multiplicative effect,[23] and stressors beyond maltreatment, such as poverty and community violence, can contribute to the harm experienced by the child.[24,25] Increasingly, pediatric literature supports taking resilience into account, which allows the pediatric provider to address these issues with a more positive and potentially empowering perspective.[26] Yet, there are no outcome studies indicating benefits of one assessment approach over the other.[27]

It is important for pediatricians to be alert to the possibility of ongoing trauma in children who have experienced past trauma and to demonstrate openness to hearing about ongoing or recurrent experiences of maltreatment. The pediatric provider can spend time with the older child or adolescent individually and ask questions such as, "How are people in the family getting along?" and "Sometimes kids are worried about their safety or the safety of someone at home. What about you?" In some settings, the pediatrician may not be the only professional in a position to ask these questions of the child and may collaborate with another professional, such as a social worker or mental

health clinician. Regardless, questions should be open-ended and appropriate for the child's age and developmental stage and ability to respond appropriately.[28] If the child discloses information about ongoing maltreatment or new exposures not disclosed previously, it is important that the pediatric provider acknowledge and validate the child's disclosure. Information that is critical to providing medical care should be obtained and documented. Medical providers are not investigators like CPS and law enforcement; thus, although medically relevant information should be obtained, questions regarding nonmedical details are not necessary. If the child reveals ongoing or new information, the clinician should support the child, document the disclosure, and tell the child that this information needs to be shared with a child protection worker to help keep the child safe. Children should not be assured of absolute confidentiality when there are safety concerns. Stating this to a child in simple terms early in the visit with a phrase such as, "What you say will be just between you and me unless you are hurting yourself, someone is hurting you, or you are hurting someone else" will help avoid a situation in which a child feels that his or her confidence has been betrayed.

Caregivers can also provide useful information about social determinants of health and safety. Questions about food insecurity and parental mental health provide an opportunity for the practitioner to assess important risk factors but require a practitioner to have a plan to respond to identified family needs. It is essential that such inquiry not put the caregiver at risk; for example, in asking about intimate partner violence, caregivers should only be asked this question during individual interviews.[29] Caregivers should also not be assured of absolute confidentiality because they may provide information that raises concerns about the safety of the child.

Certain questionnaires and instruments have been developed to gather detailed information about exposure to child maltreatment; the National Child Traumatic Stress Network (www.nctsn.org) and the Child Welfare Information Gateway (https://www.childwelfare.gov) maintain updated databases of such tools. These tools have generally been used in research studies; there is no indication that the administration of these measures through screening leads to better outcomes for children.[30] Furthermore, such measures often involve considerable time, making them not feasible for use in the general pediatric setting, and their use may lead to the collection of information that overlaps with what a CPS worker needs to ask about in conducting an assessment.

Trauma-Related Symptoms

Along with screening tools for depression, anxiety, and attention-deficit/hyperactivity disorder (ADHD), specific tools to identify traumatic stress symptoms are available for use in the pediatric setting. The UCLA PTSD Reaction Index Brief Form[31] utilized in a primary care settings is one option for traumatic stress screening that is freely available. Familiarity of the pediatric provider with the tools chosen, specific symptoms or diagnoses screened by each tool, protocols to incorporate their use into office flow, and ability to address patient or family responses are all important. One example of how this can be done is the Intermountain Healthcare Pediatric Traumatic Stress Care Process Model.[32] As discussed in the AAP clinical report on the behavioral manifestations of child maltreatment, psychiatric diagnoses, including PTSD; internalizing problems, such as depression and anxiety; externalizing problems, including disruptive behavioral disorders (oppositional defiant and conduct disorders); substance use disorder; suicidal behavior; and ADHD are associated with maltreatment.[13] The term "complex trauma" is used to describe the effects of multiple or chronic traumatic experiences, which result in a wide range of cognitive, emotional, and behavioral changes that do not fit easily into common diagnostic categories. For children and adolescents who have suffered from severe, pervasive, or prolonged maltreatment, symptoms of complex trauma can result. These include intense emotional distress; disturbed sleep; attention and concentration problems; anger; aggressive, destructive, or reckless behavior; withdrawal; intrusive thoughts; exaggerated emotional response to stimuli; hypervigilance; risk-taking; and difficulty with emotional regulation.

For the symptoms of complex trauma noted above, trauma-specific measures, such as the Trauma Symptom Checklist for Children,[33] or broad behavioral assessment tools, such as the Child Behavior Checklist, may be used. The need for additional and improved tools in primary care or specialty settings to assess for complex trauma and distinguish it from other diagnoses has been noted. However, until new methods are developed and validated, children and adolescents at risk for complex trauma require comprehensive evaluations that lead to thoughtful and parsimonious formulations rather than a laundry list of diagnoses. The National Child Traumatic Stress Network (www.nctsn.org) has commonly used standardized measures for providers to assess these patients, along with specifics regarding the domains evaluated by the measure, targeted age, format, completion time, and source of more information.

The purpose of any measures used during the assessment should be discussed with the child and caregiver. Where appropriate, feedback to the child and/or family that highlights the child's strengths should be provided. Areas in which the caregiver and child agree or disagree can be discussed during the feedback. If opinions are consistent, this is a potential strength, indicating that child and caregiver are "on the same page." Discussing discrepancies may help family members to understand that children and caregivers have different perceptions of the same symptom. The feedback process can be used to provide some psychoeducation to families and patients. It can be helpful to explore the past strategies used to address behaviors, such as strong emotions. The family can be educated about triggers of certain behaviors and advised about how treatment can potentially relieve those symptoms. These approaches assist families to consider a child's actions using a "trauma lens," which can help families and children to understand behaviors and reduce stress. The National Child Traumatic Stress Network has a number of resources specifically for families and caregivers to further their understanding of the effects of trauma.

Although beyond the scope of this clinical report, information and practical guidance in integration of these components into pediatric practice, including preparing the practice, difficult conversations, managing office flow, and coding and billing, are available in the AAP guide "Helping Foster and Adoptive Families Cope with Trauma," the AAP's "Trauma Toolbox for Primary Care" (both available at https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/healthy-foster-care-america/Pages/Trauma-Guide.aspx), and Johns Hopkins University's "Improving the Capacity of Primary Care to Serve Children and Families Experiencing Trauma and Chronic Stress: A Toolkit" (available at http://web.jhu.edu/pedmentalhealth/PICC%20TOOLKIT%201.pdf).

TREATMENT

A stable home environment with responsive and nurturing caregiving is most important for children who have experienced maltreatment with resultant emotional and behavioral difficulties. In addition, such children need to receive evidence-based treatments (EBTs) demonstrated effective in this population. An overview of the evidence-based individual and family-based psychotherapeutic interventions for maltreated children and adolescents is provided in the AAP clinical report on the behavioral manifestations of child maltreatment.[13] A 2016 AAP technical report, "Addressing Early Childhood Emotional and Behavioral Problems," outlines services for the treatment of young children[18] because young, even nonverbal, children can be significantly affected by child maltreatment–related trauma. Because access to such interventions may be limited and, even when available, may be accessed only after long waitlists, pediatric providers should provide guidance and strategies to help families bridge the time until EBT can begin. Psychoeducation, relaxation training, encouraging parent-child communication, and parenting supports are features common to EBTs. Through pediatric anticipatory guidance, pediatric providers may support families with such approaches while waiting for EBT to become available. Helping nonoffending caregivers and patients learn relaxation techniques such as using belly breathing, guided imagery, meditation, yoga, stretching, and massage can be useful in dealing with traumatic stress symptoms after maltreatment.[34]Providing guidance on the importance of adequate sleep and exercise is also important. Referrals to community resources for mindfulness programs and parenting support can be useful in supporting children and families.

Sometimes, in an attempt to preserve existing foster care placements and reduce failure of caregiving arrangements, providers will turn to psychotropic medication in an attempt to control disruptive behaviors that threaten a placement. A Government Accounting Office report from 2011 reviewed Medicaid claims data for children and adolescents both in foster care and not in foster care in 5 states: Florida, Massachusetts, Michigan, Oregon, and Texas.[35] In this report, children and adolescents in foster care were found to be prescribed psychotropic medications at rates 2.7 to 4.5 times higher than those who were not in foster care. The report also cited high rates of polypharmacy, high doses of medications, and young age at initiation of medication therapy.[35] A follow-up report from 2012 examined Medicaid and private insurance claims data and found that children and adolescents enrolled in Medicaid were more likely to be on psychotropic medication without psychosocial interventions, such as psychotherapy. In response to the increased use of psychotropic medications in foster care, child welfare agencies have adopted programs to provide psychotropic medication oversight.[36] Detailed discussion of these programs is beyond the scope of this clinical report, but they commonly include a review by a medical practitioner with a recommendation to the child welfare agency and/or the courts for action. In some jurisdictions, parents or other stakeholders may also be given the opportunity to contest the administration of medication during a court hearing.

General Pharmacotherapy Considerations

Ideally, pediatricians work closely with therapists and psychiatrists when treating maltreated children in need of pharmacotherapy. Some pediatricians work in integrated care settings that may provide colocated or collaborative care. These models tend to enhance coordination and continuity of care and are well suited to address the clinical and system-level complexity of children exposed to child maltreatment.[37] However, primary care providers are often not in a position to provide integrated mental health care, nor do they necessarily have access to evidence-based trauma-focused interventions for maltreated children. This lack of access may lead to underuse of trauma-informed, evidence-based psychotherapies and may be one of many factors leading to the increased prescription of psychotropic medication among maltreated children and adolescents.

Having to consider the use of a medication to treat symptoms in maltreated children is a reality faced by primary care providers. Therefore, it is critical for pediatric providers to remember the following key concepts when considering the use of medications:

1. Maltreated children are more likely to have complex trauma including multiple or chronic traumatic experiences that result in a wide range of cognitive, emotional, and behavioral changes that do not easily fit into common diagnostic categories. Unidentified complex trauma may lead to children and adolescents being given multiple psychiatric diagnoses in an effort to capture the many manifestations of the trauma.[38]
2. Even when phenotypically similar to common disorders, individuals with a history of child maltreatment constitute a distinct "ecophenotype" (as described by Teicher and Sampson[4]) with different underlying biological changes and, thus, may not respond in predictable ways to treatments traditionally prescribed for mental health conditions.[4] This phenomenon may be especially true for young children.[18]
3. Maltreated children and adolescents may be more susceptible to adverse effects associated with psychotropic medication, such as excessive weight gain and suicidality.[39,40] It is essential that pediatricians are cautious when considering the use of psychotropic treatments in maltreated children.
4. Accurate diagnosis of both trauma- and non–trauma-specific conditions is crucial for choosing a treatment plan to alleviate symptoms in maltreated patients.
5. When starting, continuing, or discontinuing a medication, shared decision-making and informed consent are used for the child's given placement (home, kinship, or foster care) with the appropriate caregiver or proxy (which may vary by state in foster placements) as well as assent, when indicated. Before prescribing, providers will need to consider, identify, and obtain the consents required in their locality according to the placement status of the child.[41]

Ongoing Trauma Exposure

The biological aspects of trauma-specific disorders are discussed in the AAP clinical report on the behavioral manifestations of child maltreatment.[13] When considering treatment options, it is important to remember that behaviors such as increased reactivity, hyperarousal, and poor attention to stimuli (such as school work) in the presence of ongoing danger are not pathologic but a normal stress response.[42] Furthermore, in situations in which maltreated children continue to be at risk, there is little value in a pharmacotherapy trial for possible comorbidities until the danger has been mitigated.[43] Medication trials for the child's developmentally normal response to an ongoing threat are inappropriate and invalidating to the child. In addition, focusing on medication rather than the family distracts from approaches aimed at collaboration with child welfare and other community agencies to enhance overall safety and develop enhanced safety skills for the child, which is a core component of most evidence-based trauma psychotherapies.[43]

Sleep Disturbances

Children and adolescents who have experienced maltreatment often have sleep problems that can be a manifestation of specific trauma-related symptoms or may result from poor sleep hygiene and inadequate environmental and family supports for healthy sleep.[44] When maltreated children present with sleep problems, pediatricians should begin with providing psychoeducation on the connection between traumatic exposures and sleep difficulties.[45] Along with general sleep guidance (hygiene), such as limiting screen time and decreasing caffeine intake, other strategies specific to a history of trauma may include encouraging the family to reestablish routines around bedtime that calm the child (eg, warm bath, chamomile tea, story time), enhancing the child's feelings of safety at night (eg, parent staying in room at first while child falls asleep, use of a night light), and actively decreasing distress experienced by the child through use of techniques such as focused breathing and guided imagery.[34]

There is little evidence on effective medications for the treatment of sleep problems in children and adolescents.[46] Sleep problems should prompt the clinician to assess for disorders common in maltreated

children, including PTSD, anxiety, depression, and behavioral problems. Referral to mental health providers should be made if there is an inadequate response to primary sleep interventions, sleep problems that are frequent or severe and/or worsening over time, or the identification of psychiatric comorbidity that has persisted after trauma (eg, PTSD, anxiety, depression, behavioral issues). After attempting nonpharmacologic interventions, concurrent with or before a mental health referral for persistent sleep difficulties, a trial of melatonin can be considered.[46] Melatonin has been found to be efficacious in pediatric populations at risk for insomnia, such as those with ADHD and autism spectrum disorders.[47,48] Additionally, treatment of comorbidities should be considered to avoid the risk of polypharmacy.[49] Because of the lack of evidence and the option of safer alternatives, as well as significant adverse effects and risks, first- and second-generation antipsychotics and benzodiazepines are not recommended for the treatment of sleep problems in children and adolescents.[43]

PTSD

Evidence-based psychotherapies are the most effective treatment of children with PTSD[50] and should always be considered first before initiating medication trials.[13,34] To date, no medication is approved by the US Food and Drug Administration (FDA) for treatment of trauma-specific symptoms or PTSD in children and adolescents.[43] In 2 separate randomized controlled trials evaluating the efficacy of sertraline (an FDA-approved selective serotonin reuptake inhibitor [SSRI] for PTSD in adults) in the treatment of PTSD among pediatric patients, no benefit was found, either as monotherapy or in combination with evidence-based psychotherapy.[51,52] In adults with PTSD, prazosin has been demonstrated as effective in treating nightmares and sleep disturbances.[53] Prazosin may be considered for children and adolescents with PTSD and severe sleep difficulties, according to expert consensus guidelines such as the "Florida Best Practice Psychotherapeutic Medication Guidelines for Children and Adolescents," on the basis of a review of retrospective data (Table 1).[54] However, given the substantial evidence supporting the efficacy of certain psychotherapeutic approaches for the treatment of trauma-exposed children and the paucity of rigorous studies evaluating pharmacologic agents in children with PTSD,[34,50] there is at present no evidence to support the use of medications without first providing evidence-based psychotherapies in the treatment of pediatric PTSD.

Other Diagnostic Considerations

Children and adolescents with a history of maltreatment are at increased risk of disorders that are not trauma specific and for which judicious use of medication may be indicated. Common disorders such as anxiety, depression, and ADHD are overrepresented in children with histories of child maltreatment and other types of adversity.[3,4,55,56] Depending on the experience and expertise of the pediatric health care provider, the provider should use standardized measures to assess the wide array of possible psychiatric diagnoses or refer to a child psychiatrist.[49]

Although some of the information that follows may seem outside the scope of practice for pediatricians, in fact, pediatric health care providers may be the only resource available for this type of care because of the limited availability of psychiatrists. It is often difficult to distinguish between anxiety, depression, disruptive behavior, and trauma-specific disorders, especially when the symptoms could be indicative of comorbidity or syndromic overlap (Table 2). For example, the intrusive and hyperarousal symptoms of PTSD can appear similar to symptoms of anxiety or ADHD in a child brought to primary care for possible psychotropic medication management. Assessing for additional traumatic stress symptoms, inquiring about the temporal relationship between maltreatment experiences and the onset and exacerbation of symptoms, and poor responses to previous pharmacologic interventions may provide important insights. For example, symptoms initially identified by caregivers as related to anxiety or ADHD may be better explained by PTSD and, therefore, may not be appropriate for pharmacotherapy, as described in the preceding section on PTSD. The revised PTSD criteria in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*, include negative or decreased cognition and mood with many specific symptoms, such as negative beliefs toward self, self-blame, negative emotional state, loss of interest in previously enjoyable activities, and feeling detached.[57] Determining symptoms of depression versus PTSD and possible comorbidity has significant treatment implications. Over time, when disorders such as anxiety, depression, and ADHD are clearly identified, monotherapy trials of psychotropic medications may be warranted (Table 1).

Suicidal ideation and suicide attempts are often related to the presence of mental illness generally[58] and not limited to depression alone. Older children and adolescents who have been maltreated are at increased risk of suicidality and self-harm.[59] Asking questions regarding self-harm and suicidal ideation is critical because patients may not appear suicidal in the clinical setting. Measures such as the Columbia Suicide Severity Rating Scale[60] can assist practices in standardizing their approach to

TABLE 1 Pharmacologic Treatment Considerations in Maltreated Children and Adolescents

Disorder	Initial Considerations	Ongoing Monitoring Strategy	Second-Line Considerations	Treatments Pitfalls To Avoid
General pediatric mental health concerns	Start with psychosocial treatment. Nonoffending parental involvement is essential, with involvement of other caregivers and school-based interventions as needed. In mild cases, attempt at least 12 wk of psychosocial interventions before medication.	Monitor response to treatment by using reliable and valid measures. If medications are being considered, first reassess the diagnosis and diagnostic formulation. Weigh the risks and benefits of initiating treatment with psychotropic medications.	When starting medication: • Initiate with monotherapy • When using medication, initiate at a low dose and slowly titrate (start low, go slow) • Continue psychosocial treatment during treatment with medication • Monitor for suicidality • Monitor for adverse effects of medications	• Polypharmacy • Antipsychotics should be restricted to schizophrenia, mania or bipolar disorder, psychotic depression, drug-induced psychosis, tic disorders, and severe aggression.
PTSD	The greatest level of evidence supports exposure-based therapies, of which, TF-CBT has the most data and is the most widely used. In children <6 y, may consider TF-CBT (4 mo) or CPP (6 mo) as first-line treatment.	Monitor for treatment response. When TF-CBT is not readily available or effective, consider: • Prolonged exposure therapy • Eye movement desensitization and reprocessing • Trauma and grief components therapy for adolescents • Child and family traumatic stress intervention (PTSD prevention therapy)	• For PTSD symptoms that impair sleep (eg, nightmares, nighttime hyperarousal), may consider psychotherapy augmentation with prazosin • For persistent intrusive or arousal or reactivity, may consider psychotherapy augmentation with clonidine or guanfacine	• Pharmacotherapy-absent trauma-focused psychotherapy • Polypharmacy • Antipsychotics • Benzodiazepines • Multiple antihypertensive medications
Depression	Psychoeducation and psychosocial interventions including but not limited to self-help materials, active listening or relationship building, school involvement, mood monitoring, opportunities for play and recreational activities, cognitive restructuring, family conflict reduction, sleep hygiene, and exercise.	• Psychotherapy for mild to moderate depression • For moderate to severe depression, fluoxetine or combination of CBT or IPT with fluoxetine • May consider escitalopram for patients 12 y and older	• If no clinical response to the medication in first trial, switch to other SSRI • Reassess diagnosis or medication adverse effects • Increase psychosocial intervention and medication dose if tolerated • Augment with alternate psychosocial intervention (either CBT or IPT)	• Polypharmacy • Antipsychotics • Benzodiazepines
Anxiety	Initiate treatment with exposure-based CBT. If CBT is not available, consider other evidence-based psychosocial interventions.	• If moderate to severe anxiety disorder or inadequate response to CBT, initiate treatment with fluoxetine or sertraline alone or with CBT • Treatment with CBT has been shown to be more effective than medication alone	• If first trial with fluoxetine or sertraline is not effective and/or there are treatment-limiting adverse effects, switch to the other SSRI not previously used and initiate or continue CBT	• Polypharmacy • Antipsychotics • Benzodiazepines
ADHD	When clinically feasible, observe for potential traumatic stress symptom overlap in children exposed to maltreatment. If unsafe, or if ADHD symptoms persist with EBTs for traumatic stress and home stabilization, proceed with ADHD treatment.	• Psychostimulant monotherapy (methylphenidate class or amphetamine class, either short- or long-acting) • If first choice is ineffective, try monotherapy with another stimulant or alpha-2 agonist	• Combination of extended-release alpha-2 agonist with psychostimulant or trial of atomoxetine	• Antipsychotics • Multiple concurrent antihypertensive medications

identifying and then assessing suicidality. Although most suicide screening and assessment processes have been validated for adolescents, they can be adapted for older children. When there is indication of suicidal ideation or suicidal behavior, using a standardized clinical approach may be helpful. Evidence-based approaches, such as the Family Intervention for Suicide Prevention, use behavioral assessments and family-based considerations when determining risk and protective factors for suicide and have been shown to increase linkage with ongoing mental health care for suicidal adolescents.[61] Although

TABLE 2 Potential for Diagnostic Overlap With Trauma- and Non–Trauma-Specific Symptoms

Traumatic stress and depression		
PTSD symptom clusters may mimic symptoms commonly considered indications of depression	**Negative cognition and mood sypmtoms** of PTSD include depressive similar symptoms: negative belief toward self, self-blame, negative emotional state, loss of interest, detachment	**Hyperarousal and increased reactivity** in PTSD include depressive similar symptoms[a]: irritable and angry, reckless and self-destructive behavior, poor concentration, sleep disturbances
Traumatic stress and anxiety		
Panic attacks may not indicate panic disorder if attacks are triggered by trauma reminders, better explained as intrusive and hyperarousal symptoms of PTSD	Separation challenges may be similar to **separation anxiety** but could be trauma specific depending on context of traumatic experience(s) and association with trauma reminders	**Generalized and social anxiety** are often independent of trauma-specific context and reminders; however, still important to consider symptoms in context of traumatic experiences
Traumatic stress and ADHD		
Many overlapping symptoms make differentiating trauma and ADHD symptoms in the presence of traumatic stress nearly impossible, especially in younger children	**Collateral information** from multiple settings may help clarify if symptoms are specific/exacerbated by certain relationships/settings or are more universal	**Reevaluation after treatment for traumatic stress** and reduction of trauma symptoms for possible ADHD may be needed to make diagnosis

[a] Suicidal ideation is a well-recognized symptom of major depressive disorder. However, suicidal ideation and nonsuicidal self-injurious behavior can be observed in a number of conditions in addition to depression that disproportionally affect maltreated children, including, but not limited to, PTSD, anxiety, substance use disorder, and personality, mood, and psychotic disorders.

many maltreated adolescents with significant suicidality or self-harm ideation may benefit from evidence-based therapies, such as Trauma-Focused Cognitive Behavior Therapy,[62] stabilization and enhancing safety must occur before the child can receive trauma-specific therapies in the outpatient setting. When indicated, more intensive levels of care, such as inpatient hospitalization, day treatment, or intensive outpatient treatments (such as Dialectical Behavior Therapy), are necessary before the initiation of trauma-specific outpatient therapies.[63] Of note, crisis interventions like the Family Intervention for Suicide Prevention or more intensive interventions as described above are, as of now, intended for adolescents and nonoffending family and caregivers and should be an important consideration when working with maltreated adolescents.

Discontinuing Medication

In 2009, the American Academy of Child and Adolescent Psychiatry (AACAP) identified principles to follow, including developing a specific plan, when discontinuing psychiatric medications.[49] Over the last 2 decades, there has been interest among some child psychiatrists in refinement of processes for appropriate discontinuation of medications, reflecting the frequency of psychotropic prescriptions given to children and adolescents as well as the rate of psychotropic polypharmacy.[64] Especially in vulnerable populations, such as maltreated children and adolescents, it is a priority to identify the reasons for the use of psychotropic medications.[35] The AACAP and other organizations indicate that if evidence-based prescribing practices were used and systems of care were strengthened, the use of psychotropic treatment and medication burden among maltreated children and adolescents could be lessened.[65,66]

Discontinuing medications is the process of identifying and then tapering off medications that are no longer indicated or when the existing or potential risks outweigh the existing or potential benefits.[64] Safe medication discontinuation is an area in need of further research and clear policies and practice guidance because it pertains to children and adolescents. However, pediatricians are often confronted with challenging clinical issues for which clear guidelines or definitive evidence about how to respond is absent. For example, the use of a psychotropic medication may be necessitating the administration of another psychotropic to address effects of the first medication (ie, the addition of a sleep medication to treat insomnia that has developed after beginning a psychotropic medication).[29,49] Additionally, children, adolescents, and/or families may be advocating for a simplification of the pharmacotherapy and desiring guidance as to how best to proceed.

A practical and safe approach to medication discontinuation is not simply medication cessation but rather assessing for the minimal effective dose and number of medications. Because there can be multiple reasons for prescribing psychotropic medications to children with a history of maltreatment, a broad and thoughtful approach is crucial. When a complete clinical picture is not available, pediatricians may be hesitant to reduce even substantial medication regimens because of a concern about escalation in symptoms.[67] However, it is

important to recognize that discontinuing medication is not necessarily a static, one-time event but should be considered part of an ongoing treatment plan.[64] Periodic reassessment of the diagnosis, formulation, and treatment plan is necessary as new information becomes available and in response to the currently provided treatment.[64]

Unfortunately, for many psychotropic medications, there is no standardized approach to determining when psychotropic medications are no longer required. However, Bellonci et al[64] have provided guidance and considerations on the process:

1. Ascertaining the complete medication history, which requires a comprehensive assessment in which a review of previous records is essential to assess what has been tried in the past and the basis for the current regimen.
2. Considering the risk and adverse effect profile of the current medication regimen.
3. Assessing each medication currently being prescribed in light of the comprehensive assessment.
4. Creating an order priority for each medication to be either decreased or discontinued.
5. Implementing the treatment plan.
6. Monitoring treatment plan effects and reassessing.

Additionally, when selecting medications to decrease or discontinue, factors to consider include (1) medications for which there is no clear or valid indication; (2) medications that are part of a prescribing cascade, which may occur when an adverse effect of a medication(s) is used as the basis for another diagnosis and a new medication added; (3) when actual harm or potential harm is greater than the benefits; (4) medications that appear to be duplicative, redundant, or ineffective or the symptoms have resolved; (5) medications that are preventive (prophylactic) in nature; and (6) medications that are imposing an unacceptable treatment burden for the patient and family.[64] The off-label use of medication may pose a concern to pediatric providers and their patients in clinical practice. However, the off-label use of medication is not synonymous with a lack of evidence to support its use. Levels of evidence, ranging from a lower level, such as a case series, to a higher level, such as a randomized controlled trial or a meta-analysis, provide the basis of support or indication for the off-label use of a medication. With regard to medication discontinuation, it is the level of evidence of support for the treatment, in addition to the other factors noted, that should drive the decision-making process, rather than simply basing it on whether a medication is FDA approved.[49]

As suggested by Bellonci et al,[64] this process of discontinuing psychotropic medication may be operationalized by (1) beginning with a medication that has the least evidence of efficacy or has the greatest evidence for adverse effects, (2) focusing on medications that are being prescribed at supratherapeutic doses with no reasonable justification, (3) focusing on medications that are being given in subtherapeutic doses with no evidence of effectiveness, and (4) addressing only 1 medication at a time so that there is clarity, should an adverse effect develop or symptoms return.

When to Refer to Child Psychiatry

Access to mental health assessments by psychiatrists can be difficult, often because many regions do not have enough child psychiatrists to meet the demand. Child psychiatry referrals should be made for children with diagnostic uncertainty and for those in whom multiple trials of medications have failed or who are taking 2 or more psychotropic medications (or 1 medication, if the medication is an antipsychotic).[49] Referral to child psychiatry should be considered when parents or guardians of maltreated children are advocating for treatment regimens beyond the pediatrician's regular scope of practice or the pediatrician believes that addressing the needs of child and family are beyond his or her capability.[49] Furthermore, it is important for pediatricians to routinely monitor for adverse effects from psychiatric medications. Monitoring is not limited to medications that pediatricians initiate because adverse effects of a medication initiated by a mental health provider may prompt a medical, rather than psychiatric, visit. Referral to child psychiatry should not take the place of referral to a trained therapist who can evaluate and initiate evidence-based therapies for traumatic stress.[45]

CONCLUSIONS

Children and adolescents who experience maltreatment are at great risk of revictimization and mental health sequelae, and it is incumbent on the pediatric primary care provider to work collaboratively with families and the child welfare system and to participate in the assessment, management, and appropriate referral for trauma-related conditions common among maltreated children and adolescents. Although no studies to date demonstrate that early intervention with EBT mitigates the long-term sequelae associated with child maltreatment, reducing symptoms and promoting return to healthy functioning at school and at home have important implications for quality of life and overall well-being. It is, therefore, essential that pediatric providers conduct comprehensive assessments whenever feasible to determine where EBT strategies apply and avoid the use of medications that have little or no likely benefit. There is a clear need for controlled trials of interventions

including pharmacologic agents to help determine evidence-based approaches to reducing impairment in children and adolescents exposed to maltreatment. Although medications have a role, the evidence to date is limited, and nonpharmacologic approaches are preferred.

Clinical Considerations for the Pediatrician

1. Children who experience child maltreatment are best served by providers and systems that use trauma-informed approaches to care.
2. Interactions with child welfare can be complex and can result in treatment barriers and issues.
3. When assessing traumatic experiences and symptoms, ensure that there are approaches in place to respond to the information obtained so that children who have experienced maltreatment and their families can be supported. This support could be provided by the pediatrician and/or by referrals, depending on the setting and context.
4. Treatment that is primarily focused on psychosocial interventions rather than medications and tailored to the unique needs of the child is often of greatest value and least risk to children with a history of child maltreatment.

Key Action Statements

- Pediatricians should communicate to the children and families an openness to hearing about past and present events and convey the message that the information is important in formulating decisions about treatment in the present and future.
- The pediatrician should obtain a comprehensive social history to inform a child's treatment needs after exposure to abuse and/or neglect.
- The pediatrician must be alert to ongoing trauma and violence, including exposure to intimate partner violence among caregivers, and parental mental health problems, including substance use disorder.
- Pediatricians must emphasize safety as a paramount consideration and make it clear that if a child or family is unsafe at any time, an emergent report will be made to CPS.
- Pediatricians should not assure children or caregivers of absolute confidentiality.
- Before the initiation of psychosocial or medication interventions, a focused assessment of the child should be conducted by a clinician trained in the assessment of children exposed to maltreatment.
- Children who have experienced maltreatment with resultant emotional and behavioral difficulties should receive evidence-based psychotherapies and treatments with demonstrated effectiveness.
- Pediatric providers should provide resources to bridge the period until EBT can begin, including psychoeducation, relaxation training, encouraging parent-child communication, and parenting supports.
- Pediatricians should refer children with sleep disorders after trauma to mental health providers if there is an inadequate response to primary sleep interventions.
- First- and second-generation antipsychotics and benzodiazepines should not be used for the treatment of sleep problems in children and adolescents and are not generally indicated for the treatment of the most common disorders found among maltreated children, specifically, PTSD, anxiety, depression, and ADHD.
- When anxiety, depression, or ADHD is suspected, pediatric health care providers should consider that traumatic stress may better explain the symptoms of concern and use standardized measures to assess the possible psychiatric diagnoses or refer to a child psychiatrist.
- Pediatricians should ask maltreated children and adolescents questions regarding self-harm and suicidal ideation, even if patients may not appear suicidal, preferably using standardized tools such as the Columbia Suicide Severity Rating Scale.
- Pediatricians who are considering discontinuing medications should employ evidence-based protocols that incorporate principles of optimizing the medication regimen (ie, focusing on medications with significant risk, limited evidence, or no clear clinical or symptom improvement).
- Pediatricians should make referrals to child psychiatry (if available) for children when there is diagnostic uncertainty and for those in whom multiple trials of medications have failed or who are taking 2 or more psychotropic medications (or 1 medication, if the medication is an antipsychotic).

Children With Intellectual and Developmental Disabilities as Organ Transplantation Recipients

Mindy B. Statter, MD, MBE,[a] Garey Noritz, MD,[b] COMMITTEE ON BIOETHICS, COUNCIL ON CHILDREN WITH DISABILITIES

The demand for transplantable solid organs far exceeds the supply of deceased donor organs. Patient selection criteria are determined by individual transplant programs; given the scarcity of solid organs for transplant, allocation to those most likely to benefit takes into consideration both medical and psychosocial factors. Children with intellectual and developmental disabilities have historically been excluded as potential recipients of organ transplants. When a transplant is likely to provide significant health benefits, denying a transplant to otherwise eligible children with disabilities may constitute illegal and unjustified discrimination. Children with intellectual and developmental disabilities should not be excluded from the potential pool of recipients and should be referred for evaluation as recipients of solid organ transplants.

INTRODUCTION

The American Academy of Pediatrics policy statement "Pediatric Organ Donation and Transplantation" published in 2010 provides recommendations to promote awareness for increased organ donation and the role of organ donation as an integral part of end-of-life care but does not discuss recipient candidacy and eligibility.[1] The demand for transplantable solid organs far exceeds the supply of deceased donor organs. Patient selection criteria are determined by individual transplant programs. Given the scarcity of solid organs for transplant, organs are allocated to those most likely to experience maximal benefit, taking into consideration both medical and psychosocial factors. Historically, patients with intellectual and developmental disabilities (IDDs) have often been excluded as potential recipients of organ transplants. The issue of intellectual disability (ID) in donors is not in the scope of this statement. IDD is defined as "a group of developmental conditions characterized by significant impairment of cognitive functions, which are associated with limitations of learning, adaptive behaviour and skills."[2] Patients with an

autism spectrum disorder can also be considered to have an IDD. IDDs may be secondary to genetic syndromes, chromosomal abnormalities, exposures during pregnancy (fetal alcohol syndrome, exposure to teratogenic drugs or toxins), congenital anomalies, intrauterine insult (stroke, placental problems), or postnatal insults (infections, trauma).

Intellectual impairment refers to deficits in general mental abilities, including reasoning, planning, problem-solving, abstract thinking, academic learning, and learning from experience, and is commonly defined as an IQ of ≤ 70. Adaptive functioning deficits refer to impairments in social, conceptual, and practical skills needed for self-care, self-direction, communication, home living, use of community resources, and functional academic skills.[3] In the case of developmental disabilities, it is recognized that cognitive testing alone is inadequate to characterize a person's level of disability. More important is the individual's level of adaptive functioning, which describes the skills with which an individual lives in his or her environment.[4]

People may function at, above, or below what would be expected on the basis of their cognitive ability, largely as a result of the quality of the environmental supports they receive. In this way, disability is a social construct; people with a physical or cognitive difference are also disabled by the inability of society to support them. Studies that do not take into account adaptive capabilities find a higher prevalence of ID than those taking into account a person's adaptive capability or level of functioning.[5] It is this larger view of adaptive functioning that should be examined as part of the transplant evaluation.

Richards et al[6] highlighted the inconsistencies across major pediatric transplant centers in how the presence of IDD is used as a criterion in the listing decisions for solid organ transplant. Thirty-nine percent of programs stated that they consider IDD "rarely" or "never" in the listing process, whereas 43% of programs "always" or "usually" do. The degree of a patient's delay also affects the listing decision, with 14% of programs reporting mild or moderate IDD as a relative contraindication to listing and 22% reporting that IDD was "irrelevant" to the listing decision. There was also discordance among the solid organ programs (heart, liver, and kidney). Heart programs tend to consider neurodevelopmental status more often in their listing decisions compared to liver and kidney programs, which use IQ more restrictively.[6] The official guidance from the International Society for Heart and Lung Transplantation does specifically mention "mental retardation" as a relative contraindication to heart transplant.[7] The inconsistencies among programs serve to highlight that the use of the criterion of neurodevelopmental delay for listing is heterogeneous, likely reflecting individual programmatic biases.[6]

The Americans with Disabilities Act (ADA)[8] and the Rehabilitation Act[9] prohibit disability-based discrimination by doctors' offices, state-run hospitals, and recipients of federal funding, including health care providers who are paid through Medicaid or Medicare and organizations funded through federal contracts such as the United Network for Organ Sharing (UNOS). The Organ Procurement and Transplantation Network (OPTN) is the nation's organ procurement, donation, and transplant system.[1] It is overseen by the US Department of Health and Human Services (HHS). UNOS is the nonprofit organization that operates the OPTN under a contract from the federal government. All organ procurement organizations and transplant programs in the United States are OPTN and/or UNOS members and follow OPTN policies.[1]

Discrimination under the ADA includes both the refusal to provide services to qualified individuals with disabilities and refusal to make reasonable modifications in policies and practices that are necessary to ensure people with disabilities may access services. When transplant is likely to provide significant health benefits, denying transplant to otherwise eligible people with disabilities may constitute illegal and unjustified discrimination.[8]

In 1995, Sandra Jensen, a 34-year-old woman with Down syndrome and congenital heart disease was initially refused a heart-lung transplant solely because she had trisomy 21 and mental retardation (current terminology at the time). She, with her family and other advocates, mounted a national campaign to protest this discrimination. She subsequently received her transplant on January 23, 1996, and became the first person in the world with trisomy 21 to do so. Dr William Bronston, a state rehabilitation administrator and coordinator of the campaign, in a speech delivered to the National Down Syndrome Society after Sandra's transplant in 1996, said, "Sandra's story has opened a window into the chaos and incompetence of the national transplant system as it currently exists."[10]

STATEMENT OF THE PROBLEM

Transplant centers contend with conflicting priorities that may affect the evaluation and listing of recipients with IDDs, including the need to have high transplant success rates for accreditation and to remain in payer networks. Transplant centers want to allocate limited resources to those most likely to benefit but also want to avoid negative media attention around the perception of discrimination in the referral,

acceptance, or listing processes for solid organ transplant.[11]

Among transplant centers, there is inconsistency in defining IDDs, which affects referral and listing and excludes patients from the qualifying pool of recipients. The use of IDD as a medical criterion by transplant centers is inconsistent and varied. When transplant centers use IDD as a social value criterion rather than a medical criterion, they make implicit rationing decisions that favor candidates without an IDD.[12]

The study of "implicit bias" helps us understand how unconscious assumptions about groups of people may influence perception and decision-making.[12] Tests have been designed to assess implicit bias toward individuals with developmental disabilities,[13] and unsurprisingly, clinicians are susceptible to such biases.[14] Just as transplant centers need to ensure that implicit bias does not influence decisions because of race, ethnicity, or sex, clinicians need to be aware of the existence of implicit bias toward individuals with disabilities and thoughtfully examine this bias in listing decisions for organ transplant.[15]

There is the misconception that transplant recipients with disabilities are unable to comply with posttransplant medical regimens, lack adequate support systems to ensure such compliance, have decreased life expectancy, and have a lower likelihood of transplant success.[12] There is the biased presumption that people with disabilities have a lower quality of life than those without disabilities and, therefore, do not receive as much benefit from the transplant as a person without disabilities or that they cannot be expected to derive any benefit by having their life extended by a transplant. For children with IDDs, a social value criterion focuses on their limitations and discounts the contributions that these children make to their families and society.[12] The variance in the defining of IDD and the inconsistent use of IDD as a medical criterion result in the unjustified exclusion of children with IDDs from access to solid organ transplant.

Correspondence in October 2016 from the US Congress to Jocelyn Samuels, the director of the Office for Civil Rights in the HHS, urged the agency to address what congress called "persistent" organ transplant discrimination. The letter called for guidance from the HHS clarifying that denying an organ transplant on the basis of a person's disability would violate the ADA.[16]

The most appropriate outcomes to consider when determining if a patient should be evaluated or listed for transplant are organ and patient survival with the same minimum thresholds for all patients with or without developmental disability.[17] In the determination of a qualifying pool of potential recipients, the literature suggests that there is no substantial difference in patient or organ survival between children with and without IDDs.[17,18] Studies have shown that patients with developmental or intellectual disabilities and appropriate posttransplant support have outcomes comparable to those of children without disabilities.[18]

Benedetti et al[19] described an institutional experience from 1968 to 1996 in renal transplant in adult recipients with ID. A psychologist and a social worker assessed the ability and commitment of the primary support person (the individual from the family or from the institution caring for the patient in charge of the daily medications and clinical follow-up). Only patients with expected long-term survival with a "cooperative" personality or a qualified primary support person were accepted as candidates. The average IQ was 56, chronological age range was 17 to 45 years, and average developmental age was 7.7 years (range: 3–14 years). The 1- and 5-year patient and graft survival was 100%. They found that kidney transplant in properly selected patients with ID provided excellent patient and graft survival rates and that patient quality of life and health, as judged by the primary support people, was highly improved after kidney transplant in comparison with dialysis or advanced chronic renal failure. The authors concluded that the presence of ID should not be considered a contraindication to kidney transplant.[19]

Ohta et al[20] reported data from 8 Japanese institutions from 1988 to 2004; 522 pediatric kidney transplants were performed, including 25 (4.8%) in recipients ID. Follow-up data revealed all 25 grafts were functioning during a mean observation period of 41.1 months. All people providing primary support for these children were satisfied with the transplant and believed that quality of life was improved for both the transplant recipients and themselves.[20]

Galante et al[21] reported results of renal transplant in recipients with ID; graft survival and long-term renal function was equivalent to recipients without ID. They also concluded that renal transplant may offer significant advantages when compared to the need for dialysis in patients with ID.[21]

TRANSPLANT ETHICS

In transplant ethics, the ethical principles directly applicable to the allocation of organs for transplant are respect for persons, utility, and justice.[22] Respect for persons embraces respect for autonomy; this necessitates transparency of processes and allocation rules to enable stakeholders to make informed decisions. Utility describes the effort to maximize the greatest benefit for the greatest number of

patients.[23] Utility applied to the allocation of organs should maximize the net overall good, balancing benefits and harms, thereby incorporating beneficence and nonmaleficence. For example, commonly accepted medical contraindications to transplant incorporate utility by excluding individuals whose diseases can be expected to recur after transplant, diseases that may be worsened by posttransplant immunosuppression, or diseases that make surgery unsafe for the patient.[24] In public policies related to allocation of organs, there is consensus that the social worth or value of individuals should not be considered. IDD as a social value criterion results in implicit and explicit bias that may reflect the values of the decision-makers and affect rationing decisions. For children with IDDs, a social value criterion focuses on their limitations and discounts the contributions that these children make to their families and society.[12] Justice refers to fairness in the pattern of distribution of the benefits and burdens of an organ procurement and allocation program. Equitable access to the transplant waiting list is the basis of equitable organ allocation. Justice requires that criteria for candidacy are applied in an equal manner. Equitable allocation incorporates efficiency and equity, as specified in the Final Rule implemented in 2000, "distributing organs over as broad a geographic area as feasible…and in order of decreasing medical urgency."[24]

Excluding children with disabilities from the qualifying pool of potential recipients violates these ethical principles. Children with disabilities can be deceased organ donors and contribute to the supply of solid organs, so it would be unfair to categorically exclude them as recipients of organ transplants.

Beneficence and nonmaleficence apply not only to the pediatric patient being referred, accepted, or listed for transplant but also to the family construct. The family, in addition to the patient, is a stakeholder and must be educated in the benefits, risks, and harms of transplant and collaborate with the transplant team in the decision-making process. Evaluation for transplant includes determining if there are significant medical comorbidities that unduly limit transplant survival; transplant is not offered to any patient who will be harmed by the procedure.

One pediatric transplant center stated that developmental disability alone should not preclude transplant; however, "biological survival is not a sufficient goal for transplantation. Survival for the purpose of having continued conscious experience is a minimum goal of transplantation."[25] The center's neurodevelopmental task force, drawing on federal and expert consensus guidelines, defined terms including minimally conscious state and persistent vegetative state. As such, the center's policy is to not offer transplants to patients in persistent vegetative states. The task force concluded that a scarce resource should not be used to prolong the survival of people who very likely have no conscious experience. The task force sought assistance from a community ethics committee that used an absolute lack of benefit argument, claiming that it is ethically justifiable to exclude patients in persistent vegetative state from receiving transplants.[25]

In balancing beneficence and nonmaleficence, the benefits, risks, and harms of transplant to pediatric patients with developmental disabilities, it is necessary to acknowledge that the transplant can add to or reduce the burden of treatment. The pediatric patient with disabilities may have the burden of other organ system disease in addition to the failed organ. Many children are already dependent on technology for survival, such as a feeding tube or tracheostomy. For these children with medical complexity, certain inherent aspects of the disability, such as recurrent tracheitis or pneumonia, may pose a more significant risk after transplant because of the required immunosuppression.[26]

Transplant teams have the responsibility of educating families about the benefits, risks, and possible harms of organ transplant and collaboratively making the best decision possible. Although many parents will naturally subordinate their own interests and the interests of siblings when dealing with the interests of their child with organ failure being evaluated for transplant, it is helpful to remind parents that it is acceptable to directly consider their own interests and the interests of other children when making decisions for and about their sick child. It is beneficial to have parents openly acknowledge the sacrifices associated with various treatment options and the effect on their own lives and the lives of their other children.[27] It is ethically permissible for some families to decide that because of the degree of IDD, their children may not attain enough benefit to warrant the immediate and lifelong burdens of transplant.

QUALITY OF LIFE

A core issue in the discussion of organ transplant for children has to do with the concept of quality of life. The World Health Organization defines quality of life as an "individual's perception of their position in life in the context of the culture and value systems in which they live and in relation to their goals, expectations, standards and concerns."[28] By its very nature, quality of life is individualistic, and although many attempts have been made to measure and monitor quality of life for groups of people, one must not lose sight of the individual's

understanding of his or her own quality of life.

As commonly defined, quality of life goes well beyond health-related matters and includes physiologic, psychological, and social factors.[29] Likewise, disability is commonly understood to cross multiple domains, including body functions, body structures, activity and participation, and environmental factors,[30] all of which affect an individual's assessment of his or her quality of life. This complicated interplay of medical and nonmedical factors is challenging to families and physicians who must decide whether to proceed with transplant for a child with a disability.

It is well known that many individuals with disabilities rate their own quality of life similarly to individuals without disabilities[31–33] and higher than their families or physicians do when using proxy measurements.[31,34,35] This has been called the "disability paradox"[34]; individuals with disabilities tend to base their assessment of quality of life on factors beyond their physical and mental functioning, whereas proxy reporters tend to focus on the disability.[29] Clinicians' bias as a result of their own perception of the disability may undervalue the actual quality of life of the patient. As stated by Graham and Robinson,[36] "while quality of life considerations should be considered when assessing the benefits and burdens of medical care, there is the concern that many clinicians may unconsciously use the phrase 'quality of life' to mask a set of more complicated, unspoken assumptions about the lives of the disabled." Many clinicians working in an inpatient setting may not recognize that their assessments of quality of life are based on an incomplete clinical picture and are, therefore, limited. The child's condition and function during a hospitalization provides limited insight into a patient's overall quality of life and the family's experiences, which may contribute to bias on the part of clinicians. Professional attitudes then conflict with parental assertions about the appropriateness of an intervention, not because of ethical or moral differences, but because of different perceptions about the baseline quality of life of the child.[36]

EVALUATION FOR TRANSPLANT

The evaluation for solid organ transplant is a multidisciplinary assessment that includes a psychosocial evaluation, the goal of which is to identify patient and family strengths and risk factors that may affect posttransplant outcomes. Transplant evaluations for all individuals also include an assessment of the psychosocial milieu in which the individual exists.[1] The degree of psychosocial support available to the individual is part of this determination. In transplant evaluations for all young children and for older children with disabilities, the presence of caring, able, and committed caregivers is of paramount importance. These caregivers must be committed to the immediate and long-term care of the individual and his or her medical and psychosocial needs. The American Academy of Pediatrics policy statement emphasized the goal of keeping the family unit intact during and after the transplant process.[1] For patients with disabilities, caregivers often include a number of people outside the immediate family and may include the extended family, home nurses, therapists, clergy, and educators. Developmental specialists may be of particular importance for making the individual "come alive" for the transplant committee, demonstrating how the individual functions within his or her psychosocial setting.[37] The commitment of this extended caregiving team should be taken into account when considering an individual for transplant.

The OPTN encourages individual transplant centers to develop their own criteria for these "nonmedical" evaluations, although some guidance is given.[38] For instance, they suggest addressing problems with adherence, such as for an organ failure caused by behaviors such as smoking and alcohol use, but do not give strict criteria for exclusion from transplant consideration.

The likelihood of nonadherence to posttransplant regimens and medical care is commonly cited as a disqualifying barrier for patients with disabilities. However, nonadherence is highly prevalent in other populations, particularly adolescents.[39] Patients with disabilities often require assistance with their medication regimen and, thus, have a high degree of oversight, which may improve the likelihood of adherence.[40]

The presence of behavioral and emotional problems seems to be a more important predictor of low quality of life among children with disabilities than the extent of the physical disability.[41] In typically developing children, behavioral and emotional problems would be an important determinant of eligibility for organ transplant[42] because such problems can affect the ability to adhere to complex posttransplant medical recommendations and should likewise be considered a factor for individuals with disability. Many children with chronic illnesses, particularly those with IDDs, have distress with medical visits or phlebotomy, often because of past painful interactions with the medical system.[43] Patients with these issues often respond to child life and other therapies to allow for medical tasks to take place.[44] However, if children cannot be accustomed to simple medical procedures such as phlebotomy, they would be poor transplant candidates because of the chronic and continuing need for blood tests. For such patients,

posttransplant care is not likely to be practical, regardless of the presence or absence of a developmental disability.

Although patients with disabilities commonly report good quality of life, their caregivers often report poorer quality of life, which may be related to the intensity of the care that is necessary.[45,46] The caregiving burden is often more closely related to the extent of behavioral and emotional problems than the severity of the motor or cognitive impairment.[47] The psychosocial evaluation in these circumstances should include the functioning of the broadly defined family unit rather than only the individual to receive the transplant. The family of a child with disabilities might experience an increase or decrease in the caregiving burden, and this should be explored individually.

The lack of standardized mechanisms for transplant centers to assess cognitive development and adaptive functioning was noted by Wightman et al.[48] In a large (N = 2076) retrospective cohort analysis of children receiving a first kidney-alone transplant in the UNOS data set from 2008 to 2011, they reported 16% of the recipients were children identified as having definite or probable ID. For the purpose of the study, the authors created a definition of ID on the basis of information in the UNOS data set because of the lack of standardized mechanisms for transplant centers to assess cognitive development, academic level, or academic activity. Short-term (3-year) graft and patient survival were similar between children with definite or probable ID and without ID. The authors acknowledged that their study did not assess children listed for transplant who remain on the list, patients with end-stage kidney disease not referred to a transplant center, or those refused listing by a transplant center, thereby underestimating the number of children with disabilities eligible for consideration for kidney transplant.[48] The standardization of the definition of disability including both intellectual functioning and adaptive behavior may be helpful in predicting the outcome after transplant.

SUMMARY

When transplant is likely to provide significant health benefits, denying transplant to people with disabilities on the basis of their supposed lower quality of life may constitute illegal and unjustified discrimination.[8] The decision to initiate transplant must include consideration of both the individual patient's current quality of life with the diseased organ and the potentially improved quality of life with the transplanted organ, albeit with the burdens of surgery, immunosuppression, and other posttransplant therapies.[49,50]

The notion that children with disabilities have a lower quality of life than children with typical development is both incorrect and ethically problematic in decisions regarding organ transplant. Care must be taken to ensure that medical and psychosocial factors that may affect the transplant outcome are not confused with judgments of an individual's social worth. Children without disabilities have no more claims to scarce resources, such as organ transplants, than do children with disabilities.

To address concerns regarding the fairness of transplant evaluations for patients with IDDs, a framework for transplant centers is necessary to ensure procedural consistency and transparency. The definition and assessment of ID, including the evaluation of cognitive development and adaptive functioning, and the criteria for recipient candidacy and selection require standardization and transparency, making transplant centers accountable for their decisions. One pediatric transplant center used a multidisciplinary approach to develop a center-wide transplant policy. To increase transparency and accountability with respect to candidacy decisions for patients with developmental disabilities, the task force recommended the formation of a transplant listing advisory committee. The purpose of such a committee is to ensure that institutional transplant selection criteria are fair and nondiscriminatory and that patients declined for evaluation or listing were granted a fair and unbiased review, particularly with respect to characteristics that identify vulnerable or protected classes of people, such as those with disabilities, who may be protected under the ADA.[25]

In adhering to the ethical principles of respect for persons, utility, and justice, children with IDDs should not be excluded from the potential pool of recipients and should be referred for evaluation as recipients of organ transplants. IDD alone should not be a contraindication to the referral, acceptance, or listing for solid organ transplant. The presence of an IDD is relevant but should not be the determinative factor.

RECOMMENDATIONS

1. Patients should not be excluded from consideration for solid organ transplant solely on the basis of an intellectual or developmental disability. When transplant is likely to provide significant health benefits, denying transplant to people with disabilities on the basis of their supposed lower quality of life may constitute illegal and unjustified discrimination.
2. Transplant programs should standardize the definition and assessment of ID so that transplant decisions can be individualized, equitable, and transparent. The transplant team

should consider both the cognitive and adaptive skills of the individual. Consistency in defining IDD allows the use of IDD as a medical criterion to prevent unjustified exclusion of children from access to solid organ transplant. There should be concordance among the respective solid organ transplant programs within an institution in defining IDD to avoid individual programmatic biases. The transplant team should consider both the cognitive and adaptive skills of the individual. Cognitive testing alone is inadequate to characterize a person's level of disability. The individual's level of adaptive functioning must be taken into account; specifically, the skills with which an individual lives within his or her environment (eg, the social, conceptual, and practical skills needed for self-care, self-direction, communication, home living, use of community resources, and functional academic skills) must be considered. Failure to consider adaptive functioning as part of the transplant evaluation results in an inaccurate assessment of ID.

3. The transplant evaluation is a collaborative process that should occur in person rather than by medical record review and should include caregivers such as therapists and developmental specialists who can illustrate the patient's degree of function. Evaluations for transplant to an individual with ID should include professionals with expertise in the evaluation and management of individuals with ID.[51]

Diagnosis, Management, and Treatment of Female Genital Mutilation or Cutting in Girls

- *Clinical Report*

CLINICAL REPORT Guidance for the Clinician in Rendering Pediatric Care

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN®

Diagnosis, Management, and Treatment of Female Genital Mutilation or Cutting in Girls

Janine Young, MD, FAAP,[a] Nawal M. Nour, MD, MPH, FACOG,[b] Robert C. Macauley, MD, FAAP,[c] Sandeep K. Narang, MD, JD, FAAP,[d] Crista Johnson-Agbakwu, MD, MSc, FACOG,[e] SECTION ON GLOBAL HEALTH, COMMITTEE ON MEDICAL LIABILITY AND RISK MANAGEMENT, COMMITTEE ON BIOETHICS

Female genital mutilation or cutting (FGM/C) involves medically unnecessary cutting of parts or all of the external female genitalia. It is outlawed in the United States and much of the world but is still known to occur in more than 30 countries. FGM/C most often is performed on children, from infancy to adolescence, and has significant morbidity and mortality. In 2018, an estimated 200 million girls and women alive at that time had undergone FGM/C worldwide. Some estimate that more than 500 000 girls and women in the United States have had or are at risk for having FGM/C. However, pediatric prevalence of FGM/C is only estimated given that most pediatric cases remain undiagnosed both in countries of origin and in the Western world, including in the United States. It is a cultural practice not directly tied to any specific religion, ethnicity, or race and has occurred in the United States. Although it is mostly a pediatric practice, currently there is no standard FGM/C teaching required for health care providers who care for children, including pediatricians, family physicians, child abuse pediatricians, pediatric urologists, and pediatric urogynecologists. This clinical report is the first comprehensive summary of FGM/C in children and includes education regarding a standard-of-care approach for examination of external female genitalia at all health supervision examinations, diagnosis, complications, management, treatment, culturally sensitive discussion and counseling approaches, and legal and ethical considerations.

BACKGROUND

Female genital mutilation or cutting (FGM/C)* is currently outlawed in much of the world. The United Nations,[1] the World Health Organization (WHO),[2] the International Federation of Obstetrics and Gynecology,[3] and the American Medical Association[4] are among multiple organizations that unequivocally oppose all forms of FGM/C (see Table 1).

FGM/C involves medically unnecessary cutting of parts or all of the external female genitalia, including the clitoris, prepuce, labia minora, and labia majora. FGM/C may be associated with significant morbidity and mortality and is not associated with any medical benefit. Notwithstanding this morbidity, it is still performed and has been practiced in many cultures for thousands of years, predating Judaism, Christianity, and Islam.[5] Historically and in present-day, FGM/C is a cultural practice not directly tied to any specific religion, ethnicity, or race and has been reported to still occur throughout the world, including in the United States, but with higher prevalence in parts of the Middle East, Asia, and Africa (see Fig 1). Reasons why FGM/C is performed vary by region and culture and may include a belief that it increases marriageability, preserves virginity, improves hygiene, perpetuates a traditional rite of passage, and/or upholds prescribed religious beliefs (although no sacred texts recommend this practice).[6,7] FGM/C is predominantly performed on children and adolescents ranging in age from newborn infants to 15 years; the typical age varies by region of the world, country, state, province, and even town or village[8] (see Fig 2). However, the vast majority of medical literature, teaching, and research is focused on chronic issues affecting women of childbearing age and on the management of FGM/C during pregnancy and the peripartum and postpartum periods.[9,10]

To date, there are neither national nor international clinical practice guidelines that are specifically focused on FGM/C in infants and prepubertal and pubertal girls.

This clinical report's primary goal is to educate pediatric health care providers on the continued occurrence of FGM/C, the populations that it affects, diagnosis, complications, treatment options, and the provision of culturally sensitive counseling, all while taking into consideration the legal and ethical aspects of a practice that is illegal in the United States and much of the world (see Table 2).

PREVALENCE

National and international data on the prevalence of FGM/C in children and adolescents are difficult to obtain and are based on either maternal report or estimates derived from data on the adult female population who present mainly for obstetrical care. The United Nations Children's Fund estimated that in 2018, 200 million girls and women alive at that time had undergone FGM/C worldwide.[11] Some authors estimate that more than 500 000 girls and women who live in the United States (as of 2012) have had FGM/C performed or are at risk for having FGM/C performed, but these estimates are projections based on country of origin prevalence data and may, therefore, not be precise or accurate.[13] To date, no reliable data exist quantifying the true number of girls and women residing in the United States who have had FGM/C performed.[13]

The majority of FGM/C occurs in 30 African and Middle Eastern countries, with highest prevalence in Egypt, Somalia, Guinea, Djibouti, Mali, Sierra Leone, Sudan, and Eritrea.[14] However, FGM/C also occurs with unknown frequency in Yemen, Oman, the United Arab Emirates, Bahrain, northern Iraq, India, Malaysia, and Indonesia[15] and has been reported to occur sporadically in Russia[16,17] and Colombia.[18] The practice of FGM/C is not uniformly performed throughout any given country and may be clustered on the basis of economic status, level of education, rural versus urban geographic location, ethnic and/or tribal affiliation, and religious beliefs. In half of the countries with available data on FGM/C prevalence, most girls have had FGM/C performed before 5 years of age (see Fig 2).

Although it is illegal in the United States, FGM/C has been reported in the United States in sporadic cases over the past several years.[19,20] The federal Department of Justice prosecuted its first case against a US physician accused of having performed FGM/C across state lines in up to 100 children (see The Law and FGM/C in Minors in the United States for further current case details).[21] At of time of writing, the charges were dismissed by the district judge of the Eastern District of Michigan.[22] This specific case is focused on the practice of FGM/C in the Dawoodi Bohra community in India and among a subset of the Dawoodi Bohra immigrant community in the United States. The illegal practice of US families sending their children abroad to have FGM/C

* Currently, there are few experts in the United States who care for children and teenagers with FGM/C (see Table 4 for a link to access regional specialists). As such, it is of utmost importance to identify regional specialists, including child abuse pediatricians, gynecologists, urologists, and mental health providers, with whom to collaborate if providing medical care for children and teenagers affected by or at risk for FGM/C. FGM/C is an accepted term adopted by many international organizations and in medical research papers and, as such, will be used throughout this document.[9,12,16] Infibulation refers to type III FGM/C (see FGM/C Types and Classification in addition to Fig 4). Defibulation refers to a surgical procedure that opens the scar formed in patients with type III FGM/C (see Defibulation).

TABLE 1 FGM/C Recommendations

Recommendations
FGM/C is illegal in the United States.
FGM/C is a violation of human rights.
FGM/C has no medical benefit.
FGM/C is associated with serious and potentially life-threatening complications that can have lifelong impacts on health.
Health care providers should not perform any type of FGM/C on female infants, girls, or teenagers.
Health care providers caring for girls at risk for FGM/C should actively counsel families against performing FGM/C, including when families travel to countries where FGM/C is practiced.
A genital examination allows health care professionals to identify FGM/C and other medical findings of significance.
If genital examination findings are equivocal for the presence of FGM/C and risk factors for FGM/C are present, a specialist trained in identification of FGM/C should be consulted (see Table 4).
The management of FGM/C should include complete documentation of clinical findings and the use of ICD-10 coding.
Health care providers should recommend defibulation for all girls and teenagers with type III FGM/C, irrespective of whether complications are currently present.

performed (also known as "vacation cutting") is also presumed to occur.[23,24] However, prevalence data are nonexistent to date.[13]

FGM/C TYPES AND CLASSIFICATION

The WHO has classified FGM/C into four distinct types (see Table 3), with type III associated with the most significant long-term morbidity (see Complications and Management) (Figs 3–11). To better delineate specific findings, the WHO has also included subtypes of FGM/C, categorized as Ia and Ib, IIa–IIc, and IIIa and IIIb (see Fig 12). However, the practice of FGM/C is not standardized, and physical findings may overlap between types and subtypes (see Figs 5 and 6). Type I FGM/C is classified as cutting of the glans or part of the body of the clitoris and/or prepuce; type II includes excision of the clitoris and labia minora, with or without excision of the labia majora; type III, infibulation, includes cutting and apposing the labia minora and/or majora over the urethral meatus and vaginal opening to significantly narrow it and may include clitoral excision (Figs 10 and 11); and type IV includes piercing, scraping, nicking, stretching, or otherwise injuring the external female genitalia without removing any genital tissue and includes practices that do not fall into the other three categories (Fig 13).

FIGURE 1
FGM/C global prevalence. Countries where FGM/C is practiced with unknown frequency and not pictured on this map include Oman, the United Arab Emirates, Bahrain, India, Malaysia, Russia, and Colombia.[15–18] South Sudan seceded from Sudan in 2011 but is not noted on this map.[107] Reproduced with permission from United Nations Population Fund. *Demographic Perspectives on Female Genital Mutilation.* Copyright © United Nations Population Fund 2015.

Prevalence of FGM/C subtypes is mainly influenced by ethnicity and region. Surveys of girls and women older than 15 years reveal that approximately 10% of cases are FGM/C type III, or infibulation, although these numbers are based on self-report and likely under- or

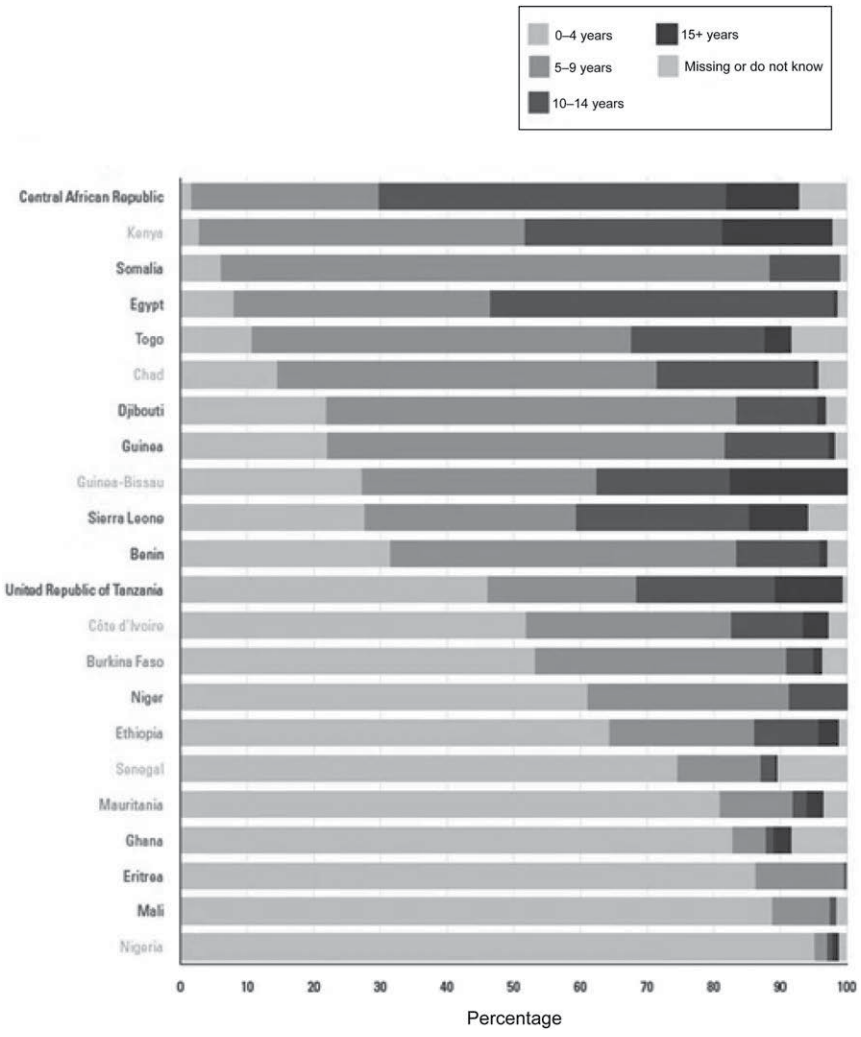

FIGURE 2
Maternal report of age that girls have undergone FGM/C, by country. Reproduced with permission from UNICEF. *Female Genital Mutilation/Cutting: A Statistical Overview and Exploration of the Dynamics of Change*. New York, NY: UNICEF; 2013:41. Copyright © United Nations Children's Fund 2013.

overestimate the actual prevalence of type III FGM/C.[8] The practice of infibulation, the removal and apposition of the labia minora and/or labia majora with or without cutting of the clitoris, is concentrated in northeastern Africa in Djibouti, Eritrea, and Somalia. Data extrapolated from 2004 to 2008 East African regional surveys of girls and women 15 years and older revealed that 82% to 99% reported to have had undergone FGM/C, and of these cases, 34% to 79% were type III (Somalia having the highest prevalence of type III).[25]

KNOWLEDGE OF, ATTITUDE ABOUT, AND PRACTICE OF FGM/C IN THE UNITED STATES

Knowledge of FGM/C is believed to be limited among US pediatric providers because there are no nationally required courses on diagnosis of type, management, or treatment of FGM/C for medical students, residents, or fellows in general pediatrics, family medicine, adolescent medicine, child abuse pediatrics, urology, or gynecology.[9,26–28] Instead, existing studies from the United States are focused on nurse midwives and obstetricians and gynecologists and note the lack of training in diagnosis, management, and cultural and legal aspects of care in adult women.[29–32] One recent US study revealed that of 79 general pediatricians surveyed, 73% had received no previous FGM/C education, 89% did not feel confident in their ability to identify FGM/C types, and frequency of performing external genital examinations on female patients at health supervision visits was inversely related to the age of the patient (with 75% performing examinations on infants, down to only 8% in 17- to 18-year-olds).[28] In literature from other high-income countries with immigrant populations from regions where FGM/C is prevalent, pediatricians have reported identifying FGM/C in pediatric patients, managing complications from remote and recent procedures, and, in some instances, being asked to perform FGM/C in children.[9,33,34] However, one survey conducted in Australia revealed that of pediatricians surveyed, most reported neither discussing nor examining children for FGM/C.[34,35]

CLINICAL HISTORY TAKING

For children with possible risk factors for FGM/C (eg, mother or sibling with a history of FGM/C, country of origin, birth country, and/or history of travel to a country where FGM/C is practiced), it is recommended that clinical assessment of FGM/C status be integrated into routine pediatric care. Nonetheless, it can be challenging. It is of utmost importance for the pediatric health care provider to establish a trusting relationship with the child or teenager and her family to allow for nonjudgmental questions and ongoing counseling. Experts suggest that health care providers ask the patient or parent the term they use to name female genital cutting. Use of the word mutilation is not recommended when discussing FGM/C with patients and

[a] Bans outlawing FGM/C were passed in some African countries, including Kenya and Sudan, during colonial rule. This table includes only legislation that was adopted by independent African nations and does not reflect earlier rulings.

[b] Later dates reflect amendments to the original law or new laws.

caregivers because it is potentially inflammatory and also difficult to translate (and may not be understood).

Given that girls who had FGM/C performed at a young age may not recall being cut (as well as the fact that parents or primary guardians may not reveal a history of FGM/C to their children), obtaining a history of FGM/C from the girl alone may yield little relevant clinical information. Instead, it is advisable that the FGM/C clinical history taking include both the girl and parent or guardian once rapport has been established. Similarly, some parents or guardians may not be aware that FGM/C performed in the country of origin before immigration is not prosecutable in the United States (see The Law and FGM/C in Minors in the United States) or may fear judgment from US medical providers, so they may initially withhold information about previous FGM/C.

When caring for girls with or at risk for FGM/C, it is important to approach FGM/C discussion, physical examination, and counseling with cultural sensitivity. Girls' genitalia may have never been examined before, although they may have had multiple physical examinations in the United States or abroad.[28] Girls and mothers who have been cut may be afraid to seek care from a health care provider because of concerns about disapproval or previous negative experiences being used to teach trainees or other health care providers about FGM/C; many will seek a physician's care only if there is a health problem. Irrespective of their culture, girls' and mothers' knowledge of female anatomy, reproductive health, family planning, and sexually transmitted infections may also be very limited. Understanding each girl's and mother's current knowledge and perception of FGM/C, addressing fears, providing age-appropriate education about pelvic anatomy, and sharing information about the importance of the annual physical examination can facilitate ongoing rapport and engagement with health care. In addition, some girls or parents may request a female health care provider as well as a female interpreter. For girls at risk for FGM/C, it is advisable that efforts be made to honor this request, if at all possible, given social and cultural expectations.

It is important for health care providers to assess each patient individually and make no assumptions about her and her parents' beliefs regarding FGM/C. Mothers and fathers may or may not hold discordant views about FGM/C, and some clinical experts suggest that mothers who have themselves undergone FGM/C may nonetheless oppose subjecting their daughters to this practice. Instead, treating patients and caregivers with respect, sensitivity, and professionalism will encourage them to return and supports health-seeking behavior.

In families with risk factors for FGM/C, including having a mother and/or other girls who have already been cut in the family, it is advisable to inquire, in a nonthreatening manner, whether the parents are planning to perform FGM/C on their daughter. Raising such a sensitive topic may elicit various emotions, but this is a vital educational opportunity to reiterate child safety, the morbidity and mortality associated with FGM/C, and its legal consequences. Such discussions may occur over multiple visits, and it is recommended to revisit these discussions, particularly if the child is being seen before a trip to countries where FGM/C is still practiced. Whether to have this discussion in front of the girl depends on the developmental age of the child,

TABLE 3 FGM/C ICD-10 Coding and WHO Classification

FGM/C Type	ICD-10 Code[109]	WHO Classification (2016)
Female genital mutilation, unspecified	N90.810	
Female genital mutilation, type I	N90.811	Partial excision of the clitoris and/or prepuce
	—	Ia: removal of prepuce only
	—	Ib: partial or total[a] removal of clitoris and prepuce
Female genital mutilation, type II	N90.812	Partial or total[a] removal of the clitoris and labia minora, with or without excision of the labia majora
	—	IIa: removal of labia minora only
	—	IIb: partial removal of the clitoris and labia minora
	—	IIc: partial removal of the clitoris, labia minora and majora
Female genital mutilation, type III	N90.813	Infibulation: narrowing of the vaginal orifice by cutting and apposing the labia minora and/or labia majora over the vaginal opening; may include excision of the clitoris
	—	IIIa: removal and apposition of the labia minora
	—	IIIb: removal and apposition of the labia majora
Other female genital mutilation	N90.818	Unclassified (all other harmful procedures for non-medical purposes), including piercing
	—	IV

—, not applicable.

[a] Although WHO classification describes total removal of the clitoris, it is the glans or the glans and part of the body of the clitoris that is cut.[110]

her degree of understanding, and the dynamics within the family. Encouraging parents to reevaluate this practice in a nonjudgmental manner and impressing on them that FGM/C causes medical complications, has no medical indications, and is also against the law (with associated legal consequences) will hopefully facilitate reconsideration of this practice. It is also essential to document these discussions in the medical chart so that health care providers are both aware that education about FGM/C medical complications and illegality has been discussed and aware of what specific issues have and have not been discussed. Similarly, given that FGM/C performed overseas and before US emigration does not constitute a violation of US law, it is of utmost importance to document past history and timing of FGM/C in the chart so that it is clear that there are no legal ramifications for the family.

FIGURE 3

EXTERNAL FEMALE GENITAL EXAMINATION: STANDARDS AND DOCUMENTATION

Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents, Fourth Edition, recommends that "each visit include a complete physical examination." A complete physical examination includes assessment of genitalia from birth to age 21.[36]

It is recommended that pediatricians and other health care providers include genital inspection as part of all health supervision examinations and be knowledgeable about the variants of normal genital anatomy and the signs of previous genital cutting.[33]

The external genital examination in girls should include the identification of the prepuce, clitoris, and labia minora and majora (see Figs 14–16), and the examination should be performed in frog-leg position with chaperone use documented, per recommendations of the American Academy of Pediatrics.[37] In prepubertal girls, it may be more difficult to identify the clitoris, and in these cases, the prepuce may need to be partially retracted to facilitate

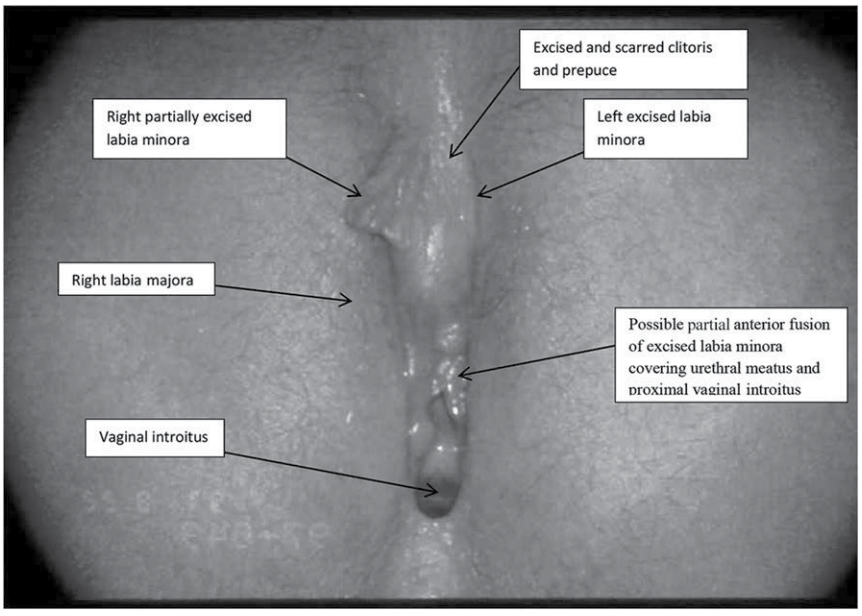

FIGURE 5
Type IIb or IIIa FGM/C in a prepubertal girl (excised clitoris, prepuce, partially excised right labia minora, absent left labia minora, and possible partial anterior fusion of excised labia minora covering urethral meatus and proximal vaginal introitus). This photo was reviewed by three FGM/C experts (J. Abdulcadir, C.J.A, and J.Y), and consensus was either type IIb or IIIa. Arrows were added by J.Y. (Reprinted with permission from Graham EA. Ritual female genital cutting [RFGC] PowerPoint slides. 2014. Available at: https://ethnomed.org/resource/ritual-female-genital-cutting-rfgc-powerpoint-slides/. Accessed April 30, 2020.)

identification. Similarly, the labia minora is less developed, and it is advisable that efforts be made to identify this structure as well. Although not systematically studied, anecdotal experience by some experts suggests that types I, II, and IV FGM/C and even some type III subtypes may be difficult to recognize during the physical examination, particularly in prepubertal girls. Similarly, prepubertal labial adhesions may be miscategorized as FGM/C (see Figs 3–6). If genital examination findings are equivocal for the presence of FGM/C and risk factors for FGM/C are present, a specialist trained in identification of FGM/C should be consulted, although currently, there are few such specialists in the United States (see Table 4 for a link to access regional specialists). However, given the subtleties of some FGM/C, it is assumed that not all cases will be identified.

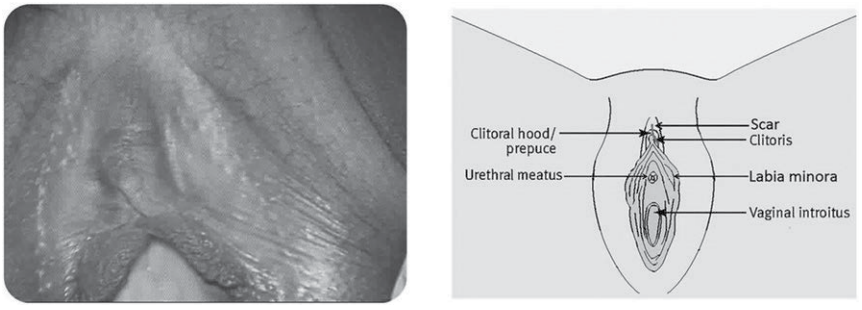

FIGURE 6
Type Ib FGM/C, scarring with excised clitoris and prepuce, or type IV FGM/C with linear scar from superficial cutting with adhesions, Tanner stage 5 female patient. This photo was reviewed by three FGM/C experts (J. Abdulcadir, C.J.A., and J.Y.), and it was unclear if it was type 1b or type IV on the basis of photos. The author of the source of the photo identifies the photo as type IV FGM/C. (Reprinted with permission from Creighton SM, Dear J, de Campos C, Williams L, Hodes D. Multidisciplinary approach to the management of children with female genital mutilation [FGM] or suspected FGM: service description and case series. *BMJ Open*. 2016;6[2]:e010311.)

If FGM/C is suspected to have occurred recently, it may also be difficult to confirm on physical examination without prompt evaluation by a specialist. The genitalia are highly vascularized tissues, healing occurs quickly, and less invasive cutting may easily be missed in some cases, given minimal or only subtle scarring.

If FGM/C is identified on examination, it is advisable that the clinician discuss findings with the caregiver and/or child if the child is old enough to participate in medical decision-making. Medical complications, depending on the type of FGM/C diagnosed, should be reviewed with the caregiver and/or child, as well as when to return for care if any of these complications develop (see Complications and Management). If an older child or teenager is unaware that she has had FGM/C performed (as may be the case if a girl had FGM/C performed at a young age), it is important that a culturally sensitive approach be taken to further discuss her diagnosis with her (see the Appendix for further guidance). Although not systematically studied, FGM/C is a community practice, and in some cultures, aunts, grandparents, or other figures of authority may make the decision to perform FGM/C on a child.[38] In these cases, theoretically, a parent may also not know of a child's previous FGM/C. It is suggested that a thoughtful, supportive discussion occur with the primary caregivers to inform them of the diagnosis, associated potential medical issues, and treatment, when clinically indicated. Given that such information may be distressing, it is advised to offer mental health

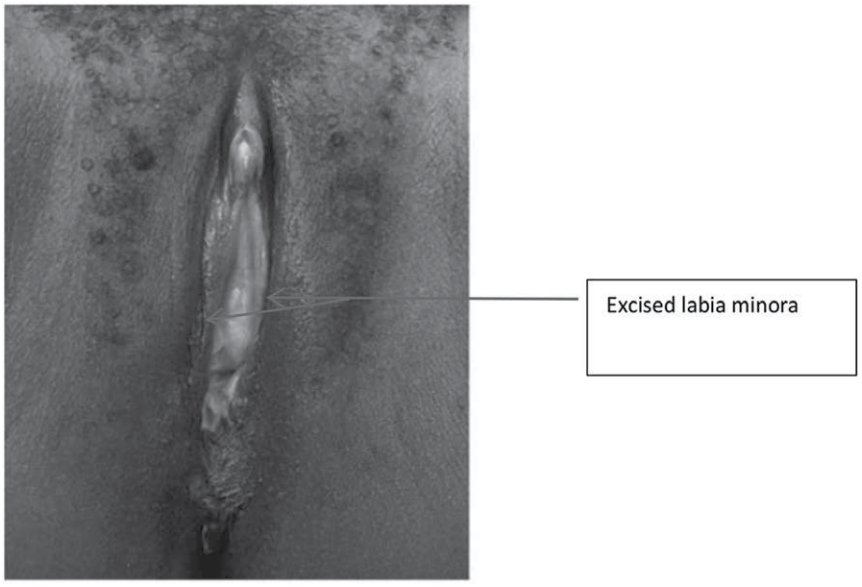

FIGURE 7

professional support to caregivers, as indicated.

CODING AND DOCUMENTATION

The management of FGM/C should include complete documentation of clinical findings and use of the *International Classification of Diseases, 10th Revision* (ICD-10) coding,[39] as indicated. A guide to ICD-10 coding and definitions and descriptions of FGM/C subtypes is provided in Table 3. In the future, appropriate coding will allow for better estimates of pediatric FGM/C prevalence. Additionally, clinical documentation of FGM/C findings may facilitate timely referral to gynecologic or urologic specialists, if needed. However, a recent review of state-level hospital discharge data in Arizona revealed that from 2008 to 2014, only 243 cases of FGM/C had been documented, as identified by *International Classification of Diseases, Ninth Revision* and ICD-10 codes, and that of these 243 cases, none were documented in children younger than 18 years (C.J.A, unpublished observations). As context, the Population Reference Bureau estimates that 7459 women and children are at risk for FGM/C in Arizona, suggesting that FGM/C is not being documented consistently by health care providers.[40]

COMPLICATIONS AND MANAGEMENT

Immediate Health Complications

Health care providers who work with children and live in countries with intermediate and high prevalence of FGM/C are likely to see immediate health complications; however, such a situation is likely rare in the United States.[41] Exceptions will be newly arrived immigrants who underwent FGM/C just before entering the United States, girls who have recently returned to the United States after undergoing FGM/C while temporarily overseas, or FGM/C that has been performed in the United States. In general, medical complications become more severe with progression from type I to type III, tending to reflect the amount of tissue being removed. If the clitoral dorsal artery or labial branches of the pudendal artery are cut, hemorrhage has been documented in the range of 4% to 19%. Active hemorrhage, subsequent hypotension, hypovolemic shock, and death may occur in these cases.[42,43]

Given the potential use of traditional nonsterile instruments, girls with FGM/C are at risk for acute infections. Girls with type III FGM/C most often have their legs bound for up to

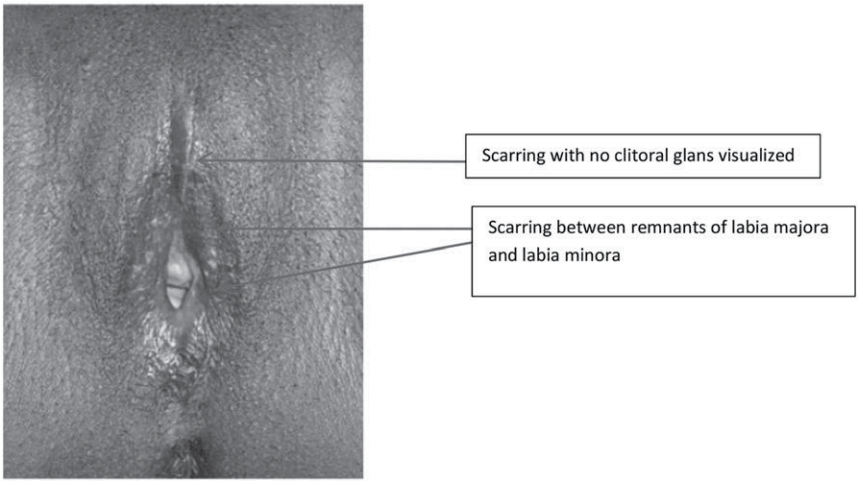

FIGURE 9

1 week after cutting (standard practice in type III cases, reportedly to facilitate scar formation). Such prolonged binding facilitates bacterial overgrowth and prevents wound healing. Girls may suffer from cellulitis or wound abscesses; gangrene, septic shock, and tetanus have also been reported. Difficulty urinating, both from pain and deliberate decreased liquid intake, is common.[41] The urethra, vagina, and/or rectum may also be inadvertently cut during FGM/C. Fractures of the clavicle, femur, or humerus also have been reported, resulting from the need to restrain a girl who was not anesthetized during the procedure[42] (Table 5).

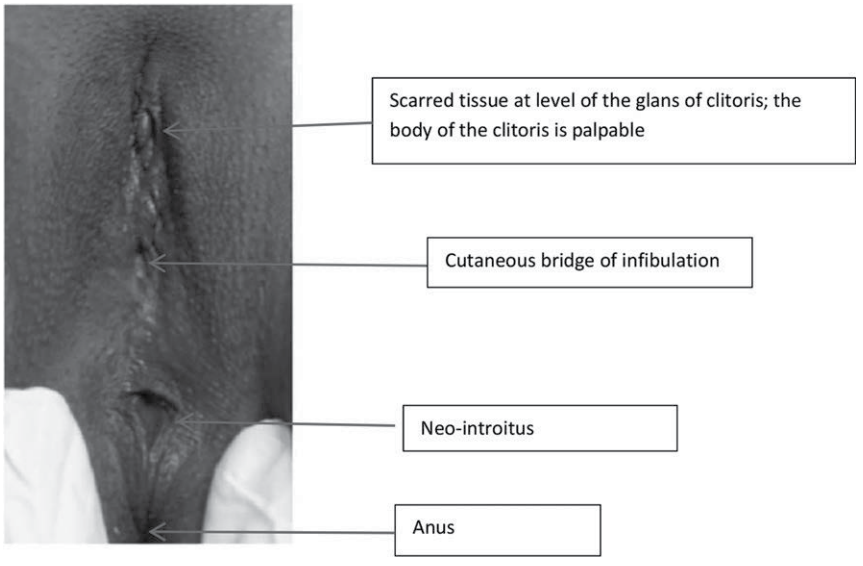

FIGURE 10

If a girl is seen with any immediate complications, it is recommended that the health care provider refer for appropriate emergency care and the patient receive vaccination against tetanus. Once stabilized, it is recommended to consult a health provider with FGM/C expertise (see Table 4) to determine the need for medical and/or surgical management. Although there are no data that directly link FGM/C to acquisition of HIV, hepatitis B, or hepatitis C, some clinical experts recommend testing for these infections at the initial visit and at least 6 months after cutting has occurred.[44] As in all children, it is advised that hepatitis B vaccination be offered to girls with FGM/C if they are neither immune nor infected.

In cases in which a girl has been recently cut, it is recommended to offer mental health supports for her, as indicated. Refer to Reporting Child Abuse and Ethical Analysis regarding scenarios in which child abuse reports are recommended.

Long-Term Complications

Studies reveal that girls and women with type III FGM/C are also at higher risk of long-term health complications than those with type I, II, or IV FGM/C. A systematic review of the literature reveals that long-term health complications include dysmenorrhea as well as psychosexual, infertility, and urinary problems.[42] However, physical and psychological complications are not necessarily proportionate to the FGM/C type. Although the authors of one study state that the relative risk of obstetric complications (including increased cesarean delivery rates), of the need for infant resuscitation, of stillbirths, and of infants with low birth weight increases with the severity of FGM/C, data are limited, and it is likely that the combination of obstructed labor and substandard

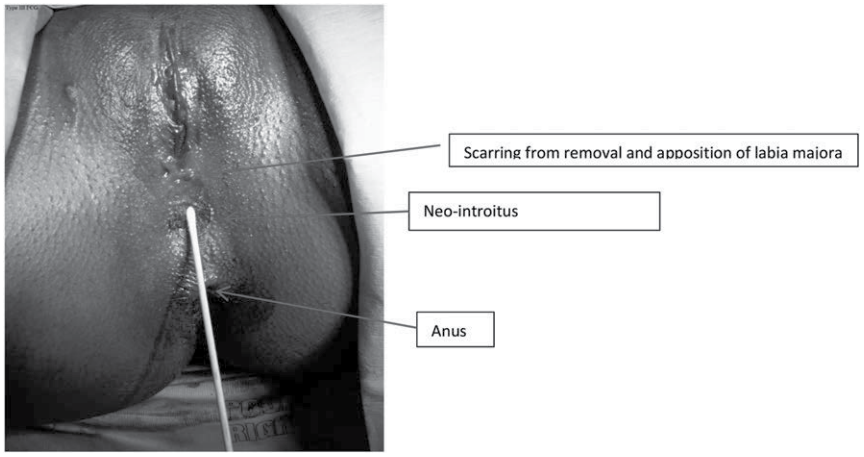

FIGURE 11
Type IIIb FGM/C in a Tanner stage 5 17-year-old with severe dysmenorrhea preventing her from going to school during menstrual flow (photo courtesy of N.N.).

health care systems contribute to such complications (Tables 6 and 7).[45]

Secondary analysis of cesarean delivery rates has revealed that health care provider unfamiliarity with defibulation and/or other management options for FGM/C may increase the risk of cesarean deliveries in some cases.[46,47]

Long-term complications can be placed into 7 major categories: pain, urinary issues, infections, scarring, infertility, sexual dysfunction,[42,48] mental health issues,[49,50] and other (Table 5).

Pain

Pain is a common long-term complication after type III FGM/C and can also be present in patients with type I and II FGM/C. In type III FGM/C, the narrow neo-introitus creates a closed environment that can obstruct urinary and menstrual flow. Because of the scarring that obstructs the introitus, the menstrual flow of women and teenagers with infibulation can last longer than usual, rendering them unable go to school during this time (see Fig 11). Menstruation may be painful and may become dark and foul smelling because of the retention of blood. In very rare cases, hematocolpos and hematometra have been documented.

Other painful complications arise when remnant foreign bodies are left in the scar during the initial procedure. These can produce sharp pains when sitting and walking. Cut or trapped nerve fibers have also been documented, creating very painful neuromas. In both of these situations, defibulation and removal of the foreign body or neuroma are recommended.[51]

Dyspareunia in sexually active teenagers with type III FGM/C has been seen (see Future Infertility) and treatment includes defibulation.[52]

One study followed 40 Somali women whose primary indications for defibulation were pregnancy (30%), dysmenorrhea (30%), apareunia (20%), or dyspareunia (15%). Of the 32 patients surveyed, 94% stated they would highly recommend defibulation to others; 100% of patients were pleased with the results, felt their appearance had improved, and were sexually satisfied, suggesting that the symptoms of teenagers who have undergone FGM/C and are experiencing dysmenorrhea will also be improved by defibulation.[52]

Urinary Issues

The narrow neo-introitus and scar in type III FGM/C create a dark, moist, and unventilated area surrounding the urethra. Urine can stagnate beneath the scar and promote abnormal bacterial growth. As a result, girls who are infibulated can experience chronic urinary tract infections. With recurrence of UTI, suppressive antimicrobial medication is an option, although defibulation is preferable; however, currently there are no known systematic studies evaluating the efficacy of prophylactic antibiotic treatment or defibulation in preventing recurrent UTIs associated with FGM/C.[53]

In general, clinical experience indicates that girls who are infibulated may describe their urinary stream as being slow and having a dripping quality. As the urine exits the urethra, it trickles under the scar and then drips past the neo-introitus. Patients also may complain of overactive bladder on the one hand or straining and urinary retention on the other. These issues may be attributable to injury of the urethra, resulting in urinary strictures and stenosis and requiring cystoscopy or urethral dilation. It is also possible for the obstructing scar to enable urinary crystals to deposit and, as a result, form urinary stones.[54] These patients routinely experience sharp pains and require defibulation for stone removal.

Scarring and Other Postinflammatory Reactions

Keloid formation is rare, although not unknown in FGM/C cases. The main problem with the infibulated scar is its obstructive nature. However, other complications in type II FGM/C include unintended labial fusions and cysts (fluid-filled, sebaceous, or inclusion cysts or abscesses). There are multiple case reports documenting epidermal cysts associated with all types of FGM/C.

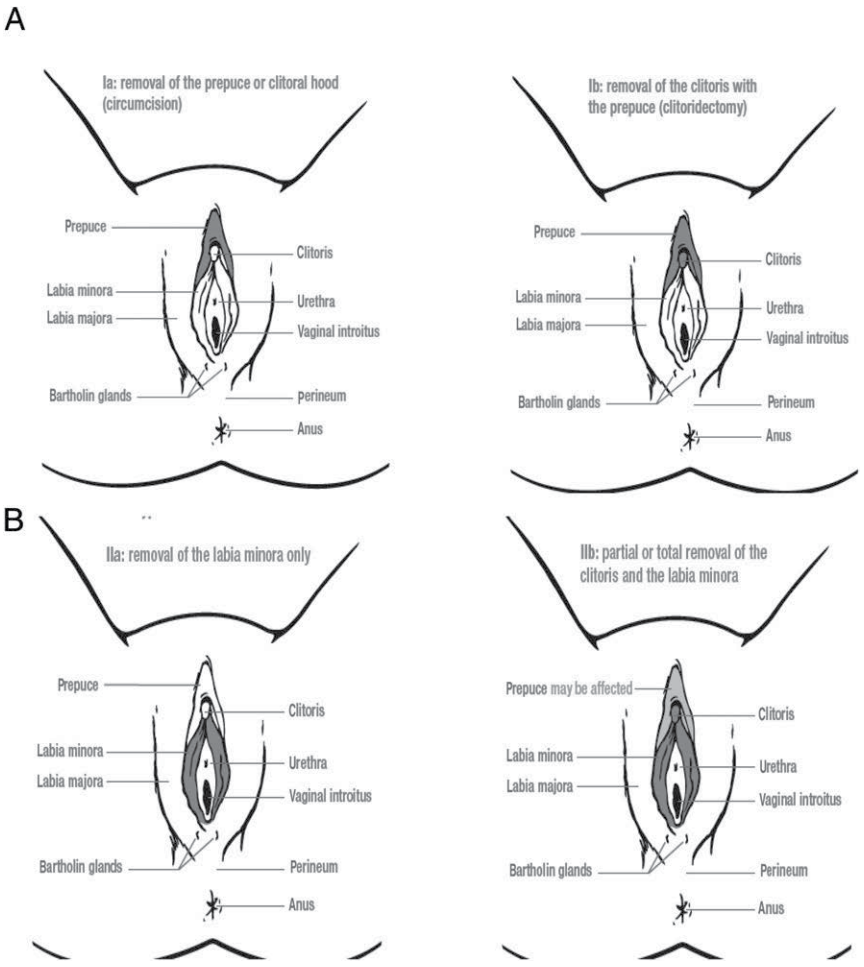

FIGURE 12

Female genital mutilation: a visual reference and learning tool for health care professionals. *Obstet Gynecol.* 2016;128(5):959–960.

Some cysts have been documented to grow up to 12 cm in size and are not only extremely painful but also become problematic for ambulation and sitting.[55,56] Dissecting the cyst and defibulating the patient is necessary in these cases (see Fig 17).

Other Infections

Given the infibulated scar, this enclosed environment fosters bacterial and fungal growth and predisposes girls to chronic or recurrent vaginal infections. In these cases, oral antifungal and antimicrobial medications are recommended. If the patient's neo-introitus is not too small and she is comfortable with introducing vaginal suppositories, this is an alternative treatment. For girls and teenagers with chronic infections, defibulation by an adolescent or general gynecologist experienced with managing FGM/C is recommended.

A study in rural Gambia of teenagers and women (15–54 years) with clinically diagnosed type I or II FGM/C (N = 671) also revealed a higher prevalence of bacterial vaginosis and herpes simplex virus 2 compared with teenagers and women without FGM/C but did not reveal an increased risk for perineal or anal damage, vulvar tumors, dyspareunia, infertility, organ prolapse, or other reproductive tract infections.[57]

Of note, large epidemiologic studies conducted in low- or middle-income countries where both FGM/C and HIV and/or hepatitis B are prevalent have not revealed an association between FGM/C and HIV and/or hepatitis B infections.[44,58,59] The authors of these studies did not evaluate risk around the time of cutting but months to years after the cutting occurred. To our knowledge, no studies have specifically addressed hepatitis C infection risks. However, given that FGM/C is often performed with unsterile equipment that may be shared between patients, some experts recommend testing girls with FGM/C for these blood-borne infections.

Future Infertility

Infertility for women with type III FGM/C is influenced by anatomic and psychological barriers as well as from possible recurrent gynecologic infections. In a Sudanese case-control hospital-based study of 99 women without hormonal, iatrogenic, or male-partner risk factors for infertility a diagnostic laparoscopy was performed, and it was found that primary infertility was associated with the increased anatomic damage inflicted by FGM/C.[60] Repeated attempts at penetration through the infibulated scar may be painful and difficult, and stretching of the infibulated introitus may take months. The learned association between sexuality and pain may a have significant negative effect on the woman's willingness to have intercourse and, thereby, on fertility. In general, if there are any issues related to FGM/C that negatively affect sexual health, referral to appropriate mental health supports is advisable for both women and their partners.

Sexuality

There are currently no studies that have been specifically focused on sexuality in teenagers with FGM/C. The impact of FGM/C on female

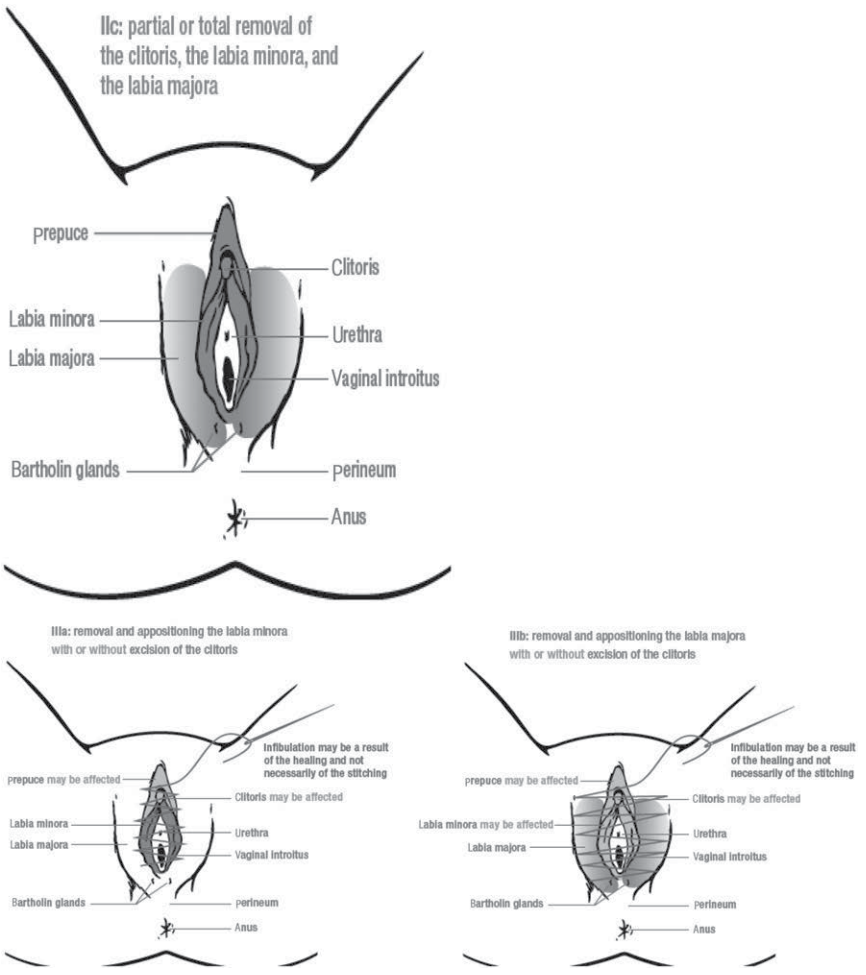

FIGURE 12
Continued.

sexuality has been evaluated in a few studies in adult women. However, the lack of standardization of FGM/C subtype studied and the use of nonvalidated questionnaires make interpretation of results difficult. Some studies reveal that women with FGM/C have reported less sexual desire, arousal, orgasms, and satisfaction compared with women without FGM/C[61] as well as increased rates of dyspareunia.[62] Other research has revealed no association between FGM/C and sexual intercourse frequency and that women with FGM/C also initiated sexual intercourse more than women without FGM/C.[63,64]

Surgical clitoral reconstruction is an emerging area of study. However, to date, there are no conclusive results revealing long-term benefits. If teenagers inquire about the option of reconstructive surgical repair, it is important to review the fact that there is still inadequate data that assure successful outcomes, including a decrease in pain and increased sexual pleasure.[65,66]

Mental Health

There has been limited high-quality research on the effects of FGM/C on the mental health of girls and women. One 2010 systematic review of the literature included 17 studies of women with and without FGM/C (*N* = 12 755) and revealed insufficient evidence to support or refute the link of FGM/C to specific mental health diagnoses.[48] In a more recent 2017 small cross-sectional study of Egyptian women and girls (*N* = 204, ages 14–19 years), those with and without FGM/C were compared, and a significantly higher prevalence of somatization, depression, and anxiety was found in those with FGM/C.[49]

Defibulation

Defibulation, also known as deinfibulation, is the procedure that opens the infibulated scar in type III FGM/C and exposes the vaginal introitus and urethral opening. In general, in some regions of the world, including Djibouti, defibulation is most often performed in newly married teenagers by a traditional birth attendant or midwife so that sexual intercourse may occur. In other regions, including North Sudan, Somalia, and areas in southern Egypt, the husband opens the neo-introitus over time through ongoing attempts at penetration. However, some teenagers and women who have access to medical care may have defibulation performed by a medical professional at marriage or after their official engagement.

Teenagers who are infibulated may present to health care providers requesting defibulation. Given the significant morbidity associated with type III FGM/C, experts believe that defibulation should be recommended for all girls and teenagers with type III FGM/C, particularly when complications are currently present. Similarly, teenagers who are pregnant should also be counseled regarding risks during and after pregnancy and should be strongly encouraged to undergo defibulation.

Of note, given that girls and teenagers who are infibulated have varying degrees of obstruction of urinary or menstrual flow, have varying degrees of pain, and/or have risks for normal vaginal delivery, such signs and symptoms should underscore the medical necessity for treatment. Given the medical necessity of

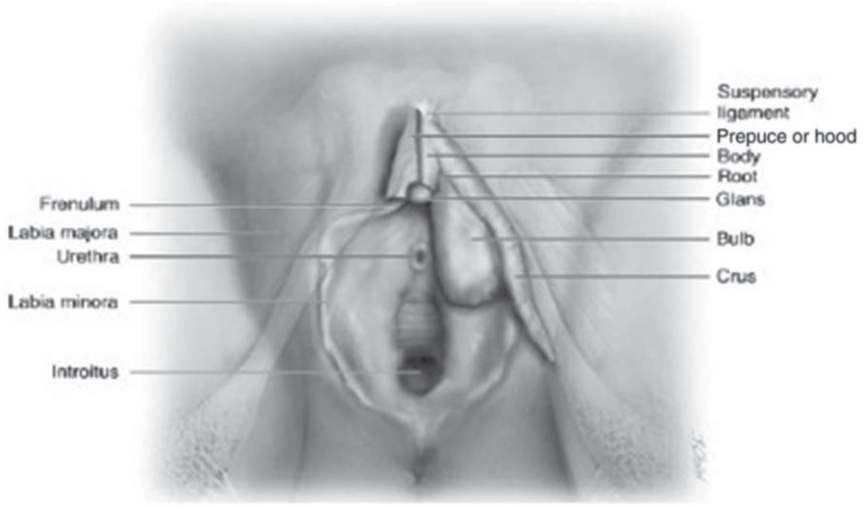

FIGURE 13
Female genital anatomic structures. Clitoral excision refers to the cutting of the glans (which is the distal part of the body of the clitoris) or the glans and part of the body. In all cases, part of the clitoral body remains intact, with scarring overlying the remaining body. The bulbs and crura, two other sexual erectile structures, have not been noted to be affected in FGM/C cases. Reprinted with permission from Abdulcadir J, Botsikas D, Bolmont M, et al. treatment in these cases, Medicaid should cover the defibulation.

In all cases of defibulation, it is advised that an experienced pediatric gynecologist (for young children), gynecologist (for older children and teenagers), urologist, or urogynecologist be identified to perform the procedure. One challenge is that there are currently few trained specialists with experience in managing FGM/C, particularly in young children. Similarly, it may be difficult to refer a girl or teenager to a male provider, and much discussion and support will need to be provided to facilitate successful care. Counseling patients who do not want to be defibulated, despite current complications, may be challenging given social and cultural pressures. This counseling may take multiple visits, and it may be necessary to dispel fears of loss of virginity in cases of defibulation.[67] Mental health and social issues may arise and need to be addressed through counseling and support. Multiple legal and ethical issues may also arise in cases in which a teenager desires defibulation but she does not want her parents to know because of fear of stigma and/or refusal by her parents (see The Law and FGM/C in Minors in the United States, Ethical Analysis, and Case 2 in the Appendix for further information).

For young children who are defibulated, general anesthesia is recommended in all cases.

If a teenager is pregnant, defibulating her under spinal anesthesia during

the second trimester is advised. In countries where spinal anesthesia may not available, local anesthesia may be used, if necessary. This allows ample time for healing and will facilitate providing care during labor. However, some teenagers may present late in the third trimester. They can still be defibulated up to 34 weeks' gestation, which will allow for the neo-vulva to heal adequately before labor. Otherwise, defibulating the patient preferably in the first stage of labor or when the baby is crowning are options and are the routine approaches in some African countries, although these approaches have not been systematically studied. Defibulation in the first stage of labor does facilitate pelvic examinations, catheterization, and general monitoring during labor while also allowing for procedures on less edematous tissues and quicker delivery. If a teenager is not pregnant, she can be defibulated under regional or general anesthesia. Although the WHO recommends local anesthesia as best practice, this recommendation is not based on strong evidence. Local anesthesia is not recommended (unless in a country where spinal and general anesthesia may not be available),[68] because women may report flashback memories from the day when they were cut, as noted in one case report.[69]

For type III FGM/C, timing and complications of defibulation have not been systematically studied in prepubertal girls. For prepubertal girls with complications, including pain, obstruction of urinary stream, and recurrent urinary tract infections, and teenagers with dysmenorrhea related to FGM/C, it is important that the health care provider begin conversations with the parents and/or child regarding the need for defibulation to treat these medical complications and associated morbidity as well as whether the girl would benefit from mental health counseling.

COMMUNITY ENGAGEMENT

Within the United States, emerging evidence indicates a misunderstanding and distrust among immigrant communities with fears of deportation, criminalization, raids by Immigration and Customs Enforcement, and fear of being reported to Child Protective Services (CPS).[70–74] Some health care and social service providers may also not understand the long-term physical and mental health-related morbidity associated with the practice of FGM/C.[75] In addition, language barriers may complicate patient-provider communication and have been demonstrated to negatively affect health-seeking behavior and health services use.[30,76,77]

A grassroots community-based and community-led approach is essential when working with affected populations to ensure that policies, preventive interventions, and advocacy are all informed by the perspectives, experiences, and needs

[a] Large systematic studies are lacking. Some small studies have revealed an association between FGM/C and mental health diagnoses.[49]

of those directly affected by FGM/C.[78] There are varying approaches to engage FGM/C-affected communities that need to be culturally and linguistically tailored on the basis of availability of local expertise, resources, infrastructure, and personnel. It is important to assess whether local efforts already exist because it will be much easier to build and/or expand on these partnerships. If there are no preexisting relationships, new community-based partnerships may need to be explored and created. It is recommended that pediatric health care professionals nurture meaningful partnerships with FGM/C-affected communities to foster greater trust, open dialogue, counseling, education, and community outreach to enhance culturally sensitive care for affected populations and to prevent FGM/C among female minors. In the past, the focus of outreach efforts has principally targeted women, who have been at the forefront of the perpetuation of FGM/C. However men, as husbands, fathers, brothers, sons, community leaders, and religious figures, also play a critical role in changing social norms; encouraging greater dialogue with

[a] One recent multicenter prospective study in the Gambia revealed no association between FGM/C and infants with low birth wt but a statistically significant increased risk of perinatal death and need for infant resuscitation (n = 1208).[127]

and engagement of their wives, daughters, and sisters in health services use; and supporting efforts toward eventual abandonment of the practice of FGM/C.[77,79] Consequently, it is critically important to include both men and women in strategies to enhance health services use and improve experiences with care while supporting community-wide FGM/C prevention efforts.

It is advisable that clinicians seek to engage within and across health care systems and multispecialty provider teams instead of staying within isolated profession-specific silos. Such multidisciplinary teams may comprise child abuse specialists, gynecologists, urologists, and general surgeons in addition to nurses, social workers, teachers, psychologists, counselors, case managers, certified medical interpreters, patient navigators, community health workers, refugee resettlement agencies, and public health departments. In addition, culturally appropriate and language-congruent resources, such as written information on FGM/C, should be made available in health care settings in the form of posters, pamphlets, or leaflets placed in private areas, such as women's restrooms, and made available in relevant languages.

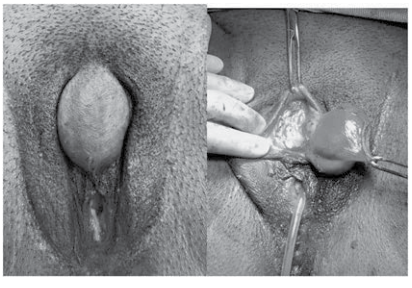

FIGURE 17
Type IIb FGM/C with large cyst, Tanner stage 5 female patient (photo courtesy of N.N.).

Since 2015, mandatory reporting legislation in the United Kingdom has come under increased scrutiny for the lack of consistent, reliable, high-quality data as well as for the lack of a routine system of monitoring.[80–83] Stigmatization of FGM/C-affected communities and distrust of law enforcement have resulted in underreporting, along with a lack of professional awareness and training.[84] Within the context of migration, the impact of acculturation, education, and length of stay on changing attitudes toward the practice are critical considerations when determining girls at risk for FGM/C[85–87] The first dedicated multispecialty clinic in the United Kingdom for girls affected by FGM/C and girls at risk with complex health needs uses a pediatric child abuse expert, a pediatric adolescent gynecologist with expertise in FGM/C, a child psychotherapist, and a specialist nurse in pediatric and adolescent gynecology, along with interpreters.[33] Referrals to this dedicated clinic are evaluated promptly with genital as well as colposcopy examinations, followed by further testing, counseling, and engagement of additional social and legal support services, as needed.

It is advised that attention also be paid to ensuring that the next generation of health care providers and scholars gain critical skills and exposure to culturally appropriate approaches to care for this population during their training. Hence, students, including medical and nursing students, residents, and fellows across various health, social science, and public health professions, should also be engaged in clinical care, counseling, education, and community outreach on FGM/C in such a way that is respectful of patients, caregivers, and communities. Models of established training guidelines and evidence-based educational competencies specific to FGM/C are lacking across all levels of health professions training. A proposed approach to instituting clinician competencies includes convening a multidisciplinary team of experts comprising key stakeholders from clinical medicine, medical education, public health, and research. Their expertise in competency development processes as well as in FGM/C would address FGM/C-specific knowledge and skills for clinical practice, patient care and handling ethical conundrums, communication skills, interprofessional collaboration (including partnering with community activists), and prevention efforts engaging individual families as well as FGM/C-affected communities.[32] Thereafter, evaluative performance metrics could be used to assess whether clinician competencies and patient care outcomes are being optimized. Moreover, an integrated team-based approach to health care delivery may more effectively address the multidimensional facets of providing holistic care, recognizing the intersection of ethnicity, migration, sex, and gender, which underlies the social construct of FGM/C.[88] Efforts to directly engage FGM/C-affected communities to engender trust, educate, promote continuity of care, and empower women and girls may enhance their health literacy and self-efficacy in seeking care for FGM/C-related concerns, navigating the health care system, and preventing future FGM/C.

ETHICAL ANALYSIS

Some have attempted to defend FGM/C by an appeal to cultural relativity, noting divergent mores and expectations in countries where it is frequently practiced.[89] Such a defense cannot overcome the fact that, as a rule, FGM/C may be physically and emotionally damaging, seriously affecting a girl's reproductive, sexual, and mental health. It is intrinsically a violation of the girl's human rights, compromising her bodily integrity without any medical benefit, without her consent (or, frequently, even her assent). It represents an extreme case of sex discrimination through attempting to control a woman's sexuality.[3] For these reasons, the practice is condemned by a vast number of health care organizations.[3,90,91]

While condemning the practice itself, as discussed previously, it is important to show cultural sensitivity to those who practiced FGM/C in their home countries. Some parents may not have felt they had a choice, given prevailing cultural expectations, believing that FGM/C gave their daughters the best chance of succeeding in a society where it was a prerequisite for marriage and acceptance.[92] Other parents might not have been fully aware of what was going to happen to their children or believed it had some medical benefit. Thus, the fact that a girl underwent this procedure is not a sign that her parents do not care about her or that they are more likely to engage in other forms of abuse.

So, although it is important to take active steps to prevent children from subsequently being subjected to FGM/C, it is also important to treat families whose children have already undergone FGM/C with compassion. Experience suggests that building rapport with parents increases the probability that they will give permission for remedial interventions. Such an approach may also help persuade the family to forgo FGM/C with their other children and perhaps enable advocacy efforts with their local community as well as extended family in their country of origin.

FGM/C performed by health care providers is not uncommon, representing 18% of cases from all countries with available data. In some countries, health care providers are responsible for three-quarters of FGM/C procedures.[93] If asked to perform the procedure, even health care professionals who are morally opposed to FGM/C might agree to do so out of a sense of cultural respect or because they believe the alternative (ie, the family seeking the procedure from traditional practitioners) to be even worse.

By agreeing to perform the procedure, however, health care providers are granting it medical legitimacy, which not only undercuts the moral prohibition on the procedure but also contributes to its spread and ongoing societal acceptance. As the WHO notes, "It can also lead some health-care providers to develop a professional and financial interest in upholding the practice,"[15] and although the immediate risks could be reduced if the procedure were performed by a trained professional, the risks of the previously noted long-term complications remain.

THE LAW AND FGM/C IN MINORS IN THE UNITED STATES

Within the United States, there are several legal issues that confront health care providers in the context of a suspected FGM/C case, including the following:

1. applicable federal and state laws;
2. consent and assent;
3. reporting child protection and/or criminal activity concerns;
4. confidentiality; and
5. documentation.

Outside the United States, many countries have laws in place that criminalize the practice of FGM/C (see Table 2).

Applicable US Federal and State Laws

The Federal Prohibition of Female Genital Mutilation Act of 1996 made it illegal to perform FGM/C in the United States on children and teenagers younger than 18 years. The act criminalizes circumcising, excising, or infibulating "the whole or any part of the labia majora or labia minora or clitoris of another person who has not attained the age of 18 years," unless deemed medically necessary, and recognizes no religious or cultural exemption for the practice of any type of FGM/C. However, a recent federal district court decision, *United States v Nagarwala*,[21,94] has found the statute unconstitutional. Despite this federal court decision invalidating the federal statute, at the time of this writing, 35 states have also enacted specific state criminal statutes against FGM/C[95,96] (see Table 8).

Although FGM/C performed in another country before US immigration is not reportable or prosecutable, transporting a child out of the United States for the purpose of FGM/C (so-called vacation cutting) was criminalized in the Transport for Female Genital Mutilation Act of 2013. When a child is at risk for FGM/C, including when traveling to a country where FGM/C prevalence is high and in cases in which the girl's mother and/or sisters have already had FGM/C performed before US immigration, it is recommended that health care providers have an open and supportive conversation with the parents regarding the significant medical complications of FGM/C (see Complications and Management) and legal implications to parents or other caregivers if they have FGM/C performed on their child.

TABLE 8 FGM/C Laws, by State (as of July 12, 2019)

State	Applicable Law	Only Applies to Minors (<18 Unless Otherwise Specified)	Vacation Cutting Provision (Bans Travel Outside State for FGM/C)	Duty To Report (Including FGM as Child Abuse)	Cultural and Ritual Reasons and/or Consent Not a Defense	Parent or Guardian and Circumciser Subject to Prosecution	Sentence
Arkansas	A.C.A. 5-14-135, 12-18-103, 16-118-116, 17-80-121, 20-82-101, 20-82-102	X	X	X	X	X	Imprisonment 3–10 y
Arizona	A.R.S. §§ 12-513, 13-705, 13-1214, 13-3620,	X	X	X	—	—	Imprisonment 5.25–35 y and fine up to $25 000
California[a]	Cal. Pen. Code § 273a, 273.4	X	—	—	—	X	Imprisonment 1–6 y
Colorado[b]	Col. Rev. Stat. § 18-6-401	<16	—	—	X	X	Imprisonment minimum 4 y
Delaware	Del. Code Tit. 11, § 780	X	—	—	X	X	Imprisonment up to 5 y
Florida	Fla. Stat. § 794.08	X	X	—	X	X	Imprisonment up to 15 y and/or fine up to $10 000
Georgia[c]	O.C.G.A. § 16-5-27	X	X	—	X	X	Imprisonment 5–20 y
Idaho	I.C 18-1506B, I.C. 19-402	X	—	—	X	—	Imprisonment up to life
Illinois	720 Ill. Comp. Stat. 5/12-34; 325 Ill. Comp. Stat. 5/3, 5/4	—	—	X	X	X	Imprisonment 6–30 y
Iowa	I.C.A. 708.16	X	X	X	X	—	Imprisonment for up to 5 y and fine of $750–$7500
Kansas	K.S.A. § 21-5431	X	X	—	X	X	Imprisonment 89–100 mo
Louisiana	La. R.S. 14:43.4	X	X	—	X	X	Imprisonment up to 15 y
Maryland	Md. Code Health-Gen. § 20-601, 602	X	—	—	X	X	Imprisonment up to 5 y and/or fine up to $5000
Michigan	1931 PA 328 § 136 1978 PA 368 § 9159	X	X	—	X	X	Imprisonment up to 15 y
Minnesota	Minn. Stat. § 144.3872, 609.2245	—	—	—	X	—	Imprisonment up to 5 y and/or fine to $10 000
Missouri	Mo. Rev. Stat. § 568.065	Under 17	—	—	X	X	Imprisonment 5–15 y
Nevada	Nev. Rev. Stat. § 200.5083	X	X	—	X	X	Imprisonment 2–10 y and/or fine up to $10 000
New Hampshire	N.H. Rev State.§ 632-A:10-d	X	—	X	X	—	Imprisonment up to 7 y
New Jersey	N.J. Stat. § 2C:24-10	X	X	—	X	X	Imprisonment 3–5 y
New York	N.Y. Penal Law § 130.85; N.Y. Public Health Law § 207(k)	X	—	—	X	X	Imprisonment up to 4 y
North Dakota	N.D. Cent. Code § 12.1-36-01	X	—	—	X	—	Imprisonment up to 5 y and/or fine up to $10 000
Ohio	OH ST §§ 2903.32, 2929.14, 2929. 18	X	—	X	X	—	Imprisonment 2–8 y, fine up to $40 000, and/or a fine up to $15 000 and an additional fine up to $25 000
Oklahoma	21 Okl. St. § 760	—	—		X	—	Imprisonment 3 y to life and/or fine up to $20 000
Oregon	Or. Rev. Stat. § 163.207	X	—		X	X	Imprisonment up to 10 y
Pennsylvania	18 Pa. C.S.A. 3132	X	X	X	X	X	Imprisonment for >10 y
Rhode Island[d]	R.I. Gen. Laws § 11-5-2	—	—	—	—	—	Imprisonment up to 20 y

West Virginia	W. Va. Code § 61-8D-3A	X	—	—	X	X	Imprisonment 2–10 years and fine $1000–5000
Wisconsin	Wis. Stat. § 146.35	X	—	—	X	—	Imprisonment 6 y and/or fine up to $10 000

States with no existing FGM/C laws (as of July 12, 2019): Alabama, Alaska, Connecticut, Hawaii, Indiana, Kentucky, Maine, Massachusetts, Mississippi, Montana, Nebraska, New Mexico, North Carolina, Vermont, Washington, and Wyoming. Adapted from Equality Now. Female genital mutilation in the United States. Available at: https://www.equalitynow.org/factsheets. Accessed May 25, 2018 and from Mishori R, Warren N, Reingold R. Female genital mutilation or cutting. *Am Fam Physician*. 2018; 97(1):52A. X, existing law; —, no current legislation addressing this issue.

[a] California: enhanced penalty for FGM/C under "Abandonment and Neglect of Children" (Penal Code).

[b] Colorado: within child abuse law and one of few states where doctor-patient and husband-wife privileges are inapplicable in prosecutions for FGM/C.

[c] Georgia: one of few states where husband-wife and other statutory privileges are inapplicable in prosecutions for FGM.

[d] Rhode Island: within assault statute.

Consent and Assent

Before discussing consent and assent issues as they pertain to FGM/C, it is appropriate to review these concepts. Informed consent is the legal authorization to provide medical care to an individual. Minor children generally lack sufficient decision-making capacity to provide true informed consent, with three notable exceptions. The first involves the so-called "minor treatment statutes,"[97] which vary by state but generally permit minors to consent to treatment of sexually transmitted infections, mental illness, substance abuse, or matters related to reproductive health (including contraception, abortion, prenatal care, and pregnancy). If treatment qualifies under a state's minor treatment statute, a minor may consent to that specific treatment but not to others that fall outside the scope of the statute. Evaluation for FGM/C and treatment of its complications could impact reproductive health and, thus, may fall under the minor treatment statute of some states.

The second exception involves a minor patient who is legally emancipated. Emancipation[98] may be automatically conferred by taking a specific action, which varies by state, such as getting married or serving in the active duty military, or may be declared by a court after the minor fulfills specific requirements such as being self-supporting and either being enrolled in high school or having obtained one's diploma.

The third exception involves being deemed a "mature minor"[99] after being assessed for relevant factors such as reasoning ability and intellectual capacity.[100]

Again, state laws vary as to the precise requirements for a minor to be deemed sufficiently mature to make her own health care decisions. It is recommended that health care providers not assume a minor is

mature unless provided with clear court documentation. Unlike the minor treatment statutes, emancipated and mature minors are granted the right to make all their own medical decisions, which would include not only evaluation of FGM/C but also interventions to treat it and its complications.

Outside these specific exceptions, parents are tasked with making nonemergency medical decisions for their minor children, which is termed "parental permission." But even if a child is incapable of informed consent, she still has a role in medical decision-making. It is recognized that a child's decisional capacity evolves over time, and so "assent" refers to a pediatric patient's agreement to evaluation and treatment to the degree that she is able to comprehend what is being proposed. This involves developmentally appropriate awareness of the nature of the condition, appreciation of what to expect with tests or treatments, and being free of inappropriate pressure.[101] In nonemergency situations, the older child and adolescent should give assent to evaluation and/or treatment.

There are two other situations in which parental permission is not required for the evaluation and treatment of a child. The first is when abuse is suspected, such as FGM/C that occurred in the United States, or as vacation cutting after immigration to the United States. Most states grant immunity to a provider who assists or participates in an investigation of allegation of maltreatment (ie, conducts a nonemergency evaluation for abuse, including the physical examination, and taking necessary photographs or radiographs and performing medically relevant tests) from any civil or criminal liability related to that participation.[102] It is prudent for health care professionals to be knowledgeable of their state-specific child maltreatment legislation (see Table 8). If questions arise, it may be wise to consult with a child abuse pediatrician.

Even if parental permission is not required for the reasons noted here, if the patient is old enough to provide assent, it is advisable to obtain this before proceeding. Additionally, maintaining open lines of communication with the patient's parents is helpful, which may include informing them of what is being performed and why.

The other context in which parental permission is not required is emergent situations such as active hemorrhage or imminent delivery with infibulation. If the parents are unavailable to provide permission, consent may be presumed if three conditions hold:

1. there is a serious and immediate threat to life or health;
2. there is a need for urgent intervention (delay in care is not safe); and
3. the health care provider administers only care and treatment of emergency conditions that pose an immediate threat to the child.[103]

In such situations in which the parents are available yet withhold permission, evaluation and treatment may proceed on the basis of the presumption of medical neglect and the duty of the state to protect the patient from harm (the doctrine of parens patriae).

Reporting Child Abuse

Health care providers in the United States are mandated reporters of suspected child maltreatment, which includes FGM/C that occurred in the United States or as vacation cutting outside the United States after this practice was criminalized in 2013. Physical examination findings suggestive of FGM/C, with previous documentation of normal genitalia, should prompt reporting to CPS. FGM/C that occurred before immigration to the United States does not meet the legal requirement for breaching confidentiality by reporting to state agencies. Furthermore, reporting past or current FGM/C runs the risk of damaging not only the therapeutic relationship with an individual patient and her family but also with the immigrant community to which that family may belong. If health care providers are perceived not only as judgmental (ie, culturally insensitive) but also as agents of the state, families may be less likely to seek out needed medical care for their children. The opportunity for advocacy to prevent future potential instances of FGM/C may also be lost.

Most states also require a report to be made if there exists reasonable cause to believe that child abuse may occur in the future. Immediate or imminent risk warrants notification of local law enforcement authorities as well. If a child experienced FGM/C before immigration to the United States, which is not reportable, health care providers might, in some cases, be concerned for other female children in the home who might subsequently be subjected to FGM/C. It is important that these situations be evaluated individually and on the basis of a culturally sensitive discussion with the child's primary care givers and child, if developmentally appropriate. It is advisable that the dialogue include a review of health risks and complications as well as legal repercussions of FGM/C. As needed, it is important that cultural concerns be addressed and that community organizations be engaged to enhance parental understanding. This dialogue should be recorded in the child's medical record.

After such education and dialogue, if a health care provider has reasonable cause to believe that a child may subsequently be subjected to FGM/C, CPS should be notified. As mentioned previously, what constitutes

reasonable cause to believe is a nuanced and case-specific question. However, it is advised that health care providers remember that the threshold for reporting maltreatment does not require incontrovertible certainty, just a reasonable suspicion. Studies have revealed that pediatricians have multiple reasons for either delaying or not reporting suspected maltreatment (ie, mistrust of the child welfare investigative system and familiarity with the family, to name a few) and that physicians sometimes require inordinately high degrees of certainty before reporting suspected maltreatment.[104]

If a clinician is uncertain whether the fact pattern of a particular case reaches the threshold of reasonable cause to believe, it is appropriate to consult a child abuse pediatrician. Expressed intention to engage in FGM/C, either in the United States or abroad, should prompt a report to CPS if the child's parent or caregiver cannot be dissuaded.

To avoid stereotyping, as well as harm to the therapeutic relationship, it is important to avoid making assumptions and to be attentive to implicit biases. Many families who originate from countries with high prevalence of FGM/C may travel back to the country of origin for many reasons wholly unrelated to FGM/C. Although some communities accept FGM/C as a sign of cultural identity or enhancing marriageability, anecdotal expert experience suggests that many mothers from high-prevalence countries do not want to subject their daughters to FGM/C. This may be particularly true when the mother herself has suffered medical complications, although this situation has not been systematically studied. Recognizing this, it is appropriate to engage in an open and supportive discussion with the family about their beliefs about FGM/C. This may involve inquiring as to the family's plans for their daughter (see Appendix). Laws and regulations regarding child abuse reporting are different in other countries. It is prudent for health care providers to be cognizant of their country-specific requirements.

Confidentiality

In the adolescent patient with past, current, or future FGM/C concerns, it is important for health care providers to have a comprehensive discussion with the patient about the expectations and limitations of confidentiality. FGM/C that occurred in the United States or as vacation cutting after it was criminalized in 2013 is subject to federal and state reporting laws.

Documentation

Objective and thorough documentation is extremely important in potential (and actual) child maltreatment circumstances. The following recommendations (Do's and Don't's) may assist health care providers in ensuring appropriate clinical documentation in the FGM/C scenario.

Do's

1. Document in the medical record the particulars regarding informed consent or permission (ie, who gave it, when it was given, for what purpose, etc).
2. For children able to assent, obtain their assent before proceeding with examination of external genitalia.
3. Carefully and objectively document any examination limitations or mishaps in the record.
4. Describe physical findings in detail. When possible, and after attaining appropriate consent, photo-document abnormal genital findings and maintain them in a secure fashion in compliance with privacy rules of the Health Insurance Portability and Accountability Act. Given that external genital examination and, particularly, photography of a girl or teenager may be difficult to explain to families from other cultures, photographs may be reserved for those times when there are concerns that suspected FGM/C constitutes child abuse.
5. Report impressions objectively, comprehensively, and in as simple language as possible. When applicable, report alternative diagnoses considered relevant to the findings and impression, such as labial adhesions or normal anatomic variants. In cases in which either identification of the diagnosis of FGM/C is not clear, it is strongly recommended to consult a health care provider who is well versed in diagnosis of FGM/C in prepubertal or pubertal girls, depending on the case, given that type I and II FGM/C may be difficult to diagnose (see Table 4). Such consultation is highly recommended before reporting to CPS, especially if the family is amenable.
6. If FGM/C has been recently performed in the United States, or abroad and after initial immigration, create the CPS report in a timely fashion, and as soon after evaluation as possible.
7. Document (in reasonable detail), where appropriate, all consultations with colleagues, patients and/or parents, and multidisciplinary partners.

Don't's

1. Insert language into the record or a report that is inflammatory, superfluous, or highly subjective (ie, "profoundly," "faulty," "sloppy," "terrible," "negligent," "careless," "horrible," "uncaring," "pathetic," "horrific," "barbaric," etc).
2. State conclusions that are not supported by specific facts or by the medical literature, especially if

the identification or diagnosis of FGM/C is unclear or uncertain.

3. Record information in the record or a report that has primarily legal implications and minimal or no patient care value.

Legal Right to Asylum Protection in the United States and FGM/C

FGM/C presents one other legal consideration for clinicians, that of US asylum protection. US asylum protection may be granted to someone who has left their native country because of persecution or fear that they will suffer from persecution,[105] including because of membership in a particular social group, in this case being female and living in a country where FGM/C is practiced. To be granted asylum, a person must either be physically present in the United States or at a port of entry to the United States, and certain other conditions must be met through a formal process with US Citizenship and Immigration Services.

The 1996 US ruling, the *Matter of Kasinga,* established the right of asylum protection for women and children potentially facing FGM/C.[106] However, the scenarios of past FGM/C and parents seeking asylum on the basis that their daughters would be subjected to FGM/C if they returned to their home country are more nuanced and case specific. It is prudent for clinicians to recognize this potential protection for their patients and to direct families to an immigration law attorney if such issues arise.

CONCLUSIONS

FGM/C in children is a complex issue with potential medical, mental health, and legal ramifications. It has no clinical benefits and is associated with significant morbidity and mortality. Health care providers caring for diverse patient populations may identify FGM/C in their patients; however, FGM/C will only be identified if primary care providers become adept at performing external genital examinations on all children at every health supervision appointment. It is recommended that health care providers who are not comfortable with making an FGM/C diagnosis or discussing treatment options consult a specialist who is trained in addressing pediatric FGM/C. Open and culturally sensitive discussions among health care providers, parents, and children regarding FGM/C is of utmost importance in addressing FGM/C that has already occurred as well as in preventing future FGM/C from occurring.

RECOMMENDATIONS

1. Health care providers should not perform any type of FGM/C on female infants, girls, or teenagers.
2. Health care providers caring for girls at risk for FGM/C should actively counsel families against performing FGM/C, including when families travel to countries where FGM/C is practiced.
3. With consent and/or assent of the guardian and/or child documented in the patient's chart, all children should have external genitalia examined at all health supervision examinations, including the identification of the prepuce, clitoris, and labia minora and majora.
4. For children with risk factors for FGM/C, it is recommended that clinical assessment of FGM/C status be integrated into routine pediatric care and that a history of FGM/C before US immigration be documented in the health record.
5. It is recommended that health care providers who are not comfortable with making an FGM/C diagnosis or discussing treatment options consult a specialist who is trained in addressing pediatric FGM/C (see Table 4).
6. If genital examination findings are equivocal for the presence of FGM/C and risk factors for FGM/C are present, a specialist trained in identification of FGM/C should be consulted (see Table 4).
7. The management of FGM/C should include complete documentation of clinical findings and the use of ICD-10 coding.
8. Health care providers should recommend defibulation for all girls and teenagers with type III FGM/C, particularly when complications are currently present.
9. In all cases in which defibulation is recommended, an experienced pediatric gynecologist (for young children), gynecologist (for older children and teenagers), urologist, or urogynecologist should be identified to perform the procedure.
10. Standardized training related to the identification, treatment, management, and culturally appropriate communication approaches needs to be developed and provided to health care providers who care for FGM/C-affected communities.
11. If FGM/C is suspected to have occurred in the United States, or as vacation cutting after immigration to the United States, the child should be evaluated for potential abuse. Expressed intention to engage in FGM/C, either in the United States or abroad, should also prompt a report to CPS if the child's parent or caregiver cannot be dissuaded.

ACKNOWLEDGMENT

We acknowledge the contribution of Zeinab Eyega (founder and executive director, Sauti Yetu Center for African

Women and Families) for her expert analysis of the case examples presented in the Appendix.

APPENDIX: CASE EXAMPLES AND EXPERT ANALYSIS

An example of an approach when discussing FGM/C with the child or teenager's mother may include statements such as the following:

I am learning about cultural practices in your country and understand that female genital cutting is done in your country. Were you cut as a child? Were your daughters cut while you were still living there? The reason I ask is that I am a physician and female genital cutting may have severe medical complications, including recurrent urinary tract infections, painful menstruation, and severe scarring blocking the flow of urine and menstrual blood. I want to make sure that you and your daughters are not having these issues because they can be treated. I also want to make sure that you understand that it is illegal to have a girl cut once she is living in the United States. This includes not sending her to another country to have her cut once she has been living in the United States.

Consider discussing FGM/C with the mother at the end of the visit after obtaining a history and performing the physical examination. Introducing a conversation regarding FGM/C early in a visit may serve as a barrier to establishing trust and rapport.

CASE 1

The patient is a 16-year-old teenaged refugee born in Mali and living in Mauritania before US arrival. She has established care with her primary care pediatrician, who explains that she needs to perform a full physical examination, including examination of her external genitalia. The teenager assents to the examination and is found to have type IIb FGM/C. The girl does not know that she has been cut and has no recollection of the procedure having occurred. She is confused and does not understand what her FGM/C means for her and how she will discuss this with her parents and boyfriend.

J.Y., General Pediatrician

Some girls do not recall undergoing FGM/C, particularly if it occurred at a young age. Expert opinion suggests that some parents do not inform their daughters of having been cut. In this case, it is important to explain physical findings to the patient and use diagrams, such as the one in Fig 4. She will need to be supported in understanding why she was cut, and it is recommended that the care provider explore how and if she would like to discuss her FGM/C with her mother, either with the medical provider present or not. If the patient is contemplating a sexual relationship, she may be concerned about her genitalia appearing different. She may also have questions about sexual function. These questions may be addressed either at this visit or at follow-up visits over time. Referral for culturally appropriate mental health supports may also be warranted in this case. If this patient has female siblings, it is recommended that they also have head-to-toe physical examinations, including external genitalia, and physical findings should be documented. It is recommended that a culturally sensitive discussion occur with the mother and father regarding the medical issues associated with FGM/C and that FGM/C performed in the United States or as vacation cutting is illegal. These discussions should be documented in the patient's chart, and the diagnosis of FGM/C should be included in the patient's past medical history as having occurred before arrival in the United States.

Zeinab Eyega, Founder and Executive Director, Sauti Yetu Center for African Women and Families

The pediatrician should ask how the patient feels about her diagnosis of FGM/C, if the teenager has questions about the practice, and if she has ever heard about FGM/C at school or through friends or family and if so, what she learned and thought. It is essential to determine the teenager's support network, whether peers, a teacher, or a counselor, that can provide regular guidance and help as needed. The teenager's boyfriend may be from within or outside of her cultural group. Over time, it is important to discuss with the teenager whether she is concerned about her appearance because of her FGM/C. If she does not have any current health issues or concerns and there are no medical problems, the discussion may be left and revisited if concerns arise.

S.K.N., Child Abuse and Legal Expert

An honest but respectful discussion needs to occur, exploring the family's current beliefs regarding FGM/C, education about medical complications and/or risks, and education about US laws prohibiting the practice. It is important to remember to obtain more history about when the family came to the United States and whether there are other female siblings who may be at risk. A private discussion with the mother is recommended to learn of when and where the FGM/C occurred. If it occurred outside US jurisdiction, FGM/C is not grounds for reporting, but the safety of other younger female siblings in the house at future risk should be considered.

R.C.M., Medical Ethics Expert

The important ethical issues (including the patient's right to understand her condition and the obligation to protect female siblings who might be at risk) are well addressed in the preceding commentaries.

CASE 2

The patient is a 17-year-old Sudanese girl with type III FGM/C performed before US immigration who has severe dysmenorrhea from partial obstruction of menstrual flow. She wants to undergo defibulation. The

teenager gives permission for the pediatrician to discuss the issue with her parents and the medical recommendation to undergo defibulation because of medical complications. The parents are very concerned about defibulation and reluctant to give permission.

J.Y., General Pediatrician

With the teenager's consent, it is recommended to arrange a meeting with the parents to discuss the complications their daughter is having from her FGM/C, including severe pain with menstruation from partial obstruction of menstrual flow. Consider initiating the conversation with the parents by asking what their understanding of FGM/C is and exploring why it is or is not important to them. It is recommended to show diagrams of the teenager's anatomy and explain the issues that the infibulation is causing as well as her risk for future complications, including possible issues with scarring, chronic pain, and infertility. Several meetings may be required to review the medical issues and the recommendation to defibulate the teenager to relieve symptoms, both short- and long-term. As with case 1, if there are other female siblings in the home, it is recommended to make arrangements to perform a full physical examination on the other female siblings, including visualization of the external genitalia, and findings should be clearly documented in the chart. A frank but culturally sensitive discussion should occur with the parents, explaining medical complications and the illegality of future FGM/C documented in the chart as well as documentation of FGM/C having occurred overseas, before immigration, in the past medical history.

Zeinab Eyega, Founder and Executive Director, Sauti Yetu Center for African Women and Families

If the teenager consents to allowing a discussion with her parents, the pediatrician should facilitate a meeting with both the teenager and parents present. It is important to learn from the parents if they have noted the medical issues, including pain, that their daughter has had because of her type III FGM/C and that the recommended treatment is defibulation. Some parents (most likely the mother) may be concerned that if their daughter is defibulated, the procedure would affect her virginity. It is important to address this concern to ensure that the teenager continues to have support from her parents after defibulation so that she does not feel isolated from her parents and other family members, both of which could negatively affect her emotional well-being. The parents may need time to process the information, and another appointment should be offered as well as the option to meet with a counselor to discuss the issue with the counselor.

S.K.N., Child Abuse and Legal Expert, and R.C.M, Medical Ethics Expert

This scenario is nuanced and could constitute medical neglect by the parents (depending on the severity of symptoms and degree of obstruction). If possible, the general pediatrician should consult a child abuse pediatrician because they will know the local CPS personnel and procedures well and may be able to provide an idea of their potential response. Furthermore, the general pediatrician should have an honest and respectful discussion with parents about the teenager's medical need for defibulation and about their failure to consent possibly requiring a report to CPS for intervention.

Although 18 years is the age of majority in nearly every state, some younger patients may possess sufficient decision-making capacity to make informed and voluntary health care decisions.[101] If her condition represents a current threat to her health (in terms of pain, suffering, or risk of morbidity or mortality), her parents' unwillingness to give permission to defibulation could represent medical neglect. Even if her condition is not an emergency, the patient could be declared by the court to be a mature minor, depending on the laws of her state,[99] and could thus have the legal right to consent to the procedure herself.

CASE 3

A 10-year-old girl born in the United States in 2008 to Ethiopian refugee parents presents for well-child care. She had a documented normal physical examination, with normal female genitalia, at her newborn visit. Well-child care examinations at 4, 6, and 8 years of age occurred with the genital examination marked as "deferred" at each visit. Of note, the girl traveled to Ethiopia in 2012 to visit relatives with her mom. A full physical examination, including external genitalia, reveals type Ib FGM/C. Once the child is dressed, the mother is separately asked if her child had FGM/C performed. She denies any knowledge of her child being cut abroad.

J.Y., General Pediatrician

It is important to ask the 10-year-old whether she recalls having been cut. If she does remember being cut, she will be able to provide more information regarding when and where it happened as well as who was involved. If she is unable to provide any information about the cutting, it is important to document this information in her medical chart. Although more likely the FGM/C occurred overseas on her visit with relatives, it is theoretically possible that she had FGM/C performed in the United States. In this case, it would be reasonable to consult with a child abuse specialist in your state. As with cases 1 and 2, if there are other female siblings in the house, these children should be examined, and physical findings and medical and

legal education regarding FGM/C should be clearly documented in the patient's health record.

Zeinab Eyega, Founder and Executive Director, Sauti Yetu Center for African Women and Families

The pediatrician should start by speaking with the parents separately from the child and explaining that her examination reveals FGM/C that was performed after she was born in the United States. It is important to show diagrams revealing the difference between a cut and uncut child so that the parents understand. Ask questions about other family members and if they have also had FGM/C. In some cases, biological parents may not be involved in the decision to circumcise their daughter and may not know that she was cut. In such cases, a respected elder in the community, such as a grandmother or aunt, may make this decision for the girl and have her cut.

S.K.N., Child Abuse and Legal Expert

Although this scenario may not be prosecutable as vacation cutting or reportable, as in case 1, it is advisable to gather more psychosocial history about the family makeup and the family's current beliefs about FGM/C.

R.C.M., Medical Ethics Expert

Although the patient is unable to provide informed consent for evaluation and treatment, she is developing the capacity for assent and thus is entitled to an explanation of her condition, provided in a nonjudgmental and developmentally appropriate fashion, with her questions welcomed and consistent promises of ongoing support. The pediatrician should also strive to establish rapport with the family, who may be denying knowledge because of fear of repercussions or may truly be unaware.

CASE 4

The patient is a 5-year-old female refugee from Somalia via a Kenyan refugee camp who had type IIIb FGM/C performed 6 months before US immigration. The child has her urethral opening covered by labia minora, and urinary stream occurs through a 2 × 2 mm opening in the otherwise sealed labia minora. The patient has reported delay in bladder emptying and pain, per maternal report. She has no report of past urinary tract infections, prolonged fever, or vomiting.

J.Y., General Pediatrician

A supportive discussion should occur with the parents regarding the pain and medical complications associated with the child's type III FGM/C, including risk for recurrent urinary tract infections and renal scarring. Diagrams should be used to demonstrate the issues associated with acute urinary obstruction. This discussion may take several visits, with strict return precautions reviewed each time, including the need to bring the child immediately for medical evaluation if the following conditions are present: fever, vomiting, dysuria, or urgency to urinate, frequency of urination, and/or the inability to pass urine. With consent of the parents, a trusted leader in the Somali community may need to be called on to help support the parents in deciding to allow their child to undergo defibulation.

Zeinab Eyega, Founder and Executive Director, Sauti Yetu Center for African Women and Families

It is important to use diagrams to review the physical findings of female genital cutting with the parents and to explain why the child is having problems emptying her bladder and has pain. Explain that it is recommended to have the child defibulated and that this will not affect her virginity or her ability in the United States to marry later in life. If there are other daughters, they should also be examined.

S.K.N., Child Abuse and Legal Expert

A thorough psychosocial history should be obtained to assess the social dynamics of the family. An honest and respectful discussion should occur that, as in case 2, should highlight the possible need to report to CPS if permission is denied for the health and safety of the child. Again, if available, consultation with a child abuse pediatrician is advised because that individual will know the local CPS personnel, procedures, and responses well.

R.C.M., Medical Ethics Expert

The patient has a condition that leads to pain and impaired urinary outflow. Irrespective of the cause, this needs to be addressed. The clinical situation should be explained to the parents as well as recommendations made to treat the urinary retention and pain. Parental refusal of the intervention to address these problems suggests they are not acting in the best interest of the child.

Digital Advertising to Children

- *Policy Statement*

POLICY STATEMENT Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN®

Digital Advertising to Children

Jenny Radesky, MD, FAAP,[a] Yolanda (Linda) Reid Chassiakos, MD, FAAP, FACP,[b] Nusheen Ameenuddin, MD, MPH, MPA, FAAP,[c] Dipesh Navsaria, MPH, MSLIS, MD, FAAP,[d] COUNCIL ON COMMUNICATION AND MEDIA

Advertising to children and teenagers is a multibillion-dollar industry. This policy statement reviews the forms of advertising that children and teenagers encounter, including newer forms of digital marketing, such as sponsored content, influencers, data collection, persuasive design, and personalized behavioral marketing driven by machine learning. Parents and pediatric health care providers need to be aware of the ways different marketing messages reach children and teenagers, including Internet sites, social media, and mobile apps. Evidence suggests that exposure to advertising is associated with unhealthy behaviors, such as intake of high-calorie, low-nutrient food and beverages; use of tobacco products and electronic cigarettes; use of alcohol and marijuana; and indoor tanning. Children are uniquely vulnerable to the persuasive effects of advertising because of immature critical thinking skills and impulse inhibition. School-aged children and teenagers may be able to recognize advertising but often are not able to resist it when it is embedded within trusted social networks, encouraged by celebrity influencers, or delivered next to personalized content. This policy statement expresses concern about the practice of tracking and using children's digital behavior to inform targeted marketing campaigns, which may contribute to health disparities among vulnerable children or populations. Pediatricians should guide parents and children to develop digital literacy skills to prevent or mitigate negative outcomes, but it is equally important that policy makers and technology companies embrace digital design, data collection, and marketing practices within today's broad digital environment that support healthier decision-making and outcomes.

THE CHANGING LANDSCAPE OF MARKETING TO CHILDREN

Advertising to children and teenagers via various forms of media has occurred for decades, with expenditures of $3.2 billion for nondigital and $900 million for digital advertising in the United States in 2018.[1] Children and teenagers encounter advertising through television, radio, print media, the Internet, and their mobile phones. Advertising can take many forms, including images, videos, and games that advertise specific brands.

abstract

[a]Department of Pediatrics, Medical School, University of Michigan, Ann Arbor, Michigan; [b]Department of Pediatrics, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, California; [c]Mayo Clinic, Rochester, Minnesota; and [d]Department of Pediatrics, University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin

Dr Radesky drafted the initial policy statement, wrote sections of the manuscript, and critically revised the manuscript on the basis of reviewer feedback; Drs Chassiakos, Ameenuddin, and Navsaria wrote sections of the manuscript and revised the manuscript on the basis of reviewer feedback; and all authors approved the final manuscript as submitted.

Policy statements from the American Academy of Pediatrics benefit from expertise and resources of liaisons and internal (AAP) and external reviewers. However, policy statements from the American Academy of Pediatrics may not reflect the views of the liaisons or the organizations or government agencies that they represent.

The guidance in this statement does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

All policy statements from the American Academy of Pediatrics automatically expire 5 years after publication unless reaffirmed, revised, or retired at or before that time.

However, since the introduction of mobile media and Internet-connected devices (eg, virtual assistants, Internet-connected toys), advertising now comprises a wider range of marketing approaches for which influences on child behavior have not been well described. The purpose of this policy statement is to review the developmental science explaining how children and teenagers are vulnerable to advertising, review the emerging research on novel marketing approaches and evidence regarding advertising and child health, and offer guidance to parents, pediatric health care providers, industry, and policy makers about the needs and rights of children in the modern digital media environment.

CHILDREN'S UNIQUE VULNERABILITY TO ADVERTISING

Research on children's understanding of television advertising[2] demonstrates that children 7 years and younger have limited ability to understand the persuasive intent (ie, that someone else is trying to change their thoughts and behavior) of the advertiser. From ages 7 to 11 years, children can start to recognize television advertising and persuasive intent with their parents' assistance but lack the abstract thinking skills that help individuals recognize advertising as a larger commercial concept. At ~12 years of age and older, teenagers were able to identify television advertisements (ads) and advertisers' intention to change behavior (which is why some countries, such as Sweden and Brazil, have laws banning advertising to children younger than 12 years).

However, recognition of persuasive intent does not necessarily lead to the ability to resist marketing, especially with highly appealing products. Marketers use emotional or subconscious approaches[3] to engage children, such as using trusted characters[4] or celebrities. At as young as age 2, a child can easily identify a familiar character as well as correctly connect them with an endorsed product.[5]

Most importantly, most research on children's understanding of advertising involves television and print ads only, but newer forms of advertising found in mobile and interactive media and smart technologies, often powered by personal data, are more difficult to identify. They do not necessarily occur in a predictable manner and are often integrated into the content.[6] Advertising may also be linked to rewards or be embedded in trusted social networks or personalized digital platforms, which may undermine children's abilities to identify or critically think about advertising messages. Regulations on television advertising[7] have not yet been updated for the modern digital environment.

NEW MARKETING APPROACHES

The nature of media used by children and teenagers has changed dramatically in the past decade, and children now spend more time on the Internet, social media, user-created content, video games, mobile applications (apps), virtual or augmented reality, virtual assistants, and Internet-connected toys. The Internet allows advertisers to contact, track, and influence users, as guided by behavioral data collection; a user's digital trail of location, activities, in-app behavior, likes, and dislikes contributes to a digital profile shared among many companies that can be used to make advertising messages more effective.

Sponsored Content and Influencers

User-created content on social media platforms and video-streaming services (eg, TikTok, YouTube) frequently involves commercial content and marketing messages. Examples include the highly popular unboxing and toy-play videos as well as influencers reviewing or using products with sponsorship from companies. Child advocacy groups have highlighted the large amount of child-directed influencer marketing, often undisclosed, which is not allowed on children's television (ie, "host selling," using stars of a television program in commercials airing during that program) because it is harder for children to identify or resist.[8]

Data and Privacy

Data collection for commercial purposes includes use of cookies in a user's browser, which record and follow Web page history; the collection of posts, likes, purchases, and viewing history by apps such as Facebook and Instagram or search engines such as Google[9]; and collection of data via apps granted permission to track device data, such as location or contacts. Software mines such data from user accounts, devices, and virtual assistants and often shares data with third-party companies to develop a profile of the user, which informs the delivery of targeted ads.[10] Collection of mobile device-derived data has been found to be highest in news and children's apps,[11] many of which evade privacy rules of the Children's Online Privacy and Protection Act (COPPA) (1998; revised in 2013) by stating that their apps are for general audiences. User data can be aggregated and stored, sold to third parties, and used to infer personal characteristics, such as sexual orientation or health problems.[12] Livingstone et al,[12] in their review of the limited literature on "datafication" of children, conclude that school-aged children up to teenagers do not comprehend the full complexity of how digital data are collected, analyzed, and used for commercial purposes. For example, studies suggest that teenagers have a more interpersonal, and less technical, conceptualization of privacy, so they may not be as aware of the ramifications of sharing data with governments or corporations

compared with sharing private information with friends or parents. Young children are more trusting of privacy-invasive technologies, such as location trackers,[13] likely because of their convenience. In a recent report commissioned by the UK Information Commissioner's Office, children and parents reported not reading the terms and conditions or privacy notices in platforms, feeling pressured to accept cookies to use Web sites, and feeling uncomfortable with their data being used for targeted advertising.[14] In addition, preschool-aged children up to teenagers in this study believed they should have the right to erase or limit the use of their digital data.[14] However, data-brokering services are highly complex, using evolving algorithms across multiple platforms, with business practices that are intentionally opaque, which even adults do not fully understand.[15]

Beyond advertising, it is also important for families to understand how data collection influences the information that reaches them through the Internet. Previous online behaviors shape what is delivered to users via news, notifications, and social media feeds, creating a filter bubble in which all input, unbeknownst to users, is tailored to their interests and creates false norms that can undermine healthy behaviors.

In the United States, COPPA is meant to "place parents in control over what information is collected from their young children online" and limit the data that child-directed Web sites, apps, or other online services collect, use, or disclose to third parties in the absence of parental consent.[16] However, COPPA leaves open many gaps in its protection. It generally does not protect children when they are using Web sites or apps that are considered targeted to a general audience, nor does it apply after a child is 13 years of age. In addition, the law has not being enforced reliably.[11] The European Union's General Data Protection Regulation (2018) is more ambitious in protecting user privacy, and the UK Information Commissioner's Office has recently introduced an age-appropriate design code to address children's vulnerabilities regarding data collection and persuasive design.[17]

Persuasive Design and Behavioral Marketing

Design elements intended to nudge users into specific behaviors (by constraining choices, highlighting preferred buttons to click, or providing rewards for preferred behavior) are now a common part of digital design.[18] These design elements extend digital engagement in ways that increase exposure to advertising, which children and teenagers may not be able to identify or resist. This targeted marketing also results in different products being advertised to different populations, which may accentuate existing disparities.[12]

Gamified Ads and In-App Purchases

Newer Internet marketing practices in the 2000s included gamified advertising ("advergames"), which rewards users for watching ads or buying products,[19] but have evolved to include advertising that is less evident to the child. For example, an analysis of the most-downloaded free apps for children younger than 5 years on Google Play revealed that 96% contained commercial content, including hidden ads, interstitial ads that pop up automatically, and ads that, when viewed, provided incentives, such as more game tokens or making gameplay easier.[6] App characters were noted to encourage in-app purchases in some games.[6]

Artificial Intelligence and Machine Learning

Artificial intelligence and machine learning form the core of many technologies accessed by children and teenagers, including virtual assistants. It is unclear how much data are being collected, how data are being processed or used to shape query responses for the purposes of marketing to children, or how parents can access the information. Young children attribute more animism to and place more trust in these artificial intelligence agents and are more likely to share information with them.[20]

SPECIFIC HEALTH-RELATED CONCERNS

Food Advertising and Childhood Obesity

Food marketing funding today is less dependent on television and is instead concentrated on integrated marketing campaigns and cross-platform promotion to spur children's requests and demands for products,[21] as highlighted in the recent comprehensive report by the University of Connecticut Rudd Center for Food Policy and Obesity.[22] Food advertising has been linked to higher obesity risk via ads for high-calorie, low-nutrient food and beverages (which influence diet and purchases).[23] Screen media consumption is inversely correlated with fruit and vegetable intake and directly correlated with energy-dense, nutrient-poor snacks, drinks, and food.[24] Ads also promote intake of foods that contribute to dental caries.[25] More fast food and sugar beverages are advertised in African American, Hispanic, and low-income communities, according to the Rudd report,[26] as are candy and cereals. Nearly 40% of ads on television targeted to African American and Hispanic populations are for fast food and other restaurants. Unhealthy food advertising in 13- to 17-year-olds is also correlated with development of media-driven norms that supersede healthier family norms.[27] Influencers can sway teenagers toward unhealthy choices; Bragg et al[28] identified popular music stars endorsing 18%

of surveyed ads; 49 (71%) promoted sugar-sweetened beverages, and 21 (80.8%) endorsed foods were energy dense and nutrient poor. In an experimental study, Coates et al,[29] found that school-aged children who viewed mock profiles of influencers promoting unhealthy snacks showed a significant increase in intake of unhealthy snacks and total calories compared with children who viewed influencers promoting nonfood items. Folkvord et al[30] observed increased caloric intake in 7- to 10-year-olds playing advergames as well, which children with high impulsivity had an especially hard time inhibiting.

Tobacco and Electronic Cigarette Advertising

Multiple studies have revealed that in teenagers, attention and receptivity to cigarette advertising is correlated with both current and future use.[31] Cigarette ads on television and radio were banned in 1971 for this reason. This correlation has been found with emerging tobacco products, such electronic cigarettes (e-cigarettes),[32,33] to which the majority of middle and high school students have been exposed.[34] E-cigarette companies have used social media influencers, hashtags, music videos, and other informal social media presence to advertise their products,[35] although companies have deleted their own official social media accounts.

Alcohol Advertising

Studies have revealed increased exposure to alcohol content for middle and high school youth via social media,[36] banner ads, and video ads, with disparate exposure for African American,[37] Hispanic, and American Indian youth.[38] A review by Jernigan et al[39] of 12 longitudinal studies published from 2009 to 2015 demonstrated a positive correlation between marketing exposure and receptivity and alcohol consumption in youth, and the authors concluded that "existing self-regulatory systems do not meet their intended goal of protecting vulnerable populations from alcohol marketing."

Marijuana Advertising

The legalization of marijuana in many states has led to media and point-of-sale advertising seen by people younger than 21 years[40] or increased exposure through social media mentions, sometimes accompanied by cartoon characters or other design elements attracting to children.[41] Point-of-service advertising has been found to be more common in areas of lower socioeconomic status and minority populations.[42] Marijuana advertising exposure is associated with heavier use, use of marijuana concentrates and edibles in young adults,[43] and higher probability of marijuana use and intentions in middle schoolers.[44]

Cultural Biases, Body Appearance, and Teenager Self-image

By presenting ideals of body appearance, ads can convey cultural biases, such as skin color (eg, skin-lightening products), hair traits (eg, hair-straightening products), or unhealthy body weight ideals (eg, diet products or muscle-building supplements). In addition, ads for indoor tanning salons often target teenagers. Because indoor tanning is considered a class 2 carcinogen, such advertising is restricted over traditional media. For this reason, tanning salons actively use social media as a strategy for attracting and retaining customers,[45] encouraging high-frequency tanning,[46] and lowering the perception of the risks of tanning.[47]

DIGITAL LITERACY

Digital literacy requires that children, teenagers, and parents understand that technology is created by other humans with their own agendas and that they can accept or reject its messages, identify advertising and persuasive intent, reflect on their own reactions to media, and engage with media on the basis of their own intentions (rather than reacting to engagement-promoting design). However, Livingstone et al[12] identified disparities in knowledge about technology and privacy among parents of different socioeconomic status or digital skills. For example, parents from lower-income backgrounds were more likely to place credence in the learning value of apps marketed as educational for their young children,[48] despite a lack of evidence-based data for most such products.[49] Thus, differences in digital literacy skills and knowledge by socioeconomic status may contribute to digital disparities.

Digital literacy programs have been developed to teach children how to think about technology, not just how to use it. For example, Zarouali et al[10] showed that teenagers responded more favorably to specifically targeted rather than nontargeted ads, but teenagers who understood the privacy intrusions that led to such targeted advertising were more skeptical and less likely to purchase the product. Educational programs and campaigns are recommended, in combination with the design changes discussed below, to mitigate this influence and persuasion.

CONCLUSIONS

Many digital media resources, including apps, programs, games, and educational materials, are subsidized and supported by advertising dollars. Children's and teenagers' unique developmental needs make them more vulnerable to negative physical, mental, and financial health effects of digital marketing. Although parents play a large role in helping their children be critical of media messages, identify surreptitious advertising approaches, and resist their influence, it is also crucial that there are measures in place in children's digital media environments to protect their needs.

RECOMMENDATIONS

For Parents

Excessive media use has been linked with negative health outcomes in children and teenagers. American Academy of Pediatrics (AAP) policies regarding media[50,51] provide guidance for parents and families regarding limiting media use and engaging in healthy conversation about media messages. However, parents should not be the only ones held responsible for child privacy in a digital environment that is predicated on a business model of advertising and data collection in which the default settings serve to compromise user privacy or potentiate disparities. Parents can be effective in teaching children and teenagers to think critically about digital media, but this AAP policy statement places the primary duty to protect children on technology developers and policy makers, who should create a digital environment in which families can access content that provides opportunities rather than delivers profits.

To empower parents to help their children, the following steps and resources are recommended:

1. Build digital, privacy, and design savviness. Know what your children are downloading and accessing so that you can help them be an informed consumer, and demand better-designed digital products for children (helpful resources: https://www.childrenscommissioner.gov.uk/wp-content/uploads/2018/11/who-knows-what-about-me-infographic.pdf and https://www.consumerreports.org/digital-security/online-security-and-privacy-guide/).
2. Enhance and monitor privacy settings on personal devices, apps, social media, virtual assistants, and wireless networks. Understand the differences between privacy settings that determine what other users can see about you and the platform collecting data about you (helpful resource: https://www.commonsensemedia.org/privacy-and-internet-safety).
3. Create a family media use plan that intentionally uses high-quality media content that has as few ads as possible, limits data collection, and encourages discussion about privacy (helpful resource: https://www.healthychildren.org/English/media/Pages/default.aspx).
4. Teach children to analyze the ads they see, identify algorithms that affect their streaming content, understand what personal data are collected, and be savvy about the persuasive intent behind the design of the technologies they use (helpful resource: Digital literacy toolkit from Sonia Livingstone: www.myprivacy.uk).
5. Talk to school administrators and teachers about the digital privacy of the technology tools they use (helpful resources: Campaign for a Commercial-Free Childhood parent toolkit for student privacy [https://commercialfreechildhood.org/pf/parent-toolkit-student-privacy/] and Common Sense Media privacy evaluations of educational technology products https://privacy.commonsense.org/evaluations/1]).

The best thing parents can do to encourage digital literacy in their children is to talk openly and critically about media from the time children are young. For example, when watching a television show or using mobile technology, parents can express their skepticism or ask children their opinions. Alternatively, when children ask to buy a specific product, parents can ask questions to explore how advertising might have contributed to that desire. Parents can speak with younger children about what ads are trying to sell or why their favorite app has design features, such as autoplay, that keep them watching longer. For older children, discussions can revolve around influencers, unpacking messages about consumerism, or whether they understand all of their privacy settings. These are just a few examples of how such discussions allow parents to understand the extent of their children's literacy (or lack thereof), help to align children's media use with their family values, and help children to feel comfortable reaching out to their parents when they have concerns about online content or privacy.

For Providers

The AAP recommends the following:

1. Understand how children and teenagers are targeted by advertisers, and help parents understand children's specific vulnerability to persuasive design and targeted ads. Encourage parents to be discerning consumers of their child's media and demand better design and data collection practices.
2. Ask patients and families about any media use concerns as a part of routine health maintenance. Encourage families to use the AAP family media use plan to set media use limits, adopt privacy-preserving behaviors, and engage in parent-child communication regarding digital media.
3. Provide educational materials and references (listed above) to help parents and patients build digital literacy, as developmentally appropriate. Consider using a parent or child's use of a mobile device during visits as a teachable moment to identify ads or persuasive design (helpful resource: *AAP News* article on building digital literacy: https://www.aappublications.org/news/2019/04/24/masteringmedia042419).
4. Recommend parents to think of themselves as role models for

digital media use, digital citizenship, and digital literacy. Encourage discussions about Internet privacy and persuasive design, and recommend settings or filters to reduce ads and improve privacy.

5. Advocate for policies and regulations that limit advertising and data collection from children and teenagers. Pediatricians can advocate with local schools to avoid educational technology that is commercial and does not protect children's privacy. Pediatricians and parents can also ask for the establishment of digital literacy curricula in public schools so that children from all socioeconomic backgrounds can build equitable understanding of digital marketing and persuasive design.

For Industry and Policy Makers

The AAP recommends the following:

1. Policy makers and technology companies should adopt stricter privacy regulations for all users (including children and teenagers), which include data collection from home technologies, mobile devices, and other Internet-connected devices or toys. Disclosure of such collection should be prominently provided at appropriate literacy and developmental levels, and technology companies should report what data will be collected, how the data will be used, with whom data might be shared, and the risks and benefits to the consumer. Information about blocking this data collection and deleting personal information permanently should be provided. Default settings for platforms, programs, apps, and Internet-connected toys should be set at the highest level of privacy.
2. Strengthen COPPA enforcement to prohibit personal and location data collection from apps and Web sites clearly used by children younger than 13 years without parental consent and by anyone 13 to 17 years of age without the user's consent. For Web sites and apps used by multiple age groups, such as search engines and YouTube, provide alternative services that do not collect or aggregate data and that limit advertising. Ban targeted (ie, data-driven behavioral) advertising to individuals younger than 18 years.
3. Ban all commercial advertising to children younger than 7 years, and limit advertising to older children and teenagers. All advertising should be clearly labeled as such (eg, as sponsored content).
4. Prohibit in-app host selling and purchases, including loot boxes that pressure gamers to spend money during game play. Require clear separation of content and advertising in media designed for children, including product placement in child-directed videos.
5. Reduce advertising of unhealthy foods and beverages to children and teenagers, particularly targeted advertising that exacerbates disparities when combined with structural sources of inequality (eg, healthy food scarcity, public underinvestment in opportunities for exercise or play).
6. In accordance with the AAP policy statement on tobacco,[52] depictions of tobacco products (including e-cigarettes), tobacco product use, and images associated with tobacco product brands in movies and video games should be restricted. Internet sales of tobacco products should be banned because they are easily accessed by minors.
7. In accordance with previous AAP policy statements on marijuana[53] and alcohol,[54] limit access and marketing of these substances to youth (eg, by using mascots, cartoon characters, or influencers popular with children and teenagers).
8. Require and fund digital literacy curricula in schools. Prohibit use of digital media that contain advertising in the classroom.
9. Fund and promote research on the effects of advertising in digital media in children and teenagers to further identify risks inherent in data collection, digital profiling, and selective targeting of disadvantaged communities and to inform age-appropriate design guidance.
10. Increase efforts to promote digital equity by improving access to quality commercial-free content.

Drugs Used to Treat Pediatric Emergencies

Rohit P. Shenoi, MD, FAAP,[a] Nathan Timm, MD, FAAP,[b] COMMITTEE ON DRUGS, COMMITTEE ON PEDIATRIC EMERGENCY MEDICINE

abstract

This clinical report is a revision of "Preparing for Pediatric Emergencies: Drugs to Consider." It updates the list, indications, and dosages of medications used to treat pediatric emergencies in the prehospital, pediatric clinic, and emergency department settings. Although it is not an all-inclusive list of medications that may be used in all emergencies, this resource will be helpful when treating a vast majority of pediatric medical emergencies. Dosage recommendations are consistent with current emergency references such as the *Advanced Pediatric Life Support* and *Pediatric Advanced Life Support* textbooks and American Heart Association resuscitation guidelines.

[a]*Texas Children's Hospital and Department of Pediatrics, Baylor College of Medicine, Houston, Texas; and* [b]*Cincinnati Children's Hospital Medical Center and Department of Pediatrics, College of Medicine, University of Cincinnati, Cincinnati, Ohio*

Drs Shenoi and Timm prepared, reviewed, revised, and approved the final manuscript, including the drug tables and references; and all authors approved the final manuscript as submitted.

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

All clinical reports from the American Academy of Pediatrics automatically expire 5 years after publication unless reaffirmed, revised, or retired at or before that time.

INTRODUCTION

Most children present for emergency medical care in physicians' offices, the prehospital setting, or the emergency department (ED). Roughly 28 million (27%) of the annual ED visits in the United States are by children younger than 19 years.[1] Approximately 7% of these children reach the hospital via emergency medical services (EMS).[1] EMS agencies provide the majority of out-of-hospital emergency care to children. Of the 4800 general and short-stay hospitals with 24-hour EDs in the United States during 2006, the majority (87%) admitted children, but only 10% were children's hospitals or had PICUs. A majority (84%) of hospitals would send pediatric patients requiring intensive care to another hospital.[2] Approximately 30% of emergency pediatric visits occurred in children's hospitals.[2] Medical emergencies may occur between once or more per week and once or more per month in pediatricians' offices.[3,4] Given the scope of pediatric emergency care in the United States and to facilitate consistency in the pharmacotherapy of medical emergencies in children, it is incumbent that all health providers who manage critically ill or injured children be knowledgeable of the medications used to treat pediatric emergencies. Changes in the pattern and scope of practice, changes in the dosages and indications of medications, availability of newer drugs, and the discontinuation of older pharmacotherapeutic agents make it necessary to stay updated.

This document will be helpful to medical practitioners in the clinic, prehospital setting, and ED. The Supplemental Information contains several tables, each listing medications used to treat pediatric emergencies on the basis of organ system or context (eg, drugs used in disasters). The indications, dosing, and practical points regarding drug administration are described. Description of medication adverse effects is limited. Some drugs may be listed in multiple places because of overlapping indications. Antimicrobial agents (except for in disaster situations), vaccines, and chemotherapeutic agents are not included. The practitioner is referred to the American Academy of Pediatrics (AAP) *Red Book: Report of the Committee on Infectious Diseases* for the treatment of infections.[5] In addition, some drugs that are used to treat pediatric emergencies in consultation with an appropriate medical subspecialist (eg, tissue plasminogen for stroke, intravenous [IV] methylprednisolone for transverse myelitis) are not listed. Dosages are generally provided as milligrams per kilogram. The format for presented dosages is consistent with AAP recommendations for reducing medication errors.[6] Some high-potency drugs, such as prostaglandins, vasopressors, nitroprusside, and fentanyl, have their dosages provided in μg per kilogram. The reader is referred to resources for the safe prescription, administration, and monitoring of medications in their patients.[6]

The IV route is preferred for the administration of medications in an emergency. However, when prompt IV access is not possible, emergency intraosseous administration is an acceptable alternative. The practitioner is advised to consult the pharmacist on the appropriate infusion system whenever possible. Certain drugs (lidocaine, epinephrine, atropine, naloxone [memory aid: LEAN]) can be administered by the endotracheal tube (ET) if no vascular access can be obtained. However, intratracheal drug administration results in lower, less predictable drug concentrations than intravascular administration and is not preferred. If the ET route is used, the drug should be administered with or diluted in 1 to 5 mL of isotonic saline solution followed by manual ventilations. ET administration of naloxone is not recommended for neonates. Newer methods of drug administration in children include the intranasal and intrabuccal routes. These are especially useful in sedation, analgesia, and seizure control. When administering drugs by the intranasal route, it is preferable to use a mucosal atomizer to mist the drug rather than a syringe to drip the medication into the nostrils.

To date, the Best Pharmaceuticals for Children Act and the Pediatric Research Equity Act have resulted in expanded labeling with pediatric-specific information for more than700 drugs.[7] However, gaps in pediatric labeling and dosing information still exist.[8] The reader is encouraged to consult package inserts, drug labels, and medical literature for more information. In some situations, pediatricians may need to prescribe certain medications "off label" for important illnesses. A drug's off-label status does not imply an improper or experimental use. The decision to prescribe these medications off label should be based on expert opinion or evidence for the medication's use in a different population. The reader is referred to the AAP policy statement "Off-Label Use of Drugs in Children"[9] and the US Food and Drug Administration (FDA) for changes in pediatric labeling of drugs.[7]

The information in this document is based on literature review and consensus opinion. References for individual drug indications and dosing are provided. Dosing should be individualized, taking into account the patient's weight in kilograms, medical illness, age, concurrently administered drugs, and drug hypersensitivity history. Within each table, the drugs are listed alphabetically and not by importance of use. The selection of a particular drug may depend on practice variability and drug availability (ie, hospital formulary or drug shortages).

The committees recommend the use of current *Advanced Pediatric Life Support*[10] and *Pediatric Advanced Life Support*[11] textbooks, updated American Heart Association guidelines,[12–14] and additional references for more detailed information on pediatric resuscitation algorithms, rapid-sequence intubation (RSI), procedural sedation,[15] and medical management in disasters.[16,17] In addition, the reader is referred to published treatment guidelines[18]; clinical reports, technical reports, and policy statements[19–31]; and consensus opinion.[32] Practitioners should consult the *Textbook of Neonatal Resuscitation* and updated American Heart Association guidelines for detailed information concerning the management of neonatal emergencies and appropriate drugs, dosages, and routes of administration.[33] The Neonatal Resuscitation Program is focused on care of the newly born infant, and there is no clear evidence to guide when it is appropriate to use *Advanced Pediatric Life Support* guidelines in the care of an infant. General recommendations are currently to decide which drug to use on the basis of the likely etiology of the problem. The use of preprinted weight-based medication cards and/or length-based resuscitation tapes[34] is recommended when treating an emergency regardless of location (prehospital, ED, hospital ward, outpatient, or community clinic).

Note that doses listed are not comprehensive, and variations in dosing may be indicated for specific patients and/or clinical situations.

POLICY STATEMENT Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN®

Electronic Documentation in Pediatrics: The Rationale and Functionality Requirements

Heather C. O'Donnell, MD, MSc, FAAP,[a,b] Srinivasan Suresh, MD, MBA, FAAP,[c] COUNCIL ON CLINICAL INFORMATION TECHNOLOGY

Clinical documentation is a fundamental component of the practice of medicine. It has significantly evolved over the past decade, largely because of the growth of health information technology and electronic health records. Although government agencies and other professional organizations have published position statements on the structure and use of electronic documentation, few have specifically addressed the documentation needs for the care of children. A policy statement on electronic documentation of clinical care by general pediatric and subspecialist providers by the American Academy of Pediatrics is needed. This statement provides insight on the unmet needs of key stakeholders to direct future research and development of the electronic media necessary to enhance the wellness of children and improve health care delivery. It also addresses the challenges and opportunities for efficient and effective clinical documentation in pediatrics.

BACKGROUND INFORMATION

The move from paper charting to electronic documentation has created a need for guidance to facilitate pediatricians' ability to effectively communicate the clinical picture while accurately reflecting the extent and quality of care provided. The American College of Physicians and the American Medical Informatics Association have published guiding principles regarding clinical documentation, focusing on the primary role of documentation for patient-centered clinical care and improving outcomes.[1–3] In addition to advancing these principles, more methods to reduce documentation burden and manage information overload are warranted. Furthermore, there are unique requirements for pediatric documentation that should be clarified for pediatric generalists and subspecialists, such as means to record adolescent information confidentially and to communicate medical history with schools.

The Agency for Healthcare Research and Quality technical brief on core functionality in pediatric electronic health records (EHRs), the Health Level Seven International Child Health Functional Profile for EHR Systems, and a few American Academy of Pediatrics (AAP) policy statements comprehensively delineate specific EHR functionality needs of pediatricians.[4–8] However, specific guidelines on documentation content and workflow in existing and future systems are imperative to align documentation tasks with the core tenets of pediatric care.

This policy statement addresses the common barriers that pediatric practitioners face in dealing with clinical documentation. A clear policy will serve as a guiding force in prioritizing the key elements of a patient note, navigating the complex world of electronic documentation implementation and enhancement, and focusing research efforts on ideas that show promise in decreasing clinical burden and improving care. The accompanying technical report provides a background for the recommendations in this statement.[9]

STATEMENT OF PROBLEM

Electronic clinical documentation is a requirement for the Centers for Medicare & Medicaid Services' Meaningful Use program (renamed Promoting Interoperability)[10] and has been adopted by the majority of hospitals and clinics in the United States,[11,12] but current certification and implementation standards for EHRs provide few specific guidelines on documentation content and workflows. In addition, the documentation needs of child health providers are often different from those of providers caring for adults. Yet, there has not been a unique focus on defining the best practices for electronic clinical documentation in pediatric populations.

The change from paper-based to electronic documentation has had many benefits but has introduced additional regulatory requirements, presented new threats to the utility of patient notes, and galvanized both the desire and opportunity to use clinical documentation for additional purposes. Multiple stakeholders with differing priorities (clinical, regulatory, research, quality, and economic) and varying abilities of some providers to interact efficiently with electronic systems have contributed to increased documentation burden and physician burnout.[13–16] Considering these issues, clear guidance on clinical documentation is needed.

SUMMARY AND CONCLUSIONS

Clinical communication and, hence, documentation are at the heart of the practice of medicine. Electronic documentation, now broadly adopted, has been accepted as the standard medium. A great deal has been learned during the transition to electronic documentation, including the opportunity to discover the unintended consequences of various tools and workflows. Importantly, we have recognized that paper notes of the past cannot be directly translated into an EHR format. Although it has offered many advantages, the transition to electronic notes has changed the very nature of the structure, workflow, and use of documentation.[17] The roles and use of documentation have expanded, but its primary role to support clinical reasoning and communication should always be paramount. Building on this knowledge, this is an opportune time for the AAP to implement guidance to direct care and clinical documentation in the 21st century to best serve the needs of pediatric providers, patients, and families.

Multiple barriers must be overcome to implement these recommendations. In local and vendor EHR development, there will always be competing priorities to this primary function of supporting clinical reasoning and communication, including regulatory obligations[18] and requirements tied to fiscal reimbursement.[10] In addition, there may be difficulty engaging vendors in pediatric-specific projects because children represent a smaller percentage of overall health care usage and burden. Gaining a consensus among child health care providers on needs and priorities and advocacy from pediatric organizations could be helpful in this regard. As part of the implementation of the 21st Century Cures Act, the Office of the National Coordinator for Health Information Technology has proposed new criteria to support voluntary certification of health information technology for use by pediatric clinicians; this may advance the recognition and prioritization of pediatric needs by EHR vendors.[19]

One of the key recommendations is ensuring representation from all stakeholders when considering electronic documentation implementation, changes, and enhancements. However, convening a large group of stakeholders and gaining consensus can be time consuming and laborious. In addition, clinical providers often do not have dedicated time or a percentage of full-time equivalents allotted for this work. Yet, the early and complete engagement of clinical providers and/or end users is critical to the successful development and implementation of electronic documentation.

Ideally, clinical informaticists should facilitate clinical documentation improvement. They can bridge the gap of understanding between frontline clinicians and health information technology professionals and vendors. Clinical informaticists

can also provide expertise on the best practices on clinical documentation improvement. When having a trained clinical informaticist is not feasible, such as in smaller health care settings, the role of EHR vendor user groups and professional clinical informatics organizations, such as the AAP Council on Clinical Information Technology and the American Medical Informatics Association, becomes vital.

This policy statement stresses the importance of research of documentation structure, content workflows, and functionalities to determine best practices. However, such evaluations may be arduous because of the difficulty in assessing documentation quality and its ability to effectively communicate information to stakeholders. Although standard measures of documentation quality are being developed,[20] they often require manual review of notes. Automated methods to continuously monitor documentation quality would be more efficient.

RECOMMENDATIONS

1. EHR documentation functionalities, including documentation templates, data entry, and display, need to support the pediatric care core values of age-based, longitudinal, and family-centered care. To address this, professional pediatric-focused organizations and health care institutions should conduct the following:
   a. work with stakeholders to build consensus on documents that should be standardized, such as school forms, for integration into all EHRs;
   b. continue to advocate for pediatric-specific documentation needs to EHR vendors and developers;
   c. support the creation and dissemination of models and best practice guidelines for pediatric electronic documentation; and
   d. promote the development of policies and methods to facilitate the seamless sharing of electronic documentation tools (eg, templates and workflows) and data across child health providers nationally.
2. Models of shared documentation among health care providers and with patients, caregivers, and other key stakeholders (eg, adolescents, schools, and immunization registries) should continue to be explored as a means to improve clinical communication among care teams, facilitate health outcomes tracking, and potentially reduce documentation burden for providers. Effective models could be incorporated in developing health information exchanges.
3. Tools and strategies aimed at relieving documentation burden should be developed and researched to understand their impact on documentation time and clinical care as well as on satisfying evaluation and management codes and other regulatory requirements. Examples of potential tools and strategies include the following:
   a. automated data entry (eg, device integration and barcoding);
   b. documentation task distribution (eg, integration of patient-generated health data);
   c. elimination of redundancy that is consistent with family-centered care (eg, linkages for family and social history); and
   d. alternative documentation methods (eg, speech recognition and scribes).
4. Mechanisms to mitigate information overload, such as enhanced data displays, search tools, and streamlined and standardized note structures, need to be developed and studied.
5. Professional organizations and health care institutions should refine pediatric data definitions and partner with EHR vendors to integrate these standards into electronic systems.
6. The reuse of clinical documentation to support regulatory requirements, evaluation and management codes, research, and quality improvement efforts should be supported. However, there must also be clear understanding and mitigation of any negative impacts on the clinical narrative, usefulness as a clinical communication tool, and documentation burden.
   a. Guidelines for the appropriate attainment of data from clinical documentation should continue to be developed and propagated. For example, the completion of a task within the EHR should be captured as its own documentation. Additional documentation that the task was completed should not be required.
   b. Although complete discrete data are often most useful for reuse, the documentation of incomplete discrete data should be enabled if clinically relevant, for example, the ability to record that a patient received a vaccine even if the exact preparation or month and day of receipt are unknown.
   c. National research organizations and the health information technology industry should support research in alternative models and technology to facilitate the reuse of clinical data (eg, natural language understanding).
7. All documentation implementation and improvement initiatives should include representation from medical providers including trainees and attending physicians as well as, if possible, patient and family representatives and specialists in health information management, quality

improvement, reporting, research, billing, and clinical informatics.

8. Medical schools, residency programs, and physician licensing boards should integrate continuing electronic documentation training into their curricula using Accreditation Council for Graduate Medical Education program requirements as a guide. Attending physicians should provide timely and frequent feedback to trainees regarding documentation quality. In addition, EHRs should support clear delineation of trainee documentation and attending attestation.

TECHNICAL REPORT

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN®

Electronic Documentation in Pediatrics: The Rationale and Functionality Requirements

Heather C. O'Donnell, MD, MSc, FAAP,[a,b] Srinivasan Suresh, MD, MBA, FAAP,[c] COUNCIL ON CLINICAL INFORMATION TECHNOLOGY

Clinical documentation has dramatically changed since the implementation and use of electronic health records and electronic provider documentation. The purpose of this report is to review these changes and promote the development of standards and best practices for electronic documentation for pediatric patients. In this report, we evaluate the unique aspects of clinical documentation for pediatric care, including specialized information needs and stakeholders specific to the care of children. Additionally, we explore new models of documentation, such as shared documentation, in which patients may be both authors and consumers, and among care teams while still maintaining the ability to clearly define care and services provided to patients in a given day or encounter. Finally, we describe alternative documentation techniques and newer technologies that could improve provider efficiency and the reuse of clinical data.

Clinical documentation is defined as the capturing and recording of clinical information, often in real time while the patient is present (eg, during consultation, assessment, imaging, and treatment).[1] However, clinical documentation has grown to encompass more than just provider notes at the time of a patient visit. Patient care activities often take place outside in-person encounters and include events involving care coordination and communication with patients and caregivers. The records of such events also represent clinical documentation. In addition, newer technologies, including patient portals, connected home monitoring devices, and patient-controlled mobile devices, potentially enable patients and families to act as authors of clinical documentation, a title previously assigned only to health care providers.[2]

Clinical documentation is primarily intended to facilitate the synthesis of patient information, develop medical care and wellness plans, and communicate patient information. Initially, documentation was intended for sharing information among various health care providers but has since

expanded to include communication with patients and their caregivers as integral members of the care team. In pediatrics, clinical care teams also include adolescents who may have the right to manage their own reproductive health, substance use, and mental health issues and the school systems that serve as important caregivers for pediatric patients. Clinical documentation also serves other important roles, including the record of patient care and services provided for billing purposes, a means to protect the legal interest of providers and patients, a resource for research data for quality monitoring and improvement, and an educational tool for health care provider trainees.[3]

The transition of clinical documentation from paper to electronic health records (EHRs) has provided many positive opportunities in clinical care and documentation but has also introduced new challenges. Most importantly, electronic clinical documentation is more accessible and legible than paper records, may include more structured data elements contained elsewhere in the medical record, and is available remotely to health care providers, patients, and other stakeholders.

One downside with electronic documentation is that providers may be overwhelmed with large amounts of textual and tabular data. In addition, nonclinical stakeholders may have a more direct influence on the design and content of clinical documentation. For example, electronic documentation tools can remind or even require (required fields, forced fields, or hard stops) an author to include specific items in his or her documentation. Interventions on paper were much less invasive (education or reminders that could be avoided) and likely less effective at changing documentation behavior. This additional input can lead to increasing documentation burden, especially when some of these requirements are redundant or not relevant to the clinical narrative, and can have the effect of blurring the understanding of the purpose of a note. There is increasing recognition that documentation burden can lead to clinician burnout, and new federal legislation is aimed at developing strategies to reduce documentation burden.[4]

Electronic clinical documentation may also be more onerous than using paper. Efficient typing and navigation of the electronic record may not be skills possessed by all providers. Documentation tools such as copying functions, templates and scripts (allowing for clicking rather than typing), or the importation of data from other areas in the medical record can alleviate some of the burden. However, these tools may introduce new unintended consequences of their own, including increased length and decreased effectiveness of notes ("note bloat") and inaccurate documentation.[5–7]

The American Academy of Pediatrics (AAP) has addressed several topics related to EHRs, including electronic prescribing systems,[8] health information technology and the medical home,[9] standards for health information technology to ensure adolescent privacy,[10] pediatric aspects of inpatient health information technology systems,[11] and electronic communication of the health record and information with pediatric patients and their guardians.[12] Although these areas cover aspects of electronic documentation, there is a lack of a single unified AAP policy statement or technical report that provides an overall view of clinical documentation of pediatric care. In this technical report, we aim to review electronic clinical documentation in pediatrics and provide background information for the recommendations in the accompanying policy statement[13] to maximize the benefits of such technology to improve the care of children as well as to mitigate the potential negative aspects.

CONTENT AND STRUCTURE REQUIREMENTS FOR RECORDING CLINICAL INFORMATION

Similar to what has been emphasized in AAP policy statements and technical reports,[9–14] an Agency for Healthcare Research and Quality technical brief,[15] and the Children's EHR Format,[16,17] pediatric care providers need certain core functionalities in EHRs, including the ability to document in a manner that supports and facilitates the care of pediatric patients. Templates or similar tools designed to guide providers through the task of documentation should facilitate longitudinal, preventive, team-based, and age- and condition-specific care central to the core of pediatric medicine (Table 1).[18] In addition, pediatric care providers have long been on the forefront of family-centered care,[19] but many EHRs lack the ability to support the hallmarks of this aspect of care, such as team-based documentation and documentation of familial connections.[9] For example, familial linkages in the EHR and the ability to share certain parts of documentation, such as family and social histories, across family members could increase the robustness of this information and strengthen the delivery of family-centered care (Table 1). This feature could also serve as a method to reduce redundant documentation tasks.

Discrete Data

Similar to other medical specialties, the documentation needs of pediatric providers include both discrete (conforming to a predefined or conventional syntactic organization) and nondiscrete documentation needs as well as the need for some flexibility between the two.[20] The value of discrete data includes

TABLE 1 Clinical Documentation Framework Based on Core Components of Pediatric Care

Core Component of Pediatric Care	Examples of Supporting EHR Documentation
Longitudinal	Support documentation over the life course of the patient: attainment of developmental milestones (even outside typical norms); physical growth (growth charts); and serial immunizations (eg, DTaP vaccine No. 2).
Preventive	Support the attainment, documentation, and review of measures designed to maintain health: immunization schedules and screening tools and testing.
Age based	Document and review data based on patient age: screenings, testing, and measurements and anticipatory guidance.
Pediatric condition specific	Document and review data based on patient conditions: dedicated growth charts for patients with conditions affecting growth parameters (eg, Down syndrome, prematurity) and documentation templates that guide assessment of patients with specific conditions (eg, evaluation of asthma severity or control for patients with asthma).
Patient and family centered	Documentation supports the family unit and includes patient and family input: shared or linked mother-infant records to support perinatal care and documentation, shared family and social history documentation across family members, integrated patient- and family-generated data and/or information, supporting adolescent confidentiality, making information such as immunization records available to patients, families, and their providers regardless of the site of receipt.
Team based	Shared documentation tasks across health care provider types, primary care and specialty physicians, and health care settings (ambulatory, acute care, and long-term care).

DTaP, diphtheria, tetanus, and acellular pertussis.

relatively easy use and reuse for clinical decision support, quality measurement, research, or reporting to regulatory agencies.[2] For example, discrete data can be used to support clinical decision aids that are valuable to pediatric care providers, including health maintenance schedules that address vaccinations and screening on the basis of AAP preventive care guidelines.[21] However, free-text or narrative documentation provides its own benefits because it allows for nuanced documentation for individual patients, which is critical for patient-centered care.

The need or desire for discrete data entry can have negative impacts on the relevance and clarity of clinical documentation and may increase documentation burden for health care providers.[20] Furthermore, the required components for some structured data entry for clinical information can result in an inability to record data that do not fit neatly into the structured syntactic organization or that are partially incomplete or unknown. For instance, some EHRs may limit the recording of immunization receipt or current medications if the exact immunization date is unknown or the patient or caregiver does not remember the name of a medication. This information, although incomplete, still may be clinically relevant, and the flexibility should be present to allow for inclusion of these data alongside other discrete data in that category, so important information is not missed.

Examples of discrete data of importance to pediatric care providers include vital signs, growth parameters, immunizations, screening tests (eg, hearing tests, visual acuity testing, and developmental and mental health questionnaires) and validated scoring and screening tools (eg, Apgar score, Pediatric Early Warning Score, Pediatric Quality of Life Inventory).[11,14,17] The discrete nature of the documentation of some of these items also makes them suitable for device integration and for machine-readable technology that streamline documentation and data entry. For example, the use of barcoding for vaccine administration eliminates the need to manually document the lot number and expiration date for every vaccine. Alternative technologies such as these can both serve to reduce documentation burden and reduce documentation errors.[22]

Data Display and Standards

Documentation should only have to be entered once for these key metrics, but retrieval and display of this information also requires careful consideration and build. Data display should be sensitive to both pediatric providers' needs and patients' conditions. As examples, immunizations should be displayed by vaccine components rather than by brand names or combinations, and vital signs should be displayed with their corresponding age-, sex-, height-, and/or weight-based percentiles.

Data elements should also be displayed on the basis of patient-specific conditions, such as growth charts for prematurity and Down syndrome. Other examples include immunization displays, the ability to document new vaccines for patients who have not responded to the original vaccine series, and patients who have received a stem cell transplant. In addition, there is a need for these displays to rapidly evolve with evidence-based updates, such as the recommendation to use the World Health Organization growth charts for children 0 to 2 years of age rather than those of the Centers for Disease Control and Prevention[23] and new guidelines for the management of hypertension.[24] Delays in updates may lead to the persistence of suboptimal or out-of-date care. However, even if optimal and current care is provided, any out-of-date

information populated in the documentation could be misinterpreted. For example, the provider made a clinical decision using the new hypertension management guidelines and blood pressure percentiles, but the old percentiles and/or guideline information still populate into the note.

Importantly, the value of discrete data is enhanced if the data can be used across health care institutions and organizations. For example, if patients' immunization records were shared seamlessly across EHRs and vaccine registries, the data at every location could be more robust and accurate. In addition, the task of documenting immunization histories into separate systems would be eliminated. For this reason, the AAP and other volunteer organizations should continue to support the creation and alignment of clinical data standards.[25,26] The integration of these standards within various EHRs would increase the likelihood that individual organizations would adopt these standards and would promote technical interoperability.

Note Structure

Given the evolution of electronic charting and regulatory requirements of documentation, note structure and the elements that should be included in various clinical note types (eg, ambulatory visit note, inpatient progress note, and operative report) need to be constantly reviewed. The increasing length and limited use of notes argue for a more streamlined structure in which the most important clinical information is more readily found.[27] A solution framework to address this pervasive issue is a modified subjective, objective, assessment, plan (SOAP) note (Fig 1), which retains the original SOAP note structure from the paper-based era[28] but mitigates known concerns of electronic note systems (M.J Curren, MD, and V.K. Reddy, MD, personal communication, 2017).

Managing Information Overload

The rapidly expanding volume of clinical documentation and its accessibility potentially across a patient's lifetime regardless of the location of care has important clinical benefits, but it has also introduced a new problem in clinical care: information overload. The concern is that the large volume of clinical information can lead to the inability of a clinical care provider to quickly retrieve appropriate diagnostic and therapeutic information when needed and may lead to a clinical care provider overlooking important clinical information. Technological solutions are likely necessary to mitigate this problem and maintain clinical care efficiency and value, including integrating graphs, tabular data, knowledge management tools, smart search engines, links to Web-based resources, and customized menus.[29] Functionalities that promote a more hierarchal display of data and promote the value of the synthesis of these data into information are needed to achieve this goal and mitigate information overload. For example, as the number of notes per patient continues to increase, standard naming convention, filtering, and semantic searching functions may help providers access necessary information in a timely manner.

Whenever possible, usability and information design should be an essential part of the EHR certification process. There should be a focus on graphical visualization of numerical data. Custom development of patient summaries for various provider types and care settings requires effort but can be valuable.

DOCUMENTATION FOR ADDITIONAL STAKEHOLDERS

Electronic clinical documentation also serves important functions for other stakeholders and plays important roles in supporting regulatory requirements, legal protections, medical research, quality improvement, and medical education. Although important, the needs of these additional stakeholders often add to the complexity and amount of information captured and contained within EHR systems.

Regulatory Requirements

Developing and implementing clinical templates, customized electronic forms, and computer-assisted coding for patient encounters may result in more complete evaluation and management (E&M) coding. There is evidence that the use of EHRs may have contributed to increased use of higher-level *Current Procedural Terminology* (CPT) codes, particularly in the emergency department setting.[30] Although it is important for EHR documentation tools to guide and facilitate providers in documenting pertinent information, the EHR should not promote the inclusion of extraneous or irrelevant information that then can be used to select a more complex CPT code.

The Office of the Inspector General holds individual physicians responsible for all professional coding in their name regardless of the EHR tools used or other coding support used to select the CPT code. For this reason, it may be useful for pediatric care providers to familiarize themselves with common CPT codes rather than relying solely on EHR tools for CPT selection guidance.[31] The Centers for Medicare and Medicaid Services (CMS) has begun the process of revising the E&M requirements in this new electronic era.[32]

In addition to E&M coding requirements, processes must be in place to ensure that the documentation for the health information used in care, research, and health management is accurate, complete, and timely because clinical

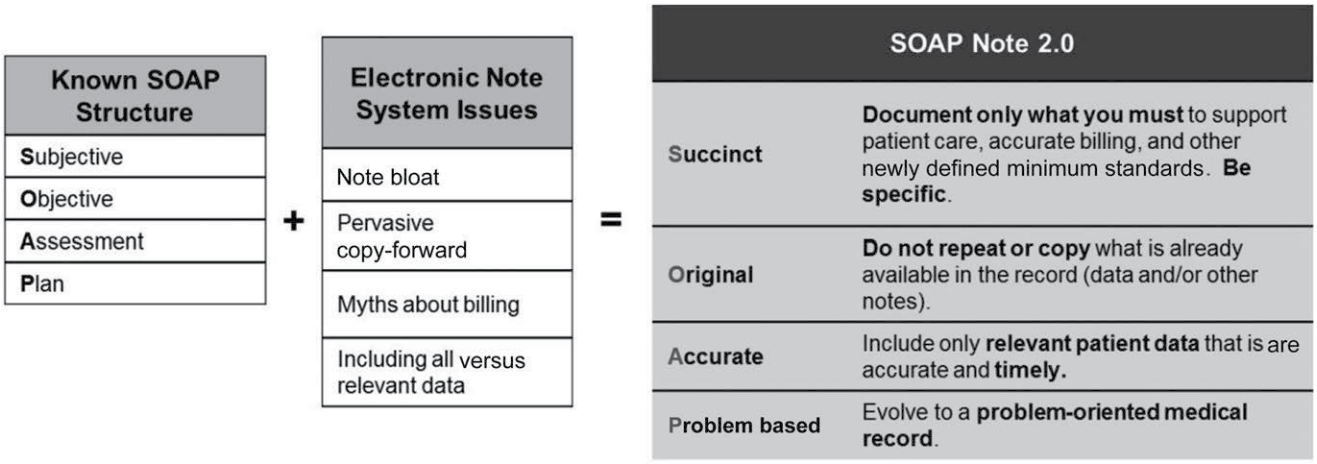

FIGURE 1
Evolution of SOAP Note 2.0 from known SOAP structure.

documentation serves as a key record to provide legal protection for providers and patients. Documentation standards should include recommendations regarding the use of electronic documentation functionalities, such as copy and paste, copy and forward, and automated insertion of data documented elsewhere in the EHR. Misuse of these functionalities can result in inaccurate, outdated, or irrelevant information, which may lead to significant quality of care and medical liability issues as well as the upcoding concerns noted previously. However, it is important to recognize that with proper use, these functionalities can save time and enhance documentation. After reviewing the literature on safety risks related to copying and pasting, the Partnership for Health IT Patient Safety made 4 recommendations that could improve the safety of its use: making copied and pasted text readily identifiable, referencing the text's origin, providing education on its safe use, and having practices in place to monitor its use.[7]

Clinical documentation is also an integral data source for reporting, quality improvement, and research. For example, electronic clinical quality measures are a set of quality objectives that have been developed for both ambulatory and inpatient hospital quality reporting programs and must be reported to the CMS.[33] A robust electronic documentation system also creates the platform for patient care–based research and quality improvement projects that are crucial for pediatric care providers to provide safer, higher-quality care.[34] The data used for these purposes often require more structured or specific data entry. Effective reporting, quality measurement, and medical research depend on accurate clinical documentation. In the development of new quality or research measures existing data should be used whenever possible and primary data entry should not be required explicitly for that measure, thereby avoiding additional documentation burden by providers. When making decisions about additional data elements required or requested from clinicians, we should take this fact into consideration and be judicious in implementation.

As electronic clinical documentation and documentation tools continue to evolve, it is key that clinicians, clinical informaticists, health information management professionals, and quality, regulatory reporting, research, and billing specialists work together on electronic documentation design, implementation, and improvement as well as the policies and procedures surrounding documentation and EHR use. The goal should be complying with billing, coding, and payer guidelines and providing data for quality reporting programs but also following best practices for electronic documentation.[35] In addition, it is crucial that the documentation burden placed on providers is not too high, and as much as possible, data solely necessary for other stakeholders should not disrupt the clinical narrative.

Documentation as a Vehicle for Medical Education

The steady shift of health care documentation from paper to electronic over the past 2 decades has had an impact on the learning process of medical students and pediatric residents and fellows. The EHR is an essential part of the daily work of medical students as they care for children and can also serve as an interactive learning tool by providing clinical decision support and ready access to the medical literature. Medical interns are estimated to spend 40% of their time dealing with EHR systems,[36] and in academic

medical centers, residents are a key source of clinical documentation.

Clinical documentation, itself, is an important learning objective of medical training, and close attention should be paid to trainees' understanding of the purpose of medical documentation and proper documentation technique in the electronic environment. In teaching institutions, trainees may be the primary documenters of clinical care because the CMS allows attending providers to verify both resident physician and medical student notes rather than redocumenting the work.[37] Trainees are often recipients of heavy workloads and may be more susceptible to some of the pitfalls of electronic documentation.[5] Medical school and residency programs should prioritize informatics resources to aid and assist in designing curriculums and providing instruction on the best practices for clinical documentation. Mentoring physicians should continue to provide feedback to their trainees regarding their documentation and proper mastery of the use of the EHR system.

In the 2013 Accreditation Council for Graduate Medical Education common program requirements, use of information technology is listed as one of the competencies under practice-based learning and improvement.[38] There are specific suggestions for EHR-related enhancements to core competencies, such as maintaining accurate problem and medication lists within the EHR to facilitate multispecialty care, which exemplifies the core competency of systems-based practice.[39]

Trainees are also in a unique position to advance health information technology. Trainees who are technically savvy and perhaps the heaviest users of the EHRs can provide important feedback on specific areas in which the EHR functionality can be improved. EHR and electronic documentation improvement efforts in teaching hospitals should include input of trainees.

UNIQUE STAKEHOLDERS FOR PEDIATRICS

Schools

Pediatricians have a unique relationship with school systems because children spend much of their time at the school and teachers and school nurses serve as important caregivers for children. Federal law, specifically the Individuals with Disabilities Act[40] and section 504 of the Rehabilitation Act of 1973,[41] ensures that all children, regardless of disability, have a right to free and public education that meets their needs. Schools are responsible for the care of any child's medical needs at school and are also important partners with pediatric care providers in ensuring that children with learning disabilities or developmental delays receive evaluations and appropriate education and therapies.

There is a vital need for school systems and child health providers to communicate and share relevant information in a bidirectional manner. Currently, much of the communication between schools and medical providers takes place via parents, who communicate between the 2 parties either with verbal information or by transporting paper school forms completed by educators and child health providers back and forth. This method leads to excessive work for parents and providers and presents multiple opportunities for error. In addition, the variability and constant changing of school forms required by private and public schools and child care centers causes great difficulty for health care providers and for the potential use of EHRs to aid form completion.

Communication between schools and health care providers could be facilitated by the streamlining and standardization of documentation essential for this process for schools and child care centers across the country. In addition, efforts should be made to enable sharing of this information electronically with parents and the school system and direct communication between health care and education providers. Privacy, consent, and security specifications would need to be defined for this information exchange.

Adolescents

Pediatric care providers need to document information regarding adolescent mental health, substance use, and reproductive health so that it can be used for their care and communicated with other providers. However, as discussed in an AAP policy statement,[10] this information is protected by federal and state laws. Although the adolescent is a minor, in some states, certain information cannot be shared with parents or guardians without the adolescent's permission unless there is a risk of harm.[10] Many EHR systems lack the technology to segment or filter confidential clinical data to prevent inadvertent disclosure to unauthorized parties, including the sharing of this protected information with parents in written form or electronically through a portal.[10,12] Unless a nationwide consensus on adolescent confidentiality issues is reached, there would also need to be flexibility in EHR settings regarding adolescents to account for state variations in laws.

NEW SHARED DOCUMENTATION PARADIGM

Shared Documentation With Patients and Families

Historically, the patient medical record, including clinical documentation, has been owned and held by medical providers and facilities, with access granted by request to patients as per regulations

in the Health Insurance Portability and Accountability Act.[42] Until more recently, most patient requests for medical records were handled in person and/or through a process of written request.

This paradigm is changing rapidly with improvements in patient portal technology and with the requirement to share information electronically with patients as part of the Promoting Interoperability Program requirements[43] and the 21st Century Cures Act.[44] In general, there is growing support that although the medical care establishment remains the steward of the data, patients should have more control over their clinical records. Although current meaningful use criteria do not explicitly require the sharing of specific clinical documentation, such as office visit notes, daily progress notes, or discharge summaries,[45] a few institutions have begun doing so and have found this sharing to be well received by patients. A study at 2 institutions in 3 geographic areas (OpenNotes) revealed improvements in patient-reported medication adherence, engagement, and satisfaction after the institutions began sharing provider notes electronically.[46]

The ease with which patients can now access their health records and information electronically could lead to a more shared model of EHRs and clinical documentation. Although concerns have been raised about the possibility of patient misunderstanding or worry regarding the information contained within the record,[47] the rates of this occurring, as reported by patients with access to clinical notes, were low.[46,48] Even so, providers should be educated on ways to document without using needless medical jargon, abbreviations, and judgmental language.[49] Guidelines on creating patient-centric notes without losing the documentation's role as a communication tool among providers and to substantiate billing are needed. In addition, because a significant portion of parents in America have basic or below-basic levels of health literacy,[50] their ability to make use of these notes to improve their child's care should be investigated.

It is also important to recognize that the sharing of clinical documentation between providers and patients could also reduce documentation burden for clinical providers. The plan section of notes and written patient instructions given to the patient (eg, after-visit summary and discharge instructions) often contain similar content but may be crafted separately. If one document could serve both purposes, it could eliminate redundancy and ensure that providers and patients communicate the medical plan effectively.

Patient-Generated Health Data

There is an opportunity in pediatrics to capitalize on patient-generated health data (PGHD), defined as "health-related data—including health history, symptoms, biometric data, treatment history, lifestyle choices, and other information—created, recorded, gathered, or inferred by or from patients or their designees (ie, care partners or those who assist them) to help address a health concern."[51,52] There is growing evidence that PGHD have value to both patients and providers.[52] The application of PGHD in pediatrics should continue to be explored and evaluated.

The value of PGHD includes the possibility of improving efficiency by the sharing of documentation tasks that would otherwise fall on providers and support staff or the time taken during the visits for patients and families to complete paper forms or questionnaires.[17] This value may only truly be reaped, however, if the data are safely and seamlessly integrated within clinical workflows and EHRs in a manner acceptable for patients and providers.

Another potential value of PGHD is the capture of important information that may otherwise be missed during a short visit and the empowerment of patients to have a significant voice in their own health care. Early-use cases in pediatrics include previsit surveys to tailor a clinical visit and questionnaires to assess and track development, quality of life, and indicators for various chronic medical conditions.[53]

Shared Provider Documentation

Communication among providers is an important function of clinical documentation. For example, to enable successful communication between a referring primary care provider and a medical subspecialist or surgical specialist, the reason for consultation and urgency should be clear and readily available. This information can then be reviewed by specialty providers and their support staff as the appointment is being scheduled and at the time of the visit. Similarly, the specialty assessment and plan should clearly delineate the plan, including which provider is responsible, and needs to be clearly communicated to the referring provider and the patient.[54]

Although primary care providers, medical subspecialists, surgical specialists, emergency physicians, and hospitalists may all provide care for the same medical problem for a given patient in the same EHR system, their documentation, including the assessment and plan, is usually housed in separate notes. Although distinct notes for each encounter are necessary for clearly documenting occurrences at a given visit or on a given day, models for shared documentation should be explored as a potential way to improve communication among providers.

Problem-Oriented Charting

Shared patient medical problem lists and problem-oriented charting could allow providers to view plans by all providers related to a particular medical problem. However, the use of problem-oriented charting has challenges, including problem list incompleteness and inaccuracies. An institution's use of problem-oriented charting or linkages between billing data and problem lists was associated with higher rates of problem list completeness.[55]

In addition, the success of maintaining accurate problem lists for patients, as well as problem-oriented documentation, is associated with a culture in which primary care physicians and medical subspecialists and surgical specialists share responsibility for the problem list.[56] However, actual completion of the problem list is difficult to both support and enforce, and that culture may not exist at every practice or institution. There is some evidence that primary care providers are responsible for the clear majority of problem list documentation, and although primary care providers believe medical subspecialists should contribute to the problem list, medical subspecialists believe it may be an incursion on the primary care provider's territory.[57,58] In addition, some medical subspecialists are likely to prefer documenting in a more systems-based format (eg, intensivists who care for more children with active multisystem issues). Providers may have differing needs for the information granularity level of any one given problem. Guidance and policies regarding how to effectively share problem lists and other shared documentation are necessary to support this new paradigm.

Although linking billing with problem lists is associated with more complete problems lists, basing a patient's problems on billable diagnosis codes (eg, the *International Statistical Classification of Diseases and Related Health Problems, 10th Revision*) can introduce additional issues. Diagnosis codes may be insufficient to reflect the clinical picture. For example, there are limited codes available for working diagnoses and for problems related to social determinants of health. In addition, multiple diagnosis codes or problems are often used for interrelated conditions, raising the concern that problem-oriented documentation does not help manage the patient as a whole individual.[59]

Medication Documentation and Management

Another example of shared documentation is medication lists. The idea behind shared medication documentation is to build on existing medication lists that multiple provider types across clinical settings contribute to rather than maintain separate lists, thereby reducing the harm caused by medication discrepancies during patient transitions.[60] However, similar to shared problem lists, not all providers believe they have ownership over the entire medication list. There is an inherent issue of medical subspecialists preferring to reconcile medications that are only relevant to their scope of care. Despite this, studies have revealed that a structured, systemwide intervention can be successful in achieving medication reconciliation compliance.[59]

One medication list may not be able to serve all purposes of medication documentation, however. For instance, there is a difference between prescribed medications and medications taken by the patient, and both are important information to maintain. In addition, many medication lists require structured entry of the medication name, concentration, dose, route, frequency, and dispense amount to prescribe medications and refills. There is also another layer of complexity when documenting medications in children, in that there may be multiple concentrations of the same liquid medication. However, even in the absence of knowing every detail, providers should be able to record partial medication information alongside all other active medications. Successful electronic medication documentation and management requires appropriate context, properly designed tools, and attention to implementation.[61,62]

EVOLVING CLINICAL DOCUMENTATION METHODS

The technologies and methodologies associated with electronic documentation continue to mature. New tools should be evaluated for their ability both to improve clinical care and to alleviate provider documentation burden. For instance, the scope of clinical documentation has expanded beyond textual rendition. Images (rashes and wound care), audio files (abnormal heart and breath sounds), and video files (seizures and endoscope findings) may be useful adjuncts in the EHR. These alternative media could prove more valuable to clinical care than text description of the findings and could reduce some documentation load. However, more information is needed about how clinicians can include these media in EHRs using existing or future technology in a way that complies with the Health Insurance Portability and Accountability Act. Another example is using alternative EHR data sources, such activity logs, to justify payment for services and eliminate the need for redundant documentation. The use of different types of media and EHR data sources as clinical documentation needs to be incorporated into E&M guidelines.

Speech Recognition

Speech (voice) recognition software is a growing technology that has the

potential to improve the efficiency of clinical documentation. As speech recognition software continues to improve, it may offer advantages over standard dictation and documentation by using a keyboard and mouse. However, further investigation is needed to assess its impact on documentation time and error rates.[63–65] The maturity and increasing use of artificial intelligence computing techniques has greatly improved speech recognition capabilities.

Scribes

In addition to technological solutions, the use of physician extenders or scribes has been considered as a possible solution to alleviate physicians' documentation burden. A scribe's core responsibility is to capture accurate and detailed documentation of the encounter in a timely manner. The general duties of a scribe may include assisting the provider in navigating the EHR, responding to various messages as directed by the provider, locating information for review, and entering information into the EHR. It is imperative that all entries regarding a patient's health information be completed in the presence of and at the direction of the provider. It is also important that authentication of each entry be completed in a timely manner as defined by a practice's policies and regulatory requirements.[66] Research in this area is limited and has shown discrepancies in whether scribes have led to improvements in provider efficiency and satisfaction.[67,68]

Technology to Enhance Data Reuse

New technologies could reduce documentation tasks by eliminating the need to document discrete information by enabling the reuse of text for research, quality metrics, and clinical decision support. Effective use of natural language-understanding tools, in which unstructured narrative information is converted into a structured form, could increase the amount of data usable for other purposes without increasing documentation burden on providers or favoring heavily structured notes over clinical narratives.[69] For example, natural language-understanding tools can enable the use of free-text information to drive clinical decision support.[70]

CONCLUSIONS

Electronic documentation is now the norm for the care of children in most industrialized countries. However, there are still struggles to fulfill the many roles of electronic documentation. Strategies to meet these multiple, often competing needs have shifted from replicating paper documentation to exploring different models that may better suit these requirements and achieve maximum value for pediatric providers and for the care of children. Examples include shared documentation and medication management. Documentation improvement is a multidisciplinary venture that should include input from clinical, research, regulatory, and education stakeholders.

Emerging Issues in Male Adolescent Sexual and Reproductive Health Care

Laura K. Grubb, MD, MPH, FAAP,[a] Makia Powers, MD, MPH, MSc, FAAP,[b] COMMITTEE ON ADOLESCENCE

abstract

Pediatricians are encouraged to address male adolescent sexual and reproductive health on a regular basis, including taking a sexual history, discussing healthy sexuality, performing an appropriate physical examination, providing patient-centered and age-appropriate anticipatory guidance, and administering appropriate vaccinations. These services can be provided to male adolescent patients in a confidential and culturally appropriate manner, can promote healthy sexual relationships and responsibility, can and involve parents in age-appropriate discussions about sexual health.

INTRODUCTION

During adolescence, several transitions occur for boys, including the physical, psychological, and social changes associated with puberty, with most male adolescents reporting the initiation of sexual behavior.[1,2] Many emerging behaviors, including sexual initiation, are associated with preventable negative health consequences such as sexually transmitted infections (STIs), unintended pregnancies, and nonconsensual sexual activity.[2] During this developmental period, the number of health encounters typically declines, particularly among older male adolescents, and there is a shift from routine to more time-limited acute visits.[3] Pediatricians and other physicians who care for natal male adolescents (cisgender or transgender female adolescents) or those who identify as male (transgender male adolescents or gender nonconforming) have unique opportunities to incorporate anticipatory guidance around issues such as puberty and sexuality not only at any health maintenance visits but also at sick and/or injury visits with adolescents and their families. For the purposes of this report, the term "male" refers to cisgender adolescents and young adults, unless otherwise specified.[4]

Even after the release of the American Medical Association's *Guidelines for Adolescent Preventive Services (GAPS)*[5] and the American Academy of Pediatrics (AAP) *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents*,[6] which recommend preventive health services for adolescents, there have been few improvements in the counseling of male

teenagers regarding the prevention of STIs or HIV infection.[7,8] Furthermore, data from outpatient medical records reveal that pediatricians are 3 times more likely to take sexual health histories from female than male patients and twice as likely to counsel female patients on the use of barrier methods.[7,9] Thus, it is important for pediatricians to have an understanding of what sexual and reproductive health care means for the male adolescent. Although boys and young men comprise approximately half of the adolescent population in the United States, standards for addressing their reproductive and sexual health needs lag behind those for adolescent girls and young women, and male adolescents continue to be a particularly vulnerable patient population.[7,8] Pediatricians are encouraged to address male adolescent sexual and reproductive health on a routine basis, including boys and young men with developmental or physical disabilities,[10,11] by taking a sexual history, discussing healthy sexuality, performing an appropriate examination, providing patient-centered and age-appropriate anticipatory guidance, performing appropriate screening, and administering vaccinations.[12]

The 2011 AAP clinical report on male adolescent sexual and reproductive health care discusses specific issues related to male adolescents' sexual and reproductive health care in the context of primary care, including pubertal and sexual development, sexual behavior, masturbation, consequences of sexual behavior, and methods of preventing STIs (including HIV) and pregnancy.[13] This revision provides updated information and recommendations since the 2011 clinical report, including the following:

- updated information concerning male adolescent sexual behavior;
- emerging issues in health confidentiality;
- data on the patterns of social media use in male sexual health;
- discussion of consent for sexual acts among adolescents;
- recommendations for counseling of male adolescents on their roles in contraception decision-making;
- updated data on STIs and treatment among male patients aged 15 to 24 years with updates on STI screening and treatment;
- recommendations on human papillomavirus (HPV) vaccine for boys;
- information on sexual dysfunction among adolescent and young adult males and recommendations for addressing in practice; and
- updated sexual and reproductive health resources (Supplemental Table 2) for pediatricians specifically for male adolescent patients.

ADOLESCENT MALE SEXUAL BEHAVIOR

According to the 2017 Youth Risk Behavioral Surveillance System (YRBSS), 41% of male teenagers of high school age reported they had sexual intercourse, defined as opposite-sex vaginal-penile contact, by the 12th grade.[2] In another study, male adolescents were significantly more likely to engage in oral sex compared with sexual intercourse and more likely to have significantly greater numbers of oral sex partners than sexual intercourse partners and indicated that during oral sex, they had never used STI protection.[14] A substantial number of young men report engaging in concerning sexual behaviors, including an earlier age of sexual debut and having more sexual partners than female adolescents.[2] YRBSS data from 2017 indicated that among surveyed male high school students, 22% reported using alcohol or drugs before last sexual intercourse, 12% reported $\geq$4 lifetime partners, 39% did not use a condom at last sexual intercourse, and 5% reported initiating sex at 13 years or younger.[2]

Adolescents with intellectual disabilities (IDs) and physical disabilities are an overlooked group in terms of sexual behavior, but they have similar rates of sexual behaviors when compared with their peers without disabilities.[15] These youth receive limited sexual education from their parents and pediatricians, who may assume they will not engage in sexual behaviors.[15] Much of the research on IDs and sexuality among adolescents and young adults is focused on contraception choices and pregnancy prevention among females, with little focus on male adolescents. Jahoda and Pownall[16] evaluated sexual knowledge and social networks among adolescents with IDs compared with adolescents without IDs. Results revealed that male adolescents with IDs scored higher in knowledge of sexual topics compared with female adolescents with IDs and discussed sexual topics more frequently in their social networks compared with female adolescents; however, male adolescents with IDs were less likely to have received information about sex from their pediatricians when compared with their peers without IDs.[16] Current research is now being focused on the importance of sexuality counseling with these adolescents and young adults so that they develop healthy sexual behaviors.[10] The AAP clinical report "Sexuality of Children and Adolescents With Developmental Disabilities" provides additional guidance and information.[11]

As the national dialogue shifts toward openness and acceptance of lesbian, gay, bisexual, transgender, and questioning (LGBTQ) individuals, adolescents are increasingly expressing sexual fluidity and flexibility. Discordance between

sexual attraction and orientation and behavior is also possible because one's sexual attraction and sexual identity do not always predict sexual behavior.[17–19] In the 2017 YRBSS, youth were asked questions to ascertain sexual identity and gender of sexual contacts. Among male students, 92% identified as heterosexual or straight, 2% identified as gay, 3% identified as bisexual, and 3% identified as not sure. Of male youth who ever had sexual intercourse, 80% reported having sexual contact with the opposite sex only and 76% reported having sexual contact with the same sex only or both sexes. Fifty-nine percent of high school students denied any history of sexual contact.[2]

Although most LGBTQ youth are resilient and emerge from adolescence as healthy adults, the effects of homophobia and heterosexism can contribute to concerning health issues for sexual minority youth (those who identify as gay, lesbian, or bisexual; those who are not sure about their sexual identity; or those who have sexual contact with only the same sex or with both sexes). Sexual minority youth, in comparison with heterosexual adolescents, have higher rates of depression and suicidal ideation, higher rates of substance abuse, and riskier sexual behaviors.[20] Sexual minority boys and young men reported significantly higher rates of violence-related behaviors, including being forced to have sex, school bullying, and being victims of physical and/or sexual dating violence.[21] Sexual minority boys and young men also reported higher rates of earlier sexual debut, ≥4 sexual partners, less barrier-method use, less contraceptive use when engaged in intercourse with female partners, and higher use of drugs or alcohol before sexual intercourse compared with their non–sexual minority counterparts.[21]

Pediatricians rarely discuss high-risk sexual behaviors during routine adolescent visits, and they discuss same-sex sexual behaviors even less frequently. Studies have revealed that pediatricians often do not discuss sensitive topics, such as sexual orientation, sexual identity, gender identity, violence prevention, or sexual or physical abuse, as part of their routine practice.[7,9,22–24] These studies reveal that pediatricians who care for adolescents are not routinely asking about sexual practices and the sexual orientation of their patients, preventing them from adequately addressing sexual health concerns and sexual risk. LGBTQ teenagers and young adults are an underserved population, many of whom struggle with acceptance of their sexuality while they are managing the other rigors of adolescence. It is important that pediatricians and other physicians obtain the skills needed to provide culturally effective, developmentally appropriate care for sexual minority youth. The 2013 AAP policy statement "Office-Based Care for Lesbian, Gay, Bisexual, Transgender, and Questioning Youth" provides additional guidance.[20]

EMERGING ISSUES IN HEALTH CONFIDENTIALITY

Adolescents' right to consent and confidentiality and health care are intertwined. Providing confidentiality supports adolescents in their development of autonomy and plays a significant role in their willingness to access necessary health care or disclose important information to pediatricians. There is no federal law that explicitly protects adolescents' right to confidential health care. There are individual state laws, and numerous international and national organizations have outlined the importance of confidentiality protections, including the United Nations, American Public Health Association, AAP, Society for Adolescent Health and Medicine, American Academy of Family Physicians, and American College of Obstetricians and Gynecologists.[25–29] The 2017 AAP clinical report "Sexual and Reproductive Health Care Services in the Pediatric Setting" provides specific guidance on the provision of confidential sexual health services.[12] The Guttmacher Institute provides updated summaries of states' consent and confidentiality laws for minors on its Web site.[30]

The expansion of electronic health records and the increased coverage of young adults (up to age 26) through their parents' insurance plans have presented additional challenges to confidentiality. Although the Health Insurance Portability and Accountability Act of 1996[31] provides protection of private health information from some disclosures, it also allows disclosure of information for the purpose of treatment, payment, or health care operations with consent.[32] Adolescents are at risk for confidentiality breaches when insurers send explanations of benefits or denials of claims to policyholders after anyone covered under their policy obtains care. These insurance documents may identify the individual who received care, the health care provider, and the type of care obtained. In 2014, the AAP, American College of Obstetricians and Gynecologists, and Society for Adolescent Health and Medicine released a policy statement on the importance of confidentiality protections in the insurance billing process.[33] The AAP also recommended confidentiality protections in its 2012 policy statement "Standards for Health Information Technology to Ensure Adolescent Privacy."[34] This guidance provides pediatricians with a framework to provide confidentiality while delivering important adolescent services.

USE OF MEDIA AND SOCIAL MEDIA

Adolescents use a variety of media to socialize and learn about and engage in sexual activity. Media uses include television, video games, social media, texting, smart phone applications, Web sites, and online pornography. Boys are more likely than girls to make online friends and communicate with them online rather than in person.[35] Recent studies of adolescents revealed that male participants were statistically more likely to receive sexually explicit texts and be sexually active and that sexual minority male youth were more likely to send sexually explicit texts than female adolescents.[36,37] In a recent study examining "sextortion" (the threatened dissemination of explicit, intimate, or embarrassing images of a sexual nature without consent, usually for the purpose of procuring additional images, sexual acts, money, or something else) of US middle and high school students, researchers found that boys and sexual minority youth were more likely to be targeted and that boys were more likely to target other youth.[38]

Of concern to pediatricians is frequent adolescent exposure to pornography. In one study, more than half of male youth Internet users 14 to 15 years of age had been exposed to either unwanted or wanted online pornography in the past year, as had more than two-thirds of those 16 to 17 years of age. Thirty-eight percent of male Internet users aged 16 to 17 intentionally visited pornographic sites in the past year.[39] There are conflicting data concerning the effects of pornography. Some studies reveal that users report positive effects on sexual health whereas others report negative effects, and there is no conclusive information concerning sexual function or dysfunction. Pornography frequently portrays male and female inequalities, specific body types (thin women with surgically enhanced breasts), normalization of aggressive or violent sexual acts and violence, and a lack of emotional intimacy between actors.[40] During the social history, pediatricians can screen for social media use, pornography viewing, patients' perceptions of such material, and any adverse effects and provide guidance on safe and sensible Internet and social media use to parents and patients. The AAP provides policies, information, advice, and resources about families' and children's interactions with various forms of media on its Web site.[41,42]

SEXUAL ASSAULT AND CONSENT FOR SEXUAL ACTIVITY

Sexual assault is a prevalent issue that can affect many adolescents, regardless of gender. Until 2012, published US Federal Bureau of Investigation annual crime data defined "forcible rape" as "the carnal knowledge of a female forcibly and against her will."[43] As a result of this definition, there are limited data concerning sexual assault of male victims and even less information for male adolescents.[44] In the 2017 YRBSS report, 3.5% of male high school students disclosed ever being physically forced to have sexual intercourse, of whom 3% identified themselves as heterosexual, 16% as LGBTQ, and 12% as unsure of their sexual orientation. Male victims who experienced sexual violence reported the sex of their sexual contacts as the following: 4% opposite sex only, 26% same sex only or both sexes, and 1% no sexual contact. In the same report, 4.3% of male high school students reported experiencing any sexual violence.[2]

For male victims of sexual assault, there are significant stigmas to reporting the assault, including the misperceptions that males in noninstitutionalized settings are rarely sexually assaulted, that male victims are responsible for their assaults, that male sexual assault victims experience less trauma than their female counterparts, and that ejaculation is an indicator of a positive experience. As a result of these misbeliefs, there is an underreporting of sexual assaults by male victims, a lack of appropriate services for male victims, and less legal redress for male sexual assault victims. By comparison, male sexual assault victims have fewer resources and greater stigma than do female sexual assault victims.[45] Pediatricians are encouraged to ask male patients about exposure to sexual assault (and other types of victimization) during the social history of routine health supervision visits. When exploring alcohol or substance use, it is important to discuss the link between impairment and vulnerability to sexual assault. It is advised that adolescents who disclose a previous assault be asked about the dynamics of their relationships (eg, exploitative, controlling, nonconsensual). The 2017 AAP clinical report "Care of the Adolescent After an Acute Sexual Assault" provides additional guidance.[46] In addition to being victims of sexual assault, there have been many high-profile founded and unfounded cases of sexual assault by boys and young men resulting in significant disruption in the victims and alleged perpetrators' lives and futures. In the United States, of people arrested or convicted of sexual assault, 96% to 99% are male. Overall, an estimated 9% of the victims of rape and sexual assault were cisgender male. Nearly 99% of the offenders described in single-victim incidents were male. In the United States, per capita rates of rape/sexual assault were found to be highest among residents aged 16 to 19 years, demonstrating tha youth are particularly vulnerable.[47]

Each state has its own statutes regarding consent, rape, and sex

crimes, and each college or institution may have its own set of policies concerning sexual consent.[48] The US Department of Justice provides the following definitions: "Rape - Forced sexual intercourse including both psychological coercion as well as physical force. Forced sexual intercourse means penetration by the offender(s). Includes attempted rapes, male as well as female victims, and both heterosexual and same sex rape. Attempted rape includes verbal threats of rape. Sexual assault - A wide range of victimizations, separate from rape or attempted rape. These crimes include attacks or attempted attacks generally involving unwanted sexual contact between victim and offender. Sexual assaults may or may not involve force and include such things as grabbing or fondling. It also includes verbal threats."[49] There is no standard definition of consent, and many institutions have attempted to define and implement policies concerning sexual consent. The Department of Justice of the Government of Canada defines sexual consent for the purposes of sexual assault offenses as "the voluntary agreement of the complainant to engage in the sexual activity in question. Conduct short of a voluntary agreement to engage in sexual activity does not constitute consent as a matter of law."[50]

When discussing sexuality, pediatricians can address issues of consent during anticipatory guidance if sexual screening warrants concern. Additionally, pediatricians can encourage patients to communicate with partners concerning sexual activity before engagement by respecting verbal and nonverbal boundaries and cues, emphasizing that consent should occur with each activity every time and that parties may change their minds. Pediatricians can educate male youth that the following situations do not involve consent: refusing to acknowledge "no"; assuming that wearing certain clothes, flirting, or kissing is an invitation for anything more; someone being younger than the legal age of consent (as defined by the state); someone being incapacitated because of drugs or alcohol; pressuring someone into sexual activity by using fear or intimidation; and assuming permission to engage in a sexual act because it has occurred in the past. Pediatricians are encouraged to include discussions of definitions and understandings of sexual consent, dispel myths concerning consent, and provide anticipatory guidance concerning consensual sexual activity to facilitate safe and healthy relationships between male adolescents and their partners.

PREGNANCY PREVENTION AND CONTRACEPTION COUNSELING

According to the 2011–2015 National Survey of Family Growth, 84% of sexually experienced cisgender male teenagers reported using contraception at first sexual intercourse.[1] These rates varied by the age of the male at first sex: boys who were 14 years and younger had lower rates of contraception use at first sex than did males who were 17 to 19 years of age (71% and 95%, respectively).[1] Ninety percent of male teenagers used some method of contraception, including withdrawal at last sex, with 61% reporting using condoms at last sex, 19% reporting some contraceptive pill use, and 35% reporting a dual method (hormonal and barriers).[2]

The male adolescent can play an important role in the couple's contraception decision-making. In many cases, male adolescents prefer their partners to involve them in discussions of contraception methods.[51] Over the past decade, there has been a growing body of evidence regarding young men's knowledge of various forms of contraception and the association with shared decision-making.[52] Richards et al[52] recruited 93 ethnically diverse adolescent men to study their knowledge of emergency contraception (EC). Their findings revealed that fewer than half of the young men had ever heard of EC. Those who were aware of EC were more likely to be older (median 19.7 years), have knowledge of other contraceptive methods, and participate in shared contraceptive decision-making with their partners. The most recent literature review regarding EC-related knowledge, attitudes, and behaviors among men revealed that male adolescents have lower knowledge of EC than their adult male counterparts and are less likely to have had a partner use this form of contraception.[53] This study reveals the importance of counseling young men on all contraceptive methods to promote increased usage.

Once it is determined that an adolescent is at risk for pregnancy, the pediatrician may take the opportunity to provide counseling regarding all forms of contraception and each method's effectiveness in pregnancy prevention. If there is not time during a routine or sick appointment, the pediatrician can schedule follow-up appointments specifically to discuss pregnancy prevention and contraception options. Contraception counseling is relevant for heterosexual and sexual minority youth because LGBTQ youth are at a higher risk for unintended pregnancies than their heterosexual peers.[54] Transgender men or transmasculine people can themselves be at risk for pregnancy (and require contraceptive counseling if appropriate), and transgender women or transfeminine people may have male genitalia and require appropriate counseling about their risk of causing pregnancy.

Male adolescents can play a vital role in pregnancy prevention and

contraceptive decision-making in their female partners. Pediatricians can encourage male adolescents to attend contraceptive visits with their partners. During these visits, there is a great opportunity to elicit pregnancy desires and/or intentions of the couple and to educate them on a variety of contraceptive methods and the importance of shared decision-making. Additionally, the provider can encourage the male partner to commit to consistent condom use as a way to have personal control over unplanned pregnancy. If the male adolescent becomes a father, either through intended or unintended pregnancy with his partner, he will require unique social supports during the journey of fatherhood. These needs are the focus of the AAP clinical report "Care of Adolescent Parents and Their Children."[55]

STIS, SCREENING, AND TREATMENT RESISTANCE

Adolescents continue to face the greatest risk of acquiring STIs and not receiving appropriate care for STIs because of insufficient screening, confidentiality concerns, lack of access to health care, and multiple sexual partners. Most cases continue to go undiagnosed and untreated, putting individuals at risk for severe and often irreversible health consequences, including infertility, chronic pain, and increased risk for HIV as well as the propagation of STIs in the population. Youth aged 15 to 24 years comprise 27% of the sexually active population in the United States but account for more than 50% of new cases of STIs each year.[56] According to the Centers for Disease Control and Prevention (CDC), youth account for the majority of new cases of gonorrhea, chlamydia, HPV, and genital herpes and nearly one-quarter of new cases of HIV and syphilis annually. In this section, CDC data refer to cisgender male patients, unless otherwise stated.

From 2016 to 2017, the CDC reported substantially large increases for syphilis, gonorrhea, and chlamydia for both men and boys aged 15 to 24 years.[56]

In 2017, males aged 13 to 24 years accounted for 17.5% of all new HIV diagnoses in the United States and 87% of all diagnoses among young people aged 13 to 24 years. Most of those new HIV diagnoses among youth (81%) were attributed to male-to-male sexual contact.[57] Young people (aged 13–24 years) accounted for an estimated 21% of all new HIV diagnoses in the United States in 2017, totaling 8164 people, of which 87% were in natal males and 13% were in natal females.[2] Also, the study revealed that 25% of transgender women were living with HIV, and the percentage of transgender people who received a new HIV diagnosis was more than 3 times the national average in 2015.[58] In 2017, 1122 youth received a diagnosis of AIDS, representing 8% of total AIDS diagnoses that year.[2]

There has been an increase in the incidence of *Neisseria gonorrhoeae* infections among male adolescents, particularly among males who have sex with other males.[59] During 2013 to 2017, the rate of *N gonorrhoeae* infection among male patients increased 86.3%, compared with the rate increase among female patients of 39.4%.[59] The 2016 Gonococcal Isolate Surveillance Project revealed significant antibiotic resistance to gonococcal infections, and isolates from males who have sex with males are more likely to exhibit antimicrobial resistance than isolates from males who have sex with females.[60] With increasing cephalosporin-resistant gonorrhea, the CDC recommended in 2012 exclusive parental high-dose ceftriaxone treatment (250 mg, intramuscular) and a second antibiotic (azithromycin, 1 g) for uncomplicated gonococcal infections.[61]

There continues to remain significant underscreening of youth for STIs in the pediatric setting.[62,63] This underscores the need for pediatricians to offer screening based on risk assessment, appropriate treatment, and review strategies for prevention of transmission to reduce STI incidence and morbidity among all adolescents. The CDC recommends that clinicians consider screening for chlamydia in clinical settings serving populations of young male patients with a high prevalence of chlamydia (eg, adolescent clinics, correctional facilities, and STI clinics). The CDC does not recommend the routine screening of adolescents who are asymptomatic for certain STIs (eg, syphilis, trichomoniasis, bacterial vaginosis, herpes simplex virus, HPV, hepatitis A, and hepatitis B) but does recommend screening for syphilis in males who have sex with males.[61] The US Preventive Services Task Force concludes that the current evidence is insufficient to assess the balance of benefits and harms of routine screening for chlamydia and gonorrhea in boys and men.[64] For males who have had sex with males, the CDC recommends at least annual screening for HIV, syphilis, gonorrhea at all sites of contact (by using urine, rectal, and pharyngeal sampling), and chlamydia on urine and rectal sampling (testing for chlamydia pharyngeal infection is not recommended) regardless of barrier-method use. More frequent STI screening (ie, for syphilis, gonorrhea, and chlamydia) at 3- to 6-month intervals is indicated for males who have sex with males if risk behaviors persist or if they or their sexual partners have multiple partners.[61] Given the significant increases in all STIs among male patients in the past 5 years, it is reasonable for pediatricians to maintain a high index of suspicion for STIs and consider testing for male patients who are

Bright Futures Medical Screening Reference Table
Adolescence Visits (11 Through 21 Years)

Bright Futures

Selective Screening	Medical History Risk Factors[c]	Risk Assessment[d]	Action if Risk Assessment Is Positive
STIs	**Chlamydia** The US Preventive Services Task Force strongly recommends that clinicians routinely screen all sexually active females ≤25 years and other asymptomatic females at increased risk for infection for chlamydial infection. The AAP recommends that sexually active males who have sex with females may be considered for annual screening in settings with high prevalence rates. • Jails or juvenile corrections facilities • National job training programs • STI clinics • High school–based clinics • Adolescent clinics for patients who have a history of multiple partners Sexually active males who have sex with males (known as MSM) should be screened annually for rectal and urethral chlamydia. Males who have sex with males at high risk should be screened every 3 to 6 months. • Multiple or anonymous sex partners • Sex in conjunction with illicit drug use • Sex with partners who participate in these activities	***At the 11 through 14 Year (Older Child/Younger Adolescent) Visits,*** *ask the parent* • Adolescents who are sexually active are at risk of acquiring STIs. Are you concerned that your older child or young adolescent might be at risk? ***At the 11 through 14 Year (Early Adolescence) Visits, 15 through 17 Year (Middle Adolescence) Visits, and 18 through 21 Year (Late Adolescence) Visits,*** *ask the adolescent or young adult* • Have you ever had sex (including intercourse or oral sex)? ○ If no, skip to the next section. • Are you having unprotected sex? • Are you having sex with multiple partners or anonymous partners? • Are you or any of your past or current sexual partners bisexual? • Have you ever been treated for an STI? • Have any of your past or current sex partners been infected with HIV or used injection drugs? • Do you trade sex for money or drugs or have sex partners who do? • **For males:** Have you ever had sex with other males?	Chlamydia test
	Gonorrhea The US Preventive Services Task Force recommends that clinicians screen all sexually active females, including those who are pregnant, for gonorrheal infection if they are at increased risk for infection (ie, they are young or have other individual or population risk factors). The AAP recommends that sexually active males who have sex with females (known as MSF) may be considered for annual screening on the basis of individual and population risk factors, such as disparities by race and neighborhood. Sexually active males who have sex with males should be screened annually for rectal and urethral gonorrhea. Males who have sex with males at high risk should be screened every 3 to 6 months. • Multiple or anonymous sex partners • Sex in conjunction with illicit drug use • Sex with partners who participate in these activities		Gonorrhea test
	Syphilis • Males who have sex with males and engage in high-risk sexual behavior • Persons living with HIV • Commercial sex workers • Persons who exchange sex for drugs • Those in adult correctional facilities		Syphilis test

Accessed June 9, 2019.)

sexually active. *Bright Futures* provides a risk assessment to assist with screening decisions (Fig 1).[65]

Only 10% of high school students have been tested for HIV, and among male students who have had sexual contact with other males, only 21% have ever been tested.[57] The AAP, in *Bright Futures*,[7] the *Red Book*,[66] and a policy statement,[67] recommends that routine screening be offered to all adolescents at least once by 16 to 18 years of age in health care settings when the prevalence of HIV in the patient population is more than 0.1%. In areas of lower community HIV prevalence, routine HIV testing is encouraged for all sexually active adolescents and those with other risk factors for HIV.[68] Additionally, the CDC recommends routine HIV screening for all patients seeking treatment of STIs, including all patients attending STI clinics, during each visit for a new complaint regardless of whether the patient is known or suspected to have specific behavior risks for HIV infection.[69] For individuals at increased risk for HIV acquisition (sexually active males who have had sex with males, individuals with an HIV-positive partner, individuals participating in anal intercourse, individuals having frequent sex without a condom, and individuals with a high number of sexual partners), the CDC recommends preexposure prophylaxis (PrEP) to reduce HIV acquisition and transmission.[69] As of this publication, the US Food and Drug Administration has approved 2 medications, emtricitabine (200 mg)/tenofovir disoproxil fumarate (300 mg) and emtricitabine (200 mg)/tenofovir alafenamide (25 mg), for PrEP in adolescents and adolescents who weigh at least 35 kg.[70,71] The CDC Web site provides an HIV risk behavior assessment, PrEP clinical practice guidelines, patient and provider education, and tool kits.[72]

The CDC publishes treatment guidelines for STIs, including recommendations for special populations such as adolescents, people in correctional facilities, males who have sex with males, and transgender men and women.[57] Effective clinical management of patients with treatable STIs includes treatment of the patients' current sex partners to prevent reinfection and reduce further transmission. Expedited partner therapy (EPT) can be a particularly useful option to facilitate partner management for adolescents who are diagnosed with chlamydia or gonorrhea. The CDC's Web site provides guidance, a provider tool kit, and a summary of states' EPT laws.[73]

HPV AND VACCINE RECOMMENDATIONS

HPV is the most common STI in the United States, with almost every person acquiring an HPV infection at some time in their life.[74] The most common clinical manifestation of HPV is warts, and the most prevalent high-risk (oncogenic) types are HPV-16 and HPV-18. Persistent infections with high-risk HPV types can cause cervical, vaginal, and vulvar cancers in natal women, penile cancers in natal men, and oropharyngeal and anal cancers in both men and women.[75] Approximately 9100 US men each year receive a diagnosis of oropharyngeal cancer caused by HPV infection.[75] During 2013 to 2014, oral and genital HPV prevalence among adults 18 to 59 years of age was significantly higher for men than women. There are no data currently available for boys younger than 18 years. Males who have sex with males are at particularly high risk for HPV-mediated anal cancers.[76]

In 2006, the CDC Advisory Committee on Immunization Practices first recommended the HPV vaccine in the United States.[77] Beginning in December 2014, after US Food and Drug Administration approval of the 9-valent HPV vaccine (which provides additional protection against HPV-31, HPV-33, HPV-45, HPV-52, and HPV-58), use of the quadrivalent HPV vaccine has been slowly phased out.[78] In October 2016, the Advisory Committee on Immunization Practices updated its recommended dosing schedule for routine HPV vaccination to a 2-dose series for adolescents initiating vaccination before their 15th birthday on the basis of available immunogenicity evidence indicating that a 2-dose schedule (0 and 6–12 months) has an efficacy equivalent to a 3-dose schedule (0, 1–2, and 6 months) if the HPV vaccination series is initiated before 15 years of age.[78] In a 2-dose schedule of the HPV vaccine, the minimum interval between the first and second doses is 5 months.[78] In clinical trials for male subjects, the most common adverse events were injection-site reactions (most of which were mild or moderate in intensity), headache, and fever. Still, male adolescent HPV vaccination rates continue to be low compared with other adolescent vaccination rates or female HPV vaccination rates. In the United States, male HPV vaccination coverage with at least 1 dose was 63%, and 53% of boys ages 13 to 17 years were up to date with the recommended HPV vaccination series.[79] The modified schedule for younger adolescents may improve rates, and pediatricians are uniquely situated to address the lag in HPV vaccination rates among adolescent boys and young men.

SEXUAL DYSFUNCTION

Healthy sexual function has an important role in the well-being and development of adolescents and young adults.[80,81] A 2016 study of sexually active males aged 16 to 21 years revealed that 79% reported a sexual problem, using the validated surveys the International Index of Erectile Function and the Premature Ejaculation Diagnostic Tool. On the International Index of Erectile Function, respondents indicate agreement with 15 items used to assess erectile function, orgasmic function, sexual desire, intercourse satisfaction, and overall satisfaction.[82] These problems are more prevalent than previously believed and cause significant distress to young men. The most common sexual problems among young men include premature ejaculation (PE) (20%) and erectile disorder (ED) (45%). Other common problems included low sexual satisfaction (48%) and low desire (46%).[80,81]

PE is a persistent or recurrent pattern of ejaculation occurring during partnered sexual activity within approximately 1 minute after penetration and before the person wishes it.[83] In a Swiss study of men aged 18 to 25 years, 11% reported PE.[84] This and another study revealed an association between PE and poor physical health, alcohol consumption, illegal drug use, tobacco use, and less sexual experience.[84,85]

ED is marked difficulty in obtaining an erection during sexual activity, marked difficulty in maintaining an erection until the completion of a sexual activity, or marked decrease in erectile rigidity.[83] ED prevalence among young men 18 to 25 years old approaches 30%.[84] Poor mental health, depression, and consumption of medication without prescription were predictive factors for ED. ED persistence was also associated with having multiple sexual partners.[85]

When pediatricians identify health issues such as mental health problems, physical inactivity, substance use, or multiple sexual partners, they may consider these an indication to screen for sexual dysfunction. Pediatricians

Substances and medications	Alcohol
	Amphetamines
	Antiandrogens (spironolactone)

have an opportunity to screen for problems with sexual functioning, to offer reassurance or treatment, or to appropriately assess for an underlying medical condition. Young patients often will not spontaneously discuss these topics because of embarrassment, pride, or masculinity or confidentiality concerns, so the onus is on the pediatrician to screen for sexual problems.[85,86] In screening for sexual problems, pediatricians may want to explore whether male patients have unrealistic expectations or misinformation concerning sex and sexual activity. When discussing medications with patients, pediatricians should discuss sexual dysfunction as an adverse effect and screen for sexual dysfunction in patients taking medications routinely or on a long-term basis. Conversely, identification of sexual dysfunction is an indicator to screen for other health problems (Table 1).

Even when patients do not initiate this conversation, they may still be receptive to screening from their pediatricians, who may use standardized tools such as the International Index of Erectile Function 5 and the Premature Ejaculation Diagnostic Tool, which were validated to screen men 18 years and older.[87,88] When male patients are identified as having sexual dysfunction, a complete medical and psychosocial history and physical examination, including genital examination with sexual maturity rating, are essential to evaluation to assess for any medical issues that can be worked up and addressed (Table 1).[89,90] Pediatricians may also screen patients concerning illicit use of any medications or supplements (prescription as well as over the counter), including pharmacologic agents for ED and performance-enhancing substances (ie, 3,4-methylenedioxymethamphetamine or supplements) because unmonitored

use may pose health risks and has been associated with increased risky sexual behavior.[91]

Several studies in men older than 18 years revealed statistically significant improved self-esteem, mood, sexual function, sexual relationship health, orgasmic function, sexual desire, and intercourse satisfaction among those, including young men, who received short-term (maximum 8 attempts with medication) pharmacotherapy for ED.[80,92,93] In treating sexual dysfunction, having an established and ongoing provider-patient relationship and addressing mental health concerns, including substance use, may be crucial therapeutic measures. Follow-up therapy may need to include mental health services, relaxation techniques, and a discussion of the skills needed to assist the adolescent in achieving some degree of voluntary control of sexual function.

It is important that pediatricians familiarize themselves with available counseling services within their communities for adolescents and young adults. This clinical report does not contain explicit recommendations for mental health services, but pediatricians can consult AAP resources for more direction, such as the Key Resources of the Mental Health Initiative (https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/Mental-Health/Pages/Key-Resources.aspx).

CONCLUSIONS

Pediatricians are in the best position to deliver high-quality sexual and reproductive health care services to male adolescents and can view even follow-up, acute care, and immunization visits as opportunities to address these health issues. Although time constraints at most adolescent visits may preclude a full exploration of many issues surrounding sexuality in adolescents, additional visits can be scheduled to address identified issues.

Pediatricians can also use "clinical hooks," such as preparticipation physical evaluations or acne follow-up, to keep male adolescents engaged in care and to deliver sexual and reproductive health care services. Staying informed on different issues of sexuality and sexual behaviors, initiating these conversations with male patients, and being prepared to provide appropriate anticipatory guidance are best practices when taking care of male adolescents.[12] The AAP publications "Sexual and Reproductive Health Care Services in the Pediatric Setting" and "Targeted Reforms in Health Care Financing to Improve the Care of Adolescents and Young Adults"[94] provide a framework to assist pediatricians in incorporating various aspects of sexual and reproductive health care into their practices and to provide guidance on overcoming barriers to providing this care routinely while maximizing opportunities for confidential health services delivery in their office.[5] The AAP has issued a policy statement on refusal to provide information or treatment on the basis of conscience. According to the policy, pediatricians have a duty to inform their patients about relevant, legally available treatment options to which they object, and they have a moral obligation to refer patients to other physicians who will provide and educate about those services. Failure to inform and educate about availability and access to these services violates this duty to their adolescent and young adult patients.[95]

GUIDANCE FOR PEDIATRICIANS

1. Discuss sex and sexuality with all male adolescents during routine visits and more frequently, as appropriate, and screen for sexual activity and high-risk sexual activity at routine visits and other appropriate opportunities;
2. screen adolescents for social media use (especially sexually explicit material), pornography viewing, perceptions of such material, and any adverse effects and provide guidance on safe and sensible Internet and social media use to parents and patients during the social history of well visits;
3. screen for nonconsensual sexual activity and discuss principles of sexual consent and nonconsent during well visits as well as other visits, as appropriate;
4. coach male adolescents on how to talk with their partners about sex and family planning, encourage joint decision-making between partners about sexual and

reproductive health matters, and encourage use of both contraception and barrier methods, as appropriate;

5. provide routine STI risk assessment screening for all male patients and appropriate testing for STIs, including HIV, syphilis, chlamydia, and gonorrhea, when warranted and on request and provide appropriate STI treatment, including prevention therapy and EPT;
6. consider HPV vaccination for boys starting at age 9 years, provide routine vaccination for all adolescent boys at age 11 years, and aim for complete HPV vaccination for all male patients, and emphasize the importance of complete HPV vaccination for male patients who participate in high-risk behaviors; and
7. provide screening for sexual problems with all sexually active male patients as part of the well visit sexual history and at other appropriate visits, consider the use of standardized screening tools for sexual dysfunction, investigate further for other health or mental health issues in male patients with sexual dysfunction, screen male patients with health and mental health issues for sexual problems, and follow-up with patients who report sexual problems and consider therapies such as counseling or pharmacotherapy, as appropriate.

Evaluation and Management of the Infant Exposed to HIV in the United States

Ellen Gould Chadwick, MD, FAAP,[a] Echezona Edozie Ezeanolue, MD, MPH, FAAP,[b,c] COMMITTEE ON PEDIATRIC AIDS

Pediatricians play a crucial role in optimizing the prevention of perinatal transmission of HIV infection. Pediatricians provide antiretroviral prophylaxis to infants born to women with HIV type 1 (HIV) infection during pregnancy and to those whose mother's status was first identified during labor or delivery. Infants whose mothers have an undetermined HIV status should be tested for HIV infection within the boundaries of state laws and receive presumptive HIV therapy if the results are positive. Pediatricians promote avoidance of postnatal HIV transmission by advising mothers with HIV not to breastfeed. Pediatricians test the infant exposed to HIV for determination of HIV infection and monitor possible short- and long-term toxicity from antiretroviral exposure. Finally, pediatricians support families living with HIV by providing counseling to parents or caregivers as an important component of care.

INTRODUCTION

Each year approximately 8500 women with HIV infection give birth in the United States.[1] Through the implementation of effective, cost-saving[2] preventive strategies during pregnancy, the rate of perinatal transmission of HIV has remained low at <1% to 2%.[1] These preventive strategies include (1) the provision of universal opt-out HIV testing for all pregnant women and for those who have HIV infection, administration of combination antiretroviral therapy (ART) during pregnancy and labor; (2) planned cesarean delivery before the onset of labor and rupture of membranes for pregnant women with an HIV viral load of >1000 copies per mL before delivery; (3) provision of antiretroviral prophylaxis to the infant exposed to HIV for 4 to 6 weeks; and (4) complete avoidance of breastfeeding. Perinatal transmission occurs mostly when there is failure of implementation of these strategies, outlined in a separate 2008 American Academy of Pediatrics (AAP) policy statement titled "HIV Testing and Prophylaxis to Prevent Mother-to-Child Transmission in the United States."[3,4] This clinical report offers guidance on the evaluation and

management of infants born to women with HIV infection.

In addition to standard clinical care for the newborn infant, it is important that appropriate steps are taken for early detection of HIV infection, appropriate vaccines are administered, and adequate counseling is provided to families living with HIV infection. The management of infants in whom HIV infection is diagnosed should be undertaken in consultation with a pediatric HIV specialist. This report updates previous AAP recommendations.[5]

IDENTIFICATION OF MATERNAL HIV INFECTION

Although there has been a dramatic decrease in the number of new HIV infections in infants in the United States since 1994, when antiretroviral prophylaxis was first documented to prevent perinatal transmission, transmission continues to occur, albeit rarely.[1] Documented cases of perinatal transmission declined rapidly after the adoption of the recommendation by the Centers for Disease Control and Prevention (CDC), the AAP, and the American College of Obstetricians and Gynecologists for routine HIV testing for all pregnant women in the United States. HIV testing is now part of routine prenatal care in most states unless the patient declines, which is also known as "opt-out" consent or "right of refusal."[6,7] A second HIV test during the third trimester, preferably before 36 weeks' gestation, has been found to be cost-effective even in low-prevalence areas and should be considered for all pregnant women.[2] In particular, pregnant women at high risk for incident HIV infection (eg, those who are incarcerated, reside in communities with an HIV incidence greater than 1 per 1000 per year, inject drugs, exchange sex for money or drugs, are sex partners of individuals living with HIV, or have had a new or more than 1 sex partner during the current pregnancy) should have HIV testing repeated in the third trimester.[8] A plasma HIV RNA test is recommended in addition to routine antigen/antibody immunoassay testing when the possibility of acute retroviral syndrome is suspected in a pregnant woman.[9]

TESTING OF THE INFANT WHEN THE MOTHER'S HIV INFECTION STATUS IS UNKNOWN

When the HIV status of the mother is unknown, expedited HIV testing should be performed on the infant after consent procedures consistent with state and local law. Expedited HIV antigen/antibody testing allows timely identification of HIV infection in women whose HIV status is unknown late in pregnancy, during labor, or in the immediate postpartum period and is generally available on a 24-hour basis at all facilities with maternity services and/or a neonatal care unit. Positive HIV antigen/antibody test results should be urgently reported to health care providers so that presumptive HIV therapy can be initiated in the infant as soon after birth as possible and ideally within 6 to 12 hours of life. In addition, breastfeeding should be postponed, and the infant should be given formula feedings. If supplemental test results are negative, antiretroviral drugs should be stopped, and breastfeeding may be reinstated.[8]

STRATEGIES FOR PREVENTION OF PERINATAL HIV TRANSMISSION

Maternal Treatment During Pregnancy

Most women with HIV infection in the United States have access to free prenatal care, which allows for the initiation of effective ART in women in whom HIV is newly diagnosed or continuation of treatment in those who are currently receiving ART.[10] The determination of the appropriate mode of delivery and the decision not to breastfeed is also made during the prenatal period. The current US Department of Health and Human Services (HHS) Panel on Treatment of Pregnant Women With HIV Infection and Prevention of Perinatal Transmission (Perinatal Guidelines Panel) recommends the use of a combination of at least 3 antiretroviral drugs during pregnancy and labor for all pregnant women with HIV infection regardless of the plasma HIV RNA viral load or $CD4^+$ T-lymphocyte count.[11]

Interventions During Labor and at Delivery

Pregnant women with HIV infection generally continue the routine dosing schedule of their ART regimen during labor if possible. Intravenous zidovudine (ZDV), also known as azidothymidine (AZT), is added for pregnant women with HIV RNA >1000 copies per mL close to delivery and may be considered for RNA levels between 50 and 999 copies per mL, but it is no longer recommended for pregnant women with documented HIV RNA levels <50 copies per mL near delivery.[12] Planned cesarean delivery before labor and the rupture of membranes at 38 weeks' gestation is recommended for all pregnant women with HIV RNA levels of ≥ 1000 copies per mL near the time of delivery regardless of maternal HIV treatment.[13] Cesarean delivery solely for the prevention of transmission is not recommended for pregnant women with HIV RNA levels <1000 copies per mL because of the low risk of perinatal transmission of HIV in this group and the increased risk of complications with a major surgical procedure.[13]

Women who present in labor with unknown HIV status should receive expedited HIV testing with a combined HIV antigen/antibody test. If the screening result is positive, supplemental testing with an HIV-1/HIV-2 antibody differentiation

immunoassay and HIV RNA testing should be performed urgently, and intravenous ZDV should be initiated pending the result of the supplemental test.[12] Prompt initiation of intravenous ZDV, followed by infant antiretroviral prophylaxis, may decrease the risk of perinatal transmission of HIV in these settings.[14] Cesarean delivery before rupture of membranes, if feasible, may also be considered, but there is insufficient evidence to determine if cesarean delivery during labor reduces perinatal transmission.[13] If the supplemental results are negative, maternal and infant antiretroviral prophylaxis should be stopped.

Antiretroviral Management for the Infant Exposed to HIV

Postnatal antiretroviral drugs should be provided to all infants exposed to HIV to reduce the risk of perinatal HIV transmission. Antiretroviral prophylaxis is defined as the administration of 1 or more antiretroviral drug(s) to a newborn infant without confirmed HIV infection to reduce the risk of HIV acquisition, whereas presumptive HIV therapy consists of the administration of a 3-drug combination antiretroviral regimen to newborn infants at highest risk of HIV acquisition. Presumptive HIV therapy is intended to be preliminary treatment of a newborn infant who is later confirmed to have HIV infection but also serves as prophylaxis against perinatal transmission. Prophylaxis has historically been achieved by giving a 6-week neonatal ZDV chemoprophylaxis regimen. However, term infants born to women who received ART during pregnancy with documented viral suppression can be given a 4-week course.[15] In higher-risk cases, experts on the Perinatal Guidelines Panel recommend combining a 6-week infant ZDV prophylaxis regimen with 2 additional antiretroviral drugs including lamivudine (also known as "3TC") and either nevirapine (NVP) or raltegravir (RAL) to construct a presumptive HIV therapy regimen (see tables in ref 15).[15] This 3-drug combination antiretroviral drug regimen is recommended for infants born to mothers who (1) received prenatal antiretroviral drugs but had suboptimal viral suppression at delivery, (2) received only intrapartum antiretroviral drugs, (3) received no antepartum or intrapartum antiretroviral drugs, or (4) have known drug-resistant virus. Decisions about using a combination antiretroviral regimen over ZDV monotherapy can be made after balancing the benefits of enhanced prevention of perinatal transmission of HIV infection over possible toxicity from multiple drugs. The most information about the use of antiretroviral combinations in neonates is available for older regimens such as ZDV in combination with either single-dose nevirapine[16–19] or 3 doses of nevirapine in the first week of life[20] or the dual combination of ZDV and lamivudine.[21–24]

When making decisions to use combination antiretroviral drugs, consultation with a pediatrician experienced in the care of children with HIV infection or the National Clinician Consultation Center (https://nccc.ucsf.edu/clinician-consultation/perinatal-hiv-aids/) is beneficial. Monitoring for hematologic toxicity is necessary for any combination of ZDV and lamivudine compared to ZDV alone. Long-lasting resistance is possible if the infant is already infected when prophylaxis is given; this was most evident when nevirapine was used as a single agent for prophylaxis.[25] The HHS Panel on Treatment of Pregnant Women with HIV Infection and Prevention of Perinatal Transmission[15] and Panel on Antiretroviral Therapy and Medical Management of Children Living with HIV[26] each publish an extensive discussion of considerations for infant antiretroviral prophylaxis regimens for different clinical scenarios and provide specific neonatal antiretroviral dosing recommendations.

The administration of ZDV (possibly with other antiretroviral agents) to the infant should be initiated as soon as possible after birth and certainly within 6 to 12 hours after delivery.[27] If the infant's HIV exposure is first recognized between 12 and 48 hours after delivery, presumptive HIV therapy should be initiated in that time period.[15] Data from animal studies indicate that the longer the delay in institution of prophylaxis, the less likely that infection will be prevented. In most animal studies, antiretroviral prophylaxis initiated 24 to 36 hours after exposure is not as effective for preventing infection.[28–30]

The full course of drug supply needed for the entire 4 to 6 weeks should be supplied to the infant before discharge from the hospital irrespective of availability of out-of-pocket payment or insurance coverage because pediatric antiretroviral formulations are not widely available in commercial pharmacies.[15]

Avoidance of Postnatal HIV Infection

Postnatal transmission of HIV through ingestion of human milk from a mother with HIV infection is well documented, and prolonged breastfeeding from untreated mothers has resulted in rates as high as 9% to 15%.[31] However, studies in low-resource countries have revealed that maternal and/or infant antiretroviral drug administration during lactation reduces the risk of HIV transmission to the infant via human milk.[32,33] Because the risk of infant mortality from infectious diseases and malnutrition is low in the United States and effective alternative sources of feeding are readily available, women with HIV infection, including those receiving ART, should be counseled not to

breastfeed their infants or donate their milk.[34] Although maternal ART has been shown to reduce the concentration of cell-free HIV in human milk, it does not affect the amount of cell-associated virus in human milk.[35] In addition, discordance between the viral load in plasma and human milk has been observed. There is also differential penetration of antiretroviral drugs into human milk, with some antiretroviral drugs having concentrations in human milk that are higher than in maternal plasma, and others have lower or undetectable human milk concentrations.[36] These factors raise concerns about infant drug toxicity and the potential for selection of drug-resistant virus within human milk. Therefore, in the United States, where safe alternatives to breastfeeding are available, all women with HIV infection should avoid breastfeeding.[37]

Cultural differences require that counseling the mother about the avoidance of breastfeeding should be conducted in a sensitive manner. For some women, not being able to breastfeed may be the hardest component of their effort to protect their newborn infant from acquiring HIV infection.[37] Other mothers, particularly those who have emigrated from parts of the world where breastfeeding is nearly universal, may feel that formula feeding their infant discloses their own HIV infection to family or friends. As a result, recommendations to prevent perinatal transmission may not always be followed. Open, nonjudgmental communication about feeding practices facilitates appropriate follow-up and testing of all infants, including those whose mothers choose to breastfeed after appropriate counseling.[34] Education covering appropriate formula feeding and the cost of formula can be provided to women. Referrals, including enrollment in the Special Supplemental Nutrition Program for Women, Infants, and Children, are helpful in many cases. Evaluation of infant feeding practices with suggestions for safer feeding options and advice against premastication (the practice of prechewing solid food before feeding it to another), which is a potential risk factor for HIV transmission, are indicated.[38]

Framework for the Total Elimination of Perinatal Transmission of HIV

Several strategies have been documented that could potentially lead to the elimination of perinatal transmission of HIV. Early detection of HIV infection in the mother and evaluation and management of infants exposed to HIV remain the key to preventing perinatal transmission. This involves coordination of clinical care and social services, long-term follow-up of infants exposed to HIV, and ongoing HIV surveillance.[39] In many cases, early detection is not achieved because of social issues such as lack of access to mental, preventive, and general health care or substance use.[40,41] Interventions targeted to at-risk populations can minimize missed opportunities for the prevention of perinatal transmission of HIV. To be most effective, these efforts should be sustained and involve integrated clinical management and social services.[39]

CARE OF THE INFANT EXPOSED TO HIV

Testing to Determine the Infant's HIV Infection Status

Identification of the infant born to a mother with HIV infection and early determination of the presence or absence of HIV infection in the infant are critical to allow early initiation of prophylaxis or presumptive HIV therapy and provision of needed care. Appropriate HIV diagnostic testing for infants and children younger than 18 months differs from that for older children, adolescents, and adults. Passively transferred maternal HIV antibodies may be detectable in an exposed but uninfected infant's bloodstream until approximately 18 months of age. Therefore, routine serological testing of infants exposed to HIV and children before the age of 18 months is generally only informative if the test result is negative.

Polymerase chain reaction (PCR) assays that directly detect HIV DNA or RNA (generically referred to as HIV nucleic acid amplification tests [NAATs]) represent the gold standard for diagnostic testing of infants and young children younger than 18 months. With such testing, the diagnosis or the presumptive exclusion of HIV infection can be established within the first several weeks of life among nonbreastfed infants. Although neonatal antiretroviral drugs may decrease the concentration of HIV RNA in infant plasma in the first 6 weeks of life,[42] HIV DNA PCR results generally remain positive in most individuals taking ART who have undetectable plasma HIV RNA. The sensitivity of both DNA and RNA PCR testing is high,[43,44] so either can be used for the diagnosis of HIV infection in infancy.[45] False-positive results with low-level viral copy numbers have been described when using HIV RNA assays,[42,46,47] reinforcing the importance of repeating any positive assay result to confirm the diagnosis of HIV infection in infancy. False-negative results occur rarely, and retesting could be considered (perhaps by using a different test) if clinical findings suggest the presence of HIV infection.

Detection of Non–Subtype B HIV and HIV-2

For infants born to women known or suspected to have infection with non-B subtypes of HIV, use of HIV RNA assays may be preferable to the use of HIV DNA assays for diagnostic testing. Women who acquire HIV infection in

North America are most commonly infected with HIV subtype B.[48] Women who acquire HIV outside of North America are often infected with other HIV subtypes. Subtypes C and D predominate in southern and eastern Africa, subtype C predominates on the Indian subcontinent, and subtype E predominates in much of Southeast Asia.[48] HIV DNA PCR assays may be less sensitive in the detection of non-B subtype HIV, and false-negative HIV DNA PCR assay results have been reported in infants infected with non-B subtype HIV.[49,50] Some of the currently available HIV RNA assays have improved sensitivity for detection of non-B subtype HIV infection, although even these assays may not detect all non-B subtypes, such as the uncommon group O HIV strain. When testing infants suspected of infection with non-B subtype HIV, consultation with a pediatrician experienced in the care of infants and children with HIV infection is recommended.

HIV-2 is a retrovirus similar to HIV and is found most commonly in western Africa. It is less virulent, with a slower rate of progression of clinical disease and lower rates of perinatal transmission.[51] However, NAATs for HIV will not identify HIV-2, so if infection with HIV-2 is suspected, consultation with the CDC via the state department of health may be sought to help arrange specific HIV-2 testing.

Timing of Diagnostic Testing in Infants With Known Perinatal Exposure to HIV

For infants with known perinatal exposure, it is recommended that diagnostic testing with HIV DNA or RNA assays be performed at 14 to 21 days of age, and if results are negative, they should be repeated at 1 to 2 months of age and again at 4 to 6 months of age (Table 1).[52] For infants at a higher risk of perinatal HIV transmission who receive multiple antiretroviral drugs, additional virological diagnostic testing at birth as well as 2 to 4 weeks after cessation of antiretroviral prophylaxis should be considered.[12]

An HIV NAAT should be performed at birth or in the first few days of life for infants at highest risk of infection, including those whose mothers received no antiretroviral drugs during pregnancy, when maternal prophylaxis was started late in pregnancy or during labor, or if the mother had primary HIV infection during pregnancy. In the absence of maternal ART, as many as 30% to 40% of infants with HIV infection can be identified by 48 hours of age.[53,54] Infants with a positive NAAT result at or before 48 hours of age are considered to have in utero infection with HIV, whereas infants who have a negative NAAT result during the first week of life and a subsequent positive test result are considered to have intrapartum infection.[55] Cord blood specimens are not used for HIV RNA or DNA testing because they are associated with an unacceptably high rate of false-positive test results.

When a mother's HIV status is unknown at delivery or after birth, expedited HIV testing (preferably a combined test for HIV antigen and antibody) for mother and/or infant should be performed. In the event of a positive initial test result, presumptive HIV therapy is initiated in the infant as soon as possible pending the result of a supplemental test.[15] Treatment should be stopped if results of supplemental testing with HIV antibody and a NAAT are negative.

TABLE 1 Evaluation and Treatment of the Infant Exposed to HIV-1 (Birth to 18 Months of Age), in Addition to Routine Pediatric Care and Immunizations

Action[a]	Infant Age						
	Birth	14 d	4 wk	6 wk	8 wk	4 mo	12–18 mo
Antiretroviral prophylaxis or presumptive HIV therapy[b]	X	X	X	X	—	—	—
Recommend against breastfeeding and premastication	X	X	X	X	X	X	X
Hemoglobin or complete blood cell count	X	—	X[c]	—	X[c]	—	—
HIV-1 DNA or RNA PCR assay[d]	[e]	X[f]	X	—	[g]	X	—
Initiate PCP prophylaxis[h]	—	—	—	X	—	—	—
Antibody to HIV-1[i]	—	—	—	—	—	—	X

X, indication to conduct the specified action; —, not applicable.

[a] See the text for detailed discussion of each action. If during this period, HIV infection is diagnosed in the infant, laboratory monitoring and immunizations should follow guidelines for treatment of pediatric HIV infection.[52]

[b] Antiretroviral prophylaxis or presumptive HIV therapy, depending on the infant's risk of acquiring HIV (see text) is initiated as soon as possible after birth but certainly within 6–12 hours. ZDV prophylaxis is continued for 4–6 weeks, at which time it is stopped.

[c] Checked at 4 weeks by some experts and rechecked at 8 weeks if the week 4 hemoglobin level was significantly low.

[d] All infants exposed to HIV-1 should undergo virological testing for HIV-1 with HIV-1 DNA or RNA PCR assays at 14 to 21 days of age and, if results are negative, they should be repeated at 1 to 2 and 4 to 6 months of age to identify or exclude HIV-1 infection as early as possible. Any positive test result at any age is promptly repeated to confirm the diagnosis of HIV-1 infection.

[e] HIV-1 DNA or RNA PCR assay testing in the first few days of life allows identification of in utero infection and should be considered if maternal antiretroviral agents were not administered during pregnancy or in other high-risk situations. A negative test result at this age requires repeat testing to exclude HIV-1 infection.

[f] A negative test result at this age requires repeat testing to exclude HIV-1 infection. Presumptive uninfected indicates a negative NAAT result at ≥14 days and ≥4 weeks (1 month) of age; definitive uninfected indicates a negative NAAT result at ≥1 and ≥4 months of age (see text for complete details).

[g] For higher-risk infants, additional virological diagnostic testing should be considered 2 to 4 weeks after cessation of antiretroviral prophylaxis (ie, at 8–10 weeks of life).

[h] Infants with indeterminate HIV-1 infection status should receive prophylaxis starting at 4–6 weeks of age until they are deemed to be presumptively or definitively uninfected with HIV-1. Prophylaxis is not recommended for infants who meet criteria for presumptive or definitive lack of HIV-1 infection; therefore, a NAAT at 2 and 4–6 weeks of age allows for avoidance of PCP prophylaxis if both results are negative.

[i] Many experts confirm the absence of HIV-1 infection with a negative HIV-1 antibody assay result at 12–18 months of age.

If an HIV NAAT for the newborn infant was not performed shortly after birth, or if such test results were negative, diagnostic testing with an HIV NAAT is performed at 14 to 21 days of age because the diagnostic sensitivity of virological assays increases rapidly by 2 weeks of age.[53] This change in assay sensitivity reflects the biology of perinatal transmission, such that when HIV is acquired at the time of delivery, it may take up to 2 weeks for a NAAT to be able to detect the virus.[55] Therefore, negative results of HIV DNA PCR or RNA tests performed before 14 days of age are less helpful in excluding HIV infection acquired at the time of birth than are results of tests performed at or after 14 days of age.

Management if an HIV Virological Test Result Is Positive

If any of the HIV NAAT results are positive, an immediate repeat HIV NAAT is recommended to confirm the diagnosis of HIV infection. A diagnosis of HIV infection can be made on the basis of 2 separate blood samples, each of which is positive for HIV DNA or RNA. If infection is confirmed, a pediatric HIV specialist should be consulted for advice regarding ART and care. HIV disease can progress rapidly in infants with HIV infection, and neither $CD4^+$ T-lymphocyte count nor HIV RNA copy number is a reliable predictor of the risk of disease progression in infants.[53]

Interpretation of Negative HIV Test Results

On the basis of analysis of HIV DNA or RNA assay results from multiple studies, the CDC has revised the case definition for exclusion of HIV infection in infants for surveillance purposes.[56] The definitions supplied here are based on the CDC surveillance definitions and are appropriate for the management of children born to women with HIV infection. These definitions of exclusion of HIV infection are only for use in infants who do not meet the criteria for HIV infection noted above.[52]

In nonbreastfeeding infants younger than 18 months with no positive HIV NAAT results, presumptive exclusion of HIV infection is based on the following:

- two negative HIV RNA or DNA NAAT results, from separate specimens, both of which were obtained at ≥2 weeks of age and 1 of which was obtained at ≥4 weeks of age; or
- one negative HIV RNA or DNA NAAT result from a specimen obtained at ≥8 weeks of age; or
- one negative HIV antibody test result obtained at ≥6 months of age.

Definitive exclusion of HIV infection in a nonbreastfed infant is based on the following:

- two or more negative HIV RNA or DNA NAAT results, with 1 negative result at age ≥1 month and 1 negative result at age ≥4 months; or
- two negative HIV antibody test results from separate specimens obtained at age ≥6 months.

In the unusual case of an infant with a positive HIV NAAT result followed by a negative NAAT result, an expert in the care of children with HIV infection can be consulted for further testing recommendations.

Many experts confirm the absence of HIV infection with a negative HIV antibody assay result at 12 to 18 months of age (see next section). For both presumptive and definitive exclusion of infection, the child should have no other laboratory (eg, no positive NAAT results) or clinical (eg, no AIDS-defining conditions) evidence of HIV infection. For infants who have been breastfed, a similar testing algorithm can be followed, with additional testing every 3 months during breastfeeding followed by monitoring at 4 to 6 weeks, 3 months, and 6 months after breastfeeding cessation.[52]

Role of HIV Antibody Testing in Infants Exposed to HIV

In infants exposed to HIV who are not infected with HIV, maternal HIV antibodies transferred in utero may persist through 18 months of age. Loss of HIV antibody in an infant with previously negative HIV NAAT results (seroreversion) definitively confirms that the infant is not infected with HIV. Many infants exposed to HIV serorevert to HIV antibody negativity by 12 months of age.[57] Many experts confirm the absence of HIV infection with a negative HIV antibody assay result at 12 to 18 months of age. If an infant exposed to HIV who is not known to be infected is tested at 12 months of age and is still antibody-positive, then testing should be repeated at 18 to 24 months of age. Performing the first antibody test at 18 months of age to confirm seroreversion may avoid the cost and pain of performing 2 tests. Positive HIV antibodies at 24 months of age or older may indicate HIV infection and should be confirmed with an HIV virological test.[26] A confirmed NAAT result at or beyond 24 months of age in an infant with infection previously excluded as outlined above suggests that the infant was infected after infancy, such as through breastfeeding, premastication of solid food by a caregiver with HIV infection,[34] or sexual abuse.

Prevention of *Pneumocystis jirovecii* Pneumonia

The most common severe opportunistic infection in infants and children with HIV infection is *Pneumocystis jirovecii* pneumonia (PCP). PCP incidence in untreated infants with HIV is highest during the first year of life, with cases peaking at 3 to 6 months of age.[58,59] Chemoprophylaxis is highly effective in the prevention of PCP and should be administered to infants in whom HIV infection is diagnosed from 4 to

6 weeks of age until their first birthday. Thereafter, the need for prophylaxis is based on age-specific $CD4^+$ T-lymphocyte counts and/or percentages.[60] Trimethoprim-sulfamethoxazole is the most common drug used for prophylaxis because of its high efficacy, relative safety, low cost, and broad antimicrobial spectrum[60] (for further discussion, see ref 60).

PCP prophylaxis is not recommended for infants with presumptive lack of HIV infection (see previous section) but should be initiated for infants with indeterminate HIV infection status starting at 4 to 6 weeks of age.[60] Thus, for infants with negative HIV NAAT results at 2 and 4 to 6 weeks of age (presumptively not infected with HIV), PCP prophylaxis can be avoided completely. For an infant exposed to HIV with indeterminate HIV infection status who initiated prophylaxis at 4 to 6 weeks of age and subsequently meets criteria for presumptive or definitive lack of HIV infection, PCP prophylaxis can be stopped.

Prevention of Tuberculosis

Increased risk of tuberculosis (TB) among adults living with HIV infection is well documented. Because infants and children with TB infection and disease are usually infected by an adult with whom they live and have daily contact, TB infection status information should be obtained about the mother and all other household contacts of infants born to mothers with HIV. Bacille Calmette-Guerin immunization is not recommended for infants born to women with HIV infection in the United States and should not be administered to infants and children with known HIV infection because of its potential to cause disseminated disease.[61]

If an infant is exposed to anyone with active TB, the infant should be evaluated for TB disease and managed according to published guidelines.[61] If the infant's mother or any other person in the family receives a diagnosis of acid-fast bacillus smear-positive TB, the infant should be separated from that person until the TB infection has been treated with anti-TB medications and a physician has determined that the person is no longer contagious. In the event that a pregnant woman has documented TB that can be spread by the hematogenous route, the infant should be evaluated for congenital TB by a pediatric infectious disease expert.

Immunizations

Each year, the CDC publishes immunization schedules for children and adolescents 0 to 18 years of age[62] as well as for children with HIV infection.[63] All routine infant immunizations should be given to infants exposed to HIV. If HIV infection is confirmed in an infant exposed to HIV, then guidelines for the child with HIV infection should be followed.[62,63]

Monitoring for Toxicity From In Utero and Neonatal Antiretroviral Drug Exposure

Monitoring for and Management of Short-term Toxicity During Infant Antiretroviral Prophylaxis

Because exposure to maternal antiretroviral drugs taken during pregnancy can cause small but apparent variations of hemoglobin and neutrophil counts, a baseline complete blood cell and differential count has been recommended for the newborn infant.[64] The risk of anemia and neutropenia is greater in infants whose mothers received ART during pregnancy, but mild anemia was also observed commonly in infants whose mothers received ZDV monotherapy compared with infants whose mothers received no antiretroviral drugs during pregnancy.[65] Nonetheless, the advantages of maternal ART for prevention of perinatal transmission are far greater than hematologic toxicity in the newborn infant.[66,67]

The 6-week ZDV regimen in infants can cause anemia, which largely remains clinically insignificant and generally resolves after termination of ZDV prophylaxis. If anemia persists even after stopping the ZDV regimen, alternative etiologies are likely responsible. Anemia can be severe in infants taking ZDV who were born prematurely or with other medical problems. Also, administration of ZDV in combination with other antiretroviral drugs can cause hematologic toxicity.[68] The timing of monitoring of hematologic toxicity from ZDV prophylaxis depends on many factors such as baseline hematologic values, gestational age at birth, clinical condition of the child, receipt of concomitant medications, and maternal antepartum therapy. Hemoglobin and neutrophil counts should be measured in infants who have taken ZDV- and/or lamivudine-containing antiretroviral regimens for 4 or more weeks.

The decision of whether to discontinue antiretroviral prophylaxis early because of identification of hematologic abnormalities is made on the basis of factors such as severity of the laboratory abnormality, associated clinical symptoms, duration of infant prophylaxis already received, the magnitude of the risk of HIV infection in the infant (as assessed by maternal receipt of ART, maternal viral load near delivery, and mode of delivery), and availability of alternative interventions (eg, red blood cell transfusion) in consultation with a pediatric HIV specialist.

Routine measurement of serum lactate concentration in asymptomatic neonates to screen for possible mitochondrial toxicity related to ZDV prophylaxis is not recommended because the clinical relevance of increased lactate concentrations in the absence of symptoms is unknown, transient elevations return to normal, and there is poor predictive value for later appearance of symptomatic

toxicity.[69,70] However, if severe clinical symptoms, particularly neurologic symptoms, develop in the infant, a serum lactate concentration should be obtained. If the serum lactate concentration is significantly elevated in an infant with compatible clinical symptoms, a pediatric HIV expert can help determine if antiretroviral prophylaxis should be terminated. In general, prophylaxis should continue unless there is a compelling reason to stop.

Long-term Toxicity

Research has not revealed significant risk of neoplasia or organ-system toxicities from in utero exposure to ZDV or other antiretroviral drugs.[71] The issue of mitochondrial dysfunction from the use of ART has been unsubstantiated[69] but remains under investigation. However, in children exposed to HIV with severe clinical symptoms, neurologic or cardiac in particular, mitochondrial dysfunction is part of the differential diagnosis in HIV infection.[70,72–77]

Information regarding in utero and/or neonatal antiretroviral exposure is an important part of a permanent record, particularly in uninfected children. Uninfected children perinatally exposed to HIV have been found to have a higher rate of childhood infections in the first year of life than unexposed children and benefit from regular medical care.[78,79] Yearly follow-up into adulthood to monitor for long-term toxicity such as cancer or neurodevelopmental or metabolic disorders is appropriate.[71]

Testing Family Members

HIV screening should be recommended and offered to all immediate family members with unknown HIV infection status; this should be performed with the mother's consent to include the infant's father and/or mother's sexual partners. All siblings of the infant exposed to HIV, regardless of age of the siblings, should be tested because it is possible, albeit unusual, for perinatally infected children to remain asymptomatic into adolescence.[80,81]

Counseling and Support

An HIV diagnosis can have a significant impact on an individual and his or her family. When counseling the mother of an infant exposed to HIV, exploring whether HIV infection was recently diagnosed in the mother during or after pregnancy and whether she needs a referral for her own care may contribute to care of the whole family. Additionally, some families may require support related to an HIV-associated illness or death in other family members.

Increased need for social and psychological support services may result from factors including economic hardship, substance use, depression, social isolation, lack of health care, unemployment, difficulty in finding housing, or domestic violence. In addition, fear of loss of existing supports and services, such as loss of support from a partner or loss of employment, insurance, or health care coverage are important considerations.[82–84] Particularly vulnerable are pregnant adolescents with HIV infection.[85]

Additional factors may be present for women who have emigrated from other countries, in particular factors related to culture and concerns about immigration status. This population may have been subject to or know of stigmatization and discrimination against people with HIV infection. In addition, distrust or misunderstanding of the US medical system may complicate care and follow-up of the infant.

An outline of plans for medical care for the infant will help new parents, foster parents, or other caregivers optimally care for their infant exposed to HIV. Important topics include adherence to medications to prevent perinatal transmission of HIV and prompt assessment of illness in the infant exposed to HIV as well as the schedule of follow-up visits for assessment and laboratory assays (both for diagnosis of HIV infection and to check for any adverse effects of antiretroviral exposure). Breastfeeding is not recommended even if mothers are receiving ART for their own HIV disease.[37]

Counseling should include education about the risks of HIV transmission, including the lack of transmission risk in family activities such as eating, bathing, or sleeping together. Planning regarding future reproductive plans for the family, likely in collaboration with the family's adult HIV and gynecologic and obstetric providers, can minimize the risk of HIV acquisition for sexual partners and perinatal transmission in future pregnancies.

Confidentiality should be maintained at all times. In some cases, one or more family members may not be aware of the HIV infection status of the mother, which warrants extra caution in the labor and delivery unit and when discussing the postpartum management of the infant or in the pediatric office when discussing care of the child.

HIV Exposure and Infection Status Reporting

Name-based HIV reporting to state health departments is required in all states and territories for surveillance purposes.[86] In addition, many states require reporting pregnancy in women living with HIV and the infection status of their infants. To facilitate the required reporting, even when reporting is delegated to another party, the pediatrician should collect the maternal antiretroviral treatment history, maternal demographics, labor and delivery record, and newborn records at the time of birth.

SUMMARY (SEE TABLE 1)

1. Whenever possible, maternal HIV infection should be identified before or during pregnancy, which allows earlier initiation of care for the woman and for more effective interventions to prevent perinatal transmission. The AAP recommends documented, routine HIV testing for all pregnant women in the United States after notifying the patient that testing will be performed, unless the patient declines HIV testing (opt-out consent or right of refusal). All HIV testing, including during the third trimester, should be performed in a manner consistent with state and local laws.
2. If the mother's HIV serostatus is unknown at the time of labor or birth, the newborn infant's health care provider should perform expedited HIV antibody testing on the mother or the newborn infant or antigen/antibody testing on the mother, with appropriate consent consistent with state and local laws. The results should be reported to health care providers quickly enough to allow effective antiretroviral prophylaxis to be administered to the infant as soon as possible after birth and certainly within 6 to 12 hours after birth.
3. Intravenous ZDV for the mother and presumptive HIV therapy for the newborn infant should be administered promptly on the basis of a positive rapid antibody or antigen/antibody test result without waiting for the results of supplemental HIV testing, and breastfeeding should not be initiated. If the rapid test result is positive, supplemental testing should be performed, and if supplemental test results are negative (indicating that the infant was not truly exposed to HIV), then antiretroviral drugs should be stopped and breastfeeding can be initiated.
4. Avoidance of breastfeeding has been and continues to be a standard, strong recommendation for women living with HIV in the United States because maternal ART dramatically reduces but does not eliminate breast milk transmission, and safe infant feeding alternatives are readily available in the United States.
5. Pediatricians should provide counseling to parents and caregivers of infants exposed to HIV about HIV infection, including routine care of the infant, diagnostic tests, and potential drug toxicities.
6. All infants exposed to HIV should undergo virological testing with HIV DNA, RNA, or total nucleic acid assays at 14 to 21 days of age. If results are negative, these tests should be repeated at 1 to 2 and 4 to 6 months of age to identify or exclude HIV infection as early as possible. If any test result is positive, the test should be repeated immediately for confirmation.
7. Initial testing in the first few days of life allows identification of in utero infection and should be considered if maternal antiretroviral drugs were not administered during pregnancy or in other high-risk situations (see text). If an HIV NAAT for the newborn infant was not performed shortly after birth, or if such test results were negative, diagnostic testing with an HIV NAAT is performed at 14 to 21 days of age because the diagnostic sensitivity of virological assays increases rapidly by 2 weeks of age.
8. For nonbreastfeeding infants and children younger than 18 months with no positive HIV virological test results, presumptive exclusion of HIV infection is based on 2 negative HIV RNA or DNA NAAT results from separate specimens, both of which were obtained at $\geq$2 weeks of age and 1 of which was obtained at $\geq$4 weeks of age, 1 negative HIV RNA or DNA NAAT result obtained at $\geq$8 weeks of age, or 1 negative HIV antibody test result obtained at $\geq$6 months of age.
9. Definitive exclusion of HIV infection in a nonbreastfed infant is based on 2 or more negative HIV RNA or DNA test results, with 1 negative result at age $\geq$1 month and 1 negative result at age $\geq$4 months, or 2 negative HIV antibody test results from separate specimens obtained at age $\geq$6 months.
10. Many experts confirm the absence of HIV infection with a negative HIV antibody assay result at 12 to 24 months of age. These laboratory tests can only be used to exclude HIV infection if there is no other laboratory or clinical evidence of HIV infection (ie, no subsequent positive results from NAATs if tests were performed and no AIDS-defining condition for which there is no other underlying condition of immunosuppression) and the child is not receiving antiretroviral drugs.
11. PCP prophylaxis is not recommended for infants who are presumptively or definitively not infected with HIV (see recommendations 9 and 10). Infants with indeterminate HIV infection status after 6 weeks of age should receive prophylaxis until they are determined presumptively or definitively not to be infected with HIV.
12. All infants exposed to antiretroviral agents in utero or

as newborn infants should be monitored for short- and long-term drug toxicity.

13. Immunizations and TB screening should be provided for infants exposed to HIV in accordance with published guidelines. A BCG vaccine should not be administered to infants in whom HIV infection is diagnosed.
14. HIV testing should be offered and recommended to immediate family members of infants exposed to HIV.
15. The practitioner providing care for an infant with HIV infection should consult with a pediatric HIV specialist. An alternative service for advice on prevention of perinatal HIV transmission or HIV management is the National Clinician Consultation Center (https://nccc.ucsf.edu/clinician-consultation/perinatal-hiv-aids/). If the infant's mother is an adolescent, consultation with a practitioner familiar with the care of adolescents is advised.

Executive Summary: Identification, Evaluation, and Management of Children With Autism Spectrum Disorder

- *Clinical Report*

CLINICAL REPORT Guidance for the Clinician in Rendering Pediatric Care

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Executive Summary: Identification, Evaluation, and Management of Children With Autism Spectrum Disorder

Susan L. Hyman, MD, FAAP,[a] Susan E. Levy, MD, MPH, FAAP,[b] Scott M. Myers, MD, FAAP,[c] COUNCIL ON CHILDREN WITH DISABILITIES, SECTION ON DEVELOPMENTAL AND BEHAVIORAL PEDIATRICS

INTRODUCTION

Autism spectrum disorder (ASD) is a common neurodevelopmental disorder with reported prevalence in the United States of 1 in 59 children (approximately 1.7%). ASD significantly influences the lives of affected children and families because they may need extensive behavioral, educational, health, and other services. Primary care providers play a critical role in identifying, diagnosing, and managing ASD in children and providing support for their families. This document provides a summary of the clinical report "Identification, Evaluation, and Management of Children with Autism Spectrum Disorder," published concurrently in the online version of *Pediatrics*. In the years since 2007, when the American Academy of Pediatrics published the clinical reports "Identification and Diagnosis of Children with Autism Spectrum Disorders" and "Management of Children with Autism Spectrum Disorders," reported prevalence rates of children with ASD have increased, understanding of potential risk factors has expanded, awareness of co-occurring medical and behavioral conditions and genetic contribution to etiology has improved, and the body of research supporting evidence-based interventions has grown substantially. The updated document discusses evaluation and treatment as a continuum in 1 publication with a table of contents to help the reader identify topic areas within the report. ASD is more commonly diagnosed than in the past, and the significant health, educational, and social needs of individuals with ASD and their families constitute an area of critical need for resources, research, and professional education.

[a]Golisano Children's Hospital, University of Rochester, Rochester, New York; [b]Children's Hospital of Philadelphia, Philadelphia, Pennsylvania; and [c]Geisinger Autism & Developmental Medicine Institute, Danville, Pennsylvania

Drs Hyman and Myers participated in the planning for this manuscript and writing and editing the manuscript; Dr Levy participated in writing and editing the manuscript; and all authors approved the final manuscript as submitted.

Clinical reports from the American Academy of Pediatrics benefit from expertise and resources of liaisons and internal (AAP) and external reviewers. However, clinical reports from the American Academy of Pediatrics may not reflect the views of the liaisons or the organizations or government agencies that they represent.

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

All clinical reports from the American Academy of Pediatrics automatically expire 5 years after publication unless reaffirmed, revised, or retired at or before that time.

1. TIMELY DIAGNOSIS, EARLY IDENTIFICATION, AND EVIDENCE-BASED INTERVENTION

- *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) diagnosis: With the publication of the DSM-5 in 2013, there is a single category of ASD, replacing the subtypes of autistic disorder, Asperger syndrome, and pervasive developmental disorder not otherwise specified in the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision*. Core deficits are identified in 2 domains: social communication and interaction and restrictive, repetitive patterns of behavior. The DSM-5 recognizes that other co-occurring conditions like intellectual disability, language disorders, and behavioral health conditions such as attention-deficit/hyperactivity disorder and anxiety disorders may also be diagnosed in individuals with ASD. A diagnosis of ASD is made by a clinical evaluation that supports the DSM-5 criteria, including history and observation of characteristic behaviors, preferably using standardized approaches. Independent of age, a child who is evaluated for ASD should have standardized assessment of psychoeducational, adaptive, and language abilities, including pragmatic or social language.
- Early identification: General developmental screening using a validated tool continues to be recommended at 9, 18, and 30 months of age. ASD is common, can be diagnosed as young as 18 months of age, and has evidence-based interventions. Research into newer tools has promise to extend the age of diagnosis lower. Therefore, ongoing developmental and behavioral surveillance in addition to screening for ASD at 18 and 24 months of age continues to be recommended in primary care. Screening or surveillance may take place in other settings, with communication of findings to the primary care provider. More accurate and culturally sensitive screening approaches are needed. Ongoing developmental surveillance through school age is important. Children with typical intellectual abilities may not be diagnosed until their social differences become evident with the increased demands of the school environment. Clinicians need to recognize that some children will be at increased risk for ASD because they have a sibling with ASD, were born preterm, were exposed to teratogens (eg, valproic acid), or have other risk factors.
- Timely diagnosis: Toddlers and children should be referred for diagnostic evaluation when increased risk for developmental disorders (including ASD) is identified through screening and/or surveillance. Most children with ASD will have other developmental issues. Standard of care requires evaluation of multiple streams of development, including cognitive, communication, motor, and adaptive skills. In many settings, this evaluation may be best accomplished by team evaluations, including, for example, psychology, speech and language, occupational therapy, physical therapy, and special education. This type of evaluation may occur through an early intervention program, school system, or appropriate insurance-funded evaluator(s) whenever ASD, with or without other delays, is suspected. Children should be referred for intervention for all identified developmental delays at the time of identification and not wait for an ASD diagnostic evaluation to take place. The referral should be to a clinician experienced in diagnosis, which might be a developmental-behavioral or neurodevelopmental pediatrician, neurologist, psychiatrist, psychologist, or primary care provider with requisite training. Clinicians should be particularly aware of the potential for delayed diagnosis in children from underserved groups and whose families speak languages other than English.
- Early and effective intervention: Clinicians should respond appropriately to family or clinical concerns and results of screening to avoid delays in diagnosis and treatment. Intervention for the communicative, adaptive, and behavioral deficits associated with ASD should take place as soon as the need becomes evident. Intervention is most effective if it is early, intense, and involves the family. Research has demonstrated that interventions using principles of behavioral intervention are associated with skill acquisition and improved outcome. There is evidence that training parents to support developmental skill building is helpful. Primary care providers should help families learn to interpret evidence about interventions so they can make informed decisions about their child's care. Many interventions, including many nutritional interventions, do not have evidence to support their use at this time. Families should be referred to community support resources and be included in the shared decision-making process.
- Etiologic evaluation: The pediatric provider needs to consider genetic and neurologic disorders that are associated with ASD. Knowledge of the etiology of the child's condition can help guide monitoring for co-occurring conditions, potentially influence therapy choices, help families understand recurrence risk estimates, and help therapists provide individualized behavioral, educational, motor, and communication intervention plans.

Families should be offered genetic evaluation, including chromosomal microarray and fragile X testing, with consideration of other cytogenetic and molecular testing, as indicated. Consultation with a pediatric geneticist may be warranted. Metabolic testing, EEG, neuroimaging, and additional workup of medical symptoms are guided by history and physical examination.

- Medical management of co-occurring conditions: The value of routine primary care visits and anticipatory guidance for children with chronic conditions is stressed. The primary care provider should be aware of common co-occurring conditions and include surveillance for and management of these conditions in the context of routine care with subspecialty referral, as appropriate. Examples of common co-occurring conditions are disorders of sleep, feeding problems, gastrointestinal symptoms, obesity, seizures, attention-deficit/hyperactivity disorder, anxiety, wandering or elopement, and others.

High-quality pediatric care calls for the development of systems to promote accurate and early identification, cost-effective and timely diagnosis, prompt implementation of evidence-based interventions, involvement of the patient and family in shared decision-making, and steps toward elimination of disparities in access to care for all children and youth with ASD. Care within a medical home, using a chronic care model in which health and community systems interact with informed patients and families to ensure more-satisfactory outcomes, is recommended for children with ASD.

2. COLLABORATION OF SYSTEMS OF CARE

- Evidence-based interventions*:* Children and youth with ASD should be provided evidence-based interventions to address the core social communication and interaction and restricted and repetitive behavior symptoms as well as associated impairments. Attention to social skills development should be addressed in school, community, behavioral health, and family settings. The primary care provider should be aware of the recommendation for educational services in the least-restrictive environment and the hierarchy of educational interventions based on a student's needs in school rather than a medical diagnosis of ASD.
- Common co-occurring conditions: Although ASD is a neurodevelopmental disorder characterized by symptoms related to social interaction and repetitive behaviors, there is increasing awareness that physical, behavioral, and mental symptoms affect the care of children and youth with ASD. Children and youth with ASD should have anticipatory guidance for common co-occurring conditions in the context of well-child care, referral as necessary for specialty care, and ongoing management as possible in the medical home.
- Behavioral health interventions*:* Providers should be aware of the common behavioral challenges faced by children and youth with ASD and be prepared to provide parent counseling and initial management of sleep problems, food refusal, and disruptive behaviors, with referral to appropriate specialty and mental health care if needed. It is important to evaluate the medical and behavioral causes for behavior change. Pain and discomfort from medical conditions and behavioral modifications should be addressed. Medication may be a useful addition for management of attention, hyperactivity, anxiety, and disruptive behaviors as part of an overall treatment strategy.
- Community services*:* The primary care provider needs to know where to refer families for information about community services, such as respite and leisure activities for individuals with ASD and other developmental disabilities. To promote wellness, communities should provide opportunities for individuals with ASD to participate in inclusive and appropriate active leisure activities. Clinicians should educate families about managing ASD as a chronic condition.

3. PLANNING FOR ADOLESCENCE AND TRANSITION TO ADULT SYSTEMS OF CARE

- Communities should build services to promote social skills appropriate for work and postsecondary education, access to appropriate medical and behavioral health services, job skills development, and community leisure opportunities. The medical home provider should support the family and youth to advocate for appropriate postsecondary work or schooling, residential supports, and activities to maintain a healthy lifestyle. The family needs to plan for the needs of the child in adulthood by making the necessary preparations for public programs (such as Supplemental Security Income) and personal financial planning.
- Pediatricians need to engage with families and youth to plan a transition to adult medical and behavioral health care.

4. PROMOTING SHARED DECISION-MAKING WITH INDIVIDUALS WITH ASD AND THEIR FAMILIES

Shared decision-making calls for the health care provider to engage in respectful, reciprocal dialogue to plan and monitor choices in care. The pediatrician can help educate youth

with ASD and their families about how to evaluate the evidence for interventions, advocate for participation in clinical research when appropriate, refer families to support organizations, include the patient in decision-making, and prepare families to navigate transitions.

5. ONGOING EDUCATION OF PEDIATRIC PROVIDERS TO SUPPORT AN INFORMED MEDICAL HOME FOR CHILDREN AND YOUTH WITH ASD

All children and youth with ASD should have a medical home, a source of care that is accessible, collaborative, culturally sensitive, knowledgeable, and cost-effective. To best serve patients and families affected by ASD, the clinician caring for children and youth with ASD should be familiar with issues related to diagnosis, co-occurring medical and behavioral conditions, and the impact of ASD on the family to provide a medical home for these patients. Actively addressing capacity building to care for children and youth with ASD requires initiatives directed at provider education and practice quality improvement and public health, educational, and social programs to support families in their journey from diagnosis to service provision to the transition to adult care.

6. SUPPORT FOR A NATIONAL AGENDA FOR BASIC, CLINICAL, AND HEALTH SERVICES RESEARCH ABOUT ASD

The American Academy of Pediatrics supports the current approach taken by the Interagency Autism Coordinating Committee of the National Institutes of Health of including representative stakeholders in planning a meaningful research agenda. Stakeholders include families and affected individuals, scientists, clinicians, and public health agencies. This committee's 2009 strategic plan, updated in 2017, identified 7 areas for research funding: (1) early detection, (2) underlying biology, (3) genetic and environmental risk factors, (4) treatments and interventions, (5) services and implementation science, (6) life span services and supports, and (7) epidemiological surveillance and infrastructure. It is important that multiple levels of inquiry be pursued simultaneously to inform evidence-based clinical care. These include the following:

- o basic and translational science in the areas of genetics and epigenetics, neurobiology, environmental risk factors, and psychopharmacology to understand the typical and atypical brain development and function to develop ASD-specific behavioral and pharmacologic therapies;
- o clinical trials to test focused interventions informed by translational studies to provide the evidence necessary for community implementation;
- o epidemiological surveillance to gather data important for planning for current and future needs, including screening, diagnosis, and life span health and mental health services, with special attention to underserved populations; and
- o health services research to provide guidance for comprehensive, accessible, and culturally appropriate medical, educational, and behavioral care for children, youth, adults, and families affected by ASD.

Research in all of these areas is critical to move forward with early diagnosis, effective treatment, and evidence-based interventions at each age. To provide appropriate care to all children and families affected by ASD, organizations responsible for health, education, social services, and public health need to collaborate and build integrated and adequately funded and staffed systems. The pediatric health care provider plays a critical role in identifying young children at risk for ASD; shepherding these children through diagnosis and into effective interventions; supporting the families, including siblings; anticipating and managing co-occurring health and behavioral disorders; and preparing the youth and family for transition to adult services. The updated clinical report provides the health care provider with information and resources to support the care of the child and family affected by ASD.

FINANCIAL DISCLOSURE: The authors have indicated they have no financial relationships relevant to this article to disclose.

FUNDING: No external funding.

POTENTIAL CONFLICT OF INTEREST: MeMix LLC is a company that makes an app (for phones). Dr Levy is on the advisory board for the app's development. This app is being developed to assist in nutritional and dietary management of children with autism. Dr Levy has not received any money yet from this company. This app is the focus of a National Institutes of Health R21 grant, for which Dr Levy is funded for ∼2% of her salary. Once it is studied and marketed (if appropriate), Dr Levy will (possibly in the future) earn some money. Dr Levy has worked with MeMix LLC from 2015 to the present. Dr Hyman is the site principal investigator of a clinical trial of a novel agent being tested to promote social function in patients with autism. The University of Rochester (Dr Hyman's institution) was 1 of >40 sites and had 2 study participants in 2018. University of Rochester will be leaving the trial in 2019 (withdrawal submitted) because of staffing, and that reimbursement for staff time does not cover the cost of participation. Funding was for the staff to complete the assessments required for the clinical trial. Dr Hyman got no personal reimbursement from the company; the funding was for staff time for recruitment and assessment and clinical research center support for the trial. Dr Myers has indicated he has no potential conflicts of interest to disclose.

Fertility Preservation for Pediatric and Adolescent Patients With Cancer: Medical and Ethical Considerations

Fertility Preservation for Pediatric and Adolescent Patients With Cancer: Medical and Ethical Considerations

Sigal Klipstein, MD, FACOG,[a,b] Mary E. Fallat, MD, FAAP,[c] Stephanie Savelli, MD, FAAP,[d] COMMITTEE ON BIOETHICS, SECTION ON HEMATOLOGY/ONCOLOGY, SECTION ON SURGERY

Many cancers presenting in children and adolescents are curable with surgery, chemotherapy, and/or radiotherapy. Potential adverse consequences of treatment include sterility, infertility, or subfertility as a result of gonad removal, damage to germ cells as a result of adjuvant therapy, or damage to the pituitary and hypothalamus or uterus as a result of irradiation. In recent years, treatment of solid tumors and hematologic malignancies has been modified in an attempt to reduce damage to the gonadal axis. Simultaneously, advances in assisted reproductive technology have led to new possibilities for the prevention and treatment of infertility. This clinical report reviews the medical aspects and ethical considerations that arise when considering fertility preservation in pediatric and adolescent patients with cancer.

INTRODUCTION

Childhood cancer affects 1 of every 285 children younger than 20 years in the United States. Because of advances in treatment, survival has steadily increased since the 1970s. With increasing survival rates, there are currently more than 375 000 survivors of childhood cancer in the United States, with 70% of them being 20 years or older.[1,2] Improvements in prognosis and survival have been observed for many childhood cancers, including hematologic malignancies, Wilms tumor, malignant bone tumors, and rhabdomyosarcomas. The relative 5-year survival rate for all childhood cancers combined is 83.8%.[2]

With the improved survival rate of children affected by childhood cancer has come a growing population of adult survivors of childhood cancer who are or will be interested in having children. Past and contemporary treatments for childhood cancer, including chemotherapy, radiotherapy, and hematopoietic stem cell transplant, can affect future fertility. In the current era, many children and adolescents who present with a new cancer diagnosis can benefit from fertility-preserving modalities initiated

before cancer treatment. Individuals whose previous treatment of childhood cancer led to infertility or sterility can often benefit from fertility treatment options such as egg and sperm donation and gestational surrogacy.

Although not specifically addressed in this report, the same strategies of fertility preservation apply to children facing gonadotoxic therapies for treatment of nonmalignant diseases such as juvenile idiopathic arthritis and Fanconi anemia. Infertility resulting from the treatment of differences of sexual development and as a result of hormonal or surgical gender-affirming therapies for transgender individuals are beyond the scope of this document.

Although this document focuses on adolescents and young adults under the age of 18 years, many individuals who received a cancer diagnosis in childhood continue to be seen by their pediatric providers well into adulthood. As such, these guidelines are generalizable beyond the age of majority and apply to decision-making for adult survivors of childhood cancers as well. Complex ethical considerations arise when counseling families confronting a cancer diagnosis regarding fertility preservation options. The difficulty of such decision-making is often compounded by the frequently limited time available to make decisions that can affect fertility. The differences between male and female reproductive physiology affect the range of options available to boys and girls. Options in adolescents who have undergone puberty are broader than those in prepubertal children. The ideal time to consider fertility preservation is before the initiation of therapies that may decrease fertility or cause sterility, but this sometimes is not possible.

It is important for physicians who care for children who develop cancer or other diseases requiring treatment with gonadotoxic therapies to understand the potential deleterious effects of the various treatments on male and female fertility and to be familiar with the American Society of Clinical Oncology (ASCO) guidelines for fertility preservation in children. Recognizing the risks associated with both radiation and chemotherapy, the ASCO recommends that oncologists (1) use established methods of fertility preservation (semen cryopreservation and oocyte cryopreservation) for postpubertal minor children, with patient assent as appropriate, and parent or guardian consent; (2) present information on additional methods that are available for children but are still investigational; and (3) refer for experimental protocols when available.[3] Establishing relationships with centers and physicians who have expertise in counseling and treating children who may benefit from fertility preservation will help oncologists better streamline care for their patients who are interested in fertility preservation. Oncologists can refer families for consultation to discuss both the effects of therapy and potential fertility preservation options in a timely manner, as long as any delay will not negatively affect the success of their treatment. In so doing, they will prevent missed opportunities for information and interventions related to fertility care.

Recognizing that older adolescents and even young adults may develop cancers that fall under the umbrella of childhood malignancies, this clinical report will include options that may be more appropriate for the patient who is older than 18 years but is still being cared for in a children's hospital.

BACKGROUND

Infertility is defined as the inability to achieve or sustain a successful pregnancy after 12 months or more of regular unprotected intercourse. Earlier evaluation and treatment may be justified on the basis of medical history, such as anovulation or erectile dysfunction. For women 35 years and older, a fertility evaluation is recommended after 6 months of unsuccessful attempts at conception.[4] Although fertility declines with age for both men and women, this decline is much more profound in women. At age 40, half of women will have trouble conceiving. If in vitro fertilization (IVF) is required, the chance of pregnancy per cycle is only 13.9% in women at age 40 and under and 4% in women older than 42 years.[5] For men at age 45, the chance of achieving a pregnancy is much higher, and for these older men, the age of their female partner is the most significant determinant of outcome.[6] The risk of infertility after cancer treatment depends on the type of malignancy and its specific treatment as well as the age of the individual both at the time of diagnosis and at the time that they wish to initiate a pregnancy.[7] In men, treatments can lead to a complete absence of spermatogenesis, a decreased sperm count, or sexual dysfunction. In women, there can be a complete depletion of viable egg production or diminished ovarian reserve, leading to subfertility and a shortened fertile window. A hysterectomy or insult to the uterus may lead to the inability to gestate a pregnancy.

NORMAL PHYSIOLOGY AND FERTILITY POTENTIAL

Differences in the male and female reproductive systems influence available options for fertility after cancer treatment.[8,9] In general, there is a lack of proven options for preservation of fertility in prepubertal boys and girls. The process of spermatogenesis begins in the prepubertal boy, but the production of mature sperm and

steroidogenesis are functions of the adult testes.[10] Spermarche (the release of spermatozoa) is an early- to midpubertal event that precedes the ability to produce an ejaculate and is associated with age-appropriate gonadotropin production.[11,12] There is a large variation in the stage of maturity among 13- to 18-year-old males with respect to sperm production. Once sperm are present, sperm quality in young boys, as determined by a semen analysis, does not seem to be affected by patient age. At this point, sperm can be collected via masturbation, electrostimulation, or surgical sperm extraction, and sperm can then be cryopreserved for future use. It is important to note that not all pediatric centers have electroejaculation equipment available, and surgical extraction requires the expertise of a urologist experienced in this technique. Many boys will, therefore, require referral to a reproductive urologist for these services.[13,14]

In girls, oocyte production peaks in the fetus during midgestation, at which time approximately 6 to 7 million oogonia are present within the ovary. This number decreases to 2 million at birth and to approximately 300 000 at puberty.[15,16] Once menarche has been initiated, mature oocytes develop, and monthly ovulation occurs. At this point, fertility treatments can stimulate multiple eggs, which can be retrieved from the ovary and cryopreserved for later use.

RISK OF INFERTILITY AFTER TREATMENT

Most children treated for cancer can expect to be cured, although the specific chance of cure depends on risk factors at the time of diagnosis, including cancer type, stage, and grade. Although permanent infertility or sterility may occur after cancer treatment, individuals may experience temporary but reversible infertility, a shortened reproductive window, or no compromise in fertility. Many survivors of childhood cancer with intact fertility worry about the potential effects of previous cancer treatment on the health of their offspring.[17] Reassuringly, decades of cumulative experience have shown that naturally conceived biological children of survivors have no increased incidence of congenital malformations,[18–22] genetic or chromosomal anomalies,[23–25] or cancer compared with sibling controls and general population data.[26–33]

Risk of Infertility in the Male Patient After Cancer Treatment

Male fertility can be affected by impairment of spermatogenesis as a result of gonadotoxic chemotherapy, gonadotropin deficiency from central nervous system–directed therapy, or functional abnormalities of genitourinary organs caused by spinal or pelvic surgery and/or radiotherapy. Deleterious effects on testicular function have been observed with alkylating agents, such as cyclophosphamide, as evidenced by increased follicle-stimulating and luteinizing hormone concentrations, indicating decreasing gonadal function.[34–36]

In a large cohort study, the St Jude Lifetime Cohort Study, testicular function was evaluated by using a semen analysis. The investigators performed a semen analysis on 214 adult male survivors of childhood cancer, all of whom had received alkylating agents without radiotherapy. Azoospermia was noted in 25%, oligospermia was noted in 28%, and normospermia was noted in 48%. Importantly, there was no identified threshold dose below which azoospermia did not occur or one above which azoospermia was uniformly present.[37]

Several large studies, including the Childhood Cancer Survivor Study (CCSS),[38,39] have evaluated the fertility outcome of survivors of childhood cancer. The most recent cohort study included almost 11 000 survivors not exposed to gonadal or cranial radiotherapy and more than 3900 sibling controls. On the basis of self-reported data, it was found that male survivors had a decreased likelihood of fathering a pregnancy compared with a sibling control group.[40] This finding confirmed results from an earlier CCSS study showing that among male patients, risk factors for impaired fertility included increasing alkylating-agent exposures and higher testicular radiation doses (Tables 1 and 2). These studies are important in counseling because although increasing chemotherapy and radiation doses are associated with a higher chance of infertility, there is no dose so low as to guarantee the maintenance of fertility and no dose so high that infertility is certain to occur.

Risk of Infertility in the Female Patient After Cancer Treatment

TABLE 2 Childhood Cancer Therapy Affecting Reproductive Tissues

	Reproductive Effect	Predisposing Therapy	Modifying Factors
Sex			
Both	Altered pubertal timing (precocious, early, rapid tempo), delayed puberty, gonadotropin insufficiency or deficiency	Hypothalamic-pituitary radiation	Altered pubertal timing more common after low-dose radiation at 18–24 Gy, gonadotropin insufficiency more common after radiation at more than 30 Gy
Female	Acute ovarian failure (ovarian failure within 5 y of diagnosis), premature menopause (cessation of menses before age 40 y)	Alkylating-agent chemotherapy, radiation affecting the female reproductive system (whole abdomen, pelvis, lumbosacral spine, total body), oophorectomy	Older age at treatment due at higher risk
	Uterine vascular insufficiency, uterine growth impairment	Radiation affecting the uterus (whole abdomen, pelvis, lumbosacral spine, total body)	History of Wilms tumor and associated Müllerian anomalies
	Vaginal fibrosis or stenosis	Radiation affecting the vagina	History of hypogonadism (estrogen insufficiency), history of chronic graft-versus-host disease
	Sexual dysfunction, dyspareunia	Pelvic surgery, hysterectomy, radiation affecting the uterus or vagina	History of hypogonadism (estrogen insufficiency)
	Spontaneous abortion, neonatal death, premature labor, neonate with low birth wt, fetal malposition	Radiation affecting the uterus (whole abdomen, pelvis, lumbosacral spine, total body)	History of Wilms tumor and associated Müllerian anomalies
Male	Azoospermia oligospermia	Alkylating-agent chemotherapy, radiation affecting the male reproductive system (pelvic, testicular, total body), orchiectomy (bilateral)	Prepubertal status at treatment does not reduce risk
	Retrograde ejaculation, anejaculation erectile dysfunction	Pelvic surgery (retroperitoneal node or tumor dissection, cystectomy, radical prostatectomy), radiation to pelvis, bladder, or spine	History of hypogonadism (androgen insufficiency)

See www.survivorshipguidelines.org for health risks to other organs and tissues resulting from treatment of childhood cancer. Adapted, with permission from Elsevier, from Hudson MM. Survivors of childhood cancer: coming of age. *Hematol Oncol Clin North Am.* 2008;22(2):218.

predispose female patients to diminished ovarian reserve and premature ovarian failure. Premature ovarian failure is defined as premature menopause occurring before age 40. This differs from diminished ovarian reserve, which can lead to increased difficulty in achieving a pregnancy or to a shortened reproductive window despite regular menstrual periods. The deleterious effects of chemotherapy are dependent on the age of the patient at the time of therapy, the specific agents used, and cumulative dosing.[41] Oocytes do not regenerate after birth, as opposed to spermatogenesis, which continues to occur from progenitor stem cells throughout a man's life. Premature ovarian failure is rare in survivors of childhood cancer and was found to have an incidence of 6% to 9% in CCSS cohorts.[42] Many women who do not have overt ovarian failure will have diminished ovarian reserve.[43] Several studies have used anti-Müllerian hormone (AMH) concentrations to estimate ovarian reserve.[44,45] Survivors of childhood cancer often have lower AMH concentrations compared with a control group.[46,47] Low AMH concentrations can predispose to diminished ovarian reserve and, therefore, a higher risk of infertility as well as earlier menopause. When evaluated by treatment exposure (alkylators only, alkylators and subdiaphragmatic radiation, or high-dose alkylating therapy), all survivor groups had diminished ovarian surface area and AMH concentrations. Ovarian reserve was worse when survivors received a high dose versus a conventional dose of alkylating therapy.

Radiation has an effect on both the brain and the end organs. When the brain is the target of irradiation, infertility can present as hypothalamic amenorrhea. High-dose cranial radiotherapy (35–40 Gy) can cause infertility via hypogonadism through its effects on the hypothalamic-pituitary axis. Such infertility can be treated medically with stimulation of the ovaries or testes with gonadotropins to induce the maturation and release of gametes. Radiation can affect the uterus and vagina, and women undergoing radiation to the uterus are less likely to both conceive a pregnancy and carry it to term.[48] Direct pelvic radiotherapy, abdominal or spinal radiation, or scatter radiation can all affect the ovaries. The oocyte median lethal dose for radiotherapy is less than 2 Gy.[49]

Several studies have been focused on infertility and achievement of pregnancy in female survivors of cancer. One CCSS cohort study found that the risk of nonsurgical premature menopause was increased for survivors of childhood cancer.[42] Survivors also had an increased risk of clinical infertility when compared with sibling

controls. This risk was most pronounced in the early reproductive years (≤24 years), when fertility is high in a general population. Increasing doses of uterine radiation and alkylators were most strongly associated with infertility. Promisingly, almost two-thirds of survivors with clinical infertility reported a pregnancy during the study period, which included both those achieving pregnancy spontaneously and those who underwent fertility treatment.[50] Another CCSS cohort study analyzed only survivors who had not received gonadal or cranial radiotherapy to evaluate the effect of chemotherapeutic agents on pregnancy. Just as with male survivors, female survivors had a decreased likelihood of pregnancy and live birth compared with sibling controls. If a pregnancy was not achieved by age 30, the likelihood of ever becoming pregnant by age 45 was further reduced compared with siblings. As with previous studies, the most deleterious chemotherapeutic agents were the alkylating agents, including lomustine and cyclophosphamide.[40]

OPTIONS FOR FERTILITY PRESERVATION

The options, burdens, and costs of fertility preservation differ for boys and girls. The availability of options also differs depending on whether the child facing cancer treatment is prepubertal or postpubertal and on the urgency with which treatment must be initiated. Some treatments are well established and have known efficacy and outcomes data, and others are still experimental. It is important to differentiate between clinically accepted and experimental treatments when counseling patients and families regarding their fertility-preserving options.

PRESERVATION OF FERTILITY BEFORE TREATMENT IN THE PREPUBERTAL CHILD

Fertility preservation in the prepubertal child is challenging. The majority of proposed treatment modalities are thus far experimental in nature and without proven efficacy. The one exception is gonadal shielding or moving the gonads out of the radiation field.[51] Familiarity with these options and the data surrounding them can assist physicians in treating and counseling their patients with cancer. Furthermore, patients who wish to undergo prepubertal fertility preservation attempts may be best served under an institutional review board (IRB)–approved clinical trial so that they can be carefully monitored and their experience used to determine if such therapies should continue to be offered in the future.

Boys

Before puberty, methods available for gonadal and gamete preservation in the male patient are primarily theoretical at the present time, with the exception of shielding the testes or moving them out of the radiation field.[52,53] Most methods involve hormonal and other manipulations to protect the testes from injury during cancer treatment or involve preserving a testicular tissue sample. Primordial sperm cells are susceptible to toxicity at all stages of life. Gonad shielding can be used during radiotherapy but is only possible with selected radiation fields and anatomy and may increase the risk of harboring malignant cells.[3] The gonad(s) can also be temporarily relocated outside of the radiation field to either the thigh or the anterior abdominal wall.[54,55]

To date, no effective pharmacologic intervention has been identified. Gonadal protection through hormone manipulation has been evaluated only in small studies in patients with cancer and is uniformly ineffective in either preserving fertility or speeding the recovery of spermatogenesis.[3] Animal studies suggest that testicular tissue cryopreservation, autotransplantation, xenotransplantation, and in vitro maturation may be successful methods of fertility preservation, but most have yet to be tested in humans.[56] Human spermatocytes have been matured in vitro to mature spermatids, resulting in at least 1 pregnancy.[57] Testicular tissue cryopreservation has been reported, and ongoing clinical trials are being conducted to address prepubertal fertility preservation in boys.[58,59] Oncologists can help their male patients and their families by sharing with them information and options regarding clinical trials to address prepubertal fertility preservation. Once testicular tissue has been cryopreserved, future options for its use may include in vitro maturation or germ cell transplant, which at this time are theoretical in nature.

Girls

Similar to prepubertal boys, most fertility preservation modalities in prepubertal girls are experimental in nature and are without adequate long-term outcomes data. The exception is gonadal shielding and oophoropexy. Shielding of the ovaries during radiotherapy and oophoropexy to remove the ovaries from the radiation field are strategies to preserve ovarian function during treatment, although radiation scatter is a concern despite best efforts to avoid radiation exposure.[60–62] Although ovarian transposition is relatively effective for preserving the endocrine function of the ovary (in 60% of cases), only approximately 15% of patients treated with transposition and wishing to become pregnant ever achieve this goal.[60] Of note, the benefit of gonadal shielding is less effective if adjuvant chemotherapy with gonadotoxic agents is required as part of the treatment regimen.

There are also potential means for preserving ovarian function in selected cases of reproductive tract malignancy, including more conservative surgery for certain early-stage tumors and choosing chemotherapeutic agents that have less gonadal toxicity.[60,63,64]

In prepubescent girls, the ovaries cannot be stimulated to produce mature eggs. Ovarian tissue cryopreservation has been proposed as a method to preserve fertility in this cohort of girls. In contrast to oocyte cryopreservation, ovarian tissue cryopreservation (via removal of a portion of the ovary or unilateral oophorectomy) is a process in which normal, functioning ovarian tissue is excised from the ovary and cryogenically stored.[65–70] Currently, this technique is only available in certain parts of the United States as an open clinical trial to assess its efficacy and safety as a potential option for preservation of fertility in prepubertal girls.[71,72] Within this context, it is the only method that can be offered to prepubertal girls.[73] This technique has been performed in children as young as 2.7 years of age, and the chance of later restoring fertility should theoretically be higher because the ovarian cortex contains more primordial and primary follicles in younger children.[73] Ideally, the stored ovarian tissue is thawed and autotransplanted into the donor once her treatment has been completed.[74] There are no data yet available regarding whether cryopreservation of ovarian tissue in prepubertal girls can lead to pregnancy and delivery. Given the potentially limited viability of the autotransplanted tissue, this procedure is more likely to restore reproductive endocrine function rather than result in preserving fertility, unless the oocytes are retrieved relatively soon after the transplant. Studies using flow cytometric evaluation have confirmed the presence of contaminating leukemia cells in histologically normal pretreatment ovarian tissue specimens removed from patients with leukemia and lymphoma before initiation of treatment, leading to the theoretical concern for reseeding the body with tumor cells after the autotransplant.[75,76] In adults, more than 70 live births have been reported in women who cryopreserved ovarian tissue, but only when the tissue was harvested postpubertally.[77–82] A potential confounder in the various case series in which live births were reported is that in the majority of cases, some native ovarian tissue was present in addition to the autotransplanted ovarian tissue. It is possible that pregnancies occurred from oocytes obtained from the native ovarian tissue and not from the transplanted material.[83]

Until recently, all of the reports of successful births after autografts of cryopreserved ovarian tissue in the pediatric population were obtained from adolescents who had already begun the pubertal transition. There has now been at least 1 published report of a live birth after an autograft of cryopreserved ovarian tissue in a prepubertal girl, who was 9 years old at the time that her ovarian tissue was cryopreserved.[84] Before this, the youngest age at the time of ovarian tissue cryopreservation was 14 years, in a girl preparing to undergo a myeloablative conditioning regimen as part of a hematopoietic stem cell transplant performed for homozygous sickle cell anemia. Although she had not yet achieved menarche, there was evidence that she had already started the pubertal transition on the basis of existence of breast development.[85] Given the unknown efficacy of this technique, ovarian tissue cryopreservation in prepubertal girls is best performed under an IRB protocol.

PRESERVATION OF FERTILITY BEFORE TREATMENT IN THE POSTPUBERTAL ADOLESCENT

Once a male adolescent is able to produce mature sperm or a female adolescent is able to be stimulated to provide mature oocytes, fertility preservation options become more viable. The options for germ cell preservation before treatment differ depending on sex.

Male Adolescents

Sperm cryopreservation after masturbation is the most established and effective method of fertility preservation in male adolescents.[71] Whenever possible, sperm should be collected before initiation of cancer therapy to prevent the risk that sperm DNA integrity or sample quality will be compromised. Sperm can be collected at infertility centers or andrology laboratories and stored either at these sites or at long-term storage facilities. Patients may be shy or embarrassed at the prospect of masturbation, such that a discussion of the available options is best conducted with the patient and his legal guardian(s) in a comfortable and accepting manner. It may be helpful to provide a space for the patient to speak privately with a medical team member in the absence of the parent or guardian to allow the adolescent to ask questions and address concerns. Physicians may be instrumental in guiding parents regarding approaches to effectively discuss sperm cryopreservation with their adolescent sons.[86] One study suggested that adolescent boys may be more successful at masturbation if a parent does not accompany them to the appointment.[87] Underlying sperm quality may be poor in certain cancer types, including testicular cancer, leukemia, and Hodgkin's disease.[88,89] Nevertheless, recent progress in andrology laboratories and with assisted reproductive technology (ART) allows for successful freezing and future use of even a limited

number of sperm and even when the sperm quality is diminished.[90]

Alternative methods of obtaining sperm besides masturbation include testicular aspiration or extraction, electroejaculation under sedation or anesthesia,[91] or retrieval from a postmasturbation urine sample.[87] Although fresh sperm samples may result in higher success rates than frozen sperm, the success rate depends more on the sperm parameters at the time of production than on whether the sample was used fresh or was previously cryopreserved.[92,93] With fair-quality frozen sperm samples, IVF is often recommended to achieve pregnancy rather than intrauterine insemination because cycle success rates are much higher and sperm are a limited resource. In cases in which only a few sperm are present, fertilization and pregnancy can be achieved by performing IVF with intracytoplasmic sperm injection (ICSI).

Female Adolescents

Although postpubertal female adolescents historically had few available options, this has changed over the past decade with improvements in oocyte cryopreservation. Oocyte cryopreservation remains generally more invasive and expensive than sperm harvesting. In October 2012, the American Society for Reproductive Medicine released a statement describing oocyte cryopreservation as no longer experimental and recommending that it be offered to adult patients facing the risk of infertility resulting from chemotherapy and other gonadotoxic therapies.[94] Embryology laboratories are increasingly able to cryopreserve, thaw, and fertilize mature oocytes, with success rates approaching or equaling those achieved with more traditional embryo freezing.[94] This opens up a viable option for the postmenarcheal pediatric patient with cancer.[95,96] Successful pregnancy rates by using previously cryopreserved oocytes have been reported to be as high as 50% in adult women cryopreserving their oocytes but would be expected to be even better in young women and adolescents.[97] Such rates have been obtained at fertility centers that are experienced with egg freezing, and patients should be encouraged to freeze oocytes at centers with ample experience using this technology. The number of infants born from frozen oocytes is increasing. Information on the health outcomes of children born via this specific technique for fertility preservation is limited but has overall been reassuring. No increases in chromosomal abnormalities, birth defects, or developmental deficits have been noted in the children born from cryopreserved oocytes as compared with other standard ART procedures, such as IVF, and with natural conception[98–101]; however, these data are not from patients who cryopreserved their oocytes after a cancer diagnosis. To date, it is not known whether success rates in this situation will mirror those achieved after oocyte cryopreservation for other indications. Nevertheless, given the reassuring outcomes data for egg freezing in other contexts and the lack of other options for many women facing gonadotoxic therapies, the American Society for Reproductive Medicine and the American College of Obstetricians and Gynecologists support the use of oocyte cryopreservation for women at risk for losing ovarian reserve because of gonadotoxic exposures.[102] This technique requires controlled ovarian hyperstimulation with approximately 10 days of subcutaneous gonadotropin hormone injections. Eggs are then retrieved from the ovaries with transvaginal ultrasonography-guided needle aspiration performed under intravenous sedation. As mentioned previously, although medically viable, this technique has limitations in the adolescent age group because of the invasive nature of the process. Although oocyte cryopreservation is a medically viable option beginning around the time of menarche, it is less clear whether it should be routinely offered to young adolescents or to any minor. The process of oocyte cryopreservation requires approximately 10 days of monitoring with transvaginal ultrasonography and blood tests, followed by a transvaginal oocyte retrieval performed under anesthesia. In some clinical situations, a delay of a week or more before initiating cancer treatment may not be possible or may compromise care such that oocyte cryopreservation may not be a viable option. For many adolescents and their parents or guardians, the invasive nature of the ovarian stimulation process and retrieval may prevent its acceptance on psychological and emotional grounds.

Women with hormonally sensitive tumors who are interested in oocyte or embryo cryopreservation present specific challenges because standard protocols for ovarian stimulation are associated with significant (albeit temporary) elevations in estradiol concentrations. Such elevations may theoretically increase the risk of tumor progression and spread.[103] There has been a growing experience with the use of selective estrogen receptor modulators and aromatase inhibitors during the stimulation portion of the cycle. Use of these agents has been shown to significantly reduce peak estradiol levels during ovarian stimulation to those more typical of a spontaneous ovulation during a normal menstrual period, thus theoretically decreasing the risk of stimulating hormonally sensitive tumors. Fortunately, this blunting of the hormones does not have a negative effect on egg quality or cycle outcome. The lower estradiol concentrations in cycles using selective estrogen receptor modulators and aromatase inhibitors do not appear to decrease the chance

of achieving a pregnancy when the resultant embryos are ultimately transferred to the uterus.[104,105]

Cryopreservation of embryos, in which oocytes are fertilized with sperm from the woman's male partner or with anonymous donor sperm, was historically the only option available to postpubertal girls and young women wishing to preserve their fertility. As compared with oocyte cryopreservation, embryo cryopreservation is more socially, emotionally, and ethically complex because the patient needs the maturity to fully comprehend all aspects of the procedure, including the fact that the eggs will be fertilized with (usually anonymous) donor sperm.[67] Given the success rate with oocyte cryopreservation, there is little need to consider fertilizing the eggs before cryopreserving them, and embryo cryopreservation should only be used in rare circumstances, for example, when an older adolescent is married or in a long-term committed relationship. Even then, cryopreserving oocytes opens up more future options than cryopreserving embryos and should be encouraged when available and when the patient is of an appropriate age and maturity level to undergo an ovarian stimulation procedure.

For women who have previously undergone pelvic irradiation, there may be scarring or other postradiation effects to the uterus and vagina that preclude conception or the ability to maintain a pregnancy. For girls who will be receiving pelvic irradiation and their families, discussion of the future use of a gestational surrogate may be warranted. If the ovaries remain functional after irradiation, it will be possible to retrieve eggs from them, fertilize them through IVF, and transfer them into a gestational carrier. When premature ovarian failure has occurred, women with uterine or vaginal compromise who wish to consider parenting options outside of adoption will require both donation from a known or anonymous egg donor and the services of a gestational carrier. There are significant costs associated with this mode of reproduction. Also, gestational surrogacy laws are complex, differ among states, and evolve over time.

There has been speculation that concomitant treatment with gonadotropin-releasing hormone (GnRH) analogs may prevent ovarian failure induced by cancer therapy by protecting against chemotherapy-induced follicle depletion. The studies looking at this option to date were performed on adult women with breast cancer, and it is not clear whether these data are applicable to children. In adults, most studies evaluating GnRH analogs to prevent ovarian failure have not demonstrated benefits,[106–108] although 1 recent randomized trial revealed a significant reduction in ovarian failure and an increased fertility rate in women receiving GnRH analogs.[109] These findings cannot be applied to prepubertal girls, in whom the hypothalamic-pituitary-ovarian axis is still quiescent.[71] The 2018 ASCO guidelines acknowledge that there is conflicting evidence regarding the use of GnRH analogs to protect fertility but suggest that in situations in which proven fertility preservation methods are not feasible, GnRH analogs may be offered to patients, with the hope of reducing chemotherapy-induced ovarian insufficiency.[3]

COSTS OF FERTILITY PRESERVATION

The costs of fertility preservation are often not covered by insurance,[110] especially given that insurance usually does not cover experimental therapies, thus compounding the psychological distress with the economic impact of infertility.[111,112] Some states have comprehensive fertility coverage because of mandates on insurance, and some have recently begun mandating coverage of fertility preservation.[113,114] The later use of stored gametes may be covered under such fertility mandates.[115] Legislative efforts are underway in a number of states to address this issue.[116] Because the cost burden on patients or families can be expected to change over time and by geographic area, good counseling will require familiarity with current regional data.[117] Some patients may benefit from fertility preservation under experimental protocols, and these should be considered when applicable and after appropriate counseling has been provided.

Sperm cryopreservation is a technique that has been used for many years and has associated benefits and a record of success that supports its widespread use in the postadolescent male patient. The cost of sperm cryopreservation after masturbation can total hundreds of dollars a year, with additional costs incurred if alternative methods, such as surgical sperm extraction, are needed to obtain sperm or for prolonged storage.[3] When ready to be used for reproduction, IVF and often ICSI may be needed to achieve pregnancy, especially given the often-limited quantities of sperm available. The relevant costs of IVF are discussed later in this section.

In postmenarcheal female adolescents, controlled ovarian hyperstimulation for the purpose of retrieving and cryopreserving oocytes is often not covered by insurance. The various components of such cycles include (1) stimulating the ovaries with daily subcutaneous injections over the course of 8 to 21 days and monitoring of the ovarian response with approximately 5 blood tests and ultrasonographic examinations over the course of the stimulation; (2) the cost of gonadotropins to stimulate the ovaries, medications to prevent early

ovulation, and medications to blunt the estrogen response in cases of hormonally sensitive malignancies; (3) egg retrieval under anesthesia; (4) embryology and laboratory fees; and (5) cryopreservation of the oocytes. A typical oocyte cryopreservation cycle can cost between $7000 and $14 000.[118–121] Medications per egg retrieval cycle can cost between $2000 and $7000, although currently, some pharmacies and pharmaceutical companies provide these medications at a discount or at no cost to patients with a cancer diagnosis. Storage fees for cryopreserved oocytes are approximately $350 to $600 per year.[3] When cryopreserved eggs are ready to be used for reproduction, there are additional costs associated with thawing the eggs and fertilizing them with sperm as well as transferring the embryos back to the uterus.

Women requiring an egg donor because of ovarian failure or diminished ovarian reserve may incur additional costs, particularly if they need to use eggs from an anonymous egg donor, who is reimbursed for her contribution. Women who require a gestational surrogate because of an inability to carry a pregnancy will incur costs of both IVF and gestational surrogacy, which often total in the tens of thousands of dollars.

Experimental fertility preservation options may be covered under a research protocol in some cases such that there may be no or minimal costs to the patient. The therapies themselves can be expensive. Once they are no longer considered experimental, the cost will be borne by the families of children using them in the future to the extent that insurance does not provide coverage.

For prepubertal boys, testicular tissue cryopreservation is a potentially costly option that has not yet proven to result in offspring in humans but has been successful in primates.[122] If successful, the tissue would either need to be retransplanted into the testes or some extratesticular location, and/or sperm would need to be extracted from the tissue after sperm maturation. If sperm were to be extracted, then IVF and ICSI would need to be used in the future to obtain viable embryos.

For prepubertal girls, the costs of ovarian tissue preservation can be separated into 3 parts: (1) the procedure to retrieve the tissue, generally laparoscopy and attendant anesthesia[123]; (2) ovarian tissue pathologic evaluation and freezing; and (3) the annual cost of ovarian tissue storage. Laparoscopic procedures, even in children, often can be performed on an outpatient basis, precluding an inpatient hospitalization cost.[74] The cost of ovarian tissue freezing alone might be similar to that of freezing testicular sperm after testicular dissection (see previous discussion), incurring an annual cost for ovarian tissue storage of several hundred dollars a year or greater. Assuming recovery of the patient after treatment, the costs will include tissue thawing and the procedure for autotransplantation, subsequent medications, and laboratory testing. Ovarian tissue preservation remains experimental and is best performed at a specialized center and under IRB approval. In some cases, enrollment in such studies does not incur a cost to the participants.

Counseling Families Regarding Options for Fertility Preservation

Counseling regarding fertility preservation options is the first step in assisting families in navigating options for fertility preservation. This counseling is best undertaken as early as feasible after a cancer diagnosis is made and before the initiation of any cancer treatment, if possible. For preadolescents, it is appropriate for one or both parents or guardians to be present for such conversations. Adolescents may benefit from the opportunity to speak one on one with their physician and/or child psychologist or reproductive specialty surgeon in the absence of their parents. For adolescent girls who may benefit from oocyte cryopreservation, a frank discussion regarding their experience with tampon use and intercourse should be undertaken because the monitoring that is required before retrieving the oocytes requires multiple transvaginal ultrasonographic examinations. For adolescent boys, a discussion of sexual experience and comfort with masturbation should occur. Recognizing that fertility preservation may create both burdens and opportunities for patients and their families, discussions regarding reproductive potential have, as their goal, the maximization of the child's future options and well-being.

Most often, a child will initially present to the general pediatrician and then be referred to a pediatric hematologist oncologist. Physicians involved in cancer treatment should be familiar with the ASCO guidelines for fertility preservation[3] and be able to provide referral for consultation and treatment to patients and families who wish to seek these out. When possible, a child should be referred to a multidisciplinary team for a comprehensive approach to the evaluation of options for fertility preservation for his or her specific circumstances. This team can provide counseling regarding appropriate treatments, their timing, and their scope. The team may consist of the patient's primary care physician, pediatric hematologist and oncologist, radiation oncologist, reproductive endocrinologist, urologist specializing in male infertility, surgeon (if surgery is part of the treatment), child-life or other integrative health specialist, and mental health professionals. Ethics consultants may be helpful when conflicts arise between medical

professionals and the patient and family.[124] Such a team approach allows families to obtain the information they require to make decisions regarding fertility preservation and allows those who decide to pursue fertility preservation options to do so in an efficient manner and maximizes the chance that fertility preservation options are initiated before starting cancer therapy. For prepubertal children, consultation with and/or referral to a center performing testicular and ovarian cryopreservation under an IRB protocol is appropriate. The type, stage, and severity of the cancer affect the time frame during which decisions surrounding fertility preservation must be made. In some cases, these decisions must be made emergently, whereas in other cases, the window for action is urgent but not emergent. In some circumstances, lifesaving treatment will need to start immediately and fertility preservation options will not be available. Even when fertility preservation is not possible because of the need for treatment or other determinants, counseling regarding the risks to fertility inherent in the various treatment options will allow patients and their families to cope with the effects of cancer treatment.

Counseling Regarding Expected Outcomes After Fertility Preservation

Physicians have an important role in counseling children and their caregivers regarding their future reproductive options when faced with a cancer diagnosis. The option of fertility preservation may be of great comfort for patients and their families and may assist them in managing the emotional trauma of the cancer diagnosis,[60] although the offer may also result in unrealistic expectations.[125] Most younger patients with cancer have historically been left with significant anxieties and insufficient information about reproductive issues.[126] Appropriate counseling of parents and patients (as appropriate for age) in developmentally appropriate language will help patients and their families understand the likelihood that cancer treatment will permanently affect fertility. Reproductive endocrinologists and urologists can be instrumental in explaining the pre- and posttreatment options and may help alleviate these anxieties.[3] The downstream options of adoption, egg and sperm donation, and gestational surrogacy can be discussed as well as the success rates, costs, surgical risks, and experimental nature of specific ART options and the acceptability of the option to decline the intervention.[125,127] As part of this discussion, families and children (as appropriate for age) should be made aware that cancer treatments do not guarantee a loss of reproductive potential and that pregnancy can occur in sexually active postpubertal adolescents and young adults. The complexity and impact of the various fertility preservation options may be overwhelming to children and their families. Whenever possible, the information should be conveyed incrementally over multiple visits. This will allow families the time to internalize the various treatment options and determine the optimal course of action for their particular situation. However, some clinical diagnoses do not allow for the luxury of time between identification of the cancer and implementation of treatment, and fertility preservation decisions must be made urgently.

Dispositional Control of Cryopreserved Reproductive Tissue

The fertility specialist can play an important role in discussing the issue of dispositional control of reproductive tissue in the event of the patient's death or incapacity. Such discussions best occur before the collection of any reproductive tissue. Posthumous use of reproductive tissue is defined as the use of gametes or embryos in an attempt to create offspring after the death of the individual who provided the reproductive tissue. Posthumous reproduction from gametes procured in childhood should not occur if the child does not survive beyond the age of majority. This is further discussed below in the section on ethics. Consent forms should designate that the disposition of reproductive tissue will be delayed until the child reaches the age of majority or discarded if the child does not survive to the age of majority. Once the child becomes an adult, he or she can make changes to the disposition of the reproductive tissue, including provisions for its posthumous use. Legal review of the institutional consent process and associated documentation can be considered to preclude future misunderstanding or a misinterpretation of tissue or specimen disposition or disposal. Because case law has evolved in the area of disposition of previously collected embryos and gametes, which has not always strictly enforced documentation in a consent form, periodic review of the program's written consents by an institutional attorney may be helpful. For this reason, involving an attorney as part of the team can be beneficial to families and medical personnel. Once the child reaches the age of majority, he or she should issue new documentation regarding his or her wishes for future storage of previously collected reproductive material.

It should also be disclosed that success rates are not guaranteed. Even with successful collection and freezing of eggs, sperm, and/or embryos, success rates will never be 100%; some children who go through the process of fertility preservation will not ultimately be successful in using their cryopreserved reproductive tissue. Additionally, there are no guarantees that stored embryos and gametes will be viable when ready for reproductive use or

be free of neoplasia. Also, unexpected catastrophes, both natural and man-made, can lead to unintended damage to or destruction of reproductive tissue.

Barriers to Receiving Counseling

Survey results of adult male and female survivors of cancer of reproductive age and studies evaluating oncology practice patterns for discussing infertility have suggested that a conversation with patients with cancer regarding the potential consequences of their treatment on future fertility was lacking in more than half of cases.[3] Pediatric oncologists admit that, despite their motivation to preserve fertility in their patients and their belief that all pubertal patients with cancer could benefit from a fertility consultation, they do not use the ASCO fertility preservation guidelines[3] and instead refer their patients to fertility specialists only a minority of the time.[128] Oncologists provide many different explanations for not referring patients for fertility preservation, including not recognizing the importance of this issue, assuming that patients cannot afford fertility preservation procedures, feeling emotionally uncomfortable discussing the topic, or choosing not to refer the patient because of a poor prognosis.[73] Additional barriers include beliefs that such discussions will add additional stress to an overwhelmed family or will violate provider or family cultural taboos on issues of sexuality. Even when counseling does occur, family satisfaction with the process is often lacking; in one study, only 30% of parents were satisfied with the fertility preservation counseling they received regarding their children.[129] In a survey study identifying reproductive concerns of adolescent girls with cancer and their parents, the concerns of the respective groups were not congruent. Parents incorrectly expected their daughters to be satisfied with only survivorship and less concerned about reproductive potential.[130] In another study in which families were to recall discussions they had regarding fertility expectations after surviving cancer, only about half of parents recalled receiving information on the topic and nearly one-third expected normal fertility.[131]

Patients themselves are generally asking for this information and have identified preservation of fertility as extremely important.[17] Most men taking one survey responded that they believed having experienced cancer increased the value they placed on family closeness and would make them better parents.[132] For men who desire children in the future, lack of timely information is the most common reason for not banking sperm. A survey of adolescent patients with cancer revealed that 81% would want to undergo investigational or research-based procedures to attempt to maintain their fertility.[133] Additional data suggest that the process of fertility preservation, in and of itself, may be therapeutic; for example, young male survivors demonstrated lower distress and enhanced coping with cancer treatment simply from the knowledge that they had stored sperm.[134,135] In addition, the long-term morbidity associated with infertility and interrupted childbearing is not minor and persists well into adulthood.[136] In addition to fertility preservation options, strategies to help survivors of cancer identify and deal with unresolved grief about cancer-related infertility are important health care interventions.

Despite its perceived importance, the process is not easy for patients and families. Making an appointment with the andrology laboratory usually is the responsibility of the patient and family. Chemotherapy induction may need to proceed expeditiously and may not allow the luxury of time for needed consultations and decision-making or may preclude the ability of the patient to provide more than 1 or 2 samples.[87] Facilitating the andrology laboratory visit and delaying the initiation of chemotherapy, if possible, are 2 approaches that might be used in appropriate cases to increase fertility options of survivors of cancer. Some situations are true medical emergencies (eg, respiratory compromise from a mediastinal lymphoma) or are significantly urgent to preclude even the short delay required for an andrology laboratory visit.

Currently available fertility preservation options are not believed to compromise the success of cancer therapy or adversely affect a survivor's health.[3] Other than hereditary genetic syndromes, large registry studies have failed to demonstrate an increased risk of genetic abnormalities,[19,23] congenital malformations,[20–22] or cancers in the children of survivors of cancer.[26–30,32,33] Disclosing this information to patients and families will provide reassurance of the potential value of fertility preservation.[137] For families with hereditary conditions that are risk factors for developing malignancies, the development of preimplantation genetic testing of embryos allows couples to undergo IVF and screen their embryos for the hereditary cancer syndrome for which their offspring is at risk. By electing not to transfer affected embryos, the risk of transmitting cancer genes to their offspring is dramatically reduced. This approach is supported by the American Academy of Pediatrics as well as by the Ethics Committee of the American Society for Reproductive Medicine for couples who wish to avoid having children with high-risk cancers.[138]

One difficulty in counseling either sex regarding risks to future fertility is that there are few absolutes, and the

discussion should be focused on a risk assessment. Some treatments have a high risk of infertility, diminished ovarian reserve, sterility, and/or premature ovarian failure. Other treatments are less likely to lead to the inability to have children. The level of concern over the potential loss of fertility should be addressed, and the spectrum of fertility options that are available to an individual should be presented.

ETHICAL CONSIDERATIONS

Fertility preservation raises several ethical issues, including the dilemma of counseling someone who has not yet reached adulthood, obtaining appropriate consent and/or assent,[125,139] managing disagreements between desires of the patient and his or her family, and later use and disposition of reproductive tissue that was acquired before the age of assent.

A central ethical concern for children facing a cancer diagnosis whose treatment may limit future fertility is that of supporting the right to an open future.[140] This encompasses a set of moral rights children possess that are derived from the autonomy rights of adults. These rights protect children from having important decisions made by others before they have had the ability to make them for themselves. The right to an open future encompasses strategies that may safeguard a child's future fertility.[141]

Of critical concern is the extent to which the minor child should be involved in decisions surrounding his or her care. Guidance on patient participation in decision-making and assent should comply with recommendations in the American Academy of Pediatrics policy statement "Informed Consent in Decision-making in Pediatric Practice."[142]

The patient's family and physicians should work together to help provide an open future for the child. At times, there may be disagreements between a parent and child or between the family and the physicians regarding fertility preservation. Reasons for this include the cultural or religious beliefs of the family or discomfort surrounding discussions of an intimate nature with a child who has not yet or only just recently reached sexual maturity. Parents should be cognizant of their biases and work to maximize options for their children. Although they may not feel completely comfortable with fertility preservation, it is important to consider that the child will become an adult who will make reproductive decisions regarding their fertility.

When possible, after the child has become an adult, he or she should have the broadest possible options from which to choose given the medical circumstances of his or her cancer diagnosis. The opportunity to parent a biologically related child is an important option to attempt to preserve for the child. Recognizing the limits of safety and current technology, medical providers should strive to discuss these options and help provide access to them. Special circumstances might be posed by specific religious beliefs or cultural values that preclude either discussing or allowing ART or that prohibit masturbation.[110] The parent(s) or guardian(s) will most likely be transferring their beliefs to the clinical situation, and these beliefs may or may not represent those of the child at the present time or in the future. Individuals who will later wish to have biologically related children may be adversely affected by decisions that are made for them by their parents or guardians. In some cultures, a person's status in their community may be culturally dependent on their ability to reproduce. It may be helpful, when such options are presented to an adolescent who is mature enough to provide assent, to discuss them without a legal guardian present to help elucidate the adolescent's feelings regarding such decisions. Such discussions should take place regardless of the child's sexual orientation because reproductive considerations remain the same as for any child. When conflicts between patient and family desires arise, involving mental health professionals and/or an ethics consultant to work through the contrasting desires is often helpful and should be considered.

Issues may arise with disposition of gametes (sperm, oocytes, embryos, or gonadal tissue) whether the child lives or dies.[110,143,144] Any procedure performed has as its aim the preservation of a child's reproductive future, and this should be discussed as part of the consent and/or assent process. If the child survives, decisions surrounding disposition of the gametes should be delayed until after the child has reached the age of majority. This stands in contrast to organ donation, in which parents do have control over donation decisions. The contrast between gamete and organ donation stems from the capacity of gametes to propagate the genome of the deceased. Posthumous gamete use in adults is ethically complex. In minors who have not survived to the age of majority, use of cryopreserved gametes is ethically impermissible. It is unethical for parents or legal guardians to arrange for gametes to be fertilized for the purpose of reproduction. The only individual ethically able to consent to the use of their gametes for reproduction is the child who has reached the age of majority. Organs and other tissues are donated for the purpose of saving a life or improving the health of another. Posthumous gamete donation does not serve either of these purposes. These issues are not unique, have precedent in case law, and need to be addressed by any person agreeing to the preservation of tissue or gametes.[144]

Eggs, sperm, and testicular and ovarian tissue obtained from a child who does not survive into adulthood should be discarded. Because a child or an adolescent who lacks capacity cannot give consent to have donated gametes used for procreation and to avoid the risks inherent in the creation of a "commemorative child," parents would not have discretion over the biological material of a child who has died, and the gametes should be destroyed. This is consistent with recommendations made by the American Society for Reproductive Medicine and the European Society of Human Reproduction and Embryology.[145,146]

GUIDANCE FOR COUNSELING OF PARENTS AND PATIENTS ABOUT PRESERVATION OF FERTILITY OPTIONS IN CHILDREN AND ADOLESCENTS WITH CANCER

1. Physicians providing cancer treatment to children should be able to counsel patients and their families regarding the risk of infertility and fertility preservation options. Although there will be cases in which cancer treatment must be initiated emergently and fertility preservation will not be an option, the impact of the treatment on fertility should be discussed.
2. When medically effective fertility preservation options exist, patients and their families should be offered timely referral to centers and providers offering these options. This may include delaying treatment to allow for fertility preservation to occur, as long as the delay does not compromise the success of the cancer therapy.
3. Physicians who provide cancer treatment should be aware that fertility preservation options are limited in prepubertal children and that most treatments in this age group are experimental at the present time.
4. When counseling families regarding fertility preservation, physicians should be clear as to whether the treatments have proven efficacy or are experimental in nature. Experimental therapies should only be undertaken under IRB approval.
5. Evaluation for candidacy for fertility preservation should be guided by an institutional policy. Such policies should be informed by a team of specialists that may include a pediatric oncologist, a specialist in reproductive medicine, a urologist with expertise in male fertility, a radiation oncologist, an ethics consultant, an expert in reproductive law, and a mental health professional.
6. Cryopreservation of sperm and oocytes should be offered whenever possible to postpubertal patients or families of adolescents, dependent on the predicted gonadotoxicity of the prescribed treatment.
7. Given the success that has been achieved with cryopreservation of oocytes, embryo cryopreservation should not be considered in children. Experience with oocyte cryopreservation is variable, and patients should be referred to fertility centers with significant experience and success with this technique.
8. The option of ovarian tissue cryopreservation for female children and adolescents and of testicular tissue in male children and adolescents is still considered experimental and should be offered only in selected institutions in the setting of a research protocol.
9. In considering actions to preserve a child's fertility, parents should consider a child's assent, the details of the procedure involved, and whether such procedures are of proven utility or are experimental in nature.
10. Instructions concerning disposition of stored gametes or gonadal tissue in the event of the patient's death, unavailability, or other contingency should be formally recorded at the center where the gametes or tissue will be stored and should include the patient if possible before collection of the tissue and/or germ cells. There should be another discussion between the patient and the physicians at the center where the reproductive tissue is stored about disposition of gametes after the child reaches the age of majority. Eggs, sperm, and testicular and ovarian tissue obtained from a child who does not survive into adulthood should be discarded by the center preserving the reproductive tissue as per the consents signed at the time of cryopreservation.
11. When conflicts arise between the parent and child regarding fertility preservation, all possible attempts should be made to support an open future for the child while respecting the family's wishes.

Fluoride Use in Caries Prevention in the Primary Care Setting

Melinda B. Clark, MD, FAAP,[a] Martha Ann Keels, DDS, PhD,[b,c] Rebecca L. Slayton, DDS, PhD,[d] SECTION ON ORAL HEALTH

Dental caries remains the most common chronic disease of childhood in the United States. Caries is a largely preventable condition, and fluoride has proven effectiveness in caries prevention. This clinical report aims to clarify the use of available fluoride modalities for caries prevention in the primary care setting and to assist pediatricians in using fluoride to achieve maximum protection against dental caries, while minimizing the likelihood of enamel fluorosis. Fluoride varnish application is now considered the standard of care in pediatric primary care. This report highlights administration, billing, and payment information regarding the fluoride varnish procedure.

Dental caries (ie, tooth decay) is an infectious disease caused by bacteria on the tooth surface metabolizing carbohydrates and producing acid, which dissolves tooth enamel. If unchecked, this process continues through the tooth and into the pulp, resulting in pain and tooth loss. This can further progress to local infections (ie, dental alveolar abscess or facial cellulitis), systemic infection, and, in rare cases, death. Dental caries in the United States is responsible for many of the 51 million school hours lost per year as a result of dental-related illness, which translates into lost work hours for the adult caregiver.[1] Early childhood caries is the single greatest risk factor for caries in the permanent dentition. Good oral health is a necessary part of overall health, and studies have demonstrated adverse effects of poor oral health on multiple chronic conditions, including diabetes control.[2] Therefore, failure to prevent caries has health, educational, and financial consequences at both the individual and societal levels.

Dental caries is the most common chronic disease of childhood,[1] with 59% of 12- to 19-year-olds having at least 1 documented cavity.[3] Caries is a "silent epidemic" that disproportionately affects poor, young, minority populations and children living below 100% of the poverty level.[1] In the United States, 25% of 2- to 5-year-old children from low socioeconomic and minority groups experience 80% of dental disease.[4] Among 3- to 5-year-olds, untreated dental decay was significantly greater for non-

Hispanic Black and Hispanic children (19.3% and 19.8%, respectively) than for non-Hispanic white children (11.3%).[4] This disparity persisted among children 6 to 9 years and 13 to 15 years of age.[4] Dental caries is a global problem, with early childhood caries prevalence among socioeconomically disadvantaged groups reported to be as high as 70%.[5] It has been suggested that health beliefs, self-efficacy, access to care, and parents' attitudes and practices related to dietary and oral hygiene behaviors may contribute to this disparity.[6]

Children with special health care needs, including those with developmental delay, complex neurodevelopmental disabilities, or congenital heart disease are also affected disproportionately.[7,8] In a study of Head Start children, those with developmental delays had a caries prevalence ratio that was 1.26 times higher than classmates without developmental delays.[8] This difference may be attributable to challenges with home care routines such as toothbrushing and use of medications with high sugar content, among other factors.[8] Children with special health care needs are frequently considered as a group when determining caries risk. However, some diagnoses place children at greater risk for caries, whereas other children are at decreased or similar risk as children without special health care needs. In a retrospective longitudinal study of children with autism spectrum disorder, Down syndrome, congenital heart disease, and cerebral palsy, Frank et al[7] determined that the caries risk among the group of children with special health care needs was higher than among the control subjects but the risk differed significantly by diagnosis. The caries burden was greatest in children with congenital heart disease, followed by those with autism spectrum disorders.[7] For children with Down syndrome, the risk was close to that of controls and considerably lower than the other 3 groups of children with special health care needs.[7]

Unfortunately, dental caries prevalence in young children increased between the previous 2 national surveys, despite improvements among older children.[9] Many children do not receive dental care at young ages, and because the risk of dental caries is heavily influenced by parenting practices, pediatricians have a unique opportunity to participate in the primary prevention of dental caries. The 2007–2016 Medical Expenditure Panel Survey demonstrated that 88.8% of infants and 1-year-olds have office-based physician visits annually, compared with only 3.6% of infants and 1-year-olds having general dental visits (American Academy of Pediatrics [AAP], unpublished analysis of 2007–2016 Medical Expenditure Panel Survey, August 2019). Studies show that health care dollars are saved with simple home and primary care setting prevention measures.[10]

The development of dental caries requires 4 components: teeth, bacteria, carbohydrate exposure, and time. Once teeth emerge, they become colonized with cariogenic bacteria. The bacteria metabolize carbohydrates and create acid as a byproduct. The acid dissolves the mineral content of enamel (demineralization) and, over time, with repeated acid attacks, the enamel surface disintegrates and results in a cavity in the tooth. Protective factors that help to remineralize enamel include exposing the teeth to fluoride, limiting the frequency of carbohydrate consumption (to 3 meals and 2 healthy snacks per day), choosing less cariogenic foods (selecting cheese or raw carrots over candy or crackers; selecting fresh fruit over dried fruit or processed fruit snacks), practicing good oral hygiene (brushing twice a day for 2 minutes and flossing between all teeth that touch), and receiving regular dental assessments and care. If carious lesions are identified early, the process can be halted or reversed by modifying the patient's individual risk and protective factors. The AAP's publications "Maintaining and Improving the Oral Health of Young Children"[11] and *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents*[12] discuss these concepts in greater depth and provide targeted anticipatory guidance. For primary prevention to be effective, it is imperative that pediatricians be knowledgeable about the process of dental caries, social determinants of oral health, prevention of the disease, and available interventions, including fluoride.

Fluoride is available from many sources, divided into 3 major categories: tap water (and foods and beverages processed with fluoridated water), home administered, and professionally applied. The widespread decline in dental caries in many developed countries, including the United States, has been largely attributable to the use of fluoride. Fluoride has 3 main mechanisms of action[13]:

1. Fluoride promotes enamel remineralization.
2. Fluoride reduces enamel demineralization.
3. Fluoride inhibits bacterial metabolism and acid production.

The mechanisms of fluoride are both topical and systemic, but the topical effect is the most important, especially over the life span.[14]

There has been substantial public and professional debate about fluoride, and a great deal of information is available, often with confusing or conflicting messages. Excess fluoride ingestion during tooth development can result in subsurface

hypomineralization and porosity between the developing enamel rods, termed enamel fluorosis.[15] Fluorosis of permanent teeth occurs when excessive fluoride is ingested during the time that tooth enamel is being mineralized; therefore, the risk is influenced by both dose and frequency of ingestion. Recent evidence also suggests a genetic susceptibility or resistance to the development of fluorosis.[16] Fluorosis develops in children younger than 8 years, with the most susceptible period for permanent maxillary incisor fluorosis (central teeth) between 15 and 30 months of age.[17–19] The vast majority of enamel fluorosis is mild or very mild and characterized by small white striations or opaque areas not readily noticeable to the casual observer and is of minimal clinical consequence. Moderate and severe forms of enamel fluorosis are uncommon in the United States but have both an aesthetic concern and, potentially, a structural concern with pitting, brittle incisal edges and weakened groove anatomy in the permanent 6-year molars.[20] After 8 years of age, there is no further risk of fluorosis except for the third molars because all other permanent tooth enamel is fully mineralized.

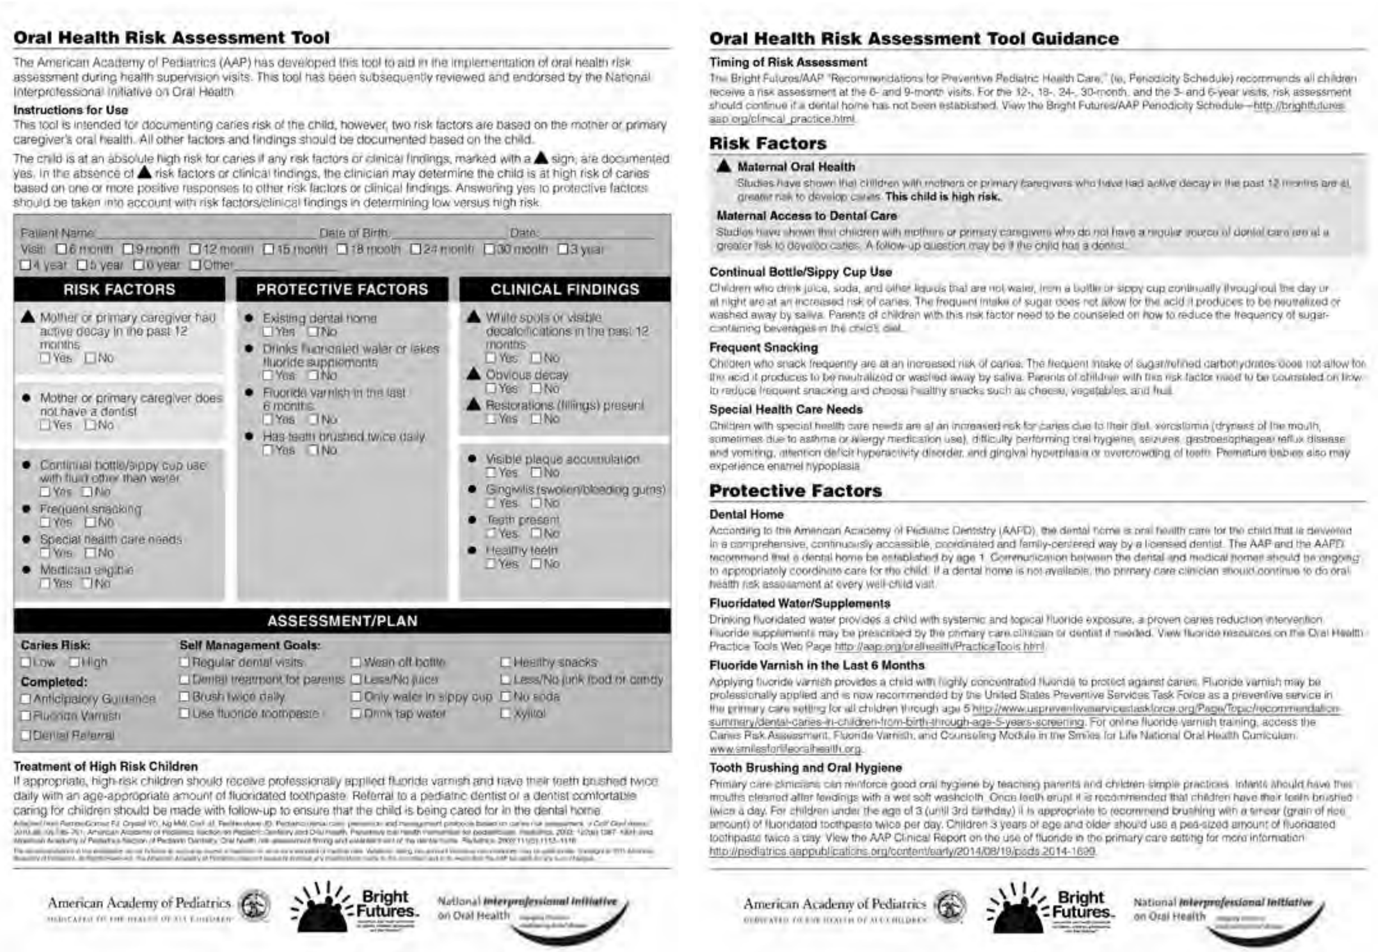
Dental and governmental organizations (the American Dental Association [ADA], American Academy of Pediatric Dentistry [AAPD], and Centers for Disease Control and Prevention [CDC]) have all published guidelines on the use of fluoride. In 2001, the AAP endorsed the CDC publication "Recommendations for Using Fluoride to Prevent and Control Dental Caries in the United States."[21]

The 2 intents of this clinical report are as follows:

1. to assist pediatricians in using fluoride to achieve maximum protection against dental caries, while minimizing the likelihood of enamel fluorosis; and
2. to clarify what advice should be given by pediatricians regarding fluoride in the primary care setting.

CURRENT INFORMATION REGARDING FLUORIDE USE IN CARIES PREVENTION

Sources of ingested fluoride include drinking water, infant formula, fluoride toothpaste, prescription fluoride supplements, fluoride mouth rinses, professionally applied topical



Oral Health Risk Assessment Tool

The American Academy of Pediatrics (AAP) has developed this tool to aid in the implementation of oral health risk assessment during health supervision visits. This tool has been subsequently reviewed and endorsed by the National Interprofessional Initiative on Oral Health.

Instructions for Use

This tool is intended for documenting caries risk of the child, however, two risk factors are based on the mother or primary caregiver's oral health. All other factors and findings should be documented based on the child.

The child is at an absolute high risk for caries if any risk factors or clinical findings, marked with a ▲ sign, are documented yes. In the absence of ▲ risk factors or clinical findings, the clinician may determine the child is at high risk of caries based on one or more positive responses to other risk factors or clinical findings. Answering yes to protective factors should be taken into account with risk factors/clinical findings in determining low versus high risk.

Patient Name: ______ Date of Birth: ______ Date: ______
Visit: ☐ 6 month ☐ 9 month ☐ 12 month ☐ 15 month ☐ 18 month ☐ 24 month ☐ 30 month ☐ 3 year ☐ 4 year ☐ 5 year ☐ 6 year ☐ Other ______

RISK FACTORS
- ▲ Mother or primary caregiver had active decay in the past 12 months ☐ Yes ☐ No
- ● Mother or primary caregiver does not have a dentist ☐ Yes ☐ No
- ● Continual bottle/sippy cup use with fluid other than water ☐ Yes ☐ No
- ● Frequent snacking ☐ Yes ☐ No
- ● Special health care needs ☐ Yes ☐ No
- ● Medicaid eligible ☐ Yes ☐ No

PROTECTIVE FACTORS
- ● Existing dental home ☐ Yes ☐ No
- ● Drinks fluoridated water or takes fluoride supplements ☐ Yes ☐ No
- ● Fluoride varnish in the last 6 months ☐ Yes ☐ No
- ● Has teeth brushed twice daily ☐ Yes ☐ No

CLINICAL FINDINGS
- ▲ White spots or visible decalcifications in the past 12 months ☐ Yes ☐ No
- ▲ Obvious decay ☐ Yes ☐ No
- ▲ Restorations (fillings) present ☐ Yes ☐ No
- ● Visible plaque accumulation ☐ Yes ☐ No
- ● Gingivitis (swollen/bleeding gums) ☐ Yes ☐ No
- ● Teeth present ☐ Yes ☐ No
- ● Healthy teeth ☐ Yes ☐ No

ASSESSMENT/PLAN

Caries Risk: ☐ Low ☐ High

Completed: ☐ Anticipatory Guidance ☐ Fluoride Varnish ☐ Dental Referral

Self Management Goals: ☐ Regular dental visits ☐ Dental treatment for parents ☐ Brush twice daily ☐ Use fluoride toothpaste ☐ Wean off bottle ☐ Less/No juice ☐ Only water in sippy cup ☐ Drink tap water ☐ Healthy snacks ☐ Less/No junk food or candy ☐ No soda ☐ Xylitol

Treatment of High Risk Children

If appropriate, high-risk children should receive professionally applied fluoride varnish and have their teeth brushed twice daily with an age-appropriate amount of fluoridated toothpaste. Referral to a pediatric dentist or a dentist comfortable caring for children should be made with follow-up to ensure that the child is being cared for in the dental home.

Oral Health Risk Assessment Tool Guidance

Timing of Risk Assessment

The Bright Futures/AAP "Recommendations for Preventive Pediatric Health Care," (ie, Periodicity Schedule) recommends all children receive a risk assessment at the 6- and 9-month visits. For the 12-, 18-, 24-, 30-month, and the 3- and 6-year visits, risk assessment should continue if a dental home has not been established. View the Bright Futures/AAP Periodicity Schedule—http://brightfutures.aap.org/clinical_practice.html.

Risk Factors

▲ **Maternal Oral Health**
Studies have shown that children with mothers or primary caregivers who have had active decay in the past 12 months are at greater risk to develop caries. **This child is high risk.**

Maternal Access to Dental Care
Studies have shown that children with mothers or primary caregivers who do not have a regular source of dental care are at a greater risk to develop caries. A follow-up question may be if the child has a dentist.

Continual Bottle/Sippy Cup Use
Children who drink juice, soda, and other liquids that are not water, from a bottle or sippy cup continually throughout the day or at night are at an increased risk of caries. The frequent intake of sugar does not allow for the acid it produces to be neutralized or washed away by saliva. Parents of children with this risk factor need to be counseled on how to reduce the frequency of sugar-containing beverages in the child's diet.

Frequent Snacking
Children who snack frequently are at an increased risk of caries. The frequent intake of sugar/refined carbohydrates does not allow for the acid it produces to be neutralized or washed away by saliva. Parents of children with this risk factor need to be counseled on how to reduce frequent snacking and choose healthy snacks such as cheese, vegetables, and fruit.

Special Health Care Needs
Children with special health care needs are at an increased risk for caries due to their diet, xerostomia (dryness of the mouth, sometimes due to asthma or allergy medication use), difficulty performing oral hygiene, seizures, gastroesophageal reflux disease and vomiting, attention deficit hyperactivity disorder, and gingival hyperplasia or overcrowding of teeth. Premature babies also may experience enamel hypoplasia.

Protective Factors

Dental Home
According to the American Academy of Pediatric Dentistry (AAPD), the dental home is oral health care for the child that is delivered in a comprehensive, continuously accessible, coordinated and family-centered way by a licensed dentist. The AAP and the AAPD recommend that a dental home be established by age 1. Communication between the dental and medical homes should be ongoing to appropriately coordinate care for the child. If a dental home is not available, the primary care clinician should continue to do oral health risk assessment at every well-child visit.

Fluoridated Water/Supplements
Drinking fluoridated water provides a child with systemic and topical fluoride exposure, a proven caries reduction intervention. Fluoride supplements may be prescribed by the primary care clinician or dentist if needed. View fluoride resources on the Oral Health Practice Tools Web Page http://aap.org/oralhealth/PracticeTools.html.

Fluoride Varnish in the Last 6 Months
Applying fluoride varnish provides a child with highly concentrated fluoride to protect against caries. Fluoride varnish may be professionally applied and is now recommended by the United States Preventive Services Task Force as a preventive service in the primary care setting for all children through age 5 http://www.uspreventiveservicestaskforce.org/Page/Topic/recommendation-summary/dental-caries-in-children-from-birth-through-age-5-years-screening. For online fluoride varnish training, access the Caries Risk Assessment, Fluoride Varnish, and Counseling Module in the Smiles for Life National Oral Health Curriculum: www.smilesforlifeoralhealth.org.

Tooth Brushing and Oral Hygiene
Primary care clinicians can reinforce good oral hygiene by teaching parents and children simple practices. Infants should have their mouths cleaned after feedings with a wet soft washcloth. Once teeth erupt it is recommended that children have their teeth brushed twice a day. For children under the age of 3 (until 3rd birthday) it is appropriate to recommend brushing with a smear (grain of rice amount) of fluoridated toothpaste twice per day. Children 3 years of age and older should use a pea-sized amount of fluoridated toothpaste twice a day. View the AAP Clinical Report on the use of fluoride in the primary care setting for more information http://pediatrics.aappublications.org/content/early/2014/08/19/peds.2014-1699.

fluoride, and some foods and beverages.[22] Preventive strategies for caries can be tailored by focusing on key risk factors for dental caries associated with diet, bacteria, saliva, and status of the teeth (both current and previous caries experience).[11] The AAP Oral Health Risk Assessment Tool (Fig 1) is recommended in *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents* and endorsed by the National Interprofessional Initiative on Oral Health. This tool can be found at www.aap.org/en-us/Documents/oralhealth_RiskAssessmentTool.pdf.

Table 1 provides condensed recommendations for use of fluoride modalities in patients at low and high risk of caries as described in the following sections.

Fluoride Toothpaste

Fluoride toothpaste has consistently been proven to provide a caries-preventive effect for individuals of all ages.[21,23] In the United States, the fluoride concentration of over-the-counter (OTC) toothpaste ranges from 1000 to 1100 ppm. This translates into 1 mg of fluoride in a 1-inch (1 g) strip of paste. A pea-sized amount of toothpaste is approximately one-quarter of an inch. Therefore, a pea-sized amount of toothpaste containing 1000 to 1100 ppm fluoride would have approximately 0.25 mg of fluoride. Most fluoride toothpastes in the United States contain sodium fluoride, sodium monofluorophosphate, or stannous fluoride as the active ingredient. Children younger than 6 years are more likely to ingest toothpaste and increase the risk of fluorosis. Fluorosis risk can be minimized by using the recommended amounts of toothpaste and storing toothpaste where young children cannot access it without parental help. Parents should supervise children younger than 8 years to ensure the proper amount of toothpaste and effective brushing technique.

Recommendations and Dosing

The use of fluoride toothpaste should begin with the eruption of the first tooth. For children younger than 3 years, the recommended amount is a smear or grain of rice size (approximately 0.1 mg of fluoride). Once the child has turned 3 years of age and is more able to consistently expectorate, a pea-sized amount of toothpaste (approximately 0.25 mg of fluoride) should be used.[24,25] It is preferable to spit, but not rinse, after brushing. Expectorating without rinsing reduces the amount of fluoride swallowed and leaves some fluoride available in the saliva for uptake by the dental plaque. Parents should be strongly advised to supervise their child's use of fluoride toothpaste to avoid overuse or ingestion, especially with children who have complex neurodevelopmental disabilities and cannot consistently expectorate.

High-concentration toothpaste (5000 ppm) is available by prescription only, and this decision is usually made by a dental health professional. The active ingredient in this toothpaste is sodium fluoride. This agent can be recommended for children 6 years and older and adolescents who are at high risk of caries and who are able to expectorate after brushing. Examples of children for whom high-concentration fluoride toothpaste might be indicated are those with history of dental caries and new lesions, children with xerostomia, and those with gastroesophageal reflux causing dental erosion. Dental health professionals may also prescribe this agent for adolescents who are undergoing orthodontic treatment because they are at increased risk of caries during this time.[26]

Fluoride Varnish

Fluoride varnish is a concentrated topical fluoride applied to the teeth that sets on contact with saliva. Advantages of this modality are that it is well tolerated by infants and young children, has a prolonged therapeutic effect, and can be applied by both dental and nondental health professionals in a variety of settings.[27] The concentration of fluoride varnish is 22 600 ppm (2.26% fluoride ion), and the active ingredient is sodium fluoride. The unit dose packaging from most manufacturers provides a specific measured amount (0.25 mL, providing 5 mg of fluoride ion). The application of fluoride varnish during an oral screening is of benefit to children, especially those with limited access to dental care. The current AAPD recommendation for children at high risk of caries is that fluoride varnish be applied to the teeth every 3 to 6 months.[28] The 2013 ADA

TABLE 1 Summary of Fluoride Modalities for Low- and High-Risk Patients

Fluoride Modality	Low Caries Risk	High Caries Risk
Toothpaste	Starting at tooth emergence (smear of paste until age 3, then pea-sized)	Starting at tooth emergence (smear of paste until age 3, then pea-sized)
Fluoride varnish	Every 3–6 mo starting at tooth emergence	Every 3 mo starting at tooth emergence
Mouth rinse OTC	Do not use	Starting at age 6 y if the child can reliably swish and spit
Community water fluoridation	Yes	Yes
Dietary fluoride supplements	Yes, if drinking water supply is not fluoridated	Yes, if drinking water supply is not fluoridated

guideline recommends application of fluoride varnish at least every 6 months to both primary and permanent teeth of those at elevated caries risk.[29] Medicaid pays both physicians and dentists for the application of fluoride varnish in all 50 states.

Under the Patient Protection and Affordable Care Act,[30] payers are required to cover, without cost-sharing, preventive services recommended by the US Preventive Services Task Force (USPSTF) and *Bright Futures* guidelines. The USPSTF recommended in 2014 that primary care clinicians apply fluoride varnish to the primary teeth of all infants and children starting at the age of primary tooth eruption (B recommendation).[31] All children 5 years and younger deserve to have application of fluoride varnish fully covered, as per USPSTF recommendations, as part of health maintenance and preventive care and for fluoride varnish application to be a covered benefit and separately paid service (ie, not considered incidental to the office visit). All practices should be paid separately and appropriately according to the definition of the *Current Procedural Terminology* (CPT) code, which defines fluoride application as a separately identifiable procedure. Fluoride varnish payment should not be bundled with routine preventive evaluation and management services because definitions of preventive care under those specific CPT codes do not include fluoride varnish application. Information regarding coding, billing, and payment for fluoride varnish application can be found on the AAP Web site (www.aap.org/oralhealth) and the Pew Center on the States Web site (www.pewstates.org/research/analysis/reimbursing-physicians-for-fluoride-varnish-85899377335). Many AAP Chapters have chapter oral health advocates who promote and advocate for pediatric oral health within their community. Contact information for these chapter oral health advocates can be found at www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/Oral-Health/Pages/Chapter-Oral-Health-Advocates.aspx.

Indications for Use

In the primary care setting, fluoride varnish should be applied at least once every 6 months for all children and every 3 months for children at high risk for caries, starting when the first tooth erupts and until the establishment of a dental home. Medical and dental professionals are encouraged to work in collaboration to ensure that fluoride varnish is being applied.

Instructions for Use

Fluoride varnish must be applied by a dentist, dental auxiliary professional, physician, nurse, or other health care professional on the basis of individual state practice acts. It should not be dispensed to families to apply at home. Application of fluoride varnish is most commonly performed in the context of a well-child visit. Teeth are dried with a 2-inch gauze square, and then the varnish is painted onto all surfaces of the teeth with a brush. The dose recommended for young children is 0.25 mL, which is available in single-dose applicator kits. Children can eat and drink immediately after application and are instructed to eat soft foods and not to brush their teeth on the evening after the varnish application to maximize the contact time of varnish on the teeth. Children should resume brushing twice daily with fluoridated toothpaste the following morning.

OTC Fluoride Rinse

OTC fluoride rinse provides a lower concentration of sodium fluoride than toothpaste or varnish. The concentration is most commonly 230 ppm (0.05% sodium fluoride). Expert panels on this topic have concluded that OTC fluoride rinses should not be recommended for children younger than 6 years because of their limited ability to rinse and spit and increased risk of swallowing higher than recommended amounts of fluoride.[32] A teaspoon (5 mL) of OTC fluoride rinse contains approximately 1 mg of fluoride. For children older than 6 years, OTC rinses provide additional topical fluoride that may assist in the prevention of enamel demineralization. However, the evidence for an anticaries effect is limited, and decisions to recommend OTC fluoride rinses should be made in consultation with the child's dental health care provider.[33,34]

Dietary Fluoride Supplements

The USPSTF recommended in 2014 that primary care clinicians prescribe dietary fluoride supplements for children living in communities with nonfluoridated water or who drink well water that does not contain fluoride.[31] Because there are many sources of fluoride in water supplies and processed food and drinks, it is essential that all potential sources of fluoride be assessed before prescribing a dietary supplement, including consideration of differing environmental exposures (dual homes and child care). As a general guideline, if the source of drinking water in the primary home is fluoridated tap or well water, children will not require fluoride supplementation, even if they primarily drink bottled water because the teeth are exposed to fluoride through food preparation and brushing. The risk of fluorosis is high if fluoride supplements are given to a child consuming fluoridated water.[35] Information about the fluoridation levels in many community water systems can be found on the CDC Web site "My Water's Fluoride" (https://nccd.cdc.gov/doh_mwf/default/default.aspx). Not all communities report this information to the CDC, so it may be necessary to contact the local water department to determine the level of

fluoride in the community water. Well water must be tested for fluoride content before prescribing supplements, and this testing is available in most areas through the state or county public health laboratory. Challenges with dietary fluoride supplementation include determining the child's fluoride exposures and proper administration of the medication.

It is important to note that the USPSTF recommendations vary from the ADA and AAPD guidelines, which both recommend fluoride supplementation only be considered for children who drink fluoride-deficient water and are also at high risk for dental caries.[36,37] No caries risk assessment tool has been validated for pediatricians to use, but the AAP Oral Health Risk Assessment Tool was piloted through the Quality Improvement Innovation Network, and more than 80% of practices found the tool easy to implement because clinicians did not need to significantly alter current practice to incorporate risk assessment. Identification of high-risk patients for oral health referral increased from 11% to more than 87% with the use of this tool (Brightening Oral Health Workgroup and Quality Improvement Innovation Networks, AAP, Brightening Oral Health: Teaching and Implementing Oral Health Risk Assessments in Pediatric Care project, unpublished data, 2009).

Guidelines for Use

The CDC-recommended fluoride supplementation dosage schedule is provided in Table 2. Supplements can be prescribed in liquid, tablet, or lozenge form. Tablets are preferable for children who can chew because they gain an additional topical benefit to the teeth during the chewing process. Liquid supplements are recommended for younger children and should ideally be added to water or put directly into the child's mouth. Addition of the fluoride supplement to milk or formula is not recommended because absorption of fluoride is reduced in the presence of calcium.[38] The risk of fluorosis can be minimized by health care providers verifying that there are no other sources of fluoride exposure before prescribing systemic fluoride supplements.

TABLE 2 Fluoride Supplementation Schedule for Children

Age	Fluoride Ion Level in Drinking Water, ppm[a]		
	<0.3	0.3–0.6	>0.6
Birth to 6 mo	None	None	None
6 mo to 3 y	0.25 mg/d[b]	None	None
3–6 y	0.50 mg/d	0.25 mg/d	None
6–16 y	1.0 mg/d	0.50 mg/d	None

Source: Centers for Disease Control and Prevention.[21]
[a] 1.0 ppm = 1 mg/L.
[b] 2.2 mg of sodium fluoride contains 1 mg of fluoride ion.

Other Sources of Fluoride

Fluoride is present in processed foods and beverages and may be naturally occurring in some areas of the country. The presence of fluoride in juices and carbonated beverages does not counteract the cariogenic nature of these beverages.

Breastfeeding and Reconstitution of Infant Formula

The AAP recommends exclusive breastfeeding for the first 6 months of life, and there is no need during this period of time to supplement with fluoride or water that is fluoridated. A study of infant feeding practices revealed that 70% to 75% of mothers who fed their infants formula used tap water to reconstitute the powdered formula.[39] According to 2014 CDC data,[40] approximately 74% of US households using a community public water supply received optimally fluoridated water.[41] Before the emergence of the primary teeth, tap water can be used to reconstitute formula. There is a small risk of fluorosis in the permanent dentition if a fluoridated water source is used to reconstitute formula.[22] If families elect to purchase water, it is appropriate to buy water with no added fluoride before tooth emergence. After tooth emergence, formula should be mixed with optimally fluoridated tap water or nursery water with fluoride, or fluoride supplements should be prescribed. It should be noted that most bottled water has suboptimal concentrations of fluoride and that fluoride content is not listed unless fluoride is added by the manufacturer. Fluoride is often added to "nursery" water, and this must be declared on the packaging. Dietary fluoride supplements should not be prescribed for children drinking infant formula reconstituted with fluoridated water.

Community Water Fluoridation

Community water fluoridation is the practice of adding a small amount of fluoride to the water supply to achieve a fluoride concentration of 0.7 ppm. Community water fluoridation was heralded by the CDC as 1 of the top 10 public health achievements of the 20th century.[42] Community water fluoridation is a safe, efficient, and cost-effective way to prevent tooth decay and has been shown to reduce tooth decay by 25%.[43] It prevents tooth decay by providing both topical and systemic exposure of low levels of fluoride to the teeth over time. Although more than 210 million Americans live in communities with optimally fluoridated water, more than 70 million others do not have access to fluoridated water in their public water system.[41] The fluoridation status of a community water supply can be determined by contacting the local water department or accessing the CDC Web site "My Water's Fluoride" (https://nccd.cdc.gov/doh_mwf/default/default.aspx).

Recommended Concentration

Community water fluoridation was initiated in the United States in the 1940s. In 2015, the US Department of Health and Human Services finalized

a recommendation to lower the optimal fluoride concentration in drinking water to 0.7 mg/L.[44] This fluoride concentration replaced the previous recommendation, which was based on climate and ranged from 0.7 mg/L in warmest climates to 1.2 mg/L in coldest climates.[44] The change was recommended because recent studies revealed no variation in water consumption by young children on the basis of climate and to adjust for an overall increase in fluoride intake through foods and beverages processed with fluoridated water, fluoridated mouth rinses, and fluoride toothpastes.

Evidence Supporting Community Water Fluoridation

Despite overwhelming evidence supporting the safety and preventive benefits of fluoridated water, community water fluoridation continues to be a controversial and highly emotional issue. Opponents express a number of concerns that have been addressed or disproven by validated research. The only scientifically documented adverse effect of excess (nontoxic) exposure to fluoride is fluorosis. An increase in the incidence of mild enamel fluorosis among teenagers has been cited as a reason to discontinue fluoridation, although this is a cosmetic condition with no detrimental health outcomes. Recent opposition has sometimes centered on the question of who decides whether to fluoridate: elected and/or public officials or the voters. Some opponents believe fluoridation to be mass medication and call into question the ethics of community water fluoridation, but courts have consistently upheld that it is legal and appropriate for a community to adopt a fluoridation program.[45] Opponents express concern about the quality and source of fluoride, claiming that the additives (fluorosilicic acid, sodium fluoride, or sodium fluorosilicate), in their concentrated form, are highly toxic byproducts of the production of phosphate fertilizer and may include other contaminants, such as arsenic. The quality and safety of fluoride additives are ensured by Standard 60 of the National Sanitation Foundation/American National Standards Institute, a program commissioned by the US Environmental Protection Agency (EPA), and testing is conducted to confirm that the concentrations of arsenic or other substances are below those allowed by the EPA.[46] Finally, there have been many unsubstantiated or disproven claims that fluoride leads to kidney disease, bone cancer, and compromised IQ. More than 3000 studies or research articles have been published on the subject of fluoride or fluoridation.[47] Few topics have been as thoroughly researched as community water fluoridation, and the overwhelming weight of the evidence (along with over 75 years of experience) supports the safety and effectiveness of this public health practice.

Naturally Occurring Fluoride in Drinking Water

The optimal fluoride concentration in drinking water is 0.7 ppm, an amount proven beneficial in reducing tooth decay.[44] Naturally occurring fluoride may be below or above these levels in some areas. Under the Safe Drinking Water Act,[48] the EPA requires notification by the water supplier if the fluoride concentration exceeds 2 ppm. In areas where naturally occurring fluoride concentrations in drinking water exceed 2 ppm, people should consider an alternative water source or home water treatments to reduce the risk of fluorosis in young children.[49] Well water should be tested for the concentration of fluoride, and this testing is most commonly performed through the local health department.

Fluoride Toxicity

Toxic levels of fluoride are possible, particularly in children, resulting from ingesting large quantities of fluoride supplements, fluoridated toothpaste, or fluoride mouth rinse. The toxic dose of elemental fluoride is 5 to 10 mg of fluoride/kg of body weight.[50] Lethal doses in children have been calculated to be between 8 and 16 mg/kg. When prescribing sodium fluoride supplements, it is recommended to limit the quantity prescribed at one time to no more than a 4-month supply. Parents should be advised to keep fluoride products out of the reach of young children and to supervise their use.

Fluoride-Removal Systems

A number of water treatment systems are effective in removing fluoride from water,[51] including reverse osmosis and distillation. Parents should be counseled on the use of these and activated alumina filters in the home and, should they choose to use one that removes fluoride, the potential adverse effects on the family's oral health. Commonly used home carbon filters (eg, Brita or PUR) do not remove fluoride.[51] Families concerned about heavy metals or other impurities in their home water supply can use an activated carbon filter and still retain the benefits of fluoridated water.

Silver Diamine Fluoride

Silver diamine fluoride (SDF) is a minimally invasive, low-cost liquid solution that is painted on cavitated lesions. In young children, SDF provides a nonsurgical technique to manage carious lesions until the child can cope with traditional restorative dental care and, potentially, avoid sedation or a general anesthetic.[52] SDF has been used in Japan for more than 40 years and was cleared by the US Food and Drug Administration in 2014 to treat tooth sensitivity in adults.[53,54] Similar to fluoride varnish, SDF (38% solution) has been used off-label in children and adults to stabilize dental caries and reduce dental sensitivity. At present, the use

of SDF in the United States is largely limited to the dental profession because there are no formal professional guidelines for use outside of dentistry. SDF is indicated for the arrest of cavitated carious lesions in primary teeth as part of a comprehensive caries management program.[52] Information about SDF is included in this report in expectation of questions to pediatricians about this increasingly publicized intervention and increasing numbers of SDF-treated teeth seen in pediatric practices. The mechanism of SDF action is poorly understood, but silver ions are known to be antimicrobial, and the fluoride prevents further enamel demineralization. After SDF application, the lesions must be followed to assess their hardness state. Additional treatments can be applied to obtain sufficient hardness. The only known contraindication to SDF is silver allergy, but SDF is not indicated for carious lesions involving the pulp. The only significant adverse effect of SDF is that the carious lesion turns black (Figs 2 and 3), which can be esthetically problematic for some. SDF can also temporarily stain the skin black if it accidentally comes into contact with the epithelium, and SDF can cause mucosal irritation for approximately 48 hours after mucosal contact. Care must be taken when applying SDF to a cavitated lesion to avoid contact with the child's mucosa or skin. Details of SDF application technique for dental health professionals are delineated in the AAPD Chairside Guide.[54]

SUGGESTIONS FOR PEDIATRICIANS

1. Know how to assess caries risk. As recommended by the AAP in "Maintaining and Improving the Oral Health of Young Children" and the fourth edition of Bright Futures, pediatricians should perform oral health risk assessments on all children at every routine well-child visit beginning at 6 months of age. The Oral Health Risk Assessment Tool has been developed by the AAP and Bright Futures and endorsed by the National Interprofessional Initiative on Oral Health. This tool can be accessed at www.aap.org/en-us/Documents/oralhealth_RiskAssessmentTool.pdf. The tool is a guide to help clinicians counsel patients about oral health and counsel in reducing risk.
2. Recommend use of fluoridated toothpaste starting at the eruption of the first tooth. A smear or grain of rice sized amount is recommended for children younger than 3 years, and a pea-sized amount of toothpaste is appropriate for most children starting at 3 years of age (see Fig 4).
3. Apply fluoride varnish according to the periodicity schedule and bill using the CPT code 99188. Fluoride varnish is a proven tool in early childhood caries prevention. Additional training on oral screenings, fluoride varnish indications and application, and office implementation can be found in the Smiles for Life Curriculum Course: Caries Risk Assessment, Fluoride Varnish and Counseling[55] at www.smilesforlifeoralhealth.org. Additionally, the AAP Children's oral health Web site is a resource for oral health practice tools at https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/Oral-Health/Pages/Oral-Health-Practice-Tools.aspx.
4. Know how to determine the concentration of fluoride in a child's primary drinking water and determine the need for systemic supplements.[21]
5. Advocate for water fluoridation in your local community. Public water fluoridation is an effective and safe method of protecting the most vulnerable members of our population from dental caries. Pediatricians are encouraged to advocate on behalf of public water fluoridation in their communities and states. For additional information and water fluoridation facts and detailed questions and answers, see the following:

FIGURE 4
Diagram of smear versus pea-sized amount of fluoride toothpaste.

- o http://www.cdc.gov/fluoridation/.

6. Understand indications for SDF and be able to recognize the clinical appearance of SDF-treated teeth.

Health Care Supervision for Children With Williams Syndrome

- *Clinical Report*

CLINICAL REPORT Guidance for the Clinician in Rendering Pediatric Care

American Academy of Pediatrics

DEDICATED TO THE HEALTH OF ALL CHILDREN™

Health Care Supervision for Children With Williams Syndrome

Colleen A. Morris, MD,[a] Stephen R. Braddock, MD,[b] COUNCIL ON GENETICS

This set of recommendations is designed to assist the pediatrician in caring for children with Williams syndrome (WS) who were diagnosed by using clinical features and with chromosome 7 microdeletion confirmed by fluorescence in situ hybridization, chromosome microarray, or multiplex ligation-dependent probe amplification. The recommendations in this report reflect review of the current literature, including previously peer-reviewed and published management suggestions for WS, as well as the consensus of physicians and psychologists with expertise in the care of individuals with WS. These general recommendations for the syndrome do not replace individualized medical assessment and treatment.

Williams syndrome (WS), also known as Williams-Beuren syndrome, is caused by a deletion of part of chromosome 7 and is a multisystem disorder that was first identified as a distinct clinical entity in 1961.[1] It is present at birth with a prevalence of 1 in 7500[2] and affects boys and girls equally. Children with WS usually come to the attention of pediatricians during infancy or early childhood. WS is characterized by dysmorphic facies (100%), cardiovascular disease (80%; most commonly supravalvular aortic stenosis [SVAS]), intellectual disability (75%), a characteristic cognitive profile (90%), and idiopathic hypercalcemia (15% to 45%).[1,3–7]

The deleted portion of chromosome 7q11.23 seen in WS is 1.5 to 1.8 Mb and contains 26 to 28 genes.[3,4,8] It includes the *ELN* gene that codes for the structural protein elastin, which is an important component of the elastic fibers found in the connective tissue of many organs. The *ELN* deletion explains some of the characteristics of WS, such as some of the facial features, hoarse voice, inguinal hernia, bladder and bowel diverticula, cardiovascular disease, and orthopedic problems. The pathogenesis of other characteristics, such as intellectual disability, is likely attributable to deletion of contiguous genes in the region. Most deletions in the WS region are de novo. Affected individuals have a 50% chance of transmitting the deletion to offspring. A specific inversion

TABLE 1 Medical Problems in WS by Organ System and Age

Organ	System Prevalence, %	Age		
		Infancy	Childhood	Adult
Ocular and visual				
Esotropia	50	x	—	—
Hyperopia	50	—	x	x
Auditory				
Recurrent otitis media	50	x	x	—
Hypersensitivity to sound	90	x	x	x
Progressive sensorineural hearing loss	65	—	x	x
Dental				
Malocclusion	85	—	x	x
Microdontia	95	—	x	x
Cardiovascular				
Any abnormality (total)	80	x	x	x
SVAS	75	x	x	x
SVPS	25	x	x	x
PPS	50	x	—	—
Other arterial stenosis	20	—	x	x
VSD	10	x	—	—
Hypertension	50	—	x	x
Prolonged QTc	13	—	x	x
Genitourinary				
Structural anomaly	5	x	x	x
Enuresis	50	—	x	—
Nephrocalcinosis	<5	x	—	x
Bladder diverticula	50	—	x	x
Gastrointestinal				
Feeding difficulties	70	x	x	—
Constipation	50	x	x	x
Colon diverticula	30	—	x	x
Rectal prolapse	15	x	x	—
Integument				
Soft, lax skin	90	x	x	x
Inguinal hernia	40	x	—	—
Umbilical hernia	50	x	—	—
Prematurely gray hair	90	—	—	x
Musculoskeletal				
Joint hypermobility	90	x	x	—
Joint contractures	50	x	x	x
Radioulnar synostosis	20	x	x	x
Kyphosis	20	—	—	x
Scoliosis	18	—	x	x
Lordosis	40	—	x	x
Awkward gait	60	—	x	x
Calcium				
Hypercalcemia	15–40[a]	x	—	x
Hypercalciuria	30	x	x	x
Endocrine				
Hypothyroidism	5–10	x	x	x
Early puberty (but rarely true precocious puberty)	20	—	x	—
Diabetes mellitus	15	—	—	x
Obesity	30	—	x	x
Neurologic				
Hyperactive deep tendon reflexes	75	—	x	x
Chiari I malformation	10	x	x	x
Hypotonia (central)	80	x	x	—
Hypertonia (peripheral)	50	—	x	x
Cognitive				
Developmental delay	95	x	x	—
Intellectual disability	75	—	x	x
Normal intelligence	5	—	x	x
Impaired visuospatial constructive cognition	95	—	x	x
Behavioral				
ADHD	65	—	x	—
Anxiety disorder (specific phobia, generalized)	70	—	x	x
Sleep disorders	65	—	x	x

Percentages are based on the following: (1) review of rates of complications in several reports of series of patients with WS and (2) a database of 582 children and adults with WS evaluated by Colleen A. Morris, MD. PPS, peripheral pulmonary artery stenosis; SVPS, supravalvular pulmonic stenosis, VSD, ventricular septal defect; —, not applicable.

[a] Hypercalcemia prevalence was greater in those <2 y of age.

polymorphism in this area can be seen in 6% of the general population and in 25% of parents of individuals with WS, indicating that the presence of this inversion may increase the chance of having a child with WS.[9] When the deletion includes only the *ELN* gene, or if the *ELN* gene contains a mutation or pathogenic variant, the result is the autosomal, dominantly inherited condition SVAS. These individuals do not have WS. Currently, the majority of cases of WS are detected through a chromosomal microarray that is done for developmental disability. Some of these cases do not have the typical deletion seen in WS and have varying phenotypes that may lack some of the most defining features of WS. The term WS is reserved for the individuals who have typical deletions. A medical genetics evaluation is recommended to discuss the clinical manifestations, natural history, and recurrence risks for parents and other family members.

The pediatrician can use knowledge of the clinical manifestations (Table 1) and the natural history of WS to anticipate medical problems and educate the family. The characteristic facial features of WS are a broad forehead, bitemporal narrowness, periorbital fullness, a stellate and/or lacy iris pattern, a short nose with a bulbous nasal tip, a wide mouth, full lips, and mild micrognathia (Fig 1 A and B). Infants have epicanthal folds, full cheeks, and a flat facial profile, whereas older children and adults often have a narrow face and long neck. Young children typically have small, widely spaced teeth; dental malocclusion is common at all ages. Mild prenatal growth deficiency and a postnatal growth rate that is ~75% of what is normal are consistently observed. Microcephaly is present in one-third of affected individuals.[10] Growth parameters should be plotted on WS growth charts[11] (Fig 2A–2F). Children with WS typically have decreased fat stores,[12] but obesity may become a problem in teenagers and adults.[13,14] The recommendations in this report reflect review of the current literature, including previously peer-reviewed and published management suggestions for WS,[3,4,13,15] as well as the consensus of physicians and

psychologists with expertise in the care of individuals with WS.

CARDIOVASCULAR

The majority of children with WS have cardiovascular anomalies secondary to elastin arteriopathy, the major source of morbidity and mortality. Although any artery may be narrowed, the most common problem is SVAS, which may worsen over time, particularly in the first 5 years. Progression is more likely if the severity of the stenosis is moderate or severe and presents in infancy or early childhood.[16] SVAS is most commonly a discrete hourglass stenosis or may be a long segment stenosis (~15%).[17] Approximately 30% of children with SVAS will require surgical correction.[18] The mortality rate is 6% for cardiac surgery or catheterization.[19] Peripheral pulmonic stenosis is common in infancy but often improves over time when occurring in isolation. Mitral valve prolapse and aortic insufficiency may occur in adolescents or adults. QTc prolongation has been reported in 13% of individuals.[20]

Hypertension is present in 50% of people with WS, may occur at any age, and is occasionally associated with renal artery stenosis.[21–23] Increased vascular stiffness, which is a risk factor for stroke, is another manifestation of elastin arteriopathy found in both hypertensive and normotensive children and adults with WS.[23] Blood pressure measurement in both arms is recommended at well-child visits with use of a manual cuff at the end of the visit to minimize anxiety. Antihypertensive therapy successfully controls hypertension in most patients and also ameliorates vascular stiffness.[21,23] Consider cardiology or nephrology referral for hypertension (blood pressure >90th percentile for age and height).[24]

Patients with WS are at increased risk for myocardial ischemia, acute hemodynamic deterioration, and sudden death because of their cardiovascular anomalies, especially in the setting of sedation and anesthesia.[25] Individuals with biventricular outflow tract obstruction are at the greatest risk.[19,26] Sudden death in WS (1 per 1000 patient-years)[27] may be related to abnormalities of the coronary arteries (ostial or diffuse stenosis or dilatation)[28] or biventricular outflow

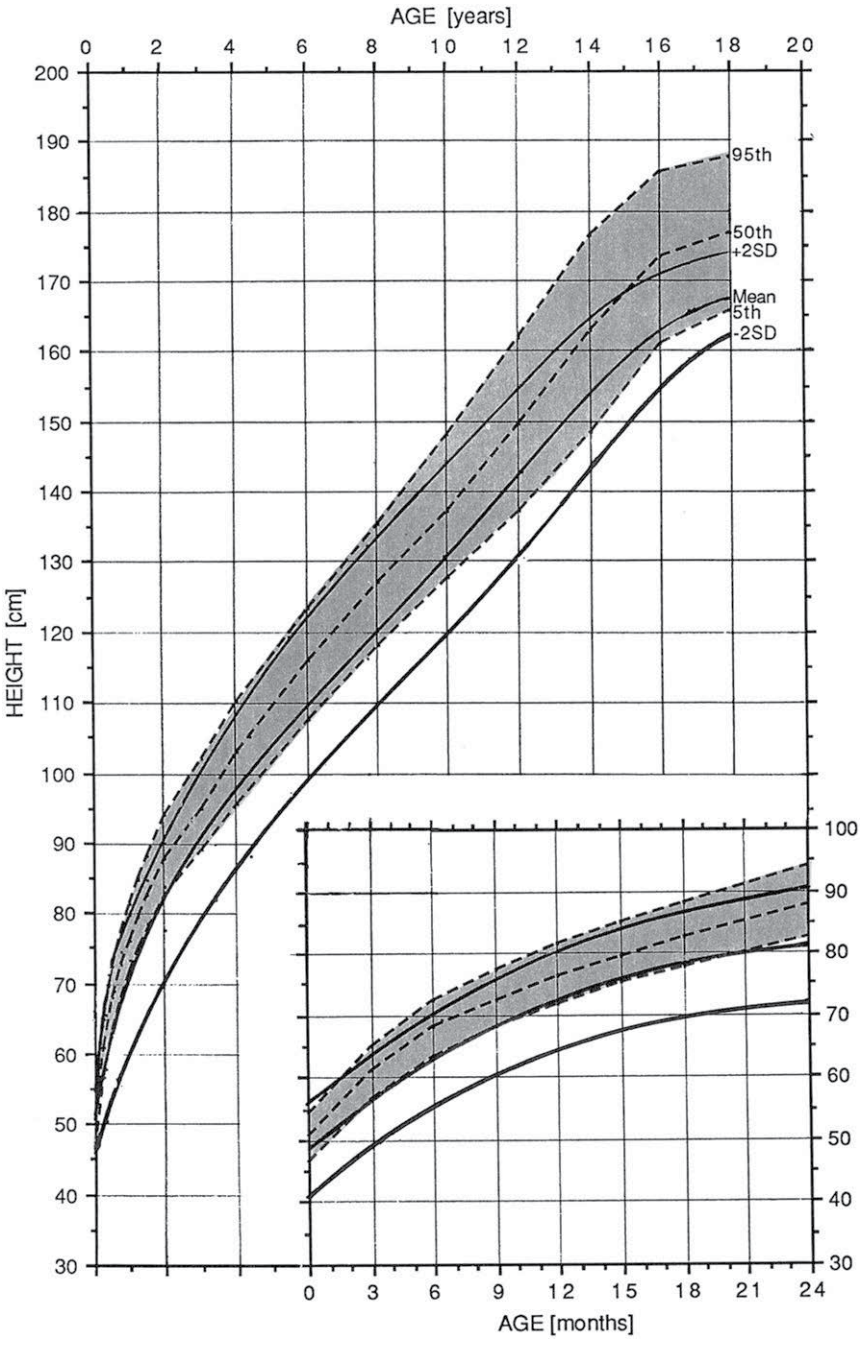

FIGURE 2B
Height for males with Williams syndrome. Normal curves = dashed lines; affected patients = solid lines. Reprinted with permission from: Saul RA, Geer JS, Seaver LH, Phelan MC, Sweet KM, Mills MS. *Growth References: Third Trimester to Adulthood.* Greenwood, SC: Greenwood Genetic Center; 1998.

tract obstruction. Because there is an increased risk of adverse events with sedation and aesthesia, recommendations have been developed for management of sedation and anesthesia in individuals with WS.[26,29,30]

Children with WS should be evaluated by a pediatric cardiologist with experience in treating WS when feasible. The initial evaluation should include 3 limb blood pressures (2 arms and 1 leg); echocardiogram, including Doppler flow studies; and electrocardiogram. Cardiology follow-up should occur frequently (every 3 months) in the first year of life and at least annually through middle childhood with subsequent intervals dictated by the nature and severity of cardiovascular disease. Children who have decreased pulses, bruits, and/or evidence of diffuse thoracic aortic stenosis will require additional cardiovascular imaging studies (computed tomography, magnetic resonance angiography, or cardiac catheterization) to define the anatomy. Because of the increased risk for serious cardiovascular complications surrounding procedures requiring anesthesia, careful perioperative planning, particularly of nonemergency procedures, is recommended with pediatric anesthesiologists who are familiar with WS and work in centers that can provide multidisciplinary support in the event of serious cardiac decompensation during sedation and anesthesia.[26,29,30]

HYPERCALCEMIA

Idiopathic infantile hypercalcemia may contribute to the presence of extreme irritability, vomiting, constipation, and muscle cramps associated with this condition.[6,31] Problems associated with hypercalcemia include dehydration, hypercalciuria, and nephrocalcinosis.[32] Symptomatic hypercalcemia is most common in the first 2 years and usually resolves during childhood,[3,33] but lifelong abnormalities of calcium and vitamin D metabolism may persist. Individuals with WS in all age groups have higher median calcium levels than controls.[32] There is increased calcium absorption from the gut; the cause of the abnormality in calcium metabolism is unknown.[14]

Serum calcium determination should be obtained every 4 to 6 months until 2 years of age, every 2 years thereafter, and when hypercalcemia is

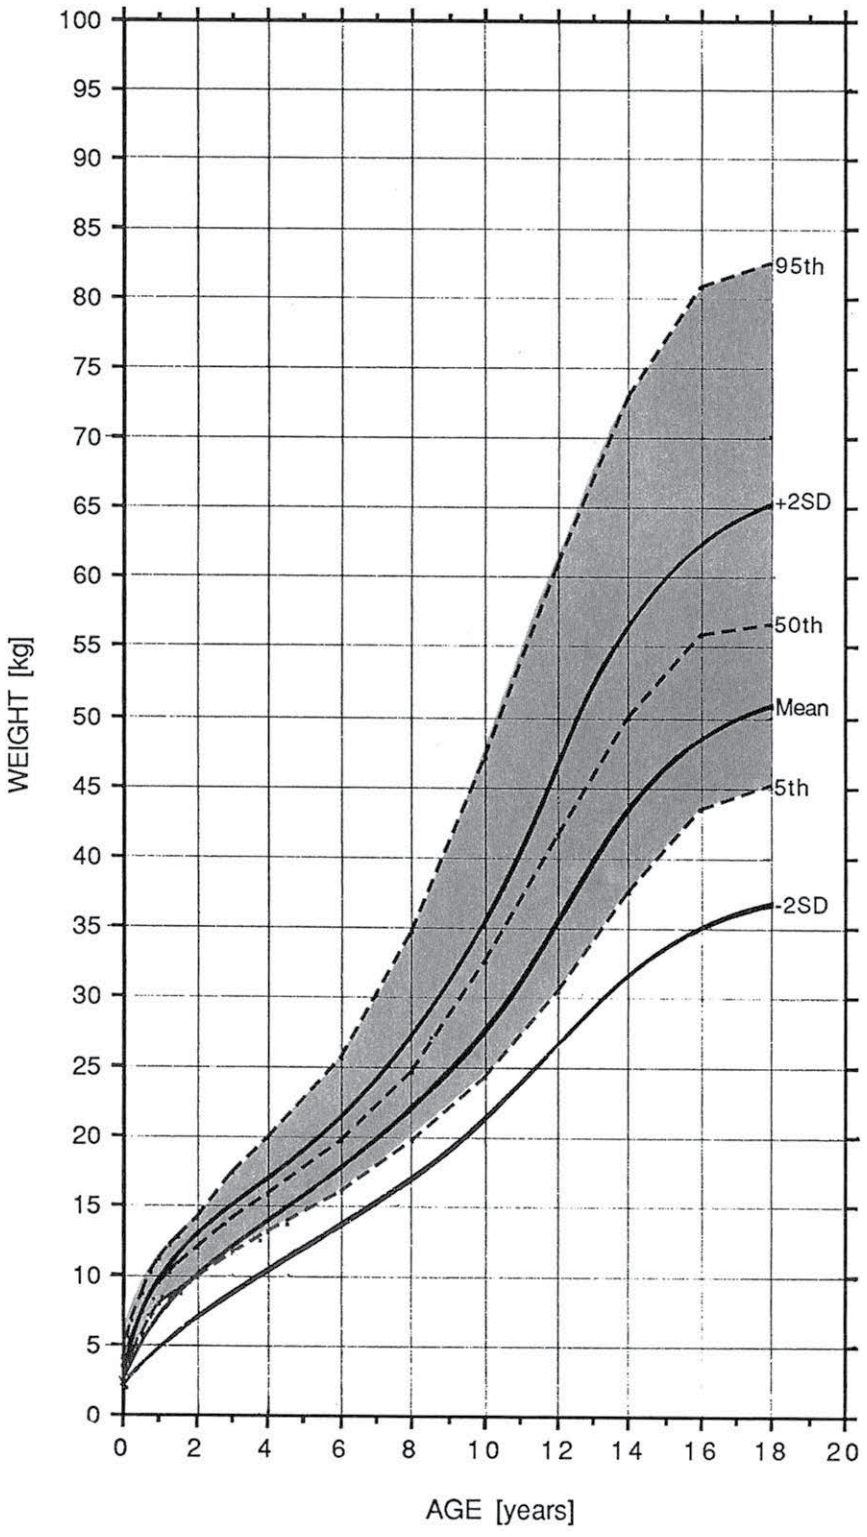

FIGURE 2C

suspected clinically. Parents should be educated regarding the signs and symptoms of hypercalcemia. Children with WS and normocalcemia should have the reference daily intake of calcium,[34] and parents should be cautioned not to restrict calcium without medical supervision.[31] Infants with hypercalcemia are usually successfully treated with a low-calcium diet and increased water intake under medical and nutritional supervision, and they require more frequent surveillance of calcium concentrations. Serum blood urea nitrogen, creatinine, vitamin D concentrations (25-hydroxyvitamin D and 1,25-dihydroxyvitamin D), and intact parathyroid hormone should be checked if hypercalcemia is present.[35] The urine calcium/creatinine ratio in a random spot urine should be obtained at the time of diagnosis and if hypercalcemia is present (Table 2). If hypercalciuria is found, hydration status should be assessed, serum calcium concentration should be measured, dietary calcium intake should be assessed, and renal ultrasonography should be performed to evaluate for nephrocalcinosis. Referral to a pediatric nephrologist and/or pediatric endocrinologist should be considered for management of persistent hypercalcemia, hypercalciuria, or nephrocalcinosis.[32] Multivitamin preparations containing vitamin D should be avoided in early childhood, and vitamin D supplementation should be used with caution in older children and adults.[4] Approximately 50% of individuals with WS have impaired bone mineral status osteopenia or osteoporosis; the etiology is unknown.[1,14]

GASTROINTESTINAL

Infants and toddlers with WS often have difficulty feeding (eg, disordered suck and swallow and textural aversion) and may be brought for medical care because there are symptoms of gastroesophageal reflux,

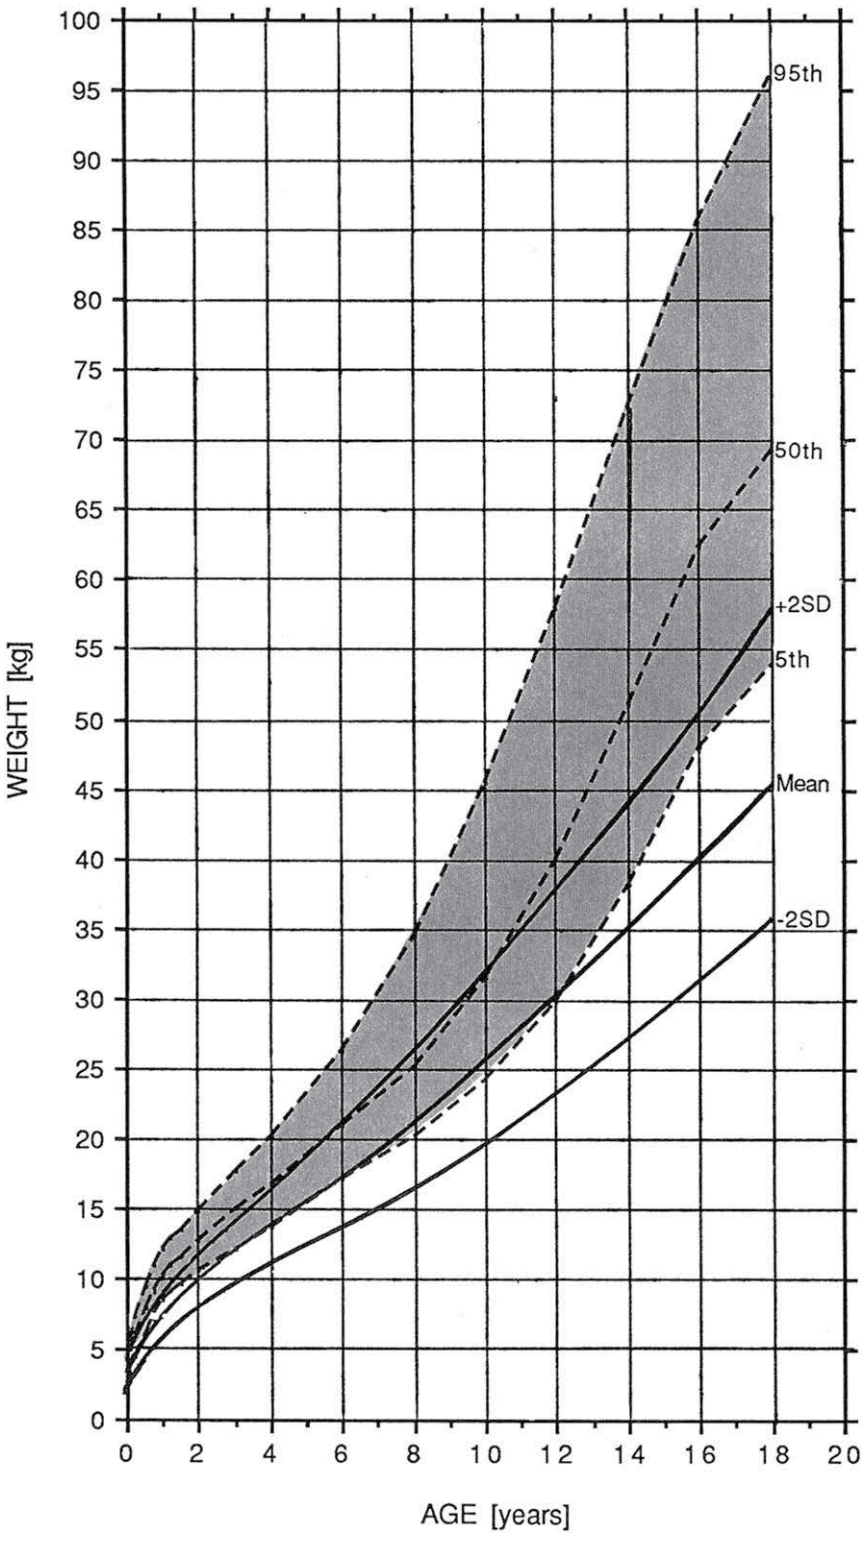

FIGURE 2D
Weight for males with Williams syndrome. Normal curves = dashed lines; affected patients = solid lines. Reprinted with permission from: Saul RA, Geer JS, Seaver LH, Phelan MC, Sweet KM, Mills MS. *Growth References: Third Trimester to Adulthood.* Greenwood, SC: Greenwood Genetic Center; 1998.

colic, or failure to achieve anticipated weight gain.[6] Feeding evaluation and therapy may be of benefit for infants having difficulty transitioning to solid foods, for assessment of aspiration risk and dysphagia, and for intervention for failure to gain weight appropriately according to WS growth curves. Feeding gastrostomy tubes are rarely necessary in WS. Obesity may become a problem for older children and adults.[13]

Chronic constipation is a common lifelong problem and must be aggressively treated. Typical interventions include increasing water and fiber in the diet followed by the addition of osmotic laxative treatment. Complications of constipation include rectal prolapse, hemorrhoids, and intestinal perforation. There is an increased incidence of diverticulitis occurring at a young age in adolescents and adults.[36] Abdominal pain is a frequent complaint in both children and adults; potential causes include gastroesophageal reflux, hiatal hernia, constipation, cholecystitis, diverticular disease, and discrete arterial stenosis causing ischemia.[37]

GENITOURINARY

Urinary tract malformations are present in 10% of children with WS,[38] bladder diverticula are present in 50%,[38,39] and a history of urinary tract infection is present in 25%.[40] Bladder capacity is reduced and detrusor overactivity is found in 60% of patients,[36] leading to urinary frequency in 69% and enuresis.[40] Daytime urinary continence is typically achieved by 4 years of age, and nocturnal continence is present in 50% at 10 years of age.[6] Children 4 to 12 years of age have a daytime urinary incontinence rate of 18% and nocturnal enuresis rate of 45%, whereas 2.7% of teenagers have daytime incontinence and 13.5% have nocturnal enuresis.[41]
Ultrasonography of the kidneys and

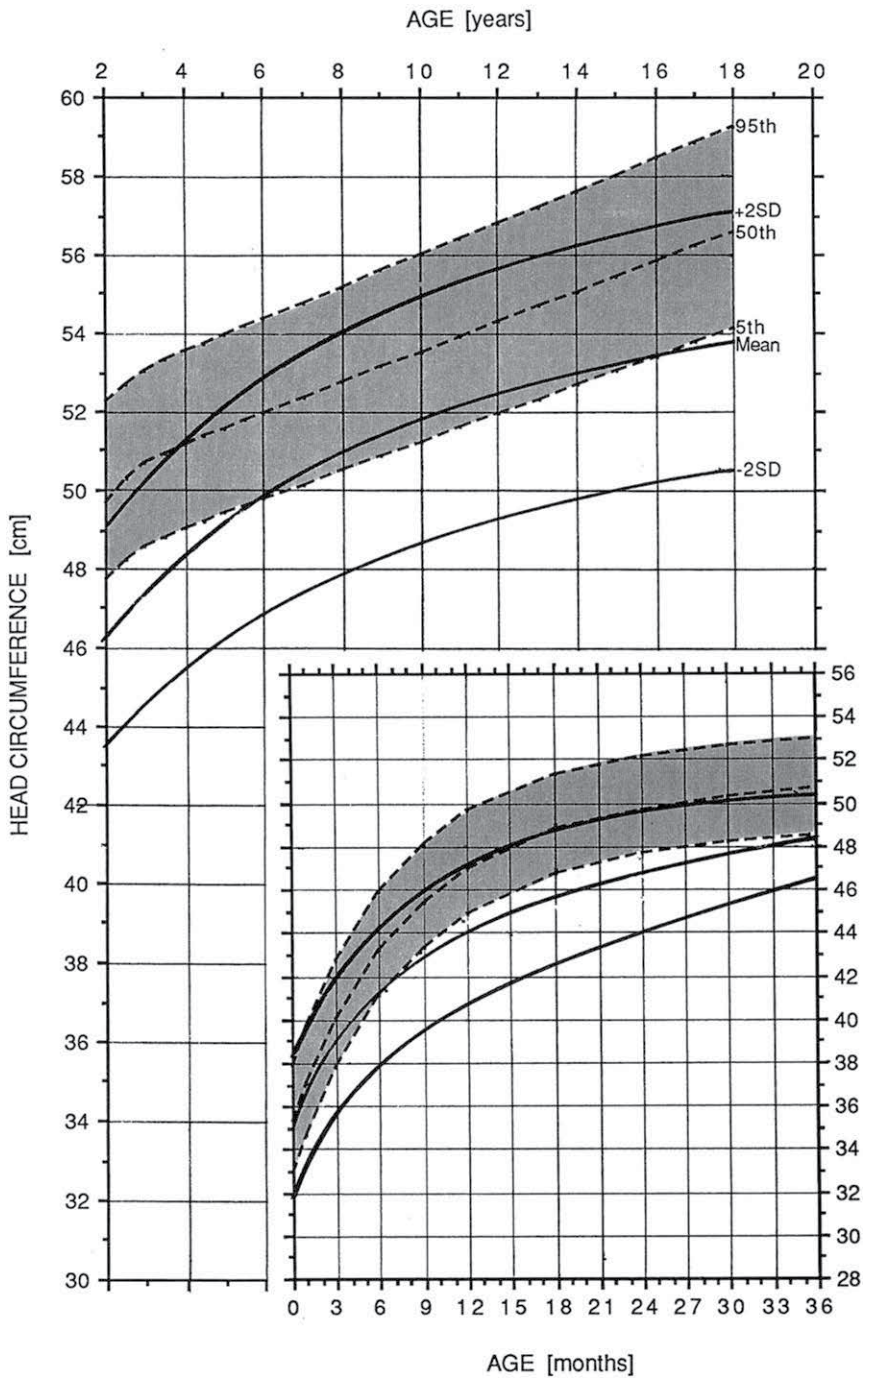

FIGURE 2E
Head circumference for females with Williams syndrome. Normal curves = dashed lines; affected patients = solid lines. bladder should be completed at the time of diagnosis. Individuals with recurrent urinary tract infections may require additional urologic evaluation. The practitioner should maintain a low threshold for lower urinary tract imaging (voiding cystourethrography) for the evaluation of voiding dysfunction and/or urinary tract infection. Diverticula may lead to both of these symptoms and can be recurrent after surgical repair. Kidney function should be assessed at the time of diagnosis (serum urea nitrogen and creatinine concentrations and urinalysis).

NEUROLOGY, DEVELOPMENT, COGNITION, AND BEHAVIOR

Neurologic problems include axial hypotonia and peripheral hypertonia with increased deep tendon reflexes in the lower extremities. Signs of cerebellar dysfunction, such as ataxia and tremor, may increase with age.[42] Posterior fossa size is reduced in WS, although cerebellar volume is preserved and may contribute to Chiari I malformation in some individuals with WS.[43] Symptoms of headache, dizziness, and dysphagia should prompt the clinician to consider a pediatric neurology referral for evaluation for Chiari malformation. Developmental milestones are delayed,[6] and children should be referred to an early intervention program for physical, occupational, and speech therapy evaluation and treatment. Hippotherapy referral may be considered; hippotherapy uses equine movement during physical, occupational, and/or speech therapy and addresses problems of balance.[44] Although joint laxity is present in young children, joint contractures occur in older children and adults and lead to an awkward gait.[45] Nightly stretching range-of-motion exercises are often recommended. Radioulnar synostosis, found in 10% of affected children, does not respond to physiotherapy or surgical intervention.[46] Lordosis and kyphosis are common at all ages; 18% have scoliosis.[6,47]

Children with WS have a unique cognitive and behavioral profile.[7,48,49] Cognitive, motor, and language delay are universal, and in 75% of children, intellectual disability is ultimately diagnosed. Children demonstrate

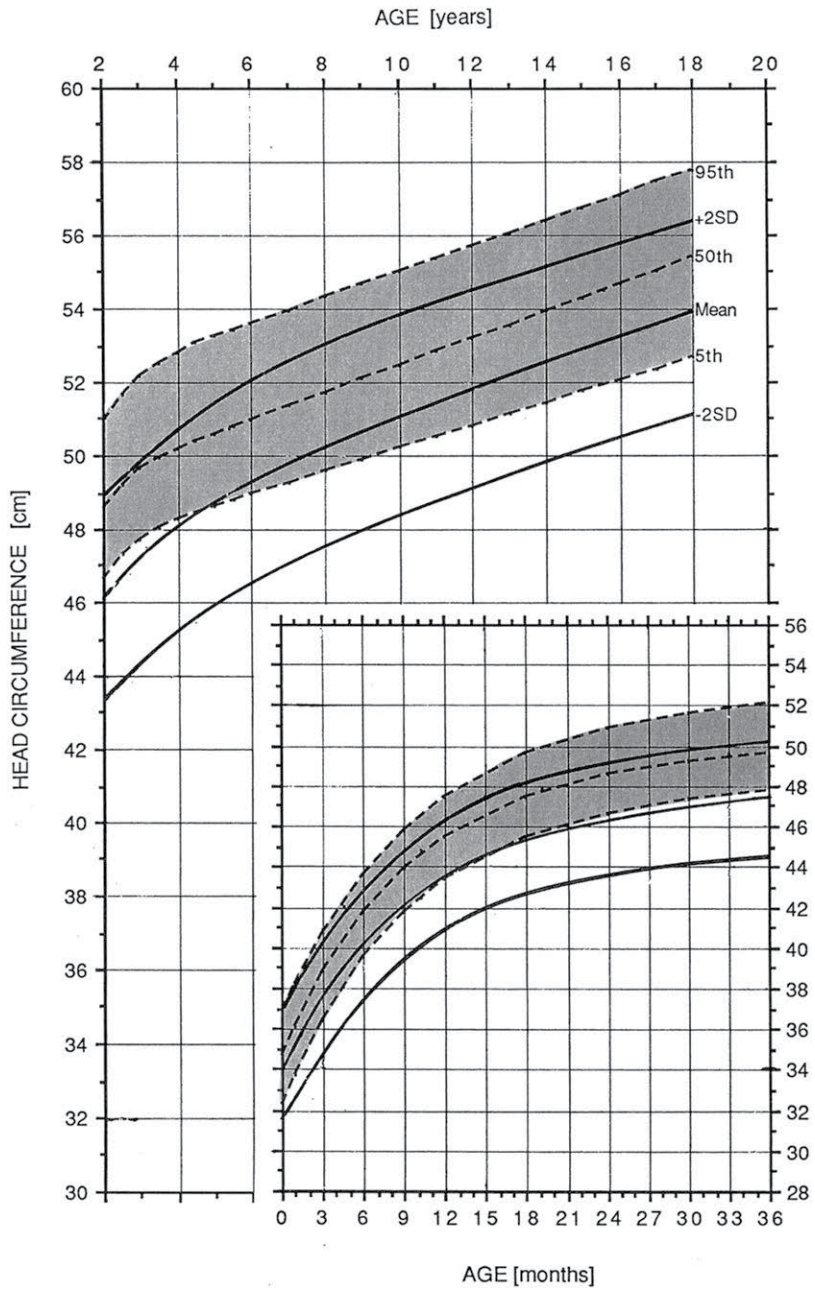

FIGURE 2F
Head circumference for males with Williams syndrome. Normal curves = dashed lines; affected patients = solid lines. a relative strength in language and verbal short-term memory, with a significant weakness in visuospatial construction.[7] A detailed psychoeducational evaluation with information provided by the primary care pediatrician to the school regarding the unique cognitive and behavioral profile is important for school-aged children to develop an appropriate educational plan. A referral to a neuropsychologist may be of benefit. Speech and language, physical, and occupational therapies are important for school-aged children.

Behavioral problems may include hypersensitivity to sound, attention-deficit/hyperactivity disorder (ADHD), and nonsocial anxiety.[50] Approximately 50% of children with WS will require pharmacologic treatment of ADHD and/or anxiety. Although overfriendliness and an empathetic nature are commonly observed, many individuals have difficulty with emotional regulation.[51] In young children who have limited language, there may be symptom overlap with autism spectrum disorder, such as restricted interests and repetitive behaviors.[52] A referral for assessment for autism may be considered in those children. Behavioral interventions based on applied behavior analysis may be helpful, and older children benefit from social skills training and training to master daily living skills.[48] Adaptive behavior skills in both children and adults are often more impaired than would be expected for IQ.[53,54] Adults require vocational training and instruction in community living skills. Mental health problems, most commonly anxiety, are reported in 25% to 75% of adults.[13,55]

Sleep disorders are common (50% to 65%), including sleep onset delay, frequent awakenings, decreased sleep efficiency, and increased respiratory-related arousals.[56,57] An abnormal or absent melatonin peak may explain disturbance of circadian rhythm in some children.[58,59] The clinician

should discuss appropriate sleep hygiene and consider a sleep study if obstructive sleep apnea is suspected.

OCULAR AND AUDITORY

Hyperopia, nasolacrimal duct obstruction, and strabismus are common in WS.[60] An ophthalmologic evaluation should be performed at the time of diagnosis with follow-up as necessary. Mild to moderate sensorineural hearing loss is present in 60% of children and 90% of adults.[61] Audiologic assessment should be performed between 6 and 12 months of age and repeated annually.[61] Recurrent otitis media is common. The use of noise-canceling headphones is helpful to children who have increased sensitivity to sound or specific phobia for loud noises. Earwax buildup is a common problem and may be treated with cerumen-softening drops.[13]

DENTAL

Dental problems include microdontia, missing teeth, and localized enamel hypoplasia.[62] Poor fine motor skills cause difficulty with maintenance of dental hygiene and increase the risk of dental caries. A dental home should be established by 1 year of age or within 6 months of the eruption of the first tooth. The dental recall interval should be based on caries risk; dental cleaning every 4 months has been recommended.[4] Caregivers should be instructed to assist with brushing and flossing. If dental procedures require anesthesia, WS-specific sedation and anesthesia recommendations should be followed.[29,30] Dental malocclusion is present in 85% of individuals with WS and responds to orthodontic treatment. An orthodontic assessment should be part of the evaluation in the dental home.

ENDOCRINE

Hypothyroidism is present in 5% to 10% of children[33] At a minimum, thyroid function should be assessed at the time of diagnosis, annually for the first 3 years, and every 2 years thereafter. Subclinical hypothyroidism (mild thyroid-stimulating hormone elevation with normal thyroxine [T4]) is present in 30%.[63] Puberty often occurs early (18% of girls), but true precocious puberty is rare.[64] A gonadotropin-releasing hormone agonist may be used to treat early puberty; treatment in girls successfully delays menarche and results in taller height compared with controls.[65] Abnormal glucose tolerance test results have been documented in 60% to 75% of adults with WS with an increased prevalence of type 2 diabetes mellitus.[66,67] An oral glucose tolerance test is recommended at 30 years of age and should be repeated every 5 years if results are normal.[13]

MEDICAL HOME AND TRANSITION

Establish a medical home with a clear emphasis on continuity of care and the role of the family members as partners in the ongoing management and care of the child. A summary of anticipatory guidance is provided in Table 3. Counsel the family regarding networks of support, such as extended family, friends, clergy, support groups, and community agencies that serve children and adults with disabilities. The diagnosis should be reviewed and discussed with the affected individual in adolescence with referral to support groups for the adolescent (see American Academy of Pediatrics policy statement "Transition of Care Provided for Adolescents With Special Needs").[68]

Assist in transition to adult care (especially for cardiology care). Many pediatricians feel comfortable continuing to provide primary care

well into young adulthood. Pediatricians can educate the adult and family regarding medical management for adults with WS.[37] Counseling should be provided regarding sexuality and reproductive issues, and genetic counseling should be provided. Vocational training and social skills training are essential for successful transition to independent functioning within the community for adults.

Health Supervision for People With Achondroplasia

Julie Hoover-Fong, MD, PhD, FACMG,[a] Charles I. Scott, MD, FAAP,[b] Marilyn C. Jones, MD, FAAP,[c] COMMITTEE ON GENETICS

Achondroplasia is the most common short-stature skeletal dysplasia, additionally marked by rhizomelia, macrocephaly, midface hypoplasia, and normal cognition. Potential medical complications associated with achondroplasia include lower extremity long bone bowing, middle-ear dysfunction, obstructive sleep apnea, and, more rarely, cervicomedullary compression, hydrocephalus, thoracolumbar kyphosis, and central sleep apnea. This is the second revision to the original 1995 health supervision guidance from the American Academy of Pediatrics for caring for patients with achondroplasia. Although many of the previously published recommendations remain appropriate for contemporary medical care, this document highlights interval advancements in the clinical methods available to monitor for complications associated with achondroplasia. This document is intended to provide guidance for health care providers to help identify individual patients at high risk of developing serious sequelae and to enable intervention before complications develop.

The original "Health Supervision for Children with Achondroplasia" policy from the American Academy of Pediatrics (AAP) in 1995 provided useful management recommendations to pediatricians caring for children with achondroplasia from birth through early adulthood.[1] The first revision in 2005 expanded the scope of the document to include new information about the molecular genetics of achondroplasia and improvements in anticipatory guidance in terms of prevention and treatment of complications of the condition.[2] The majority of the information provided in those documents remains pertinent and accurate in the current care of patients with achondroplasia. This revision highlights additional interval advancements in the clinical methods available to monitor for complications associated with achondroplasia, including adult health complications that may be rooted in childhood and should, therefore, be monitored and managed from birth. This document also incorporates a few of the more recent treatment options for achondroplasia to provide an informational core from which the general pediatrician can explore

abstract

[a]Greenberg Center for Skeletal Dysplasias, McKusick-Nathans Department of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, Maryland; [b]Nemours/Alfred I. duPont Hospital for Children and Sidney Kimmel Medical College, Thomas Jefferson University, Wilmington, Delaware; and [c]Department of Pediatrics, University of California, San Diego and Rady Children's Hospital, San Diego, California

Drs Hoover-Fong and Scott wrote new content and edited content from the previous AAP statement and responded to reviews; Dr Jones provided editorial and content review, shepherded the document through multiple stakeholders review, and addressed specific concerns; and all authors approved the final manuscript as submitted.

Clinical reports from the American Academy of Pediatrics benefit from expertise and resources of liaisons and internal (AAP) and external reviewers. However, clinical reports from the American Academy of Pediatrics may not reflect the views of the liaisons or the organizations or government agencies that they represent.

The guidance in this report does not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

All clinical reports from the American Academy of Pediatrics automatically expire 5 years after publication unless reaffirmed, revised, or retired at or before that time.

additional resources with patients. The authors recognize the audience for this document may have variable medical resources at their disposal to monitor and treat patients with achondroplasia. The intent of this consensus document is to provide guidance that may be adapted to each individual patient in his or her unique environment. Children and adolescents with achondroplasia should have care coordinated through a medical home; however, some of the surveillance and counseling suggested in this document will be provided by a number of specialists with expertise in the management of achondroplasia, if these individuals are available.

Achondroplasia is the most common condition associated with severe, disproportionate short stature, with an estimated birth incidence of 1 in 10 000 to 1 in 30 000.[3,4] There is no recognized ethnic or sex predisposition. The diagnosis can usually be made on the basis of clinical characteristics and specific features on radiographs, including a square shape of the pelvis with a small sacrosciatic notch, short pedicles of the vertebrae with interpedicular narrowing from the lower thoracic through lumbar region, rhizomelic (proximal) shortening of the long bones, proximal femoral radiolucency, and a characteristic chevron shape of the distal femoral epiphyses. Other clinical features include short stature, macrocephaly (absolute and relative), trident configuration of the hands, and long, near-normal-length trunk.

Achondroplasia is an autosomal dominant disorder, meaning a person with achondroplasia has a 50% chance of passing the condition on to each of his or her offspring regardless of the sex of the parent or child, provided the other parent is unaffected. Approximately 75% to 80% of patients with achondroplasia are born to average-stature parents, representing a new dominant mutation in the fibroblast growth factor receptor type 3 *(FGFR3)* gene in that affected individual.[3,5,6] Because virtually all of the causal mutations occur at exactly the same nucleotide within the gene,[6] genetic testing for achondroplasia is straightforward. It is not necessary to perform molecular testing in every child with a clinical diagnosis of achondroplasia. However, *FGFR3* testing should be considered when a confirmed achondroplasia diagnosis is needed. For example, infants or children with an atypical achondroplasia presentation may have a second genetic condition.[7] Such children also should be referred for clinical genetics evaluation. Different mutations in the *FGFR3* gene can also cause 2 other short stature dysplasias: hypochondroplasia and thanatophoric dysplasia. A child with hypochondroplasia has the same clinical features as one with achondroplasia, as listed above, but milder overall. Growth hormone therapy may be considered as a treatment option for those with hypochondroplasia, but it has not been shown to be effective in patients with achondroplasia.[8–11] Thanatophoric dysplasia usually can be distinguished from achondroplasia and hypochondroplasia because severe thoracic and lung hypoplasia are expected to be lethal in the pre- or early postnatal period in the former.[12] Rare exceptions of a patient with thanatophoric dysplasia surviving are reported but only with aggressive measures of resuscitation at delivery and significant respiratory support thereafter.[13,14] Age-specific recommendations pertaining to genetic counseling and testing are also included in each age category discussed later in this report.

A great deal is known about the natural history of achondroplasia that can be shared with the family.[4,15] The average adult height in achondroplasia is approximately 120 to 135 cm (4–4.5 ft) (Fig 1).[16] The most common complication, occurring in adulthood, is related to lumbosacral spinal stenosis with compression of the spinal cord or nerve roots.[17–19] This complication is usually treatable by surgical decompression, with less sequelae if treated at an early stage. Most children with achondroplasia do well. However, children affected with achondroplasia commonly have delayed motor milestones (Fig 2),[20–22] otitis media, and bowing of the lower legs.[23] Less commonly, infants and children may have serious health consequences related to craniocervical junction compression because of a relatively small foramen magnum, hydrocephalus, upper-airway obstruction, or thoracolumbar kyphosis. Although they are less common, anticipatory care should include identifying children at highest risk and intervening to prevent potentially serious sequelae. Most individuals with achondroplasia are of normal intelligence and are able to lead independent and productive lives.[24] Because of their disproportionate short stature, however, a number of psychosocial problems can arise.[25] Chronic pain, a problem that may begin in childhood and magnify into adulthood without intervention, may be playing a larger role in overall life satisfaction and coping than has been previously appreciated.[26] Further investigation is needed to better understand the temporal relationship among pain, function, and medical or surgical treatment to allow for the highest quality of life possible. Families can benefit from anticipatory guidance and the opportunity to learn from other families with children of disproportionate short stature. The consensus-based guidance in this report is designed to help the pediatrician care for children with achondroplasia and their families. Issues that need to be addressed at various ages are outlined in Table 1.

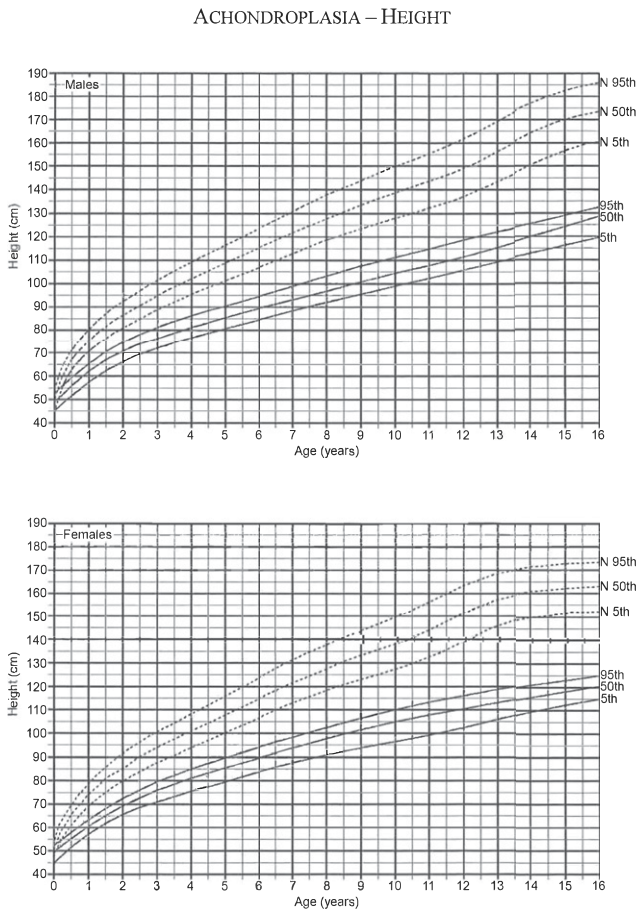

FIGURE 1

Fifth, 50th, and 95th percentiles for height for children with achondroplasia (solid lines) compared with height growth curves for the general population (dotted lines), based on 1955 observations from 162 boys and 131 girls with achondroplasia. Adapted from Hoover-Fong JE, Schulze KJ, McGready J, Barnes H, Scott CI. Age-appropriate body mass index in children with achondroplasia: interpretation in relation to indexes of height. *Am J Clin Nutr*. 2008;88(2):364–371. It should be noted that these suggestions are not appropriate for other skeletal dysplasia diagnoses because each type has its own natural history, complications, and specific management recommendations. The most recent nosology of genetic skeletal disorders includes 436 different disorders with primary bone manifestations, and more than half of these are considered to be skeletal dysplasias.[27] Because of the vast range of medical considerations for patients with these diagnoses, it is important that pediatricians and their patients partner with a physician with special experience and expertise concerning skeletal dysplasias, particularly achondroplasia, early in the child's life. This report provides generally applicable suggestions that must be tailored to a particular child's condition and needs. For reference, the American Board of Medical Genetics and Genomics has an online resource to search for a certified geneticist throughout the United States and in several countries around the world (http://www.abmg.org/pages/searchmem.shtml).[28]

Similarly, the Little People of America, Inc, the largest US patient support group for short-stature skeletal dysplasia patients and their families, may be a suitable resource for information for medical providers and families (http://www.lpaonline.org/).[29]

In addition to the age group–specific guidance presented in this report, 3 topics often arise in early discussions with families about potential treatment of achondroplasia: growth hormone therapy, surgical limb lengthening, and, more recently, drug trials for new medications to alter bone morphology and growth. The following is not meant to be an exhaustive review of these issues but rather a brief foundation on which further discussions can be built.

First, in reference to supplemental growth hormone treatment, there have been longitudinal studies of relatively small groups of patients with achondroplasia treated with growth hormone of various doses and durations.[8–11] A recent meta-analysis of 12 trials showed a clinically insignificant increase of –5 to –4 SD below the mean when children with achondroplasia were treated with growth hormone.[10] Some authors also suggest that the rapid (although unsustained) linear growth predisposes to worsening scoliosis and kyphosis in these patients.[10] In contrast, a few studies have shown a greater adult height in patients with hypochondroplasia treated with growth hormone therapy.[8] As noted previously, genetic testing would be useful to differentiate these 2 conditions before embarking on a long and expensive course of supplemental growth hormone treatment.

With respect to limb lengthening, there is a body of medical literature addressing different surgical methods of lengthening, complications of the procedures,[30] perspectives on lengthening the upper extremities,[31]

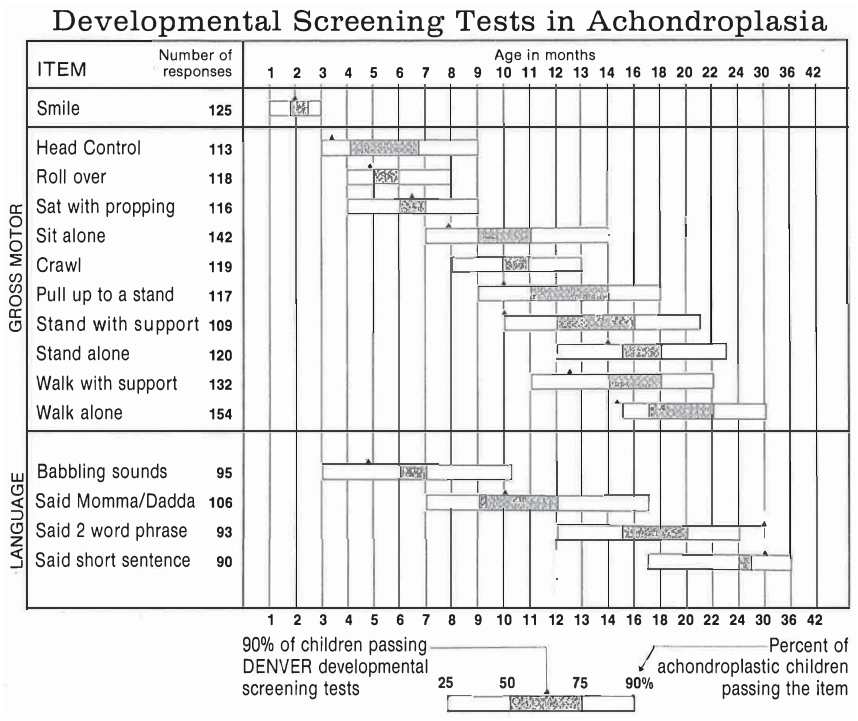

FIGURE 2

Developmental screening tests in achondroplasia, based on questionnaire information from 197 individuals. The bar scale reveals the percentage of children with achondroplasia passing the item. The black triangle on top of the bar reveals the age at which 90% of normal children pass the same item. Illustration is from *Growth References*. Third edition. 2011. Permission for use was granted by the Greenwood Genetic Center.

and reviews of the entire process.[32] Opinions about the use and success of surgical limb lengthening vary widely. Regardless of a patient or family's position, however, it is important for the pediatrician to be aware of a few key issues surrounding surgical limb lengthening. Limb lengthening is a long and costly process, associated with significant physical pain for the young patient. The age at which this procedure is recommended varies among surgeons, but implementation before epiphyseal closure is the norm, with many encouraging commencement at younger than 10 years. Medical decision-making in this age group rests with the parent or legal representative who could make a decision without involving the child in the discussion. Per AAP policy on informed consent,[33] it is highly desired that the child and parents engage in discussion about such elective procedures before a decision is made. Finally, this procedure is associated with complications. Therefore, it is critical that the surgical team is readily available to manage short- and long-term complications associated with limb lengthening.

The last novel issue to address is the pharmaceuticals under development to potentially increase long bone growth and/or ameliorate the skeletal complications of this condition. There are several compounds currently at various stages of development with different targets and mechanisms.[34,35] More information about these trials can be found online at https://clinicaltrials.gov. The trial process often takes several years, and final approval is required from the US Food and Drug Administration for a new drug to become available through a prescription. For families contemplating enrollment of their child with achondroplasia in one of these trials, it is important to know that a physician conducting a clinical trial should have sufficient experience with the condition to differentiate complications (or a response) to a research pharmaceutical from the natural history of that condition.

THE PRENATAL VISIT

Pediatricians may be asked to counsel expectant parents whose fetus has achondroplasia or is suspected to have achondroplasia because of recognition on ultrasonography of disproportionate small stature and relative large head size. In some situations, the pediatrician may be the primary resource for counseling the family. At other times, counseling may already have been provided to the family by a clinical geneticist, genetic counselor, or maternal-fetal medicine specialist. Because of a previous relationship with the family, however, the pediatrician could be called on to review this information and assist the family in the decision-making process.

The diagnosis of achondroplasia in the fetus is made most often with certainty when one or both biological parents have this condition. In this circumstance, the parents are usually (but not always) knowledgeable about the disorder, the inheritance, and the prognosis for the offspring. However, specific inquiry about the presence of a short stature diagnosis in both parents is recommended when only the mother is present for the clinical visit and may not spontaneously offer that her partner also has short stature. Additionally, it is important to establish clearly the specific short stature diagnosis in both parents. If both parents have achondroplasia, for example, review of the potential outcome of this and each future pregnancy (25% average stature, 50% achondroplasia, 25% homozygous or "double dominant" and, therefore, lethal) is

straightforward. In the situation in which one parent has achondroplasia but the partner has a different dysplasia diagnosis, the recurrence risk discussion must be tailored to their specific diagnoses and associated inheritance. Often, there is little medical literature available to reference and anticipate the medical course of a compound heterozygous offspring. Ideally, such genetic counseling should be provided by genetic medicine professionals, such as genetic counselors and/or clinical geneticists.

Most often, the scenario presents when the diagnosis of achondroplasia is suspected late in gestation on the basis of long bone foreshortening incidentally discovered via ultrasonography in the fetus of an average-stature couple. It is rare for ultrasonographic features of achondroplasia to be noticeable before 26 weeks' gestation, although Boulet et al[36] reported a new prenatal ultrasonographic diagnostic sign for achondroplasia they named the "collar hoop" sign, which may be evident earlier. If long bone anomalies and/or disproportion are appreciated earlier in gestation, a skeletal dysplasia more severe than achondroplasia is likely.[37] Higher-level ultrasonography and examination for other diagnostic features are then required. Confirmation of diagnosis on the basis of ultrasonographic features

characteristic of achondroplasia can be provided by molecular testing (*FGFR3* mutational testing) of prenatal specimens (chorionic villus sampling at 11–13 weeks' gestation or amniocentesis after 15 weeks' gestation). Typically, this would be performed at a specialized prenatal center. If no such confirmation for achondroplasia (or any other dysplasia) has been completed, caution should be exercised when counseling the family.

Prenatal consultation involving a couple in which one or both carry a skeletal dysplasia diagnosis and are seeking genetic counseling and anticipatory guidance is best arranged before pregnancy.[38] Typically, this visit would be with a medical geneticist or genetic counselor. In this scenario, there is ample time to confirm the parental dysplasia diagnoses and evaluate the woman (if she is short stature) for neuraxial complications or previous surgical procedures, which could influence anesthesia options for delivery (ie, general versus spinal or epidural).

Depending on the prenatal situation, the pediatrician may consider the following steps as needed:

1. Review, confirm, and demonstrate laboratory or imaging studies leading to the diagnosis.
2. Explain the mechanisms for occurrence of achondroplasia in the fetus and the recurrence risk for the family, depending on the presence of a dysplasia in both, one, or neither of the parents.
3. Explain that up to 80% of patients with achondroplasia are born to average-stature parents. In these affected children, their achondroplasia occurred because of a spontaneous mutation in the *FGFR3* gene. In this situation, recurrence risk is empirically approximately 1% for future pregnancies for this specific couple because of the possibility of gonadal mosaicism.
4. Review the natural history and manifestations of achondroplasia, including variability.[4,15]
5. Discuss additional studies that could be performed in the newborn period to confirm the diagnosis (eg, blood test for mutation in *FGFR3,* radiographs to review for achondroplasia-specific features). If miscarriage, stillbirth, or termination occurs, confirmatory testing is important if the woman or family desires optimal genetic counseling. If specific molecular testing cannot be offered immediately, try to secure a blood or tissue sample for future testing.
6. Review currently available treatments and interventions, including efficacy, complications, adverse effects, costs, and other burdens of these treatments. Discuss possible future treatments and interventions. Please see the medical evaluation and anticipatory guidance discussions in the sections on health supervision for children ages 1 month to 1 year, 1 to 5 years, and 5 to 13 years.
7. Explore the options available to the family for the management and rearing of the child by using a nondirective approach. In cases of early prenatal diagnosis, these options may include discussion of pregnancy termination, continuation of pregnancy and rearing of the child at home, foster care, or adoption. If adoption is planned, the Little People of America, Inc, has adoption resources available (http://www.lpaonline.org/adoption).[39]
8. If the pregnant woman carries the diagnosis of achondroplasia, inform her that a cesarean delivery will be necessary because of the characteristic small pelvis and cephalopelvic disproportion (regardless of whether the fetus is average stature or has achondroplasia also and, therefore, macrocephaly). Prenatal consultation with a high-risk maternal or fetal medicine specialist is recommended to investigate whether general anesthesia or spinal or epidural anesthesia will be needed for delivery. In an average-stature pregnant woman carrying a fetus with achondroplasia, a cesarean delivery may also, but not always, be necessary because of fetal macrocephaly.
9. Establish where the infant with the suspected (or possible) skeletal dysplasia diagnosis will be delivered. Pediatric services to manage potential medical complications at or shortly after delivery may be necessary and are not available at all hospitals.
10. When both parents are of disproportionate short stature, assess the possibility of the fetus inheriting both conditions. Infants with homozygous achondroplasia usually are stillborn or die shortly after birth.[40]
11. Be aware that many of these discussions will be coordinated with the prenatal team, including a medical geneticist, genetic counselor, and/or maternal-fetal medicine specialist. The importance of a knowledgeable medical home for the expected infant should be reviewed.

HEALTH SUPERVISION FROM BIRTH TO 1 MONTH OF AGE: NEWBORN INFANTS

Diagnosis, Genetic Counseling

1. Confirm the diagnosis by radiographic studies in the newborn period. External physical

features may not be highly obvious for achondroplasia. Radiographs should include anteroposterior and lateral skull, anteroposterior and lateral cervical spine, anteroposterior and lateral chest and abdomen with pelvis and upper femurs, anteroposterior of each upper and lower extremity long bone, and anteroposterior of hands and feet separate from long bones. Molecular studies may be pursued if desired.

2. Discuss genetics of achondroplasia with the parents, including the following:
   a. Autosomal dominant inheritance: Any person with achondroplasia will have a 50% chance of passing this condition on to each offspring, regardless of the sex of the parent and child.
   b. Approximately 80% of children born with achondroplasia represent spontaneous new mutations in the *FGFR3* gene.
   c. Germ-line mosaicism (in which some germ cells are derived from a normal cell line and some are from a cell line with a mutation, also known as gonadal mosaicism) has been reported in families with achondroplasia. This means that 2 average-stature parents have had more than 1 child with achondroplasia attributable to gonadal mosaicism. The recurrence risk of achondroplasia in sporadic cases via gonadal mosaicism is approximately 1%.[41–43]
   d. Recurrence risk when both parents have a skeletal dysplasia diagnosis should also be reviewed.
3. Recognize the potential psychosocial implications for both parent and child related to short stature.
   a. Refer the family to a support group, such as Little People of America.[39]
   b. If parents do not wish to join a group, offer meeting individually with other affected individuals or parents.
   c. Discuss how they will tell their family and friends about their child's diagnosis.
   d. Refer to other support resources, such as clergy, social workers, and psychologists.
   e. Remind parents that most people with achondroplasia lead productive, independent lives.
   f. Supply the parents with educational books and pamphlets (http://www.lpaonline.org/).[29]
   g. Discuss the realistic functional difficulties for affected individuals.

Medical Evaluation

1. Measure and plot total body length, weight, and occipitofrontal circumference on achondroplasia-specific growth charts (Figs 1 and 3–5)[16,22,44] at birth and every health supervision visit. Review these growth parameters with both parents.
2. Use achondroplasia-specific developmental charts at every health supervision visit (Fig 2).[20,22]
3. Assess every infant with achondroplasia for craniocervical junction risks as soon as the diagnosis is recognized[45] via the following:
   a. Careful neurologic history and examination. This includes inquiry about feeding ability, choking or gagging with feeding, prolonged apnea while sleeping, cyanosis of lips or mouth with feeding or sleeping, symmetry of limb movements, and axial and appendicular tone.
   b. Polysomnography (overnight sleep study, evaluated by a pediatric pulmonologist, including end tidal carbon dioxide in addition to standard measures of apnea, hypopnea, saturation) to assess for unusual central apnea.
   c. Neuroimaging, provided it can be performed safely by appropriate medical personnel if sedation or anesthesia is required to obtain images. If abnormalities suggestive of craniocervical compromise are detected in the medical history, neurologic examination, or sleep study, then neuroimaging is indicated. Neuroimaging should not be used in isolation to determine when or whether surgery is indicated.
4. Consider the pros and cons of the neuroimaging options:
   a. Computed tomography with thin cuts and bone windows:
      i. Can compare foramen magnum size with published achondroplasia norms.[46,47]
      ii. May be possible without sedation.
      iii. Does not provide adequate images of brainstem and upper cervical cord to determine if there is neural compromise, signaling change.
   b. MRI:
      i. Provides direct assessment of the brainstem and upper cervical spinal cord, but no standards for estimation of foraminal size by MRI are currently available.
      ii. May require general anesthesia if fast MRI protocol is not used or available. General anesthesia should only be

performed in a clinical setting in which a pediatric anesthesiologist, nurse anesthetist, or other airway specialist is present to manage the procedure. Often, a newborn infant can be wrapped and scanned while asleep without sedation or anesthesia, particularly when a faster magnetic resonance scanner is available.

iii. Evidence that flexion or extension of the cervical spine during MRI may reveal dynamic cord compression and alteration of cerebrospinal fluid (CSF) flow in achondroplasia, which is a better indicator of the need for surgical intervention.[48,49]

5. Refer in a timely manner to experienced neurosurgical specialist if any of the following are detected during the aforementioned craniocervical junction assessment:
   a. Abnormal neurologic examination marked by hypotonia or "floppiness," weakness, sustained lower extremity clonus, asymmetric reflexes, or choking or gagging with eating.
   b. Poor weight gain on achondroplasia-specific growth charts, especially if caloric intake and/or infant feeding is sufficient.
   c. Sleep study showing hypoxemic episodes with oxygen saturation <85% and/or central apnea beyond that expected in an average-stature, healthy newborn infant.[50]
   d. Imaging showing marked smaller foramen magnum size, substantial deformation of the upper cervical spinal cord, or lack of CSF around the spinal cord.
6. Establish care with a pediatric orthopedist to monitor the spine.
7. Confirm newborn screening hearing result and follow-up failed screening results with formal audiology assessment.

Anticipatory Guidance

1. Discuss the following possible severe medical complications and methods of prevention:
   a. Unexpected infant death occurs in 2% to 5% of all infants with achondroplasia[50,51] if aggressive, early assessments are not pursued to detect central apnea resulting from compression of the brainstem and arteries at the level of the foramen magnum.
   b. The universally small foramen magnum may result in a high cervical myelopathy,[52,53] also detectable by the aforementioned early assessments.
   c. Macrocephaly with excessive extra-axial fluid and asymptomatic ventriculomegaly is a normal feature of achondroplasia[54] but may be complicated by hydrocephalus.
      i. Should head circumference increase unexpectedly on an achondroplasia-specific curve, the fontanelle bulge or become hard to palpation, or lethargy, irritability, poor weight gain, or marked developmental delay occur, the imaging and potential referral to a neurosurgical specialist is indicated.
      ii. Benign extra-axial fluid and asymptomatic ventriculomegaly visualized by MRI should not be misinterpreted as indicative of need for shunt placement.
   d. Restrictive pulmonary disease occurs in less than 5% of children with achondroplasia who are younger than 3 years.[55] Living at high elevation may exacerbate pulmonary complications as in average-stature individuals. Obstructive pulmonary disease is much more common and warrants systematic assessment.[15,56,57]
2. Be aware that most infants with achondroplasia develop thoracolumbar kyphosis. More severe kyphosis is associated with unsupported sitting before there is adequate trunk muscle strength and tone.[58,59] Borkhuu et al[60] observed developmental delays in motor skill acquisition (compared with other children with achondroplasia) to be highly associated with progression of thoracolumbar kyphosis.[61]
   a. Back support should be provided during bottle and/or breastfeeding.
   b. Unsupported sitting and devices that cause curved sitting or "C sitting," such as "umbrella-style" strollers and soft canvas seats, should be avoided during the first year of life.
   c. Care with a pediatric orthopedist should be established to monitor the spine.
3. Be aware that the common complication of spinal stenosis rarely occurs in childhood but manifests in older individuals with numbness, weakness, and altered deep tendon reflexes.[52] Severe thoracolumbar kyphosis can greatly exacerbate spinal stenosis; thus, the recommendation is to avoid unsupported sitting before there

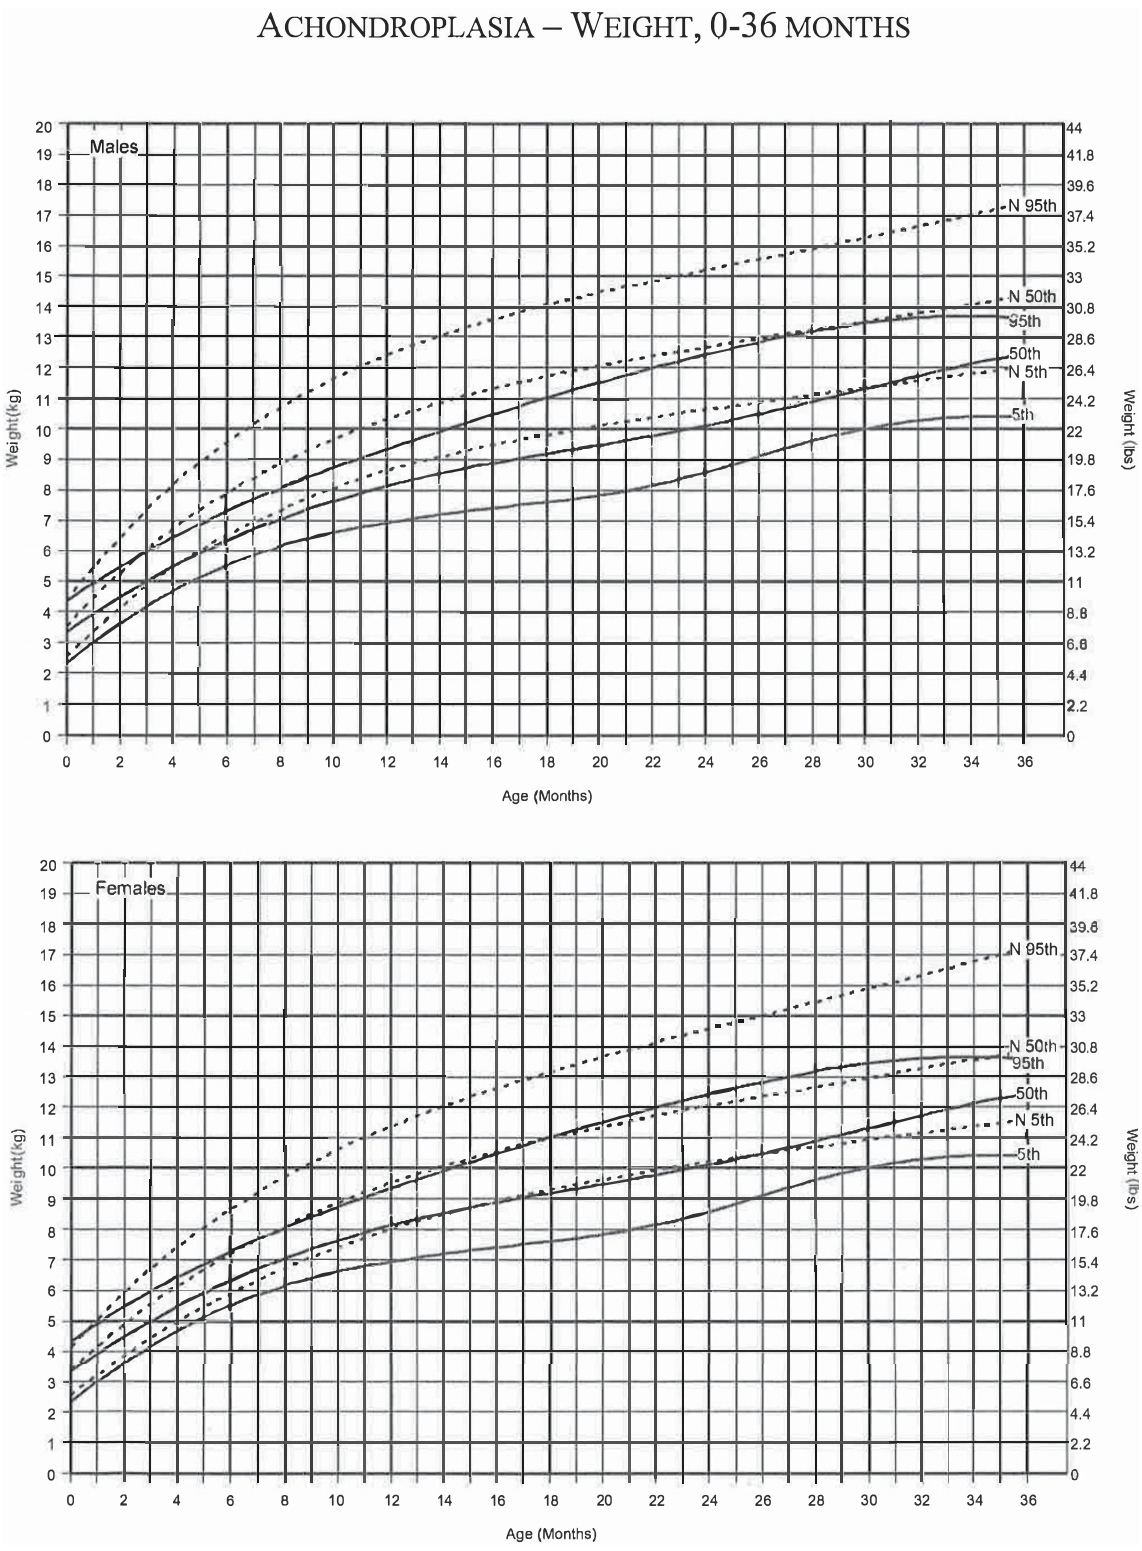

FIGURE 3

Fifth, 50th, and 95th percentiles for weight for boys (top) and girls (bottom) 0 to 36 months of age with achondroplasia (solid lines) compared with those of the general population (dotted lines), based on 1853 observations from 155 boys and 128 girls with achondroplasia. Adapted from Hoover-Fong JE, Schulze KJ, McGready J, Barnes H, Scott CI. Age-appropriate body mass index in children with achondroplasia: interpretation in relation to indexes of height. *Am J Clin Nutr.* 2008;88(2):364–371. Curves for the US population are from Kuczmarski RJ, Ogden CL, Guo SS, et al. *2000 CDC Growth Charts for the United States: Methods and Development.* Hyattsville, MD: National Center for Health Statistics; 2002. Illustration is from *Growth References.* Third edition. 2011. Permission for use was granted by the Greenwood Genetic Center.

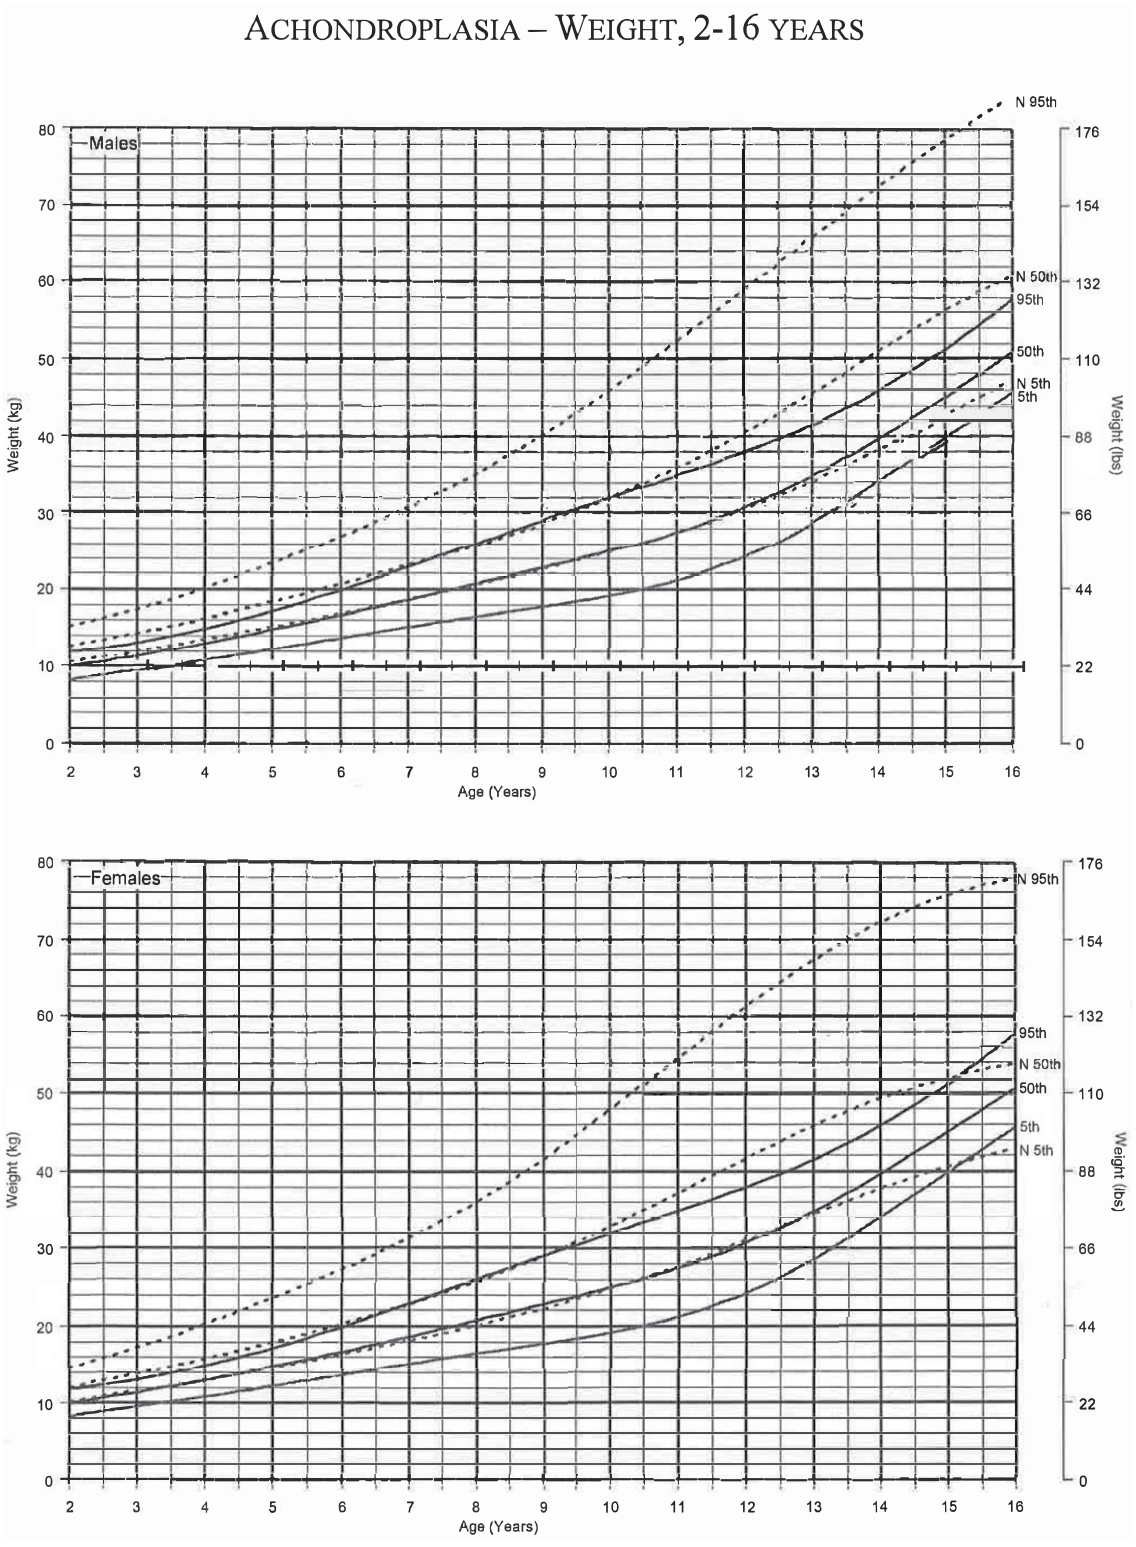

FIGURE 4

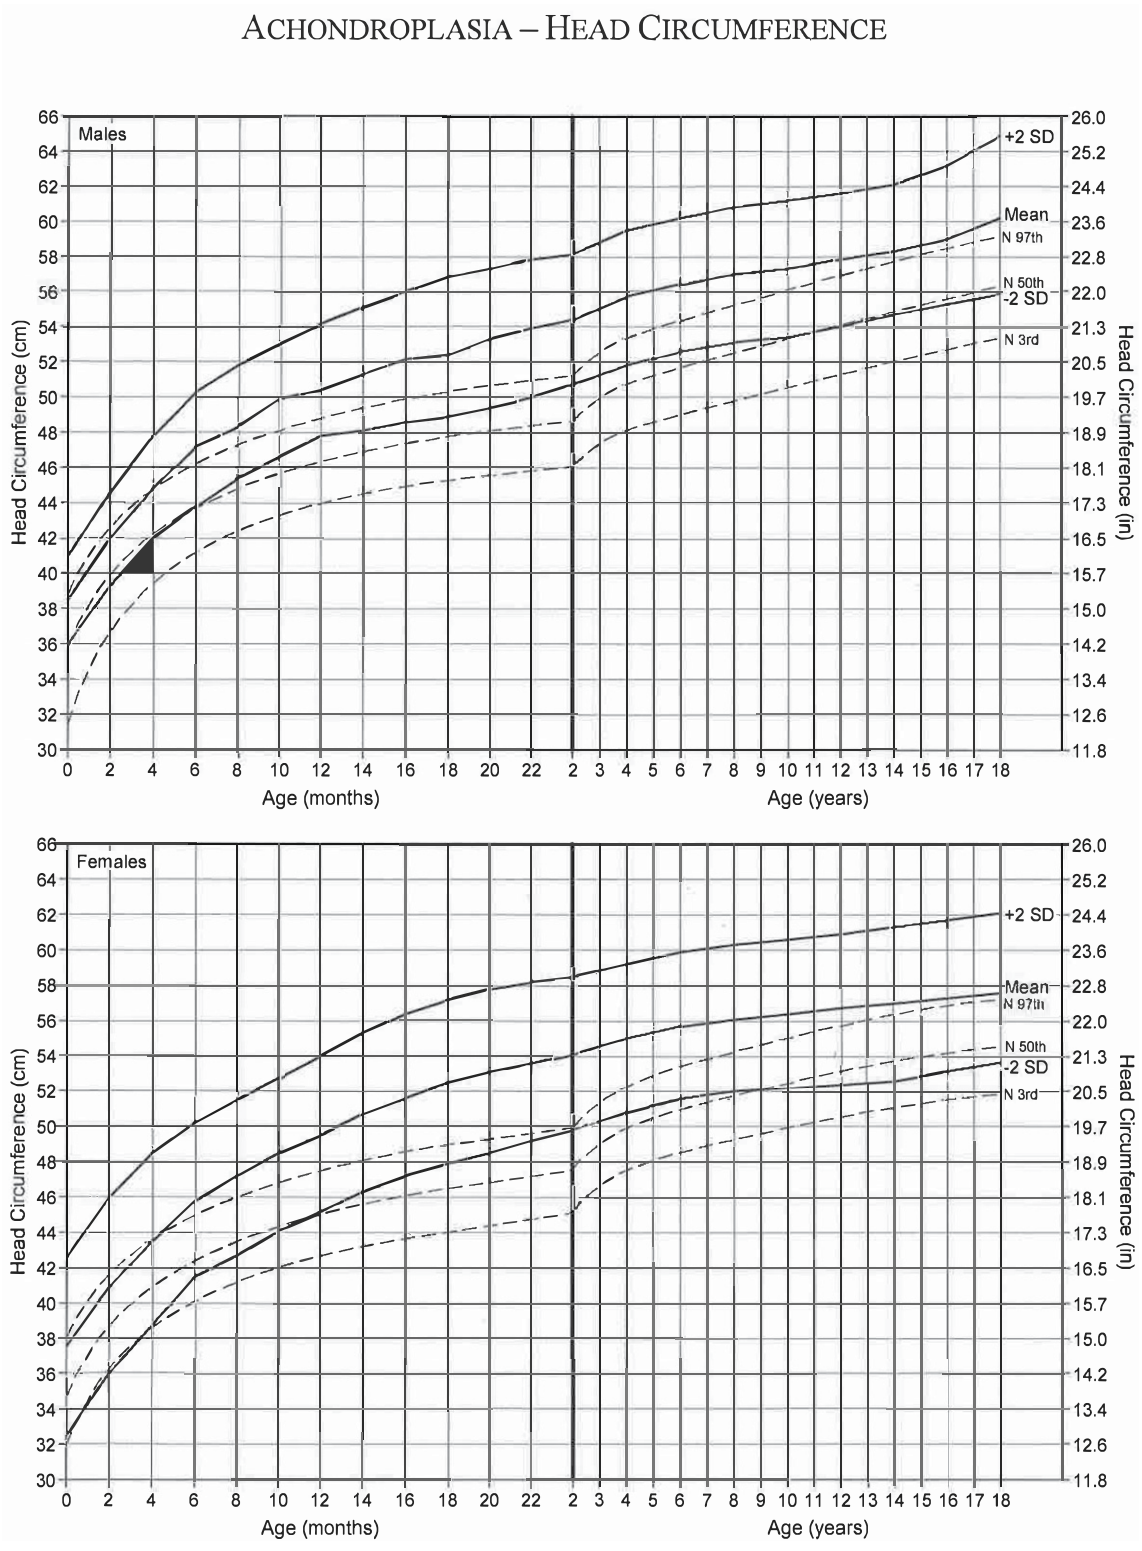

FIGURE 5

Head circumference curves (mean ± 2 SD) for children with achondroplasia (solid lines) compared with those for the general population (dashed lines). Data are derived from 114 boys and 145 girls. Graphs are adapted from Horton WA, Rotter JI, Rimoin DL, Scott CI, Hall JG. Standard growth curves for achondroplasia. *J Pediatr.* 1978;93(3):435–438. General population curves are from Rollins JD, Collins JS, Holden KR. United States head circumference growth reference charts: birth to 21 years. *J Pediatr.* 2010;156(6):907–913.e2. Illustration is from *Growth References.* Third edition. 2011. Permission for use was granted by the Greenwood Genetic Center.

is adequate trunk muscle strength and tone.

4. Advise parents to use an infant seat or infant carrier that has a firm back (not excessive padding) to support the neck and to use a rear-facing car safety seat for as long as possible.
    a. Car seat laws vary by state (and country) as to the age, weight, and/or height of a child required to convert their seat to forward-facing. Inquire with local experts (eg, police, hospital, or fire station where car seat installation clinics are offered) or online motor vehicle administration.
    b. Infants should not sleep unattended in car seats; this is especially important in those with achondroplasia because decreased axial tone and strength in combination with the large head creates great risk of craniocervical and airway compromise.
5. Avoid use of products like mechanical swings and carrying slings to limit uncontrolled head movement around the small foramen magnum. There is a risk of death if the cervicomedullary junction is compromised, even in infants in which there were no signs of abnormal neurologic status. Always support the head and neck with the caregiver's hand, minimizing flexion and extension (also known as head bobbling).
6. Advise parents that normal intelligence is expected.
7. Advise parents that overall, people with achondroplasia have fairly normal life expectancy. However, the following should be noted:
    a. Wynn et al[61] demonstrated 10-year earlier mortality.[62]
    b. Longitudinal studies are required to determine the cause for this, but serious problems may occur during infancy (eg, cervicomedullary compression, central sleep apnea), as noted.
8. Inform parents that growth hormone and vitamin supplements are not effective in significantly increasing stature. Growth hormone may cause a temporary increase in growth velocity, but little to no significant increase in end height has been shown.[8–11]
9. Discuss the availability of extended limb lengthening using a variety of surgical techniques, which can result in an increase in ultimate height.
    a. This is a long process with high cost and associated physical pain and can have postoperative adverse effects.
    b. If a family undertakes this procedure, it is critical that the affected child and parents have discussed this at great length and that they are in agreement that proceeding with this surgery is the appropriate decision for them.
    c. If pursued, it should be completed at a well-established surgical center with experience and the capability to manage these patients long-term for complications.
10. Inform parents that the final expected adult height for people with achondroplasia is approximately 120 to 135 cm (4–4.5 ft).
11. If an individual with achondroplasia requires anesthesia and surgery, consider the following[63]:
    a. Care should be taken in manipulation of the neck because uncontrolled neck movement (as may occur with intubation) could lead to unintentional spinal cord compression secondary to constriction of the foramen magnum.
    b. Medication should be dosed for patient size, not age.
    c. Venous access may be more difficult because of incomplete elbow extension.
    d. In general, spinal or epidural anesthesia should be avoided unless neuroimaging reveals adequate space inside the spinal canal and there are no signs of neurologic compromise.

HEALTH SUPERVISION FROM 1 MONTH TO 1 YEAR OF AGE: INFANCY

Diagnosis, Genetic Counseling

1. For infants not diagnosed in the newborn period, confirm diagnosis by radiographs and physical examination and offer molecular confirmation, if desired.
2. Inquire about personal support available to the family.
3. Inquire about contact with support groups.
4. Observe the emotional status of parents and intrafamily relationships.
5. Discuss the importance of normal socializing experiences with other children.
6. Ask the parents whether they have educated their family members about achondroplasia and offer resources to the Little People of America or local genetic counselors; discuss sibling adjustment.
7. Review genetics of achondroplasia as outlined in the Birth to 1 Month section, as needed.

Medical Evaluation

1. Assess growth (length, weight, head circumference) and

development only in comparison with children with achondroplasia (Figs 1–5).

2. Perform physical examination, including neurologic examination.
3. Check motor development and discuss development; note on the milestone charts for achondroplasia.[20,22] Expect motor delay as compared with average-stature, age-matched children but not social or cognitive delay.
4. For infants not diagnosed in the newborn period, arrange for polysomnography and neuroimaging at the time of diagnosis.
5. Refer the infant to a pediatric neurologist or pediatric neurosurgeon if any of the following are present:
   a. Head circumference disproportionately large for length and weight on achondroplasia-specific curves or head circumference crossing percentiles.
   b. Fontanelle bulging or becoming hard to palpation.
   c. Abnormal neurologic examination marked by hypotonia or "floppiness," lethargy, irritability, weakness, sustained lower extremity clonus, asymmetric reflexes, choking or gagging with eating, or early hand preference, which may be attributable to hydrocephalus or craniocervical junction compromise.
   d. Poor weight gain on achondroplasia-specific growth charts, especially if caloric intake is sufficient.
   e. Polysomnography showing hypoxemic episodes with oxygen saturation lower than 85% and/or central apnea beyond that expected in an average-stature, healthy infant.[50]
   f. Imaging showing marked smaller foramen magnum size, substantial deformation of the upper cervical spinal cord, or lack of CSF around spinal cord.
6. Check for serous otitis media. Formal behavioral audiometric assessment should be completed by 9 to 12 months of age and managed as part of routine health care for patients with achondroplasia, ideally on an annual basis.[62,64] Language delay may be present secondary to conductive hearing loss.
7. Continue to monitor for progression of kyphosis at the thoracolumbar junction.
   a. Parents and therapists (if used) should be instructed to provide back support during the first year of life.
   b. Avoid unsupported sitting and devices that cause curved sitting or "C sitting," such as "umbrella-style" strollers and soft canvas seats, during the first year of life.
   c. Position the infant for feeding with a straight back and head and neck in alignment, supported by firm pillows; a feeder seat may be a good option.
   d. Mild, mobile (nonfixed) thoracolumbar kyphosis will often improve or resolve when the child begins to walk.
   e. If severe kyphosis appears to be developing, seek pediatric orthopedic assessment to determine if bracing is needed. Rarely, surgical intervention may be necessary.[59,60]

Anticipatory Guidance

1. Discuss early-intervention services if needed. This is not a uniform recommendation simply because of the diagnosis of achondroplasia.
2. Review the increased risk of serous otitis media because of short eustachian tubes. Indicate that an ear examination is appropriate with any persistent or severe upper respiratory tract infection or when parents suspect that ear pain may be present.
3. Recommend annual audiology assessment as part of routine health care for patients with achondroplasia.[62,64]
4. There is a risk of jugular bulb dehiscence (absence of the temporal bone "roof" over the jugular bulb) in patients with achondroplasia. This malformation predisposes to accidental puncture of the jugular bulb during tympanostomy tube placement.[65]
5. Avoid infant carriers and seated positions that "curl up" the infant or young child and avoid prolonged unsupported sitting.
6. Advise parents to use an infant seat or infant carrier that has a firm back (reduced padding) to support the neck and to use a rear-facing car safety seat for as long as possible.
   a. Car seat laws vary by state (and country), so inquiry with local experts (eg, police, hospital, or fire station where car seat installation clinics are offered) or online motor vehicle administration is recommended.
   b. Infants should not sleep unattended in car seats; this is especially important in those with achondroplasia because decreased axial tone and strength in combination with the large head creates great risk of craniocervical and airway compromise.
7. Be aware that external rotation of the hips is commonly present and usually disappears spontaneously when the child begins to bear weight. This finding does not require bracing for the infant.

8. Discuss the option of filing for Supplemental Security Income benefits as appropriate.

HEALTH SUPERVISION FROM 1 YEAR TO 5 YEARS: EARLY CHILDHOOD

Diagnosis, Genetic Counseling

1. Review genetics of achondroplasia as outlined in the Birth to 1 Month section, as needed.
2. Inquire about contact with support groups.

Medical Evaluation

1. Assess growth (length or height, weight, head circumference) and development in comparison only with children with achondroplasia (Figs 1–5).
2. Assess BMI on achondroplasia-specific charts[66] in accordance with AAP recommendations to measure BMI.
3. Perform physical examination, including neurologic examination.
4. Check motor development and discuss development; note on the milestone charts for achondroplasia.[20,22] Expect motor delay as compared with average-stature, age-matched children but not social or cognitive delay.
5. Continue to monitor for thoracolumbar kyphosis. Any kyphosis present should resolve as the child begins to bear weight. Lumbar lordosis usually develops but rarely requires specific intervention. Weight bearing and walking may occur late; however, they are expected by 2 to 2.5 years of age. When weight bearing begins, the external rotation of the hips should self-correct to a normal orientation within 6 months.
6. Anticipate some bowing of the legs. Many children will also have instability of the soft tissues surrounding the knee and internal tibial torsion. If positional deformity and instability leads to difficulty walking, a thrust at the knee (uncontrolled lateral or medial movement with weight bearing), or chronic pain, consult a pediatric orthopedist.
7. Check the child's hips for hip flexion contractures. Refer to physical therapy or pediatric orthopedics for exercise recommendation to decrease lumbar lordosis and hip flexion contractures if indicated. Stretching of the hip is performed gently so as not to cause subluxation.
8. Ensure that the patient has an audiology assessment every year in conjunction with establishment of care with an otolaryngologist.[62,64]
9. Ensure that the patient has a speech evaluation at no later than 2 years of age. If speech is delayed, conductive hearing loss attributable to chronic serous otitis media should be excluded.
10. Because most children with achondroplasia snore, monitor closely for signs of obstructive sleep apnea (increased retraction, glottal stops, choking, intermittent breathing, apnea, deep compensatory sighs, secondary enuresis, recurrent nighttime awakening or emesis) is recommended. If obstructive sleep apnea is suspected, then pulmonary consultation and polysomnography are indicated.
11. Be aware that gastroesophageal reflux disease may be more common in children with achondroplasia and may be more common in those with neurorespiratory complications.[67] In addition to usual treatments for gastroesophageal reflux disease, consider referral to a pediatric gastroenterologist or pulmonologist.
12. Do not misinterpret greater-than-average sweating as indicative of serious medical problems; it is normal in many children with achondroplasia, particularly while sleeping. But if there is sweating with eating or the sweating increases dramatically while sleeping and airway obstruction is observed, consider further evaluation with a sleep study.
13. In rare instances in which diagnosis of achondroplasia is delayed beyond 1 year of age, arrange for polysomnography for all individuals and neuroimaging on the basis of clinical signs and symptoms concerning for craniocervical compression, as discussed previously.

Anticipatory Guidance

1. Consider adapting the home so that the child can become independent (eg, lower the light switches, use lever door handles and lever sink faucets, make the toilet accessible, and supply step stools). Determine if an occupational therapy consultation is needed to help adapt the home.
2. Discuss adapting age-appropriate clothing with snapless, easy-opening fasteners and tuckable loops because children with achondroplasia have smaller fingers and shorter arms. Determine if an occupational therapy consultation is needed.
3. Discuss adaptation of toys, such as tricycles, to accommodate short limbs.
4. Discuss adaptation of toilets to allow comfortable, independent use. An extended wand for

wiping is rarely needed in this age group, provided surgical spinal fusion has not been performed. Discuss toileting at school and special preparations needed by the school because of the child's short stature.

5. Discuss the use of a stool during sitting so that the child's feet are not hanging. Feet need support while the child is sitting at a desk, in a chair, or on the toilet. A cushion behind the child's back may be required for good posture and to prevent chronic back pain.
6. Counsel parents for optimal protection to use a convertible rear-facing car safety seat to the highest weight and height allowed by the manufacturer of the seat.[68] A rear-facing seat provides the best support protection and positioning angle for a child with macrocephaly and skeletal dysplasia.
7. Review weight control and eating habits to avoid obesity, which often becomes a problem in mid to late childhood and through adulthood.
8. Discuss orthodontic bracing and the potential need for palatal expansion in the future.
9. Encourage all physical activities in which the child can participate safely. All children should avoid trampolines[69] and high-impact, body-contact, and collision sports.[70]
10. Discuss how to talk with the child and friends or family members about short stature.
11. Encourage preschool attendance so that the child can learn to socialize in an age-appropriate way, and work with parents to prepare the teacher and the other children so that the child is treated in an age-appropriate manner (ie, not dictated by the child's height).

HEALTH SUPERVISION FROM 5 TO 13 YEARS: LATE CHILDHOOD

Diagnosis, Genetic Counseling

1. Review genetics of achondroplasia as outlined in the Birth to 1 Month section, as needed.
2. Inquire about contact with support groups. They are especially useful at this age.

Medical Evaluation

1. Assess growth (height, weight, head circumference) and development in comparison only with children with achondroplasia (Figs 1–5).
2. Review weight control.[44,66] Encouraging and maintaining physical activity with dietary intake is important.
3. Complete a general and neurologically oriented physical examination.
4. Check deep tendon reflexes yearly for asymmetry or increased reflexes that suggest spinal stenosis.
5. Continue to assess history for possible obstructive sleep apnea (increased retraction, glottal stops, choking, intermittent breathing, apnea, deep compensatory sighs, secondary enuresis, recurrent nighttime awakening or emesis). If obstructive sleep apnea is suspected, then pulmonary consultation and polysomnography are indicated.
6. Ensure that formal hearing assessment is conducted as part of annual health maintenance for patients with achondroplasia,[62,64] with ear, nose, and throat follow-up should problems be identified.
7. Assess for pain and its effects on activities of daily living and desired physical activity.[26]

Anticipatory Guidance

1. Determine school readiness.
2. Discuss preparation of the school and teacher for a child with short stature. Suggest adaptive aids for the school to cope with heavy doors, high doorknobs, reaching for the blackboard, foot support, and a regular-sized desk. Also, be sure that the child can use the restroom independently.
3. Prepare the child for the questions and curiosity of others.
4. Assure the parents that children with achondroplasia usually are included in the regular education program.
5. Counsel parents to use a child safety seat with a full harness to the highest weight allowed by the manufacturer of the seat and then to transition to the belt-positioning booster seat for optimal seatbelt positioning.
6. Review socialization and foster independence.
7. Maintain orthopedic surveillance every 1 to 2 years or sooner, if problems occur.
8. Emphasize supported sitting in school desks and while doing homework to avoid kyphosis.
9. Develop an activity program with acceptable activities, such as swimming and biking. The child should avoid competitive gymnastics and collision sports because of the potential for neurologic complications secondary to cervical spinal stenosis.
10. Review orthodontic and speech status.

HEALTH SUPERVISION FROM 13 TO 21 YEARS OR OLDER: ADOLESCENCE TO EARLY ADULTHOOD

Diagnosis, Genetic Counseling

1. Discuss the diagnosis with the adolescent to be sure that he or she has the vocabulary and the understanding of the genetic nature of achondroplasia.
2. Discuss contraception. People with achondroplasia usually are fertile. The importance and use of

contraception should be discussed with both male and female adolescents with achondroplasia, just as it should be for average-stature adolescents. Tailored to the maturity and sexual activity of the adolescent or young adult, review recurrence risk counseling with the patient, as outlined in the Prenatal Visit section previously. The parents of adolescents or young adults may have heard this information for their recurrence risk counseling; now the adolescent needs this information for his or her reproductive decision-making. Ideally, discussions about prenatal testing, pregnancy, and delivery are conducted before conception occurs.[38]

3. Continue to encourage participation in social activities and support groups. It is particularly useful during this age period.
4. Per the published AAP guidelines for adolescent health, proceed with discussions regarding smoking, drug use, alcohol use, sexual activity, gender identity, exposure to weapons, food and shelter security, and a focus on bullying and psychological health.

Medical Evaluation

1. Continue to record growth parameters.
2. Review weight control and diet. Encouraging and maintaining physical activity with dietary intake is necessary.
3. Complete a general and neurologically oriented physical examination. Monitor for any signs or symptoms of nerve compression and check deep tendon reflexes, tone, and sensory findings.
4. Continue to assess for possible obstructive sleep apnea and obtain polysomnography on the basis of symptoms.
5. Formal hearing assessment is recommended as part of routine health care for patients with achondroplasia, ideally on an annual basis.
6. Assess for pain and its effects on activities of daily living and desired physical activity.

Anticipatory Guidance

1. Check on social adaptation. Foster independence.
2. Review orthodontic status.
3. Continue weight counseling.
4. Encourage the family and affected patient to set career and life goals high and appropriate, as for other members of the family.
5. Discuss college, vocational planning and training, and other plans after high school.
6. Discuss driving. A driver's license is obtainable. Drivers usually require a vehicle that is adapted with pedal extenders; extenders that can be easily mounted and removed as needed are available. Consultation with a local driver rehabilitation specialist or the Association for Driver Rehabilitation Specialists (http://www.aded.net/; phone 866-672-9466) may be helpful if vehicle modifications are needed. Individuals who want to have an air bag on-off switch must read an informational brochure and submit an official request to the National Highway Traffic Safety Administration (1-888-327-4236; www.nhtsa.gov).
7. Assist in transition to adult health care.

HEALTH SUPERVISION FOR ADULTS WITH ACHONDROPLASIA

Health supervision for adults with achondroplasia, which includes genetic counseling, medical concerns and surveillance, and anticipatory guidance, is multifaceted. Health supervision requires specific management recommendations based on the scope of the disease and symptomatology of the patient. Several of the key features that should be addressed in adulthood are included in the Prenatal Visit section for short-stature adults and noted in Table 1.

Identification, Evaluation, and Management of Children With Autism Spectrum Disorder

• *Clinical Report*

CLINICAL REPORT Guidance for the Clinician in Rendering Pediatric Care

American Academy of Pediatrics

DEDICATED TO THE HEALTH OF ALL CHILDREN™

Identification, Evaluation, and Management of Children With Autism Spectrum Disorder

Susan L. Hyman, MD, FAAP,[a] Susan E. Levy, MD, MPH, FAAP,[b] Scott M. Myers, MD, FAAP,[c] COUNCIL ON CHILDREN WITH DISABILITIES, SECTION ON DEVELOPMENTAL AND BEHAVIORAL PEDIATRICS

Autism spectrum disorder (ASD) is a common neurodevelopmental disorder with reported prevalence in the United States of 1 in 59 children (approximately 1.7%). Core deficits are identified in 2 domains: social communication/interaction and restrictive, repetitive patterns of behavior. Children and youth with ASD have service needs in behavioral, educational, health, leisure, family support, and other areas. Standardized screening for ASD at 18 and 24 months of age with ongoing developmental surveillance continues to be recommended in primary care (although it may be performed in other settings), because ASD is common, can be diagnosed as young as 18 months of age, and has evidenced-based interventions that may improve function. More accurate and culturally sensitive screening approaches are needed. Primary care providers should be familiar with the diagnostic criteria for ASD, appropriate etiologic evaluation, and co-occurring medical and behavioral conditions (such as disorders of sleep and feeding, gastrointestinal tract symptoms, obesity, seizures, attention-deficit/hyperactivity disorder, anxiety, and wandering) that affect the child's function and quality of life. There is an increasing evidence base to support behavioral and other interventions to address specific skills and symptoms. Shared decision making calls for collaboration with families in evaluation and choice of interventions. This single clinical report updates the 2007 American Academy of Pediatrics clinical reports on the evaluation and treatment of ASD in one publication with an online table of contents and section view available through the American Academy of Pediatrics Gateway to help the reader identify topic areas within the report.

INTRODUCTION

Autism spectrum disorder (ASD) is a category of neurodevelopmental disorders characterized by social and communication impairment and

restricted or repetitive behaviors.[1] ASD affects more than 5 million Americans, with an estimated prevalence of approximately 1.7% in children.[2] The care needs of children with ASD are significant, affect parents and siblings as well, and require substantial community resources. Direct and indirect costs of caring for children and adults with ASD in the United States in 2015 were estimated to be $268 billion, more than the cost of stroke and hypertension combined.[3] The lifetime cost of education, health, and other service needs for an individual with ASD ranges from $1.4 to $2.4 million dollars, depending on whether he or she has any co-occurring intellectual disabilities.[4] To deliver timely and effective medical, behavioral, educational, and social services across the lifespan means that primary care providers must understand the needs of individuals with ASD and their families. ASD is more commonly diagnosed now than in the past, and the significant health, educational, and social needs of individuals with ASD and their families constitute an area of critical need for resources, research, and professional education.

In the 12 years since the American Academy of Pediatrics (AAP) published the clinical report "Identification and Evaluation of Children With Autism Spectrum Disorders"[5] and its companion, "Management of Children With Autism Spectrum Disorders,"[6] reported prevalence rates of ASD in children have increased, understanding of potential risk factors has expanded, awareness of co-occurring medical conditions and genetic contribution to etiology has improved, and the body of research supporting evidence-based interventions has grown substantially. This updated clinical report builds on previous reports and guidance for care of children and youth with ASD. It also reflects changes in diagnostic criteria after publication of the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5)[1] in 2013. The DSM-5 established a single category of ASD to replace the subtypes of autistic disorder, Asperger syndrome, and pervasive developmental disorder not otherwise specified in the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, Text Revision* (DSM-IV-TR). With the current reported prevalence rate of 1: 59 children (approximately 1.7%), all primary care providers can expect to have children and youth with ASD in their practices.[2] As noted in earlier clinical reports, the primary care provider has critical access to the child in the context of the medical home to identify symptoms of ASD early in childhood, support the family through the process of diagnosis and intervention, address etiologic evaluations, help the family understand how to interpret the evidence supporting different interventions so they can effectively engage in shared decision-making, and manage co-occurring medical conditions that may influence outcome and affect daily function. The primary care provider can help minimize disparities in age of diagnosis of African American and Hispanic children and be alert to the potential for gender bias in symptom recognition.[7] This updated document aims to provide primary care providers with a summary of current information in a single report that will help guide them in providing a medical home for the patient with ASD.

SECTION 1: PREVALENCE

Incidence is the onset of new diagnoses over time in a selected cohort. Without consistent longitudinal data in a specified cohort, incidence cannot be determined. Because of the heterogeneity of symptoms and severity in ASD, it may be diagnosed in children at different ages. What is reported is age at recognition of symptoms, not the actual onset. As a result, prevalence is more typically reported than incidence, reflecting rates of ASD in the population at a point in time.

The reported prevalence of children with ASD has increased over time, and primary care providers are often asked about the reasons for this increase. This increase may be attributable to several factors, including broadening in the diagnostic criteria with ongoing revisions of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM), the more inclusive definition of pervasive developmental disorder with the adoption of the *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition* (DSM-IV) in 1994,[8] increased public awareness of the disorder and its symptoms, recommendations for universal screening for ASD,[5,9] and increased availability of early intervention and school-based services for children with ASD. In part, the increasing numbers of children with a diagnosis of ASD may reflect diagnostic substitution, the recognition of ASD in children previously primarily diagnosed with intellectual disability or a co-occurring genetic syndrome.[10] A true increase in the prevalence of ASD associated with other biological risk factors is also possible.

Prevalence rates in US populations are similar to those of other industrialized countries,[11] and lower rates are reported in resource-limited countries, where epidemiological data are more difficult to collect.[12] Data on national samples suggest that the prevalence of ASD is stabilizing.[2,13] Ongoing epidemiological studies help to understand changes in the reported prevalence over time. Epidemiological data help to predict the need for services and identify potential risk factors. Surveillance methods include regional, state, and/or national registry systems;

records- or services-based analyses; surveys; and other methods, including population-based case findings.

In 2000, the US Centers for Disease Control and Prevention (CDC) established the Autism and Developmental Disabilities Monitoring (ADDM) Network as a population-based public health surveillance system to estimate the prevalence of ASD in children 8 years of age. ADDM reports published in 2014 and 2016 revealed comparable prevalence rates (approximately 1 in 68),[14,15] but the report published in 2018[2] revealed a slightly increased rate (1 in 59). Additional data over time will help determine if rates have stabilized. The data also revealed some variation in prevalence rates across the participating states, with the highest rates in the locations where both educational and health records were available for chart abstraction and standardized application of diagnostic criteria. Regional variation in prevalence may also reflect availability of services, local provider practices for ASD screening, educational policies, school and/or community resources, and insurance mandates, among other factors. The CDC also published data on the prevalence of ASD in children who were 4 years of age in 2010. A lower prevalence rate for diagnosis (1.34%) was reported in these children (approximately 30% less than that of children 8 years of age). The lower identified prevalence and higher proportional rate of children 4 years of age with ASD and intellectual disabilities may be attributable, in part, to later diagnosis of children with ASD and average-range cognitive abilities.[16] The National Survey of Children's Health (2011–2012) and the National Survey of Children with Special Health Care Needs (2009–2010) were analyzed for the age the parents reported diagnosis as well as for parent-reported subjective severity. The minority of children were identified as having ASD before 3 years of age. Diagnosis later than 6 years of age was reported in one-third to half of children. Later age at diagnosis was associated with reported mild presentation.[16]

CDC surveillance data published in 2014 revealed that white, non-Hispanic children were approximately 20% more likely to be identified with ASD before the case review than were non-Hispanic African American children and were about 50% more likely to be identified with ASD than were Hispanic children.[14] Recent prevalence data reveal increasing rates of ASD in Hispanic and African American children. This may reflect more widespread awareness of the symptoms among parents, schools, and health care providers and improved rates of screening in health supervision care.[2] Studies examining the effects of race and ethnicity on age at diagnosis are conflicting,[7] but earlier diagnosis of ASD is associated with higher socioeconomic status and access to services. African American and Hispanic children diagnosed with ASD by age 4 years were more likely to have coexisting intellectual disability than were white, non-Hispanic children, suggesting that some African American and Hispanic children with ASD and average to above-average intelligence may not have been identified.[17]

SECTION 2: CLINICAL SYMPTOMS

Despite advances in understanding the neurobiology and genetics of ASD, the diagnosis of ASD continues to be based on identifying and reporting behaviorally defined clinical symptoms. The challenges in determining accurate prevalence rates, in part, relate to the need for consistency in clinical diagnosis of a very heterogeneous disorder. In 2013, the DSM-5 consolidated the diagnosis of ASD into a single category and emphasized the importance of identifying coexisting developmental and behavioral disorders and symptoms. In the years since the 2007 AAP clinical reports on ASD, both professional education and public awareness have promoted recognition of symptoms that might lead to early identification of ASD, use of standardized screening approaches, and management of associated medical and behavioral features of ASD from infancy through adolescence.

Core Symptoms

Although symptoms of ASD are neurologically based, they manifest as behavioral characteristics that present differently depending on age, language level, and cognitive abilities. Core symptoms cluster in 2 domains (social communication/interaction and restricted, repetitive patterns of behavior), as described in the DSM-5.[1] Atypical development in several functional areas contribute to symptoms of ASD. Abnormalities in understanding the intent of others, diminished interactive eye contact, and atypical use and understanding of gesture presage atypical development of social communication and pretend play as well as interest in other children. Symptoms of ASD are further shaped by deficits in imitation and of processing information across sensory modalities, such as vision (gesture) and hearing (language). Repetitive behaviors and perseveration may be primary compulsions but may also be related to atypical processing of sensory information or may reflect a desire to instill predictability when an individual does not understand the intent of others. The CDC "Learn the Signs. Act Early" Web site provides free resources to help families recognize developmental concerns, including autism (https://www.cdc.gov/ncbddd/actearly/), and Autism Navigator (www.autismnavigator.com) has a video glossary of early symptoms in toddlers.

Approximately one-quarter of children with ASD will be reported to have a regression in language or social skills, most typically between 18 and 24 months of age.[18,19] The reason for this loss of previously acquired milestones is not yet known. Although medical evaluation of loss of milestones is indicated, a history of regression in language and social interaction in children with ASD within the expected age range is not likely to be attributable to seizures or neurodegenerative disorders. Note that the processes underlying regression are not yet well understood. Current theories include synaptic "over pruning" in response to genetic factors.[20]

Diagnostic Criteria: DSM-5

The DSM has been central in establishing criteria for diagnosing mental and behavioral disorders. The diagnosis of infantile autism was introduced in the *Diagnostic and Statistical Manual of Mental Disorders, Third Edition* nearly 30 years after the first edition of the DSM was published in 1952. The initial descriptions were narrow and referred to individuals with profound impairment. Publication of the DSM-IV in 1994 expanded the diagnosis to a spectrum of symptoms called pervasive developmental disorders (PDDs), which included the diagnoses of autistic disorder, Asperger disorder, pervasive developmental disorder not otherwise specified (PDD-NOS), childhood disintegrative disorder, and Rett disorder. The PDDs included individuals with lower- and higher-functioning cognitive skills. PDD-NOS was a diagnostic category requiring some, but not all, of the core symptoms necessary for other diagnoses in this category. Subsequent research has demonstrated that the subgroupings within PDD were not reproducible across research sites by using the same diagnostic data[21,22] and were not stable over time. The overlap between DSM-IV–defined subgroups paired with inconsistency in their application across research sites supports the decision to consolidate the subgroups into 1 diagnostic category, ASD, in the DSM-5. The DSM-IV divided the symptoms of ASD into 3 areas: qualitative impairment of social reciprocity, qualitative impairment of communication, and restricted and repetitive behaviors. In the DSM-5, core symptoms were divided into 2 domains (social communication and social interaction and restrictive, repetitive patterns of behaviors).[23] To fulfill diagnostic criteria for ASD by using the DSM-5, all 3 symptoms of social affective difference need to be present in addition to 2 of 4 symptoms related to restrictive and repetitive behaviors. Examples in Table 1 are illustrative but not exhaustive. The recognition of symptoms of ASD related to sensory processing led to the inclusion of sensory symptoms, such as hyper- or hyporeactivity to sensory input or unusual interests in sensory aspects of the environment. Examples include apparent indifference to pain or temperature; sensitivity to sound, taste, or textures; and intense visual interest in objects or movement. The DSM-5 notes that a diagnosis may be made at older ages, when the demands of the social or school environment may result in functional impairment.

Almost all individuals with a diagnosis of autistic disorder or Asperger syndrome by using DSM-IV criteria would be diagnosed with ASD by using DSM-5 criteria.[24] To determine if the same patients would be identified by the DSM-IV and DSM-5 criteria, the CDC ADDM Network looked at its chart abstraction data on 8-year-old children.[25] This analysis revealed that more than 80% of children diagnosed with PDD-NOS would also be diagnosed with ASD.[25] It is possible that the narrative in the charts that were abstracted was influenced by knowledge of the DSM-IV criteria.[26] There is a high level of agreement of surveillance data by using DSM-IV-TR and DSM-5 criteria.

The DSM-5 criteria have been shown to appropriately identify younger children and those with mild symptoms.[25,27] These children with milder cognitive and adaptive symptoms may be the ones most likely to have significant change with early intervention services.

The DSM-5 also introduced an approach to severity rating, which is summarized in Table 2. Severity rating reflects the impairment of the ASD symptoms and the resultant service needs of the individual. Severity rating is not a quantifiable score that can be used to monitor progress at this time; in clinical use, it often reflects the impact of cognitive limitations.[28] Measures have been published that attempt to capture severity of core symptoms[29,30] and allow for measurement of improvement with intervention.[31] To date, no single measure adequately reflects the combination of medical, behavioral, and educational severity in a fashion that will help clinicians and families determine progress with intervention across multiple functional domains. Coexisting medical disorders also affect the perception of severity and the prognosis for children with a diagnosis of ASD. The DSM-5 includes course specifiers that help describe the variation in symptoms of individuals with ASD. Course specifiers include the presence or absence of intellectual impairment, language impairment, catatonia, medical conditions, and known genetic or environmental etiologic factors. Patients with Rett syndrome are no longer automatically considered to have a diagnosis of ASD according the DSM-5, although individuals with this neurogenetic disorder may also meet diagnostic criteria for ASD. Specific genetic causes of ASD should be recorded as specifiers for individuals with ASD when identified. The DSM-5 promotes

TABLE 1 DSM-5 Criteria for Autism Spectrum Disorder

Domains	Criteria: Deficits	Examples
A. Persistent deficits in social communication and social interaction across multiple contexts, as manifested by the following, currently or by history; must have all 3 symptoms in this domain	1. Social-emotional reciprocity	Abnormal social approach and failure of normal back-and-forth conversation; reduced sharing of interests, emotions, or affect; failure to initiate or respond to social interactions
	2. Nonverbal communicative behaviors used for social interaction	Poorly integrated verbal and nonverbal communication; abnormalities in eye contact and body language or deficits in understanding and use of gestures; total lack of facial expressions and nonverbal communication
	3. Developing, maintaining, and understanding relationships	Difficulties adjusting behavior to suit various social contexts; difficulties in sharing imaginative play or in making friends; absence of interest in peers
B. Restricted, repetitive patterns of behavior, interests, or activities, as manifested by at least 2 of the following, currently or by history; must have 2 of the 4 symptoms	1. Stereotyped or repetitive motor movements, use of objects, or speech	Simple motor stereotypies, lining up toys or flipping objects, echolalia, idiosyncratic phrases
	2. Insistence on sameness, inflexible adherence to routines, or ritualized patterns or verbal nonverbal behavior	Extreme distress at small changes, difficulties with transitions, rigid thinking patterns, greeting rituals, need to take same route or eat food every day
	3. Highly restricted, fixated interests that are abnormal in intensity or focus	Strong attachment to or preoccupation with unusual objects, excessively circumscribed or perseverative interest
	4. Hyper- or hyporeactivity to sensory input or unusual interests in sensory aspects of the environment	Apparent indifference to pain/temperature, adverse response to specific sounds or textures, excessive smelling or touching of objects, visual fascination with lights or movement

Symptoms must be present in the early developmental period (but may not become fully manifest until social demands exceed limited capacities or may be masked by learned strategies in later life). Symptoms cause clinically significant impairment in social, occupational, or other important areas of current functioning. These disturbances are not better explained by intellectual disability (intellectual developmental disorder) or global developmental delay. Intellectual disability and ASD frequently co-occur; to make comorbid diagnoses of ASD and intellectual disability, social communication should be below that expected for the general developmental level. Specify whether: with or without accompanying intellectual impairment, language impairment or associated with a known medical or genetic condition or environmental factor. Add code 293.89 if catatonia is also present.

notation of all coexisting diagnoses as specifiers.

Social pragmatic communication disorder is a new diagnosis described within the DSM-5 that describes individuals who exhibit functionally impairing symptoms in social language use but do not have habitual or repetitive behaviors.[1] Individuals who are affected must have deficits in using language for social purposes, impaired ability to match their communication style with the context for communication, difficulty following the conventional rules for conversation, and difficulty with idioms and unstated meanings in language (Table 3). As with ASD, the symptoms cannot be better explained by another DSM-5 diagnosis. Research and experience with DSM-5 diagnoses over time will give clinicians a better sense of how ASD and social communication disorder are similar and different in terms of etiology, prognosis, and treatment. Evaluation of pragmatic (social) language use by a speech-language pathologist provides additional information to consider this diagnosis.[32] The characteristics of social pragmatic communication disorder and how best to address symptoms require additional study.

Although the DSM-5 provides the criteria and definitions to accurately assign mental health and behavioral diagnoses, the *International Classification of Diseases, 10th Revision, Clinical Modification* is the standardized code set used for payment as well as for statistical tracking through electronic medical records. The *International Classification of Diseases, 10th Revision, Clinical Modification* continues to include the subtypes of diagnoses as defined by the DSM-IV.[33] The DSM-5 provides the clinician with criteria and definitions for diagnosis of ASD and should guide the clinician in the diagnosis and management of ASD.

Co-occurring Symptoms and Conditions

Co-occurring conditions are common in children with ASD and may have great effects on child and family functioning and clinical management (see also Section 5: Interventions). Examples include medical conditions such as sleep disorders and seizures; other developmental or behavioral diagnoses, such as attention-deficit/hyperactivity disorder (ADHD), anxiety, and mood disorders; and behavioral disorders, such as food refusal, self-injury, and aggression.[34] Approximately 30% of children with

TABLE 2 ASD Symptoms by Level of Severity

Severity Level	Social Affective	Restricted and Repetitive Behaviors
Level 1. "Requiring support"	Without supports in place, deficits in social communication cause noticeable impairments. Difficulty initiating social interactions, and clear examples of atypical or unsuccessful response to social overtures of others. May appear to have decreased interest in social interactions.	Inflexibility of behavior causes significant interference with functioning in one or more contexts. Difficulty switching between activities. Problems of organization and planning hamper independence.
Level 2. "Requiring substantial support"	Marked deficits in verbal and nonverbal social communication skills. Social impairments apparent even with supports in place. Limited initiation of social interactions and reduced or abnormal responses to social overtures from others.	Inflexibility of behavior, difficulty coping with change, or other restricted and repetitive behaviors appear frequently enough to be obvious to the casual observer and interfere with functioning in a variety of contexts. Distress and/or difficulty changing focus or action.
Level 3. "Requiring very substantial support"	Severe deficits in verbal and nonverbal social communication skills cause severe impairments in functioning, very limited initiation of social interactions, and minimal response to social overtures from others.	Inflexibility of behavior, extreme difficulty coping with change, or other restricted and repetitive behaviors markedly interfere with functioning in all spheres. Great distress at or difficulty with changing focus or action.

a diagnosis of ASD will also have intellectual disability,[2] and 30% are minimally verbal.[35] Increasingly, researchers and clinicians recognize how co-occurring disorders help identify phenotypic differences within populations affected by ASD, which can influence prognosis and choice of interventions.

Prognosis

The prognosis and trajectory of development for a young child diagnosed with ASD typically cannot be predicted at the time of diagnosis. However, most children (≥80%) who are diagnosed with ASD after a comprehensive evaluation at less than 3 years have retained their diagnosis.[36,37] It may be more difficult to recognize mild symptoms of ASD in children younger than 3 years of age, especially if they have average or above-average cognitive abilities.[38] Across early childhood development, communication skills and social affective symptoms may improve, whereas repetitive behaviors may change, possibly reflecting maturation and/or intervention.[39] In general, young children with ASD with language impairment appear to have more social difficulty than do children with ASD without language impairment. Children with ASD and intellectual disability have the most difficulty developing social competence.[40] The prognosis for children with ASD in phenotypic and demographic subgroups (eg, girls, racial and ethnic subgroups, children with macrocephaly) needs additional study.

Approximately 9% of children who are diagnosed with ASD in early childhood may not meet diagnostic criteria for ASD by young adulthood. Youth who no longer meet criteria for ASD are more likely to have a history of higher cognitive skills at 2 years of age, to have participated in earlier intervention services, and to have demonstrated a decrease in their repetitive behaviors over time.[41] A change in clinical diagnosis (eg, to ADHD or obsessive-compulsive disorder [OCD]) is more likely in children who were diagnosed with ASD before 30 months of age or had a diagnosis of PDD-NOS per the DSM-IV.[42,43] Severity scores are most likely to improve in youth who have had the greatest increase in tested verbal IQ.[44] Executive function difficulties

TABLE 3 DSM-5 Social (Pragmatic) Communication Disorder (DSM-5 315.39)

A. Persistent difficulties in the social use of verbal and nonverbal communication as manifested by all of the following:
   1. Deficits in using communication for social purposes, such as greeting and sharing information, in a manner that is appropriate for the social context.
   2. Impairment of the ability to change communication to match context or the needs of the listener, such as speaking differently in a classroom than on the playground, talking differently to a child than to an adult, and avoiding use of overly formal language.
   3. Difficulties following rules for conversation and storytelling, such as taking turns in conversation, rephrasing when misunderstood, and knowing how to use verbal and nonverbal signals to regulate interaction.
   4. Difficulties understanding what is not explicitly stated (eg, making inferences) and nonliteral or ambiguous meanings of language (eg, idioms, humor, metaphors, multiple meanings that depend on the context for interpretation).

B. The deficits result in functional limitations in effective communication, social participation, social relationships, academic achievement, or occupational performance, individually or in combination.

C. The onset of the symptoms is in the early developmental period (but deficits may not become fully manifest until social communication demands exceed limited capacities).

D. The symptoms are not attributable to another medical or neurologic condition or to low abilities in the domains or word structure and grammar and are not better explained by ASD, intellectual disability (intellectual developmental disorder), global developmental delay, or another mental disorder.

are associated with poorer adaptive outcomes, independent of IQ.[45] Measured intelligence (eg, IQ) and language ability in childhood tend to predict outcome in adulthood.[46] However, reported quality of life in high-functioning adults with ASD was associated more with the presence of family and community supports than their symptoms related to ASD.[47]

TABLE 4 Red Flags: Early Symptoms of ASD

	Symptom
By 12 months	• Does not respond to name
By 14 months	• Does not point at objects to show interest
By 18 months	• Does not pretend play
General	• Avoids eye contact and may want to be alone
	• Has trouble understanding other people's feelings or talking about their own feelings
	• Has delayed speech and language skills
	• Repeats words or phrases over and over (echolalia)
	• Gives unrelated answers to questions
	• Gets upset by minor changes
	• Has obsessive interests
	• Makes repetitive movements like flapping hands, rocking, or spinning in circles
	• Has unusual reactions to the way things sound, smell, taste, look, or feel

Information from this table is adapted from http://www.cdc.gov/ncbddd/autism/signs.html.

SECTION 3: SCREENING AND DIAGNOSIS

The AAP recommends screening all children for symptoms of ASD through a combination of developmental surveillance at all visits and standardized autism-specific screening tests at 18 and 24 months of age in their primary care visits[5] because children with ASD can be identified as toddlers, and early intervention can and does influence outcomes.[48] This autism-specific screening complements the recommended general developmental screening at 9, 18, and 30 months of age.[9] Efficient screening of all children would be aided by inclusion of valid screening tools in the electronic health record with appropriate compensation for the staff and professional time necessary to complete the administration, scoring, and counseling related to screening.[49]

Screening tools are designed to help caregivers identify and report symptoms observed in children at high risk for ASD. The screens are based on early manifestations of symptoms of core deficits related to social communication. Some of these early symptoms that may alert the provider to the risk for ASD have been called "red flags" (Table 4).

Developmental surveillance for ASD includes asking caregivers about concerns they have about their child's development or behavior, informal observation, and monitoring of symptoms in the context of routine health supervision. The "Learn the Signs. Act Early" parent resources developed by the CDC may help educate families about developmental and behavioral milestones (https://www.cdc.gov/ncbddd/actearly/index.html). Developmental surveillance alone is not sufficient to identify children who need further evaluation because children with ASD may not demonstrate characteristic symptoms in brief office visits,[50] and caregivers may not volunteer social and emotional concerns unless specifically asked. Use of a standardized screening tool for ASD can help families identify potential symptoms. In a large study evaluating universal screening with the Modified Checklist for Autism in Toddlers (M-CHAT), researchers asked physicians to note whether they were concerned about ASD. Sensitivity of physician clinical concern was low (0.244; 30 of 123 cases; 95% confidence interval 0.17–0.32). The sensitivity of the M-CHAT when used as directed in this low-risk population was 0.91.[51] Accurate early identification has been a goal of the AAP since the publication of the 2 previous autism clinical reports in 2007, with focused continuing medical education and a tool kit (AAP Autism Toolkit: https://toolkits.solutions.aap.org/toolkits.aspx). The goal of universal screening, including screening for ASD, has been supported by public health agencies[52] and family support organizations.[53] Rates of screening for both developmental delays and ASD in primary pediatric care have increased steadily. In the 2015 AAP survey of screening practices, almost three-quarters of pediatricians who responded reported routine ASD screening.[54] Pediatricians increasingly report including office staff for efficient workflow, including administration and scoring of screening tests. Although time and remuneration remain as concerns, fewer pediatricians rate these as barriers. Referral for and tracking of evaluation and services remain a challenge associated with lack of office-based systems for making referrals and after screen-positive outcomes.[43]

The authors of the 2019 AAP developmental surveillance and screening clinical report discuss strategies for billing for screening and counseling in primary care.[49] The following sections describe tools commonly used to screen and diagnose ASD and emphasize the importance of ongoing surveillance, especially in children at high risk.

Screening

Results of a screening test are not diagnostic; they help the primary care provider identify children who are at risk for a diagnosis of ASD and require additional evaluation. General developmental screening tools used for screening at ages 9, 18, and 30 months identify language,

cognitive, and motor delays but may not be sensitive to social symptoms associated with identification of ASD.[43,55] This limitation associated with general developmental screening is why ASD-specific tools[56] are needed to capture differences in social interaction, play, and repetitive behaviors. See the AAP clinical report "Promoting Optimal Development: Identifying Infants and Young Children With Developmental Disorders Through Developmental Surveillance and Screening,"[49] Table 1 (developmental screening tests; a description of general developmental and behavioral screening tests), and Table 5 in this report for resources and guidance on developmental screening.

Parent-completed questionnaires are the most common screening tests used in primary care. Commonly used autism-specific screening tools that are based on questionnaires and observation are summarized in Table 6. Many clinician-administered screening tests require specific training (eg, the Screening Tool for Autism in Toddlers and Young Children [STAT]).[5,57] A clinician-administered test like the STAT increases the likelihood of an ASD diagnosis on further testing and may be used to support a preliminary diagnosis of ASD to obtain services.[58] Identification of infants and toddlers at risk for ASD based on neurophysiologic makers or other biomarkers is discussed in the subsection The Biology of ASD in Section 4: Etiologic Evaluation.

Screening by Age Group

Children Younger Than Age 18 Months

Earlier diagnosis of ASD may lead to earlier treatment. The M-CHAT is the most studied and widely used tool for screening toddlers for ASD. Additional tools are under investigation and are listed in Table 6 as promising autism screening tests. Language delay can be identified by using the Infant and Toddler Checklist (parent questionnaire) in low-risk infants and toddlers between 12 and 18 months of age.[43,59] This questionnaire might be useful in identifying infant siblings of children with ASD who are at increased risk for ASD. Additional research may allow for screening of toddlers as young as 12 months by using parent-administered questionnaires such the Communication and Symbolic Behavior Scales Development Profile and the Infant and Toddler Checklist.[58]

Primary care providers are tasked with identifying all children who would benefit from early intervention, not just children at risk for ASD (see the AAP clinical report "Promoting Optimal Development: Identifying Infants and Young Children With Developmental Disorders Through Developmental Surveillance and Screening"[49] for further information). It is important to identify all clinically significant delays in children with referral for appropriate diagnostic evaluation and intervention. Problems with sleep, eating, constipation, and state regulation are common in the general population but may be particularly challenging in young children with ASD. Pediatricians can help families with management of these symptoms.

Children Ages 18 to 30 Months

The most commonly used questionnaire-based screening tool is the M-CHAT. It has been further validated, and the scoring has been modified for ease of administration in primary care settings for children ages 16 to 30 months.[51] The Modified Checklist for Autism in Toddlers, Revised with Follow-Up (Questions) (M-CHAT-R/F) eliminates 3 questions from the previous version. Children who score ≥8 are at high risk for ASD or another developmental disorder and should be referred immediately for diagnostic assessment. For children with scores of 3 to 7, publicly available scripted follow-up interview questions are required for the items scored as positive. Children who continue to have 3 to 7 items positive for ASD diagnosis after clarifying follow-up questions have a 47% risk of having ASD diagnosed and a 95% chance of being identified with some other developmental delay that would benefit from intervention. Children screened with the M-CHAT-R/F are identified with ASD at younger ages than predicted by national statistics.[49] Children who do not pass ASD screening tests or who score as at risk for a diagnosis should be referred for both diagnostic assessment and intervention services. A definitive diagnosis is not necessary to institute services for documented delays that would be served through early intervention or school services. Although the M-CHAT-R/F appears to be useful for general screening of diverse populations,[60] decreasing the disparity in early diagnosis will require adapting and validating measures and addressing cultural and linguistic barriers to screening.[61]

Measures under development may provide rapid screening while addressing clinician concerns for compatibility with an electronic record system and open access.[62]

The AAP does not approve/endorse any specific tool for screening purposes. This table is not exhaustive, and other tests may be available. ADOS-G, Autism Diagnostic Observation Schedule – Generic; CARS, Childhood Autism Rating Scale; CHADIS, Comprehensive Health and Decision Information System; EHR, electronic health record; ICD-10, *International Classification of Diseases, 10th revision*; IMFAR, International Meeting for Autism Research; NPV, negative predictive value; PPV, positive predictive value.

Further adaptations of the Communication Symbolic Behavior Scale for use in screening for language delays in addition to ASD have the potential to identify children at risk for both disorders (functional communication; ages 6–24 months).[49,59] Use of this or other screening tools may be coupled with the online support of a video glossary of symptoms of ASD, such as that in the Autism Navigator (http://www.autismnavigator.com/). These and other online approaches to support screening strategies may be integrated into efficient patterns of practice. Results of screening conducted online, in community settings, and in preschools should be communicated to the primary care provider to ensure appropriate evaluation of etiology, co-occurring conditions, referral for diagnosis, and follow-up to ensure that intervention is accessed.[49]

A systematic review by the US Preventive Services Task Force (USPSTF) concluded that the literature on existing screening tools did not demonstrate sufficient specificity to justify universal screening.[63] The USPSTF noted that no study has directly examined whether children with ASD detected by early screening have better outcomes than those detected by other means. However, such a study would require random assignment of large representative samples from across the country to either a screening or nonscreening condition, with follow-up of long-term outcomes and societal costs. Given that early treatment of children younger than 36 months has been shown to result in positive outcomes,[43,64] such a study would be challenging to support. The USPSTF concluded that further research is indicated to evaluate the appropriate ages and populations of children who should be screened for ASD and that more accurate and culturally sensitive measures should be developed. The AAP continues to recommend screening using the most valid of current measures at 18 and 24 months of age. Pediatricians cannot assume that early intervention systems will screen participants being served for language or global delays for ASD at the recommended ages. Universal screening is recommended because symptoms of ASD can be identified in early childhood, and a diagnosis of ASD by skilled professionals is accurate in children as young as 18 months of age.[65] Diagnostic stability is high for children who are diagnosed with ASD at 18 to 36 months of age.[43] Early screening does not identify many children with milder symptoms and typical cognitive ability as at risk for ASD; therefore, ongoing surveillance remains necessary.[16] Participation in early intervention in general is greatest among children who had screening and surveillance.[66]

Children Older Than 30 Months

At present, for children older than 30 months, there are no validated screening tools available for use in pediatric practice, nor are there current recommendations by the AAP for universal screening for ASD in that age group. The Social Communication Questionnaire (SCQ) (see Table 6) has been studied in different populations (eg, clinical sample, population reference sample, community sample, and convenience sample), with best results in population samples[67] when using the lifetime version, and appears to have reasonable psychometric properties. However, questionnaires like the SCQ may identify symptoms that overlap with other conditions, such as ADHD, that affect function at school age.[68,69] Further validation of population-based screening tools for children older than 30 months is needed before recommendations for universal screening of school-aged children can be made. At this time, ongoing surveillance in the context of primary care is recommended.

Barriers to Identifying Risk for ASD

Children with milder symptoms and/or average or above-average intelligence may not be identified with symptoms until school age, when differences in social language or personal rigidities affect function. Some children who are later diagnosed with ASD are initially believed to have precocious language, reading, or math skills, and it is not until the social demands of school that the social language symptoms become problematic. It has also been suggested that girls may have lesser intensity of symptoms and fewer externalizing behaviors. These differences may, in part, result in underdiagnosis in girls.[70] Specific coexisting conditions may prevent clinicians from recognizing symptoms of ASD in early childhood. For example, 1 study revealed that children who were initially identified with ADHD in primary care were diagnosed with ASD 3 years later compared with children who did not have earlier symptoms of ADHD.[69] Recognition and referral for older children with social-skill deficits would be facilitated by the development of accurate and brief screening tests for use in primary care and school settings.

Population surveillance data reveal later age at diagnosis for African American and Hispanic children, suggesting that there are barriers to screening and surveillance and referral for diagnosis in groups with other unmet health needs.[2] Race, ethnicity, and socioeconomic status did not affect the accuracy of routine screening tests for ASD in low-risk toddlers, suggesting that screening with appropriate supports for follow-up care can lower the age at diagnosis in diverse populations.[60] Language barriers, inaccurate translations, and low parental literacy may compromise use of parent-completed questionnaires.[71] Limited understanding of cultural differences experienced by the patient's family

and lack of trust in the health care provider may further limit identification and reporting of symptoms of autism.[72] Screening tools need to be developed for populations of individuals whose primary language is not English and who are also sensitive to cultural barriers that may limit reporting of symptoms of ASD.[73]

Diagnostic Evaluation

Once a child is determined to be at risk for a diagnosis of ASD, either by screening or surveillance, a timely referral for clinical diagnostic evaluation and early intervention or school services, depending on his or her age, is indicated.[74] Children with developmental delay with or without an ASD diagnosis should be referred to early intervention or school services, in which cognitive and language testing may be completed. The primary care provider should discuss with the family the importance of both the assessment of developmental status and evaluation for an ASD diagnosis and assist the family in navigating through the process, including connecting them with community resources. Families with low income or language barriers may need additional attention to take the next steps.

Although most children will need to see a specialist, such as a developmental-behavioral or neurodevelopmental pediatrician, psychologist, neurologist, or psychiatrist, for a diagnostic evaluation, general pediatricians and child psychologists comfortable with application of the DSM-5 criteria can make an initial clinical diagnosis. Having a clinical diagnosis may facilitate initiation of services. At this time, there are no laboratory tests that can be used to make a diagnosis of ASD, so careful review of the child's behavioral history and direct observation of symptoms are necessary.[75,76] To meet diagnostic criteria, the symptoms must impair function. Formal assessment of language, cognitive, and adaptive abilities and sensory status is an important component of the diagnostic process.

Short clinical visits may not allow even a skilled clinician the opportunity to accurately recognize symptoms of ASD.[50] An accurate history needs to reflect a longitudinal experience with the individual and reflect the effects of symptoms on the patient's ability to function in family, peer, and school settings. This history is obtained by interview with the patient and caregivers, reports of behavior in other environments (such as school), and descriptions of behavior during formal testing. The history of symptoms of ASD can be supported by questionnaires such as the SCQ[77] or Social Responsiveness Scale (SRS).[78] None of these questionnaires is sufficient alone to make a diagnosis of ASD, but all provide a structured approach to elicit symptoms of ASD. Measures such as the Behavior Assessment System for Children,[79] Diagnostic Interview for Social and Communication Disorders (DISCO),[80,81] and the Child Behavior Checklist[82] are used to assess children and youth for other behavioral health conditions but may also identify behavioral profiles consistent with ASD.

In some clinical and research settings, the behaviors associated with ASD are reported through the Autism Diagnostic Inventory-Revised (ADI-R), a lengthy, semistructured parent interview.[83,84] It supports a knowledgeable clinician in applying diagnostic criteria of ASD. The SCQ was designed to elicit similar information to the ADI-R in an abbreviated questionnaire format. The SRS is a 65-item questionnaire that may be used to measure autistic traits on a continuum as part of a more complete evaluation of ASD.[78,85] Elevated scores may be seen with greater severity of symptoms of ASD as well as with intellectual disability, communication difficulties, and behavioral challenges.

Structured observation of symptoms of ASD during clinical evaluation is helpful to inform the diagnostic application of the DSM-5 criteria. Validated observation tools used to provide structured data to confirm the diagnosis include the Autism Diagnostic Observation Schedule, Second Edition (ADOS-2) and the Childhood Autism Rating Scale, Second Edition (CARS-2).[86] No single observation tool is appropriate for all clinical settings. The observation tool is meant to support application of the DSM-5 criteria informed by history and other data.

The ADOS-2 was developed to elicit atypical social language and behaviors. With the ADOS-2, modules are specific for use across the age span of toddlers to adults.[87,88] The ADOS-2 requires intensive training to accurately administer and score and takes 30 to 45 minutes to administer. It is often a component of both research and clinical evaluations. The information obtained from the ADOS-2 is used by the clinician in conjunction with the history of peer interactions, social relationships, and functional impairment from symptoms to determine if the DSM-5 criteria are met. The CARS-2 is another structured approach a clinician might use to support a clinical diagnosis of ASD.[89] The clinician completes a 15-point scale that is based on history and observation. The ADOS-2, CARS-2, and SRS (Parent and Teacher) all rate children similarly in approximately half of identified cases.[90] The integration of historical information and objective observation by a clinician trained to diagnose autism and related conditions to inform the DSM-5 diagnostic criteria is the

critical element to diagnostic evaluation.

Evaluation of Co-occurring Developmental Conditions

Patients with ASD may have intellectual disabilities, learning disabilities, ADHD, anxiety disorders, or speech and language disorders, among others. These conditions may influence the presentation of the symptoms of ASD. These conditions may influence the presentation of symptoms of ASD and may influence the social and functional impairment of the individual in different ways at different ages. Valid assessment of cognitive and language ability is an important component of the diagnostic evaluation. In the United States, early intervention services and school systems will evaluate children in these domains to assess educational needs. In some areas, initial evaluations are performed in clinical settings and paid for by insurance.

Cognitive Testing

A range of standardized measures are used to determine developmental levels of younger children and IQ in children older than 3 years. The intelligence test selected by the psychologist will depend on the age and language level of the child. Administration of a valid cognitive test is important in ascribing symptoms to ASD as part of the initial diagnosis but also helps to establish co-occurring diagnoses with ASD, such as intellectual disability. There are valid tests that can be used in children who are nonverbal. Although the prevalence of a diagnosis of ASD is increased in children with an intellectual disability,[91] other children diagnosed with intellectual disability may have some symptoms of ASD without meeting diagnostic criteria for the disorder.

Language Testing

Inherent in the core symptoms of ASD are differences in the use of verbal and nonverbal communication for social interaction. Formal assessment of communication by a speech or language pathologist at the time of diagnosis should include the documentation of expressive and receptive language skills as well as the pragmatic or conversational use of language.[92]

Adaptive Function Testing

A caregiver report and/or teacher report of adaptive functioning complements objective cognitive testing. Determining the extent that ASD affects daily function is necessary to establish eligibility for some publicly funded programs as well as to identify and monitor developmental goals for treatment. Adaptive behaviors are typically delayed in people who have intellectual disability with ASD but can be impaired in people with ASD and an average-range IQ.[93,94] Commonly used adaptive measures include the Vineland Adaptive Behavior Scales and the Adaptive Behavior Assessment System.[95]

Motor Assessment

Children with ASD are more likely to have mild delays in gross motor skills and coordination compared with children in the general population and may meet DSM-5 criteria for developmental coordination disorder in addition to ASD.[96] General screening tests or adaptive measures may suggest motor delays that would benefit from formal evaluation by an occupational or physical therapist. A relationship of early motor delays and subsequent language and adaptive development in children with ASD has been proposed.[97,98]

Sensory Assessment: Hearing

Children with language delay or inattention to language should have an evaluation of their hearing as part of their initial evaluation.[99] Hearing loss may co-occur with ASD and needs to be considered in children with language delays, behavior problems, or inattention. Appropriate amplification should be offered, if indicated. The clinical utility of auditory processing evaluations available in current practice remain an area of study.[100,101]

Sensory Assessment: Vision

Visual function should be considered in the initial evaluation of children who are visually inattentive, have stereotypical behaviors (such as eye poking or close visual scrutiny), or do not make eye contact. Decreased visual acuity may affect interactive gaze and require accommodations in the educational setting.[102] Children with visual impairment may also demonstrate stereotyped motor behaviors.

Sensory Assessment: Sensory Processing

The DSM-5 includes sensory symptoms in the diagnostic criteria for ASD. The DSM-5 does not include sensory processing disorder as a discrete diagnosis. Commonly used evaluation tools (such as the Short Sensory Profile and others) quantify parent perception of sensory differences relative to smell, taste, vision, hearing, and touch.[103,104] In addition to capturing what is conventionally considered as a sensory disturbance, questionnaires that are used to assess sensory symptoms also capture motor hyperactivity and hypoactivity as sensory-seeking or sensory-avoiding behaviors. These latter symptoms may reflect co-occurring ADHD. Sensory symptoms may be more evident at younger ages and may define subtypes of the disorder.[105,106]

SECTION 4: ETIOLOGIC EVALUATION

Children with a diagnosis of ASD should be assessed for potential etiology and common coexisting medical conditions. At the time of the 2007 AAP clinical reports on autism, karyotype and DNA testing for fragile X syndrome were the state-of-the-art

etiologic investigations. Soon thereafter, chromosomal microarray (CMA) was endorsed by the American College of Medical Genetics and Genomics and the American Academy of Child and Adolescent Psychiatry as the most appropriate initial test for etiologic evaluation of children with ASD.[76,107–110] Despite rapid technological advances in neuroimaging and other areas, many of the recommendations for clinical evaluation published in 2007 are unchanged. This section summarizes recent advances in understanding the etiologies of ASD and how they translate into recommendations for clinical practice.

Medical Workup of the Child With ASD

Genetic Testing

Advances such as the development of CMA and next-generation sequencing technologies and the application of these technologies to well-characterized patient cohorts have led to progress in the understanding of the complex genetics of ASD and other neurodevelopmental disorders in the last decade. Identifying a genetic etiology provides clinicians with more information for families about prognosis and recurrence risk and may help to identify and treat or prevent co-occurring medical conditions, guide patients and families to condition-specific resources and supports, and avoid ordering unnecessary tests (Table 7).[111–117] Most parents find this information to be useful.[118] As research progresses, genetic testing may contribute to identifying effective interventions related to specific etiologies.

Etiologic investigation begins with a careful medical, developmental-behavioral, and family history and a thorough physical and neurologic examination.[109] The history should include potential prenatal exposure to teratogens (such as medications, alcohol, drugs) and other factors that increase risk for ASD.[109,119] The physical examination should include assessment of growth relative to typical curves (including head circumference), dysmorphic features, organomegaly, skin manifestations of neurocutaneous disorders (eg, tuberous sclerosis and neurofibromatosis), and neurologic abnormalities.[109] Genetic evaluation should be recommended and offered to all families as part of the etiologic workup. A stepwise general approach is provided in Table 8 as a practical guideline.[110,120] The presence of dysmorphic features or intellectual disability is generally associated with

TABLE 7 Potential Benefits of Establishing a Genetic Etiologic Diagnosis

- Improving accuracy of counseling provided to patients and families:
  - o Prognosis or expected clinical course
  - o Recurrence risk for the family and the individual affected
- Providing condition-specific family support, such as:
  - o Improving psychosocial outcomes for patients and their families (eg, knowledge and sense of empowerment, parental quality of life)
- Preventing morbidity and treating medical conditions associated with the genotype, such as:
  - o Conditions or anomalies likely to be present at diagnosis
  - o Conditions that may develop later
- Refining treatment options, including:
  - o Avoiding therapeutic interventions that may be based on unfounded etiologic theories
  - o Avoiding ineffective or potentially harmful treatments
  - o Providing access to emerging etiology-specific treatments
- Facilitating acquisition of needed services and access to research treatment protocols
- Avoiding additional diagnostic tests, which may be unnecessary, expensive, and/or uncomfortable

TABLE 8 Genetic Etiologic Investigations in Patients With ASD

Step	Genetic Etiologic Investigations
1	Consider referral for pediatric genetics evaluation
2	Comprehensive history (including 3-generation family history with emphasis on individuals with ASD and other developmental, behavioral and/or psychiatric, and neurologic diagnoses) Physical examination (including dysmorphology, growth parameters [including head circumference], and skin examination) • If syndrome diagnosis or metabolic disorder is suspected, go back to step 1 (genetics and/or metabolism referral) and/or order the appropriate targeted testing • Otherwise, proceed to step 3
3	Laboratory studies • Discuss and offer CMA analysis • Discuss and offer fragile X analysis; if family history is suggestive of sex-linked intellectual disabilities, refer to genetics for additional testing • If patient is a girl, consider evaluation for Rett syndrome, *MECP2* testing • If these studies do not reveal the etiology, proceed to step 4
4	Consider referral to genetics, workup might include WES

increased likelihood of finding a genetic abnormality.[121] However, authors of some clinical studies have identified similar yield for genetic testing in children without these risk factors.[122,123]

In some cases, individuals with clinical genetic syndromes, such as fragile X syndrome, tuberous sclerosis complex, and others (such as those described in Supplemental Table 13), also meet criteria for ASD.[124,125] When a specific syndrome or metabolic disorder is suspected, the clinician should proceed with the appropriate targeted testing or referral to a pediatric geneticist or neurologist. For example, a girl with significant developmental delays, deceleration in head growth velocity, and characteristic midline hand movements should prompt genetic testing for a mutation or deletion or duplication of *MECP2*, the gene implicated in Rett syndrome.[109,126] Another specific example would be a boy with ASD with marked macrocephaly and pigmented macules on the penis, findings that would warrant sequencing and deletion or duplication analysis of the *PTEN* gene.[127] Descriptions of these and other clinical syndromes associated with ASD are provided in Supplemental Table 13.

CMA is recommended if the etiology for developmental disability is not known. CMA identifies copy number variants (CNVs) at this time, which are DNA duplications or deletions that alter the function of genes (Table 8, step 2). CMA reveals a definitively pathogenic CNV in 5.4% to 14% (median 9%) of individuals with ASD in clinical samples.[121,128–135] When CNVs of uncertain significance are included, approximately 17% to 42% of patients with ASD have findings on the CMA. Some of the variants of uncertain significance may be determined as pathogenic in the future. The most commonly identified recurrent pathogenic CNVs among individuals with ASD are provided in Supplemental Table 14.

Because fragile X syndrome increases risk for ASD, DNA testing for fragile X syndrome should be recommended for all children with ASD, but especially for boys and children with a suggestive family history of male members with intellectual disability. Physical examination might reveal the common features of a large head size, prominent jaw, large ears, ligamentous laxity, and, in male patients, large testes after puberty. The cytosine-guanine-guanine trinucleotide repeat expansion that is responsible for fragile X syndrome is not detected on CMA and must be ordered as a separate test. The current estimate is that approximately 0.45% of individuals with ASD have the full mutation for fragile X syndrome, and many of them are female.[130,132,135–137] Because fragile X syndrome testing is relatively inexpensive and the condition has important genetic counseling implications, it is reasonable to consider testing both male and female patients with ASD, at least until more data become available to clarify the issue.

When the history and physical examination, CMA, and fragile X analysis do not identify an etiology, the next step at this time in the etiologic evaluation for ASD is whole-exome sequencing (WES). WES technology allows for the identification of single-nucleotide variants, including pathogenic loss-of-function mutations and missense mutations, which have been found to be associated with ASD.[138–142] Examples of ASD risk genes identified or confirmed in WES studies are provided in Supplemental Table 15. As with other tests, clinicians ordering this test should be familiar with both pretest counseling and interpretation of the results. A genetic counselor is helpful in explaining the reason for testing as well as the results. Large clinical WES studies have consistently been used to identify a molecular diagnosis in 26% to 29% of individuals for whom neurodevelopmental disorders were the primary indication for testing.[143–145] Authors of studies of clinical populations with ASD have reported diagnostic yields of 8% to 20%.[121,144] The yield of WES is higher when both the parents and the child who is affected are evaluated[144] to allow for comparison of the child with parents who are unaffected.

Some geographic areas may have limited availability of pediatric subspecialists (eg, in genetics or metabolism) who can guide the genetic workup, so primary care providers may be in the position to consider and direct etiologic evaluation. The complexity of genetic testing is such that most primary care providers may want to consult with a specialist to plan testing and interpret results. The clinical etiologic evaluation should be tailored to the individual patient, taking into consideration information from the history and physical examination[109,110] and the values and wishes of the family. The stepwise general approach summarized in Table 8 can be used to guide this process.

It is important for families to understand that genetic tests may explain the cause of their child's ASD or provide information about the statistical risk of ASD, but they are not diagnostic of ASD; the diagnosis of ASD is made on the basis of clinical symptoms. Unlike CMA and WES, commercially marketed tests may not have the potential to provide a molecular etiologic diagnosis. Genomic testing technology is evolving rapidly, as is our understanding of the genetic architecture of ASD, and these recommendations for testing will need to be updated as new studies are published.[146] For example, it is anticipated that CMA and WES will soon be combined because of

improvements in accurate identification of CNVs using sequence data and that sequencing of the exome will be replaced by sequencing of the entire genome as issues with interpretation and cost become more manageable.[121,130,147–150]

Parents of a child with ASD should be counseled regarding recurrence risk in subsequent offspring, and the nature of the counseling depends greatly on whether a specific genetic cause of the child's ASD has been identified. When a specific genetic etiology has been determined, the family can be provided with information about the risk of recurrence in subsequent offspring. However, when genetic testing has not been completed or has not revealed the etiology of the child's ASD, recurrence risk counseling is based on group averages derived from the existing literature. For a couple with 1 child with ASD of unknown cause, the current best estimate of recurrence in a subsequent child is approximately 10% (range 4%–14%[151–153]). If a couple already has ≥2 children with ASD of unknown etiology (idiopathic), the chance of a subsequent child having ASD may be as high as 32% to 36%.[151,154] However, the risk is not limited to ASD. Siblings of children with ASD who do not have ASD themselves may have a 20% to 25% risk for language disorders and other neurodevelopmental and psychiatric disorders.[152,155,156]

Neuroimaging

Specific clinical neuroimaging findings are not more prevalent in ASD compared with other neurodevelopmental disorders, nor do specific abnormalities correlate with clinical, etiologic, or pathophysiological aspects of ASD.[120,157,158] Incidental findings are common in neuroimaging studies obtained in the workup of children diagnosed with ASD but rarely provide etiologic information or require intervention.[159,160] The need for clinical MRI should be directed by a history and physical examination. MRI may be indicated in the evaluation of atypical regression, microcephaly, macrocephaly, seizures, intracranial manifestations of genetic disorders, abnormal neurologic examination, or other clinical indications.[76,109,161,162] Imaging technology used to examine brain structure and function provides valuable insight into the neurobiology of ASD in research settings and may lead to useful clinical applications in the future.

Metabolic Testing

The yield of routine metabolic testing for children with ASD is low and not recommended for regular use.[163–167] However, large population-based studies are lacking, so accurate prevalence and diagnostic yield estimates are not available. Metabolic workup should be informed by history, family history, symptoms, and examination and might include measurement of fasting plasma amino acid levels, urine organic acid levels, and acylcarnitine metabolite levels and other testing for specific metabolic disorders. History of atypical regressions (later than 2 years of age, motor regression, or multiple regressions), family history of early childhood death or diagnosed metabolic disorders, and physical features, such as significant hypotonia or weakness, visual and hearing impairment, and dysmorphic features, would suggest consultation with a specialist to guide evaluation for metabolic or mitochondrial disorders.[109,168] Children who present with motor delay should be evaluated with creatine kinase and thyroid-stimulating hormone testing, according to AAP recommendations.[9,49] Although metabolic disorders are uncommon causes of ASD, the potential impact is high because treatment may be available and the inheritance pattern may be known.[109,124] Examples of metabolic conditions that may be associated with an ASD phenotype are provided in Supplemental Table 16. There is no evidence at this time for routine testing of hair, blood, or urine for environmental toxins or heavy metals outside of laboratory screening for lead exposure.[169]

EEG

Children with ASD have an increased risk for seizures, and EEG abnormalities are common in the absence of clinical seizures (see Seizures section for more information).[170–175] However, EEG is not recommended as a routine baseline evaluation in the absence of clinical concern about seizures, atypical regression, or other neurologic symptoms on history or examination that would suggest an EEG is indicated.[161,170,172,176] Late or atypical loss of language, as might be observed in electrical status epilepticus of sleep with loss of language, should be evaluated with an overnight EEG.[161,170,172,176] Primary care clinicians should discuss the increased risk and the signs and symptoms of seizures with the families of children diagnosed with ASD, maintain a high index of clinical suspicion for seizures, and consult with a pediatric neurologist when concerned about atypical regression or the possibility of seizures.[170,172,176]

The Biology of ASD

Genetics and ASD

ASD is clinically and etiologically heterogeneous yet highly heritable. The rate of ASD in siblings is much higher than the rate in the general population. Twin studies demonstrate substantially higher concordance rates for symptoms of ASD in monozygotic twins than in dizygotic twins.[177] A meta-analysis involving 6413 twin pairs revealed a 98% concordance in monozygotic twins, a 53% to 67% concordance in dizygotic twins, and heritability estimates from 64% to 91%.[177,178]

Siblings may also be at risk for symptoms related to ASD that do not meet the threshold for a diagnosis of ASD and have been described as the broader autism phenotype.[141,179] These data provide strong evidence for a genetic contribution to ASD risk.[180–184]

Risk for ASD also is increased in the children of both older fathers and older mothers.[185–187] The increased risk with parental age may be related to germline mutations in older fathers.[143,188] Mechanisms mediating the effect of advancing maternal age on ASD risk are less clear.[143] Increased maternal and paternal age are independently associated with ASD risk, and a joint effect seems to occur as well.[185–187]

Important aspects of the genetics of ASD are still poorly understood, including the role of common variants, epistasis (gene-gene interactions), and environmental modification of genotype effects. In contrast, advances such as CMA and next-generation sequencing technologies have resulted in identification of large-effect (pathogenic) rare variants that appear to be causally associated with ASD, including CNVs, which are deletions or duplications ≥1000 bp in size that alter the dosage of genes, and sequence-nucleotide variants.[189–192] Pathogenic rare variants may arise de novo or be inherited as autosomal dominant, autosomal recessive, or X-linked mutations. Researchers of CMA and WES studies have established that although de novo and inherited rare variants of large effect size are collectively common, no individual pathogenic variant accounts for more than 1% of cases of ASD.* Genes that contribute to ASD are involved in a variety of biological functions, with convergence on aspects of brain development and function, including synaptic structure and function, intracellular signaling, transcription regulation, and chromatin remodeling.[139,190,191,196] It is important to note that no specific mutation has been identified that is unique to ASD; there is substantial genetic overlap between ASD and other neurodevelopmental disorders, including intellectual disability, epilepsy, and schizophrenia.[197–204]

Genes, Environmental Exposures, and ASD

The potential environmental factors that may be related to increased reported prevalence of ASD is an area of active study that, as yet, is without firm conclusions.[119] Environmental factors associated with ASD include in utero exposure to medications such as valproate and thalidomide. Other prenatal influences, such as short interpregnancy interval, multiple gestation, maternal obesity, gestational bleeding, gestational diabetes, advanced parental age, and infections (eg, rubella and cytomegalovirus), may be associated with increased risk for ASD.[205–209] Perinatal factors, such as preterm birth, low birth weight, fetal growth restriction (ie, small for gestational age), intrapartum hypoxia, and neonatal encephalopathy, are associated with increased ASD risk.[205,210–212] Environmental factors may present independent risk to prenatal brain development or may affect gene function in individuals with genetic predisposition.[213] Population-level associations with ASD have been examined for organophosphates and certain other pesticides, metals, volatile organic compounds, and air pollution, particularly particulate matter and nitrogen dioxide.[214–216] Research on environmental exposures may be of great importance in identifying modifiable risk factors related to ASD and other developmental disorders. It is prudent to limit exposure of children and pregnant women to known neurotoxicants.

Genes, Immunologic Exposures, and ASD

It has been proposed that children with ASD-associated CNVs may be more susceptible to environmental insult in the form of maternal immune activation. Report of maternal infection or fever during pregnancy may be associated with increased severity of ASD-related symptoms in offspring who are affected.[217] The pathogenic role of circulating maternal antibodies directed to fetal brain tissue and the potential value of maternal antibody panels as biomarkers of ASD are currently being studied.[218–222] Unless otherwise indicated (eg, history suggestive of autoimmune or immunologic disorder), no immune testing is recommended in the etiologic workup of a child with ASD.

Epigenetics

Epigenetic modifications, such as DNA methylation and posttranslational histone modification, produce heritable changes in gene expression that do not involve a change in the DNA sequence. Some genetic disorders associated with ASD (eg, Rett syndrome; CHARGE syndrome; 15q duplication; Angelman syndrome; and fragile X syndrome), involve genes that either encode epigenetic regulators or are sensitive to alterations in their epigenetic regulation.[223,224] Because epigenetic modifications can be influenced by environmental factors, such as prenatal maternal exposures and postnatal experience, they represent 1 interface between genes and environment. However, epigenetic modifications are not the only mechanisms by which gene expression is regulated, and epigenetics should not be conflated with the broader category of environmental effects.[223,225] Currently, the evidence that alteration of gene expression by environmental factors plays a causal role in ASD is very limited.[223–228] Investigation of

* Refs 121, 144, 189–195.

the role of epigenetic and other nongenetic modifications that alter gene activity without changing the DNA sequence is an active area of etiologic research in ASD.

Vaccines

The scientific literature does not support an association of vaccination as an environmental factor that increases the risk for ASD. Children with ASD should be vaccinated according to the recommended schedule. Epidemiological studies do not demonstrate any association of the measles-mumps-rubella vaccine, mercury exposure by thimerosal-containing vaccines, aluminum in vaccines, or increased level of immunologic exposure attributable to a larger number of vaccines (either given at 1 time or cumulatively) with ASD.[214,229–246] Vaccines used for children in the United States have not contained thimerosal since 2001. The authors of a 2012 Cochrane review[234] and a 2014 quantitative meta-analysis of pooled data from cohort studies involving 1 256 407 children and case-control studies involving 9920 children reviewed the scientific literature and came to this conclusion.[231] Evidence implicating immunizations as a "second hit" conferring ASD risk in genetically susceptible subgroups is lacking. It has been shown that the measles-mumps-rubella vaccine is not associated with increased risk for ASD, even among children who are already at higher risk because of having an older sibling with ASD.[229] Media coverage of vaccine issues may inflate the perception of uncertainty by equal coverage of vaccine proponents and opponents. The overwhelming weight of evidence supports vaccine safety.[247] Communicating information about vaccine safety is a critical component of pediatric practice.[248]

Brain Structure and ASD: Neuropathology

Neuropathological research has been limited by the small number of postmortem brains available for study. Developmental brain abnormalities in people with ASD are reported in the cerebral neocortex; limbic system structures, including the hippocampal formation and amygdala; basal ganglia; thalamus; brainstem; and cerebellum. These brain abnormalities include dysplasia, altered neurogenesis, and abnormal neuronal migration.[249–251] The vast majority of abnormalities described originate during prenatal brain development.[249,251,252] Findings in the cerebral cortex may include focal disruption of neuronal migration, minicolumnar abnormalities, and variations in neuronal density.[249,251,252] A decreased number of Purkinje cells in the cerebellum is 1 of the most consistently reported neuropathologic findings associated with ASD. Although it was initially thought to be of prenatal onset, evidence now indicates that this phenomenon is more likely to be an acquired process that occurs postnatally, potentially related to seizures, medications, and/or ischemia near the time of death or factors other than ASD.[249] No uniform neuropathology has been identified in people with ASD.

Biomarkers

Objectively measured biological characteristics, or biomarkers, of ASD could potentially be used to predict ASD risk, enhance screening, and permit presymptomatic detection. Their use could improve the reliability and validity of clinical diagnosis (identifying clinically meaningful subgroups that would allow for prediction of prognosis or treatment response), identify mechanisms for developing treatment, and confirm the need for a specific intervention.[221,253–255]

Early Brain Overgrowth

Cross-sectional and longitudinal studies suggest that as a group, children later diagnosed with ASD may have an average or below-average head circumference at birth, with an acceleration in brain growth before 2 years of age.[256] This rapid brain growth leads to significantly above-average head circumferences and MRI brain volumes in toddlers, followed by a plateau in brain growth, with brain volumes in adolescence and adulthood similar to those of controls.[257,258] Almost 16% of young children with ASD have a head circumference greater than the 97th percentile.[258] A preliminary study suggested that infant siblings of children with ASD who exhibited a larger head circumference at 12 months and showed more slowing of head circumference growth from 12 to 24 months had an increased chance of demonstrating symptoms of ASD.[259,260] Although this finding raises the possibility that patterns of brain growth might be used for early identification, the rate of head growth did not predict which infants developed ASD in the first 3 years of life in a large prospective study of high-risk infants.[261] It is possible that a large head size is unrelated to ASD and/or may be part of general somatic overgrowth.[262–265]

Neuroimaging Patterns Associated With ASD in Research Studies

Although there are conflicting findings, structural MRI volumetric studies suggest that young children with ASD differ from controls in total brain volume, cortical gray and white matter volume (particularly frontal, temporal, and cingulate cortices), extraaxial cerebral spinal fluid volume, and amygdala volume.[266–271] A research-level analysis also has identified asymmetries in multiple brain structures in people with ASD.[272] Diffusion tensor imaging has been used to identify altered patterns in white matter by 6 months of age in

infants later diagnosed with ASD.[270,273] Functional MRI has demonstrated differences in people with ASD relative to controls in efficiency of visual processing, executive function, language, and basic and complex social processing skills.[274,275] Functional MRI in research settings demonstrate differences in the mechanisms of attention to social stimuli, modulation in response to task demands or intensity of stimuli, and executive function in people with ASD.[274] Functional underconnectivity has also been demonstrated across a wide variety of the brain regions that support language, executive function, social cognition, emotion processing, and motor tasks, especially for long-range, frontal-posterior networks.[274,276,277]

Electrophysiologic Testing and Measurement of Eye Tracking

Electrophysiologic research studies demonstrate differences in auditory processing (including language processing), visual processing (including face processing), somatosensory response, multisensory integration, attentional shifting, selective attention, recognition memory, and neural connectivity in people with ASD.[278–281] Continuous measures of resting-state and task-related quantitative EEG are used to calculate and describe spectral power, complexity, and coherence. Although promising, the clinical utility of these measures as biomarkers requires additional study.[279] Eye tracking has been used to determine if infants who are younger siblings of children with ASD and, therefore, at increased risk for ASD exhibit differences in fixation on faces.[282-284] Preliminary evidence suggests that infants later diagnosed with ASD exhibit a decline in gaze fixation from age 2 to age 6 months.[285]

Other Potential Biomarkers

Although some studies have attempted to differentiate people with and without ASD on the basis of differences in laboratory profiles of platelet serotonin, plasma melatonin, urine melatonin sulfate, redox status, placental trophoblast inclusions, and immune function, currently no diagnostic laboratory tests have been approved for ASD.[286,287] To date, none of these potential biomarkers under study has sufficient evidence to be recommended.

Biomarkers: Future Directions

Proposed biomarkers for ASD risk include genetic and biochemical findings in blood, urine, or brain tissue; placental pathology; maternal autoantibody profiles; structural and functional MRI patterns; electrophysiological test results on EEG, including event-related potentials; responses in eye tracking; and physical parameters such as head circumference growth trajectory. Although none of these proposed biomarkers has demonstrated sufficient predictive validity for clinical use at this time,[221,253–255,288] the search for biomarkers is a major research focus. Biomarker research has important ethical issues,[253] and concerns have appropriately been raised regarding premature translation of research data into commercially available tests marketed to patients and families.[221,253,289,290] However, the capabilities to screen large numbers of bioactive compounds, examine the entire genome, and simultaneously analyze large data sets have accelerated research into the neurobiology of ASD and may result in the identification of valid biomarkers.[221,255,291]

SECTION 5: INTERVENTIONS

The goals of treatment of children with ASD are to (1) minimize core deficits (social communication and interaction and restricted or repetitive behaviors and interests)[1] and co-occurring associated impairments[292-294]; (2) maximize functional independence by facilitating learning and acquisition of adaptive skills; and (3) eliminate, minimize, or prevent problem behaviors that may interfere with functional skills.[6,295,296] Treatments should be individualized, developmentally appropriate, and intensive, with performance data relevant to treatment goals to evaluate and adjust intervention.[6,297] All interventions should be based on sound theoretical constructs, rigorous methodologies, and objective scientific evidence of effectiveness. Since the publication of the 2007 AAP clinical reports on autism, a substantial published literature has examined the effectiveness of interventions.[48,295,297,298] Legal mandates in education law in the United States, which include the Individuals with Disabilities Education Improvement Act of 2004 (IDEA) (Public Law 108–446) and the No Child Left Behind Act of 2001 (Public Law 107–110) and its successor, the Every Student Succeeds Act of 2015 (Public Law 114–95), require the use of practices supported by scientifically based research (IDEA and the No Child Left Behind Act of 2001) or evidence-based practices (Every Student Succeeds Act of 2015) (https://www.ed.gov/). Early intervention services under part C of IDEA provide for assessment and intervention for children younger than 3 years with developmental delays, including ASD.

Interventions for children with ASD are provided through educational practices, developmental therapies, and behavioral interventions. Treatment strategies may vary by the age and strengths and weaknesses of the child. For example, intervention for a toddler with a recent diagnosis of ASD may include behavioral and developmental approaches (individually or in the context of

comprehensive approach) and, as he or she progresses, involvement in a specialized or typical preschool program. For older children, intervention is more likely to occur in educational settings, with integration of behavioral and developmental therapies to promote skill development. In addition to variation by age of the child, interventions differ in theoretical approach and scope (eg, focused and targeted or comprehensive), settings and/or modality of delivery (eg, individual versus group or classroom, delivered by a professional versus a trained parent, and school versus home setting), and targets of intervention.[48,297] Interventions may be provided through public and/or not-for-profit agencies, schools, and early intervention services, and some may be paid for through insurance.[299] Families should be involved in the selection of intervention approaches and remain an involved participant in subsequent educational and therapeutic decisions. There is regional variation in the availability of various types of therapy and providers that sometimes results in long waits for service, less-than-desired intensity, or inability to obtain a desired intervention altogether. By law, students with ASD should receive an appropriate educational program, although it may not include all of the components desired by the family. Advocacy is often necessary to obtain desired services through schools or through mechanisms paid for by insurance. It is noted that many of the interventions in common use do not have a strong evidence base. Some types of intervention may not be paid for by insurance.

Systematic reviews of the evidence base for treatment have been completed on early intensive intervention,[44,300] medical treatments,[301] behavioral interventions,[294,298] and evidence-based practice guidelines.[292,302]

Wong et al[295] described 2 categories of evidence-based interventions, the comprehensive treatment model (CTM) and focused interventions. These interventions may be provided in different settings (eg, the home, classroom, naturalistic environment, or community), by different providers (eg, developmental specialist, behavioral therapist, educator, or trained parent), individually or in group settings, and by using a set curriculum or guide.

The CTM uses a central conceptual framework to address a broad array of symptoms and is designed to address specific skill(s) or symptom(s). A CTM should be replicable, intense, and designed to address multiple therapeutic goals over a period of time. Provision of services may occur in individual instruction or class settings (specialized or inclusive), should include parents, and may involve technology-assisted intervention.[303]

Applied behavior analysis (ABA), developmental approaches, and/or naturalistic approaches may be used in CTMs.[303] Examples of CTMs include early intensive behavioral intervention, Treatment and Education of Autistic and Related Communication-Handicapped Children (TEACCH), and the Early Start Denver Model (ESDM).[295,303]

Focused intervention practices are designed to address a single or limited range of skills, such as increasing social communication or learning a specific task, and may be delivered over a short period of time.[295,297,303] Focused intervention practices may be behavioral, developmental, and/or educational. Focused interventions may be grounded in principles of ABA, in which specific skills are taught in a stepwise progression by using principles of reinforcement or developmental theory, in which the emerging skills inherent in neurobehavioral maturation are promoted. These interventions are provided in a structured setting by an adult, in naturalistic environments with peers, or as a component of a more comprehensive approach.[295] Focused interventions may be effective for promoting skill development and communication.[295,297,304,305]

Pediatricians may be asked to advise families on therapy choices or write prescriptions for therapies.[306] It is helpful for clinicians to have an understanding of intervention terminology and of the evidence base so they can effectively communicate the rationale for medically indicated treatment recommendations with families, educators, therapists, and other service providers as well as with insurance companies, health care administrators, funding agencies, and policy makers.[295]

This report describes various types of interventions provided for children and youth with ASD. Additional research is needed to evaluate the effectiveness of current approaches and develop interventions that address core deficits of ASD. At the time of diagnosis, parents of young preschool children may ask their provider to help them decide what type of intervention they should elect. Two common theoretical approaches to intervention for symptoms of ASD are ABA and developmental models.[296–298,307] Although these approaches have important distinctions, they also have significant overlap, and interventions increasingly are incorporating aspects of both. There is considerable regional variation in the availability of various interventions. Table 9 describes common characteristics of empirically supported interventions.[296,297,308,309]

Approaches to Intervention

ABA

Most evidence-based treatment models are based on principles of ABA. ABA has been defined as "the

TABLE 9 Characteristics of Effective Interventions

Features of Practice	Common Characteristics of Empirically Supported Interventions
Assessment and goals	Systematically assess skills
	Include input of family (shared decision-making)
	Select individualized measurable goals and instructional procedures on the basis of objective assessment of each child
	Use assessment-based, empirically supported instructional methods to build, generalize, and maintain skills and reduce problem behaviors
Instructional methods	Address core symptoms in social communication and restricted and repetitive behaviors as well as skill deficits
	Provide a student/teacher ratio low enough to address the child's individualized goals
	Interventions should be by providers who are properly trained and should maintain fidelity with the treatment approach selected
	Ensure that multiple providers work collaboratively
Services and supports	Individualize services and support
	Make use of the child's interests and preferences in determining reinforcement systems
	Incorporate preferred activities to increase engagement in activities
Environment	Provide a structured learning environment that helps children anticipate transition between activities, including a predictable routine and visual activity schedules
	Organize workspaces to minimize distraction and promote task completion
	Limit access to things that may distract a student
	The environment should promote opportunities for the student to initiate communication and interact with peers
Behavioral management	Implement a functional behavioral analysis to identify the reasons why challenging behaviors occur and develop a behavior improvement plan based on this assessment (IDEA-mandated approach)
	Teach children more appropriate responses using the behavior improvement plan
Progress	Systematically measure and document the individual child's progress
	Adjust instructional strategies as necessary to enable acquisition of target skills
Family support	Involve and educate families so they can use the behavioral strategies at home and in the community
Transition planning	Plan for transitions in school settings and to adulthood (eg, from home-based early intervention to preschool services, preschool to elementary school, elementary school to middle school, middle school to high school, high school to work or postsecondary education, and home to community living)

Gait variability of patients with intermittent claudication is similar before and after the onset of claudication pain. *Clin Biomech (Bristol, Avon).* 2011;26(7):729–734; and Myers SM. Management of autism spectrum disorders in primary care. *Pediatr Ann.* 2009;38(1):42–49.

process of systematically applying interventions based upon the principles of learning theory to improve socially significant behaviors to a meaningful degree, and to demonstrate that the interventions employed are responsible for the improvement in behavior."[310] The use of ABA methods to treat symptoms of ASD suggests that behaviors exhibited can be altered by programmatically reinforcing skills related to communication and other skill acquisition.[311,312] Thus, ABA treatments may target development of new skills (eg, social engagement) and/or minimize behaviors (eg, aggression) that may interfere with a child's progress.

ABA interventions vary from highly structured adult-directed approaches (eg, discrete trial training or instruction, verbal behavior applications, and others) to interventions in natural environments that may be child led and implemented in the context of play activities or daily routines and activities and are altered on the basis of the child's skill development (eg, pivotal response training, reciprocal imitation training, and others).[297,309,312,313] To determine what intervention is most appropriate, the behavioral clinician works with the family and child to determine which skills to target for development and maintenance and what goals are appropriate.

ABA programs are typically designed and supervised by professionals certified in behavior analysis. The majority of states at this time have licensure for board-certified behavior analysts with provisions for payment by insurance. ABA may be prescribed or recommended by a physician or licensed psychologist.

A comprehensive ABA approach for younger children, also known as early intensive behavioral intervention, is supported by a few randomized controlled trials (RCTs) and a substantial single-subject literature.[297] When only RCTs are considered, few interventions have sufficient evidence to be endorsed either for children younger than 12 years[298] or for adolescents.[314]

Children younger than 12 years receiving more hours per week of ABA were found to be more likely to achieve the individualized goals identified in their programs.[315] In retrospective studies, more intense ABA therapy was associated with achieving optimal developmental outcomes.[316] Given the heterogeneity of the ASD phenotype, the service needs of children, youth, and adults need to be individualized by using available clinical data.

In some instances, a behavioral intervention is needed to address acute serious problem behaviors that

must be given priority, for example, because of safety issues.[295] Whether a student is getting formal ABA under IDEA or not, a family can request that challenging behaviors be evaluated in the school setting by using behavioral principles through a functional behavioral assessment. The target symptoms to treat may then be divided into component parts that are addressed in a stepwise fashion (task analysis).[313,317] Once the reasons for the behavior are understood, a behavior improvement plan may be implemented.

Developmental Relationship–Focused Interventions

Intervention for young children also may be derived from developmental theory, which is focused on the relationship between the caregiver's level of responsiveness and the child's development of social communication.[296,318–320] Through interaction with others, children learn to communicate and regulate emotions and establish a foundation for increasingly complex thinking and social interaction. Therefore, developmental models designed to promote social development in children with ASD are focused on the relationship between the child with ASD and his or her caregiver through coaching to help increase responsiveness to the adult (ie, the interventionist or parent or caregiver) through imitating, expanding on, or joining into child-initiated play activities. This approach may address core symptoms of ASD, such as joint attention, imitation, and affective social engagement.[296,297,321,322]

Developmental models for intervention are focused on teaching adults to engage in nondirective interactive strategies to foster interaction and development of communication in the context of play. One such approach is known as DIRFloortime (The Developmental, Individual Differences, and Relationship-Based model). In 1 RCT comparing parent coaching using this approach to community intervention alone (N = 112) in children ages 2 to 5 years, parents who were taught this approach were less directive, and their children were rated as more socially responsive, although IQ and language scores were no different between groups, and half of the children in the control group improved in their affective ratings.[323] A similar approach is relationship development intervention,[324] and more research is needed to evaluate efficacy and community use.

Naturalistic Developmental Behavioral Intervention

Naturalistic developmental behavioral interventions (NDBIs) incorporate elements of ABA and developmental principles, such as emphasis on developmentally based learning targets and foundational social learning skills, with delivery of interventions in the context of naturally occurring social activities within natural environments. They use child-initiated teaching episodes, naturally occurring opportunities for learning, and turn-taking interactions within play routines and implement ABA-based approaches to address measurable goals.[296]

The most extensively studied NDBI approach is the ESDM, which prepares children to learn in naturalistic environments.[325] In a multisite trial of ESDM, early age at entry to therapy and more hours of total therapy were associated with improved outcome.[326] Of note, the 48 children randomly assigned to ESDM or community treatment in the original trial were studied by using event-related potentials and spectral power on EEG while viewing faces as opposed to objects and were compared with typical controls on these tasks. This is an early demonstration of improvement on a neurophysiologic measure associated with improvement on a clinical measure of social behavior through an early intervention program.[327]

Combined Approaches

Common factors in combined developmental and behavioral approaches include use of principles of ABA to reinforce skill building; a systematic approach with a manual for training practitioners who would use the intervention in a standard fashion; individualized treatment goals for the child and means of measuring progress; child-initiated teaching, imitation, and modeling; and adult prompting that fades over time to promote independence.[296] It may be difficult to advise parents on specific programs in community settings because the way the program is conducted may differ from the research settings.[328] However, it is always accurate to describe the common characteristics of empirically supported interventions and recommend that families seek interventions that incorporate these features (Table 9).

Parent-Mediated Treatment or Parent Management Training

Increasing evidence reveals that focused interventions delivered by trained parents or other caregivers can be an important part of a therapeutic program.[297,329–332] More RCTs have been published on parent-mediated therapies than on other nonpharmacologic interventions. What is sometimes called parent management training is divided into 2 categories: parent support and parent-mediated interventions. Parent support interventions, which are knowledge-focused and provide indirect benefit to the child, include care coordination and psychoeducation. Parent-mediated interventions, which are technique-focused and provide direct benefit to the child, may target core symptoms of ASD or other behaviors or skills and may be built on ABA approaches in natural settings.[331]

Training sessions for caregivers may be delivered in the home, clinic, school, or other community settings or remotely by telehealth.[297,329–331,333–337] An RCT involving 86 toddlers and their primary caregivers demonstrated that 10 weeks of hands-on parent training in joint attention, symbolic play, engagement and regulation (an NDBI) was superior to a parent-only psychoeducational intervention for increasing joint engagement.[338] A parent training approach may be used to promote compliance with instruction, social communication, and other identified goals of the caregiver, such as reducing maladaptive behaviors.[331,339–342] Including parents in the intervention process is critically important.[43,326,343]

Educational Interventions

Classroom-Based Models

It is the expectation that school-aged children will be educated in classroom settings with supports for a broad effect on the symptoms of ASD and associated deficits. Educating students with ASD in the least restrictive environment typically requires an individualized program that is modified to meet the Individualized Education Program (IEP) goals set by the family, student, and school team. Some students who do not qualify for an IEP by educational criteria may be supported with accommodations through a Section 504 plan or with classroom-level accommodations. Many students with ASD are educated in inclusive classrooms with supports. Other school-aged children and youth benefit from disorder-specific approaches. Examples of classroom-based models include Learning Experiences and Alternative Programs for Preschoolers and their Parents (LEAP) and TEACCH.[344]

LEAP blends principles of ABA with special and general education teaching techniques for elementary-aged pupils in inclusive settings for teaching social interaction.[344–346] An RCT of 294 preschool-aged children revealed that LEAP was associated with improvement in socialization, cognition, language, and challenging behavior and that LEAP was superior to a treatment-as-usual method.[345]

TEACCH class settings are visually organized to promote engagement and learning.[344] The TEACCH approach to skill acquisition includes assessment-based curriculum development and an emphasis on structure, including predictable organization of activities and use of visual schedules, organization of the physical environment to optimize learning and avoid frustration (eg, by minimizing distractions and/or sensory dysregulation), and adaptation and organization of materials and tasks to promote independence from adult directions or prompts.[344,347] Instruction is organized in a predictable fashion and uses visual schedules with promotion of independence in activities planned into the instruction.[347] This approach is associated with a small, but measurable, benefit in perceptual, motor, verbal, and cognitive skills in students with ASD, with less measured effect on adaptive and motor function[347] and challenging behaviors. Rigorous studies of educational interventions for students with ASD at school age and beyond are necessary to understand the effectiveness of different models.[298]

A comparison of the effects of LEAP and TEACCH classrooms with those of standard special education classes taught by teachers familiar with ASD revealed that the common features of these interventions may be responsible for improvements seen in all students. TEACCH was associated with more reported improvement in ASD severity for students who had greater cognitive delays. This finding may speak to the benefit of the environmental and behavioral supports.[344] Research interventions may not be comparable with community-provided school programs. Future research is needed to address how best to provide evidence-based intervention in classroom settings.

Education in the Least Restrictive Educational Environment

Pediatricians have an important role in advocating for children and youth with special health care needs, including ASD, in the educational setting. Students have a right to a free and appropriate public education. Educational programs for school-aged children with ASD should promote language, academic, adaptive, and social skills development and prepare them for postsecondary education or employment.[348] Most, but not all, students with ASD will have some individualization of their education under the guidance of an IEP determined by the school multidisciplinary team in conjunction with the family. Others may receive accommodation and/or environmental modifications under Section 504 of the Rehabilitation Act of 1973.[349] A medical diagnosis of ASD alone does not automatically translate into eligibility for school-based services. Functional impairment that affects participation in the typical curriculum is required to qualify for supports in the educational setting and may lead to an IEP for the educational handicap of autism. Most youth with ASD and average-range intelligence will likely require academic intervention because of coexisting learning disabilities, executive function challenges, ADHD, motor processing deficits, the effects of their pragmatic language differences on reading and writing, and/or challenges in comprehension of spoken or written language.[350] Attention to the needs of the individual student must be central to the IEP process. Social skills of students with ASD may benefit

from students being in class and on the playground with peers with typical development.[351,352] However, spending more than 75% of their time in an inclusive educational setting alone was not sufficient in transition-aged youth to increase rates of college attendance, high school graduation, or functional ratings.[353] How to best support students with ASD in the least restricted environment requires further study.

Social Skills Instruction

Social skills deficits may present differently depending on language abilities, developmental level, and age. Examples of social skills deficits include the following:

- challenges with entering, sustaining, and exiting interactions;
- difficulty attending to, understanding, and using nonverbal and verbal social cues, such as eye contact, facial expressions, and gestures;
- difficulty in understanding "unwritten" social rules of the environment;
- not understanding the perspective of others;
- struggling with negotiation, compromise, and conflict resolution; and
- problems with interactive play or participation in leisure activities.

The importance of caregiver involvement in teaching social skills to preschool-aged children needs to be emphasized for families of young children with ASD. Reinforcing social interaction is central to the success of evidence-based ABA, developmental, and NDBI approaches.[296,354] Teaching and coaching social interaction involves both behavioral therapy and speech and language therapy approaches.

School-aged children and adolescents with ASD, including those with typical academic skills, should have social skills support considered in their school and perhaps in other therapeutic settings if indicated.[351,354–356] Although families identify the need to address social skill developments in settings outside of school, the success of these types of interventions is variable. Interventions may be divided into adult-mediated (skill building with the individual child), peer-mediated (skill building with the child and typically developing classmates), and mixed approaches. Child-directed social skills interventions are often delivered individually or in small groups with other children with similar needs. Therapy may be provided in behavioral health settings to complement the social skills interventions at school.

Interventions addressing social skills may increase the child's knowledge of the cues for social behavior and teach strategies for social problem-solving. A popular method uses the social narrative to help a child define the social context of an anticipated or experienced situation, put it in perspective, and then develop statements on how it makes the child feel and on what to do in response to the event and feelings.[357] This coached rehearsal strategy may be included within other programmatic approaches. Implementation may use a cognitive behavioral intervention strategy in which the child identifies feelings and thoughts and learns to substitute more socially appropriate alternatives.[354] Video- and computer-based social skill interventions may extend access to intervention once an evidence base is established. A systematic review of RCTs of social skills training for children aged 6 to 21 years revealed that interventions improved social competence and friendship quality but did not result in differences in emotional recognition and social communication. Transfer of skills to other settings was inconsistent.[356]

Because child-mediated interventions taught separately from social settings have not had consistently beneficial effects, interventions have been developed for implementation in the social settings that include peers, such as the classroom and playground. These interventions demonstrate improved playground interaction between children with and without ASD and improved identification as friends by typical peers.[351] Peer-mediated intervention for students with ASD have revealed improved social connectedness and reduced social isolation and provide evidence to support the use of these interventions in the classroom and playground. An evidence-based approach designed for group administration, the Program for the Education and Enrichment of Relational Skills, may improve both teacher-reported social functioning and adolescent-reported social cognition.[358] Fewer studies are available to guide programs to promote social skills development for adults with ASD. However, the Program for the Education and Enrichment of Relational Skills group model has been demonstrated to improve social skills in young adults with ASD.[359]

Families should be counseled to include development of social skills with discrete goals and interventions in the IEP or educational plan as well as to be cognizant of potential opportunities to promote social interaction in the natural environment and in the context of other therapies.[360] Implementing IEP goals across the day and generalizing specific skills to promote conversation and nonverbal communication, such as providing eye contact, directing facial expressions, and using appropriate gestures, is important, independent of age, and should involve both the caregivers and professionals. More information about IEPs in

general can be found at http://www.wrightslaw.com/info/iep.index.htm.

Other Therapeutic Interventions

Speech and Language Interventions

Delayed language is an early concern for many children who are later diagnosed with ASD. The communication symptoms included in the DSM-5 criteria for ASD reflect core deficits in social communication and interaction, such as failure of back-and-forth communication, deficits in nonverbal communication (such as eye gaze and use of gesture), difficulty adjusting behavior to suit the social context, and restricted and repetitive behaviors leading to perseverative vocalization, echolalia, and preoccupation with restricted topics of interest. All children with ASD should have documentation of specific coexisting speech and language diagnoses so that appropriate intervention might be provided.

Speech-language therapy is the most commonly identified intervention provided for children with ASD.[361] The strategies used by speech-language pathologists to reinforce sound repetition and word use in children with typical development are often initially used with young children with ASD. Such strategies include reinforcement of speech sounds and communicative acts, imitation of the sounds the child makes, and exaggerated imitation and slowed tempo.[362] The literature offers the most support for approaches with preverbal children with ASD in which adult prompts are used for communication, prompt fading, and reinforcement of their own attempts at communication. Intervention in naturalistic settings and involvement of caregivers may help reinforce the initiation of communication and functional use of sounds, gestures, and words.

A significant minority (up to 30%) of individuals with ASD ultimately do not acquire verbal speech.[363] Delayed onset of speech may be complicated by general delays in development (intellectual disabilities) or coexisting speech disorders, such as childhood apraxia of speech. Although using communicative spoken phrases before age 4 years is considered a good prognostic sign for language development in youth with ASD, emergence of phrase speech may occur to at least age 10 years, especially in children with preserved nonverbal skills and evidence of social engagement.[364]

When children do not spontaneously speak, augmentative and alternative communication (AAC) may be introduced. Examples of AAC strategies include sign language, the Picture Exchange Communication System, and speech-generating devices.[365,366] The use of AAC may help promote social interaction and understanding of the purpose of communication and does not delay onset of speech. Indeed, it may enhance emergence of spoken words by pairing nonverbal and verbal communication.

The Picture Exchange Communication System is used to build communication through picture identification and exchange as communication. With training, pictures can be sequenced to build on communicaiton.[367] Picture strips that sequentially explain medical procedures, for example, take advantage of this approach. Use of speech-generating devices and programs that use AAC on digital tablets also are increasing. These devices provide acoustic feedback to the child, and touch-screen tablets are relatively inexpensive and portable. Medical providers are often asked to justify the purchase of touch-screen tablets or AAC devices. It cannot be assumed that the use of AAC alone will lead to functional oral communication without a therapeutic plan.[368] Current scientific evidence does not support the use of facilitated communication in which a nonverbal individual is guided to communicate.[369,370] This differs from AAC, in which the individual is taught to communicate independently. Future strategies to promote communication are expected to incorporate evolving knowledge about sensory processing and connectivity of brain functions in people with ASD.

Children and youth with ASD often have deficits in pragmatic language that can affect social interaction with adults and peers and academic performance as more complex language becomes required for reading comprehension and analysis of information. In addition, literal interpretation of language and difficulty in understanding the intent of other people leads to behavioral challenges in some people with ASD and affects success in school, leisure activities, and employment. School-aged students with spoken language should have their pragmatic language assessed as part of their school-related reevaluations, with consideration of pragmatic language testing if academic problems and inattention are noted in the classroom. Interventions may include individual and group approaches that include teaching and practicing conversation. The pediatrician may refer the child for private speech-language therapy if he or she is not eligible for services in school or if increased intensity of intervention is desired. Although the impact of speech-language therapy on structural language improvement has not been adequately studied, improvement in ratings of conversational competence by parents and of classroom learning skills by teachers supports the recommendation for social skills and social language interventions for students with ASD.[371]

Motor Therapies

Children with ASD may have low muscle tone or a developmental

coordination disorder. Although the ages for sitting and walking do not differ between children with ASD and children with typical development, both fine and gross motor skills may be delayed in preschool-aged children with ASD.[372] Attention to position in space in children with a coexisting diagnosis of ADHD may further complicate delays in coordination.[373] Occupational therapy services may be indicated to promote fine motor and adaptive skills, including self-care, toy use, and handwriting. Almost two-thirds of preschool-aged children with ASD are reported to receive occupational therapy services.[374]

Similarly, some children with ASD may have gross motor impairment on formal testing that may benefit from therapeutic intervention focused on building strength, coordination, motor planning, or skill acquisition to promote safer mobility or play. Toe walking is common among children with ASD as well as in other developmental disorders in early childhood. The etiology of toe walking in ASD is unclear, although sensory aversion and habit or perseveration have been proposed. Common interventions for toe walking may include passive stretching, orthotics, and casting. Impairment in gross motor function may affect the capacity of a child with ASD to participate in leisure activities with the family or with peers and may impair participation in sports or interactive play beyond the effect of their social skills alone. Impaired motor skills may further decrease opportunities for social skills development and active learning and may be a risk factor for overweight and obesity.[375] For motor therapies to be provided in the educational setting, a significant delay for age that affects function in school must be identified on a valid assessment measure.

Sensory Therapies

In 2012, the AAP published a clinical report, "Sensory Integration Therapies for Children With Developmental and Behavioral Disorders," providing important background information and recommendations for pediatricians.[376] Since that publication, the DSM-5 criteria now includes sensory symptoms in the diagnostic criteria for ASD in recognition of the fact that individuals with ASD have sensory challenges that may be related to repetitive and other challenging behaviors.[377] Indeed, sensory symptoms exhibited by young children, such as food selectivity, covering their ears for certain sounds, and visual scrutiny of aspects of objects, may be among the earliest differences families identify in their children's development. Sensory goals may be included in treatment objectives for students with ASD. Adult-directed approaches provided through sensory-based interventions may be included in the context of motor and behavioral therapies and in educational settings. Despite the increasing scientific understanding of the neurobiological basis for sensory symptoms in individuals with ASD, empirical interventions in common practice have modest evidence to support their general use at this time.[378] Commonly used sensory-based interventions, including brushing of the skin, proprioceptive stimulation by using weighted vests, or kinesthetic stimulation (such as swinging or use of specialized seating, such as a therapy ball, to modulate level of arousal), are not yet supported in the peer-reviewed literature.

Proponents of sensory integration therapies distinguish them from interventions with sensory modalities because of the active engagement with the child in skill building or desensitization. This type of therapy requires a trained clinician, often an occupational therapist, to work with a child by using play and sensory activities to reinforce adaptive responses. The therapist explains the child's behaviors and responses to caregivers in sensory terms and provides them with strategies to help the caregivers accommodate the child's sensory needs to decrease functional impairment and tolerate environmental triggers. Advocates of these interventions claim that dysfunction in integration of sensory input contributes to inefficiencies in learning and to behavioral challenges and that therapeutic approaches to sensory integration need to be considered separately from focal sensory-based treatments.[379] Although sensory-based therapies are among the most commonly requested therapies by caregivers,[361] the evidence supporting their general use remains currently limited.[378,379] As with any other intervention, specific goals for sensory-based therapies should be identified, and outcomes should be monitored so that the utility for any given child can be documented.[376]

Medical Management of Co-occurring Conditions

Co-occurring medical and other conditions, such as seizures, sleep disorders, gastrointestinal (GI) disorders, feeding disorders, obesity, catatonia, and others, have a significant effect on the health and quality of life for children and youth with ASD and their families.[380,381] In this section, the co-existing conditions commonly observed in children and youth with ASD are described, and anticipatory guidance and management strategies that primary care providers may consider are provided.[380]

Seizures

There is both an increased risk for ASD among children and youth with epilepsy and an increased risk for seizures in those with ASD. The pooled risk for ASD among children

with epilepsy is 6.3%, with almost 5 times as many in samples with the highest rates of co-occurring intellectual disabilities.[173,382,383] The rate of seizures among people with ASD in community-based populations has been reported to range from 7% to 23%, with rates as high as 46% reported in clinically ascertained samples.[170] It has been suggested that the risk for seizures is not increased in individuals with ASD without intellectual disability. Risk factors for the increased likelihood of seizures in people with ASD include intellectual disability (as noted), female sex, and lower gestational age.[174] Specific genetic disorders associated with ASD, such as tuberous sclerosis, also may contribute to seizure risk in early childhood. Onset is bimodally distributed, with most first seizures occurring in early childhood and in adolescence; 20% of first seizures occur in adults with ASD.[170] Children with ASD and seizures tend to have more behavioral challenges, independent of cognitive skills.[382] Screening EEGs are not recommended for patients who are asymptomatic. An overnight EEG should be considered when the clinical history suggests seizures and atypical regression. Response to conventional antiepileptic drug therapy varies greatly, with some reports suggesting an increased risk for treatment-resistant epilepsy in individuals with early onset of seizures and delayed global development.[384]

GI Symptoms

GI symptoms, such as abdominal pain, constipation, diarrhea, gastroesophageal reflux, and feeding problems, are more commonly reported in children and adolescents with ASD than in those with developmental delay or typical development.[385–387] A large prospective cohort study revealed differences as early as 6 to 18 months of age in stooling patterns and feeding behaviors in children who were later diagnosed with ASD.[388] Because of language delays and atypical sensory perception or report of pain, individuals with ASD may be less likely to report specific GI discomfort and may present with agitation, sleep disruption, or other behavioral symptoms rather than GI discomfort.[387] Characteristics of ASD that might affect GI symptoms include resistance to change (feeding and constipation), comorbid anxiety (pain, feeding, and motility disorders),[389] and altered sensory perception (pain, feeding, and constipation). At present, there is no evidence of an association of ASD with celiac disease, specific immune dysfunction, or motility disorders (eg, gastroesophageal reflux) in children with ASD.

It would be expected that these disorders would occur at least as frequently among individuals with ASD as among individuals in the general population, and they should be considered when the child has a history of GI symptoms or a change in behavior.[390,391] Ongoing research is focused on whether differences are present in immunologic function, motility, or the microbiome in individuals with ASD.[392–394]

Selective eating is common in children with ASD.[386] A limited diet may influence GI symptoms, such as constipation,[395] and alter the intestinal microbiota. GI disorders should be considered in patients with ASD if they present with typical GI symptoms or with agitation, food refusal, or sleep disturbance.[387,396] The indicated GI workup will depend on the specific symptoms. Children with ASD should be offered the same approaches to treatment of GI disorders as other children. Modifications of conventional interventions to accommodate for symptoms of ASD might include consistent behaviorally informed approaches for constipation and encopresis.

Feeding Disorders

Up to three-quarters of children with ASD have problems related to eating, including food selectivity based on texture, color, or temperature; rituals around food presentation; and compulsive eating of certain foods.[397–399] Behavioral refusal may also present as the child holding food in the mouth, volitional gagging, and emesis. Common related problems include pica (eating of nonfood items) and rumination (self-stimulatory emesis and reswallowing of stomach contents). By age 16 months, children who are later diagnosed with ASD are observed to be more selective in their eating patterns than are other toddlers.[400] Problems around mealtime behavior and food choice often persist into adolescence. The frequency of feeding challenges in children and youth with ASD may relate to the core symptoms of restrictive and repetitive behavior and differences in sensory perception related to smell, taste, and texture.[401]

Children with developmental delays may also have delayed oral motor skill development and may demonstrate food refusal of textures that they cannot physically chew or swallow. Discomfort can lead to food refusal, so initial evaluation should include consideration of gastroesophageal reflux, dental pain, food allergies, lactose intolerance, and significant constipation.[387] If oral-motor concerns are observed, speech or occupational therapy assessment is indicated.

Because feeding problems are so common among children with ASD, a dietary history should be obtained at health supervision visits. Physiologic needs for macronutrients and micronutrients are the same for children with ASD as for other children. As with other children in the United States, insufficient intake of fiber, vitamin D, and calcium are common.[402] Rare cases of severe nutritional deficiencies, such as

rickets (vitamin D),[403] scurvy (vitamin C),[404] and keratoconus (vitamin A),[405] have been reported in children with ASD with severe food aversions. If supplements are used to correct for poor vitamin D or calcium intake, it is important to confirm that the dose is sufficient for the age and sex of the child.[406] Food fortification in the United States may supply adequate amounts of vitamins and minerals for some children with selective diets, so additional multivitamins may not be necessary.[407] Consultation with a registered dietitian may be helpful to be able to guide families regarding the nutritional sufficiency of their child's diet.

The clinician can counsel families about offering children routine meals and snacks, discouraging snacking through the day, promoting self-feeding, and using basic behavioral approaches to encourage mealtime structure and predictability with minimal distraction. Children with ASD need to be offered new foods multiple times to become familiar with them. Feeding problems that affect nutrition or family function or that are specialized, such as mouth packing, rumination, severe pica, and intense aversions, are likely to need the support of professionals with expertise in behavior management and/or oral-motor therapies (speech or occupational therapy).[408,409] Food refusal may stem from discomfort, so consultation with a gastroenterologist may be helpful. Gastrostomy-tube placement and nonoral feeding should only be considered after appropriate behavioral intervention has failed.

Obesity

Children and youth with ASD have greater risk for overweight and obesity than those in the general population.[410–413] People with ASD have fewer opportunities and perhaps less interest for active leisure or organized sports, have repetitive eating patterns that may include energy-dense foods, and are more likely to be prescribed medications, such as atypical neuroleptics (or antipsychotic medication) and anticonvulsants, that often contribute to excessive weight gain. Sleep disorders may further predispose them for obesity. Primary care providers should monitor a child's age-specific BMI percentile in the context of health supervision care and address modifiable risk factors through anticipatory guidance for their patients with ASD. Programs that address healthy weight for children and youth with typical development may need to be modified for successful use for patients with ASD.[414]

Dental Health

Children with ASD commonly have unmet dental needs. Difficulty cooperating with hygiene and professional care are reported barriers for dental care. Even when insurance coverage is available, children with ASD have fewer visits for routine care.[415] There are limited data about the prevalence of caries or gingival disease in children with ASD. As with other children, anticipatory guidance should include attention to dental hygiene and fluoride use, if appropriate, from a young age. Behavioral strategies may be helpful to prevent the need for dental care under sedation.

Pica

Children and youth with ASD may put nonfood items in their mouths long after the developmental period of early childhood, when pica is expected. Pica is reported in up to one-quarter of preschool-aged children with ASD and is documented to persist in individuals with intellectual disability.[416,417] The persistence of pica may be attributable to sensory differences, perseveration or obsession, and oral exploration of the environment. Clinicians need to be aware of persistence of pica in children and youth with ASD because of the risk for toxic ingestions, risk for lead intoxication, potential for infection, and the risk for mechanical ingestions ranging from batteries to bezoars.[418] Obstruction and perforation need to be considered in children with pica who have acute abdominal symptoms. Iron deficiency is associated with pica in the general population.[419] Laboratory monitoring of blood lead and iron deficiency in children with pica is suggested in the context of primary care. Behavioral intervention includes reinforcing appropriate behaviors, ensuring adult supervision, and putting into place environmental safeguards for prevention.

Sleep Problems

Sleep disturbance is common in individuals with ASD and may be associated with exacerbation of problematic daytime behavior.[420–427] Problems with initiating and maintaining sleep are reported for 50% to 80% of children with ASD.[428] Children who are later diagnosed with ASD are reported to have had sleep problems by 30 months of age.[429] Sleep problems in individuals with ASD persist; almost half of adolescents with ASD continue to have sleep symptoms.[430] Adolescents are more likely to have shorter sleep duration, daytime sleepiness, and delayed sleep onset compared with younger children with ASD, who are more likely to have bedtime resistance, parasomnias, and night-waking. Reasons for the increased frequency of sleep disturbances in children and youth with ASD may include differences in melatonin metabolism,[431] developmental disruption of other neurotransmitter systems critical to sleep, and lack of social expectations, among other explanations. Genetic disorders, such as Smith-Magenis syndrome, are associated with both ASD and sleep disruption.[432] Biological reasons for disrupted sleep that are not unique to

children with ASD may include restless leg syndrome, which may be associated with low iron stores,[433] and coexisting neurologic or behavioral diagnoses, such as epilepsy, anxiety, ADHD, or mood disorders. The most common cause of both delayed sleep onset and night wakings are learned behaviors. As with other children, the evaluation of the child with ASD with delayed sleep onset, night wakings, and/or early-morning wakings should include a history of comorbid medical conditions that might disrupt sleep, such as gastroesophageal reflux, seizures, asthma, allergies, eczema, or enuresis. Snoring might suggest obstructive sleep apnea and would prompt referral for additional assessment. Children who play video games or engage in other screen time close to bedtime have later bedtimes and may have more difficulty falling asleep.[434,435] Restless sleep and night wakings would suggest a need for laboratory evaluation for ferritin and other indicators of iron sufficiency to determine if low iron stores might be present.[428] An environmental history of the household may help to determine if household noise, parental work hours, or other factors may affect sleep. The bedtime routine and response to night-waking should be reviewed to determine the behavioral approaches to consider.

Empirical support exists for the effectiveness of parent education and behavioral interventions for children with ASD and sleep disturbances.[425,436–440] Behavioral intervention includes parents establishing bedtime routines and making clear their expectation that the child sleeps in his or her own bed. This may be difficult to establish for children with ASD, who may not appreciate the social conventions around sleep time and may have repetitive rituals and comorbid anxiety or ADHD. Despite these challenges, behavioral strategies are successful when consistently implemented.[440]

No medication is currently approved by the US Food and Drug Administration for the treatment of insomnia in children with or without ASD. Any medication elected should be started at a low dose and monitored for adverse effects.[427] Sleep onset may be aided by treatment with melatonin[441,442] at doses from 1 to 6 mg[443] and may be maintained with long-acting melatonin.[442] Adverse effects are uncommon but may include nightmares. α-adrenergic agents (eg, clonidine) and antihistamines (eg, diphenhydramine) are often prescribed to help with sleep onset or to address night-waking in children, but the literature provides little support for their use.[444,445] Disordered sleep is associated with challenging daytime behaviors in children with ASD[446]; addressing one may help with the other.

Wandering

Accidents, including drowning, are a major cause of morbidity and mortality in children and youth with developmental disabilities, including ASD.[447,448] Children and youth with ASD may have decreased awareness of social convention and community rules as well as impulsivity and perseverative interests that draw them to potential dangers, such as bodies of water and busy roads. Wandering off (also called elopement) places them at risk for injury. Wandering, if present, should be included in the problem list as a coexisting diagnosis in patients with ASD. In an online study, 1218 families of children with ASD were questioned about elopement.[447] Nearly half of children with ASD between the ages of 4 and 10 years had tried to elope. Almost half of those children were missing long enough for their parents to contact the police. Of those children, approximately two-thirds were at risk for traffic-related injury and almost one-third were reported to have had near-drowning episodes. Data from a national survey revealed that elopement attempts in the past year were reported by approximately one-third of parents whose children had ASD with or without intellectual disability.[449] Wandering may persist into adulthood.

In the survey by Anderson et al,[447] parents reported that the most common perceived reasons for elopement were enjoyment of running, attempts to get to a desired location (such as a park), pursuit of an intense interest (eg, water), and escape from situations or sensory events that made them anxious. Because the risk for elopement increases with the severity of ASD and with co-occurring intellectual disabilities, many of the individuals at greatest risk have limited language and cannot tell first responders their names, addresses, or phone numbers if they get lost. Police may interpret aggression caused by fear as combative behavior.

Prevention is the most important intervention for elopement. Parents participating in a large national survey of children with special health care needs reported primarily using physical and electronic barriers to try to prevent elopement, especially in children who also had intellectual disabilities.[447,449] Information on prevention and management of wandering is available for parents and clinicians (http://nationalautismassociation.org/big-red-safety-box/). Consistent, adequate adult supervision is important in all environments: school, home, and community settings. Families note that increased supervision needs result in increased family stress. Families may need to consider deadbolts, fencing, and alarm systems for safety as well as personal GPS devices and identification bracelets or other identification. Local law enforcement

agencies may support GPS tracking. Alerting neighbors and local law enforcement officials as well as securing pools in the neighborhood and creating a family emergency plan are suggested. If impulsivity and motor hyperactivity contribute to elopement, examining the utility of medication as part of an overall plan may be considered. Similarly, addressing sleep issues becomes important if the child is at risk for wandering at night. Teaching safety skills and appropriate community behaviors is critical to prevention. All children with ASD, no matter their level of cognitive skills, are at risk for wandering.[449]

Motor Disorders

There is increasing appreciation that individuals with ASD may have developmental coordination disorder and other neurologic problems. Tic disorders occur with an increased frequency in children with ASD.[450] Distinguishing complex tics from stereotyped movements may be challenging.

Catatonia was added as a possible coexisting condition to ASD in the DSM-5. Slow initiation of movement and reported deterioration in motor performance have been treated with lorazepam, electroconvulsive therapy, and behavioral interventions, but the therapies do not have a strong literature base.[451] Later loss of motor skills in adolescence should prompt evaluation by a neurologist for underlying reasons. Regression in language or social interest is reported in approximately one-quarter of children later diagnosed with ASD. It is recognized most commonly between 18 and 24 months of age. Regression later in childhood requires evaluation.

Co-occurring Behavioral Health Conditions

Co-occurring behavioral symptoms include hyperactivity or inattention, aggression, outbursts, and self-injurious behaviors. Although these behaviors are not core features of ASD, they commonly interfere with functioning in school, at home, and in the community and contribute substantially to the challenges faced by families.[293,294,381,452–457] Psychiatric conditions (such as ADHD, anxiety, OCD, mood disorders, conduct disorders, or others) are identified in 70% to 90% of children and youth with ASD.[458,459] Behavioral challenges have a significant effect on health and quality of life for children and adolescents with ASD and their families.[460] Patients with ASD, like other children and adolescents, should be regularly screened for behavioral and/or emotional conditions, as recommended by the AAP.[461] The effect of behavior on home and school functioning is often assessed as part of school testing by using parent and teacher questionnaires, such as the Behavior Assessment System for Children, Third Edition, Parent Rating Scales,[79,462] or the Child Behavior Checklist.[82,463,464]

With change in behavioral symptoms, physical sources of discomfort and behavioral intervention should be considered.[465] If behavioral interventions are insufficient to address the challenges or are unavailable at the time, medication might be considered (see Table 10 for guidance on prescribing medication).

ADHD

Changes in DSM-5 criteria have provided flexibility to diagnose other DSM-5 disorders in addition to ASD, which can help guide treatment. Approximately half of children and youth with ASD also may fulfill diagnostic criteria for ADHD.[459] Pediatricians should keep in mind that some children who are later diagnosed with ASD may have been initially identified as having ADHD.[69] Symptoms of ADHD may further compromise social skills function in children with ASD because of inattention to social cues and impulsivity. Standard rating scales used to assess symptoms of ADHD have not yet been validated for

TABLE 10 Considerations Surrounding Medication Use

No current medication corrects core social and communication symptoms of ASD
Accurate diagnosis of coexisting psychiatric conditions guide therapy
Medication is used to help manage
• Coexisting behavioral health disorders (eg, ADHD, mood disorders, or anxiety disorders)
• Associated problem behaviors or symptoms causing significant impairment and distress
o Examples include the following: aggression, self-injurious behavior, sleep disturbance, mood lability, anxiety, hyperactivity, impulsivity, inattention
Medication should only be considered after
• Careful accounting of when the behavior started and what seems to exacerbate it
• A functional behavioral assessment should guide development of a treatment plan in the school setting
o Consider whether the behavior serves as communication of distress or refusal
• Consider referral to a behavior therapist outside of school to assess the reasons for the behavior, provide the family with strategies, and collaborate in care
• Careful history and physical to look for medical factors that may cause or exacerbate challenging behaviors (eg, gastroesophageal reflux and acute sources of pain, such as otitis media, dental injury, fracture, and others)[34,380,391,485,579]
Consider medication after treatable medical conditions and behavioral factors assessed and intervention does not address the symptoms of concern
Include the family and patient in shared decision making that considers their goals and values[543]

individuals with ASD. However, they are useful in determining the clinical impact of symptoms for an individual patient and in monitoring treatment. It is important, however, to consider the differential diagnosis of inattention and hyperactivity in the context of the language impairment and perseverative focus that often accompanies ASD. Children with delayed language may appear more inattentive. If they are expected to perform activities (including schoolwork) that they are not able to understand or accomplish, a child with ASD may engage in behaviors to escape, which can be interpreted as inattention and hyperactivity. Patients with ASD may be focused on their perseverative interests and may be internally distracted, as opposed to distracted by the environment. Evaluation of the symptom of inattention or impulsivity includes assessing language and educational abilities. Appropriate educational modifications and use of language for instruction that the student can understand are critical for successful intervention. Behavioral strategies should address reinforcement of on-task behaviors, breaking down tasks into units that can be completed successfully, breaks for activity (often included in sensory activities), and adult supervision appropriate for the demands. The same medications that are used for symptoms of ADHD in children without ASD are used in similar doses for children with ASD.[466] Routine monitoring is important because children with ASD may be at greater risk for adverse effects[467] (Table 11). The evaluation of a child for a possible co-occurring diagnosis of ADHD also should include consideration of a co-occurring diagnosis of anxiety.[464,466]

Anxiety Disorders

The DSM-5 classification system separates anxiety disorders into separation anxiety disorder, selective mutism, specific phobia, social phobia, panic disorder, agoraphobia, and generalized anxiety disorder as well as unspecified anxiety disorder. As many as 40% to 66% of school-aged children and adults with ASD are reported to also have anxiety disorders.[458,459] Anxiety disorders are most commonly identified in children with ASD and typical cognitive and language abilities.[468,469] Symptoms may be present in early childhood and manifest as behavioral challenges, such as overreactivity. Biological predisposition to both ASD and anxiety may be attributable to common genetic factors and/or altered neurophysiologic responses to stress.[470]

Core symptoms of ASD decrease the ability of individuals with ASD to predict the actions or interpret the beliefs of others, which may lead to a constant state of heightened worry. Repetitive behaviors may, in part, serve to instill predictability, so anxiety may lead to increased stereotyped behaviors or perseverative thoughts. Evaluation of anxiety requires consideration of the language demands of the environment, academic expectations, social demands, and underlying fears or phobias. Youth with ASD may lack sufficient language or insight to describe their symptoms. Getting information from multiple sources and looking at the behavioral manifestations related to context will help to correctly identify anxiety in patients with ASD.[471]

Strong evidence from RCTs supports the use of cognitive behavioral therapy for anxiety symptoms in school-aged children with ASD, especially those with typical-range intelligence.[295,298,472–475] Anxiety may be associated with reported GI and sensory symptoms.[389] Some individuals find that sensory redirection or sensory activities used in the context of a behavioral program are helpful to diminish feelings of anxiety. Other individuals may find symptom relief with the introduction of routine and structure if anxiety is exacerbated by uncertainty or associated with sensory under- and overreactivity.[377] Nonpharmacologic approaches, such as neurofeedback and digitally delivered approaches to self-regulation, are being evaluated for their therapeutic potential. Medications used for anxiety in the general population may be considered as part of an overall treatment plan for children and youth with ASD (see Table 11 for psychopharmacotherapy of children with ASD and anxiety).

Mood Disorders

Depressive disorders are more common among children and adults with ASD than in the general population. Reported rates of coexisting depression in adults and children are highly variable, ranging from 12% to 33%.[458,476,477] Symptoms of depression are more likely to lead to dual mental health and developmental disability diagnoses in adolescents and adults with ASD than in children. The coexistence of mood disorders and ASD may be associated with genetic and neurobiological factors as well as environmental factors related to chronic stress and difficulty with understanding social situations. Both elevated and depressed mood may present as behavioral symptoms in youth with ASD. Changes in affect, participation, sleep habits, and eating may be symptoms of an underlying mood disorder. Attempted suicide is reported to occur more frequently in people with ASD than in the general population. Risk factors include peer victimization, behavioral problems, minority race or ethnicity, male sex, lower socioeconomic status, and lower level of education.[478] The AAP recommends screening for depression in patients older than 12 years. Until ASD-specific measures are developed, the same approaches used for all other adolescents at increased risk for depression should be considered.[479]

TABLE 11 Psychotropic Medication Options for Common Target Symptoms

Target Symptoms	Medication Class (Examples)	Comments
Hyperactivity Impulsivity Inattention Distractibility	Psychostimulants (methylphenidate, dexmethylphenidate, mixed amphetamine salts, lisdexamfetamine, dextroamphetamine)[466,580–587]	With other coexisting symptoms, medication may not appear as effective May be more sensitive to adverse effects Steps: • Behavioral approaches implemented • Problems persist, trial of medication management • Start with a low-dose stimulant (eg, methylphenidate or mixed dextroamphetamine salts) and increase as needed and tolerated May be most effective in children without comorbid intellectual disability Targets symptoms of impulsivity and hyperactivity • If there are adverse effects or if not effective: Consider atomoxetine, especially if also with social anxiety Consider α-2 agonists (eg, short- or long-acting guanfacine, clonidine) Other medications (less evidence): atypical antipsychotic medications may decrease hyperactivity; their primary use is for irritability and aggression Adverse effects: Psychostimulants: appetite suppression and insomnia; also irritability, depressive symptoms, and social withdrawal; it does not appear to worsen repetitive behavior or oppositional behavior Guanfacine, clonidine: drowsiness, fatigue and irritability; may also include appetite suppression, nausea, sleep disturbance, and decreased blood pressure and heart rate; rebound if not weaned
	SNRIs (atomoxetine)[588–590]	
	α-2 adrenergic agonists (clonidine, guanfacine)[591–594]	
	Atypical (second generation) antipsychotics (aripiprazole, risperidone)[595–598]	
Irritability and severe disruptive behavior • Vocal and motoric outbursts of anger, frustration, and distress • Acts of aggression, self-injury, property destruction • Behaviors referred to by caregivers as "agitation," "tantrums," "meltdowns," or "rages"	Atypical (second generation) antipsychotics (aripiprazole, risperidone)[595–608]	Medication most effective if combined with behavioral strategies addressing identified environmental causes for the behavior and developing more appropriate responses for the child DB/PCs strong support for 2 second-generation atypical antipsychotic medications (risperidone and aripiprazole) for reducing irritability, stereotyped or repetitive movements, self-injury, and hyperactivity • Risperidone and aripiprazole are currently the only medications with FDA-approved labeling specific to irritability in ASD Adverse effects and monitoring: • Common adverse effects include wt gain and dyslipidemia • Monitoring: periodic assessment for extrapyramidal symptoms; measurement of wt, height, and BMI; and laboratory monitoring of glucose and lipid levels • Metformin might be a useful treatment to help control wt gain.[609] Other agents in this class, such as olanzapine and quetiapine, may have utility on the basis of their adverse effect profiles but do not have current FDA package insert indication for use in children with ASD
	α-2 adrenergic agonists (clonidine, guanfacine)[591,610]	Small studies documenting beneficial effects on irritability; need larger trials; may have better adverse effect profiles than atypical antipsychotics
	SSRIs (fluvoxamine, citalopram)[611,612]	Few studies focused on irritability and/or aggression; some reporting improvement in irritability; insufficient evidence to advise practice

TABLE 11 Continued

Target Symptoms	Medication Class (Examples)	Comments
	Anticonvulsant mood stabilizers (valproic acid and divalproex sodium)[613–618]	Small studies suggestive of improvement in irritability; need larger studies; a limited number of placebo-controlled studies either do not support or are inconclusive regarding anticonvulsant medication as a treatment of irritability in patients with ASD
	Serotonin-norepinephrine reuptake inhibitor (venlafaxine)[619]	Effect size of improvement associated with venlafaxine was small, and irritability was not the primary outcome measured
Repetitive behavior • Stereotyped motor mannerisms • Compulsions • Behavioral rigidity, insistence on sameness	Atypical (second generation) antipsychotics (aripiprazole, risperidone)[595–598,620]	Multiple DB/PCs documenting improvement in repetitive behavior; short-term treatment Common adverse effects include increased appetite, fatigue, drowsiness, dizziness, and drooling More effective for targets of tantrums, aggression, and SIB
	Anticonvulsants (valproic acid and divalproex sodium)[613,621,622]	Modest improvement has been reported with divalproex sodium treatment May have improvement with topiramate as a second agent with risperidone Most antiseizure drugs have potential for sedation, cognitive adverse events
	SSRI (fluoxetine, fluvoxamine)[480,509,611,612,623–627]	Studies to date have not revealed effectiveness of SSRI medications for repetitive behaviors related to ASD, although they may diminish anxiety SSRIs may be effective for reducing symptoms of OCD and of anxiety when included in a comprehensive approach to treatment Need comprehensive behavioral approaches to minimize repetitive behaviors
Anxiety, depression	SSRIs[469,628]	Anxiety relief has been reported in trials of citalopram and buspirone, with fluvoxamine revealing some effect in female patients with ASD; documented utility in children and youth without ASD
	α-adrenergic (clonidine, guanfacine)	Hyperactivation is an adverse effect of SSRIs in children and youth with ASD that may result in stopping the medication The anxiety disorders most amenable to treatment are generalized anxiety disorder, separation anxiety disorder, and social phobias
	Atypical (second generation) antipsychotics[469,620]	If a mood dysregulation disorder is identified, treatment with a mood stabilizer and/or a second-generation antipsychotic is recommended, although an SSRI may be used to treat comorbid anxiety, OCD, or depression; behavioral activation with hypomanic or manic switches has been reported First-line treatment is a program of cognitive behavioral therapy to reduce symptoms[472–475] Few studies have examined the specific effects for these symptoms; clinicians may consider use of these agents; although SSRIs, SNRIs, and/or buspirone may be effective for the treatment of anxiety in children with ASD, they have not been rigorously evaluated for this purpose[507,626,627,629,630] Medications to consider include sertraline, fluoxetine, citalopram, or escitalopram for symptoms of anxiety and α-2 agonists (eg, guanfacine and clonidine and β-blockers such as propranolol), which may be useful for anxiety-related physiologic symptoms and behavioral dysregulation, and a short-acting benzodiazepine, such as lorazepam, could be considered for event related anxiety

DB/PC, double-blind placebo-controlled trial; FDA, US Food and Drug Administration; SIB, self-injurious behavior; SNRI, selective norepinephrine reuptake inhibitor. Adapted from Riddle MA. *Pediatric Psychopharmacology for Primary Care*. 1st ed. Elk Grove Village, IL: American Academy of Pediatrics; 2016.

As in children and youth with typical development, assessment of depression and other mood disorders must include family history, history of environmental stressors, the potential for toxic ingestions, and evaluation for comorbid conditions. Interventions for depression include supportive therapy, cognitive behavioral therapy, and medication, if indicated, as coordinated interventions (see Table 11 for medication use). Antidepressant use in people with ASD has not been demonstrated to address aggression and has inconsistent effect on anxiety.[480] Medication recommendations are based on data from the general pediatric population and expert consensus.[469]

The DSM-5 criteria for bipolar illness include changes in activity, energy, and mood. It may be difficult to make a diagnosis in people with ASD with limited language. The co-occurrence of bipolar illness and ASD in individuals with typical intelligence ranges from 6% to 21%.[481] Lifetime diagnosis of bipolar illness in adults with ASD is reported to be 9%.[458]

OCD-Related Disorders

Although restricted and repetitive behaviors are symptoms of ASD, some individuals with ASD may also have coexisting OCD. Obsessions are recurrent, unwanted, and persistent thoughts, images, or urges that cause distress. Compulsions are repetitive behaviors or thoughts with rigid rules performed to reduce anxiety. Unlike the stereotypic behaviors of ASD, compulsions usually follow an obsession, diminish anxiety, and are not desired by the individual or perceived as pleasurable.[482] Under the DSM-5, OCD-related disorders include hoarding disorder, excoriation (skin-picking) disorder, trichotillomania, substance- or medication-induced obsessive-compulsive and related disorder, and obsessive-compulsive and related disorder due to another medical condition. The perseverations associated with ASD may be qualitatively different and less sophisticated than the repetitive and intrusive thoughts and actions associated with OCD.[483] Repetitive behaviors in general may help an individual with ASD regain a sense of predictability. Anxiety, phobias, and/or depression may coexist with OCD in youth with ASD.

Behavioral approaches are recommended as the first line of treatment of symptoms of OCD, depending on the language and cognitive level of the patient. Cognitive behavioral therapy, including exposure and response prevention with or without a selective serotonin reuptake inhibiter, has been demonstrated to be the most effective treatment for youth with OCD who do not have ASD. Cognitive behavioral therapy may be less effective, with fewer remissions, in youth who also have ASD[484] (see Table 11 for medication management).

Disruptive Behavior Disorders: Aggression, Self-Injurious Behavior, and Tantrums

Disruptive behaviors, such as aggression, self-injury, and tantrums, may complicate home and community management of individuals with ASD. Behavioral outbursts may occur in response to stressful events in the environment, in reaction to a medical condition, as functional communication, or as a symptom supporting diagnosis of a co-occurring mental health disorder.[485] Functional behavioral analysis and implementation of behavioral strategies can be an important initial step in management.[486] A proposed pathway for the primary care setting for management of irritability that leads to disruptive behaviors in youth with ASD is proposed by McGuire et al.[485] Disruptive behaviors may serve as communication to escape from a demand or an undesired situation. If successful, they may become part of a behavioral pattern. New onset of severe behaviors requires consideration of potential medical reasons (see Table 12). Pharmacologic treatment should be considered if no medical etiology is identified and if the behavior is associated with irritability, is not responsive to available behavioral interventions, or is related to a co-occurring diagnosable behavioral health disorder, such as anxiety, mood

TABLE 12 Common Presentations of Self-Injurious Behavior and the Medical Conditions to Consider If New Onset

Type of Self-Injury	Potential Associated Conditions	Potential Associated Injury
Head banging	Headache, toothache, sinus infection, ear infection	Detached retina, abrasions, contusions
Head hitting or slapping	Headache, toothache, sinus infection, ear infection	Fracture of bones in hand, detached retina, abrasions, contusions
Eye poking	Vision loss, eye pain	Eye abrasion
Gum or tooth digging or banging	Dental pain, gingivitis	Gum injury, tooth autoextraction, tooth fracture
Scratching and skin picking	Allergy, eczema, drug reaction, skin infection or infestation (eg, fleas, scabies)	Infection, scarring
Finger and toenail biting or picking	Pain	Infection, nail removal, ingrown nails, paronychia
Kicking or stomping	Restless leg syndrome, leg pain	Bruises, fractures
Rumination	Gastroesophageal reflux, eosinophilic esophagitis	Esophageal ulceration and bleeding, dental damage, nutritional compromise, precancerous lesions of esophagus

disorders, thought disorders, and/or ADHD.

It has been reported that between 8% and 68% of children with ASD demonstrate aggressive behavior, depending on how stringent the definition is.[454] Aggressive behaviors were reported on the Child Behavior Checklist for one-quarter of children attending an ASD clinic, with similar rates from 2 to 16 years of age. Aggression was associated with hyperactivity, lower cognitive skills, sleep problems, and internalizing behaviors such as anxiety. There was no association with sex. Researchers of other studies have observed increased rates of physical aggression in children with ASD who have lower adaptive skills and frequent repetitive behavior.[487] Management of co-occurring sleep problems and hyperactivity may be helpful in a treatment plan[488] that includes behavioral intervention to address aggression and targeted pharmacotherapy.[487]

Self-injurious behaviors are reported in 40% to 50% of individuals with ASD at some point across the lifespan[489] and may occur more frequently in people with ASD who also have aggressive behaviors and sleep problems.[490] Self-injurious behaviors in individuals with ASD may be repetitive and self-stimulatory (such as scratching, pica, or rumination). Head banging and self-hitting may occur as part of a tantrum. Like aggression and other disruptive behaviors, self-injurious behaviors may serve as communication to escape from demands or situations that the individual does not want to be in. The type of self-injurious behavior may change if the intervention of prevention or blocking is not associated with addressing the underlying reason for the behavior. Persistence of self-injurious behaviors in individuals with ASD is associated with more limited cognitive and language abilities, hyperactivity, impulsivity, repetitive behavior, and more challenges with social interaction.[491] There is an association of self-injury with specific genetic disorders that are not associated with ASD, such as the severe self-biting of Lesch-Nyhan syndrome. Self-injurious behavior is associated with genetic disorders that are also associated with ASD, such as Cornelia de Lange syndrome, fragile X syndrome, and Smith-Magenis syndrome.[492] In the case of aggressive, self-injurious, and disruptive behaviors, the primary care provider needs to assess the safety of the child and family in an ongoing fashion. Referral to community services and for behavioral intervention should take place if behaviors are unsafe or if the patient is not responding to the treatment plan.

Psychopharmacologic Approaches to Management

The use of medications to treat behavioral and psychiatric symptoms in children and youth with ASD has increased significantly since the publication of the 2007 AAP clinical reports.[493,494] With a shortage of specialists, more medication management, including prescription of atypical antipsychotic medications, is taking place in the primary care setting.[495,496] Large national studies of insurance claim data from Medicaid and commercial insurers reveal rates of psychopharmacology prescription for patients with ASD to be 56% to 65%.[476,493,497] One or more psychotropic medications are prescribed for 1% of children with ASD younger than 3 years, for 10% to 11% of children aged 3 to 5 years, for 38% to 46% of children aged 6 to 11 years, and for 64% to 67% of adolescents aged 12 to 17 years.[498,499] Psychotropic medication use increases with increased age, lower range of cognitive skills and/or presence of intellectual disability, and higher prevalence levels of challenging behavior or coexisting psychiatric diagnoses.[476,497–501] Prescription of medication also appears to be affected by demographic factors, such as race, ethnicity, and geography.[497,498,502] Reported polypharmacy rates range from 12% in a registry cohort recruited from diagnostic clinics[499] to 29% to 35% in large studies of Medicaid claims data.[476,493]

Medication may be helpful to address co-occurring symptoms or disorders. Clinicians should carefully weigh potential risks and benefits before prescribing medication for behavior and use psychotropic medications as part of a comprehensive treatment approach. The prescribing clinician should understand the indications and contraindications, dosing, potential adverse effects, drug-drug interactions, and monitoring requirements of the medications they prescribe.[6] Table 10 provides guidance for principles of prescribing medication, and Table 11 lists pharmaceutical options for common behavioral-symptom clusters. Psychopharmacogenomic testing for genetic variants that increase the likelihood of adverse effects is an emerging area for precision medicine. Prescribers should consider CYP2D6 and CYP2C19 metabolizer status in making medication decisions for selective serotonin reuptake inhibitors (SSRIs), for example, despite limited data at present to guide practice.[503,504] The limited data on the utility of psychopharmacogenomic testing at the time of this publication limits insurance coverage for many patients. Recommendations for testing are expected to rapidly change with ongoing research.[503–505]

Areas of Psychopharmacologic Research

As the neurobiology of ASDs are better understood, novel psychopharmacologic agents might be developed that will better manage

co-occurring symptoms and/or address core deficits. Some potentially important lines of research involve medications that modulate metabolism of excitatory neurotransmitters (such as glutamate and γ-aminobutiric acid), block acetylcholinesterase and/or nicotinic acid receptors, and act as hormones that naturally promote social affiliation (such as oxytocin and vasopressin). Drug trials involve newly formulated agents as well as repurposing exiting medications used for other purposes.[506–509]

Better understanding of the neurobiology responsible for the symptoms of ASD will allow for the identification of targeted psychopharmacologic interventions. The use of psycho-pharmacogenomics to identify which patients might genetically be at greater likelihood of benefit or at increased risk for adverse effects from specific medications is an important area of research.[510]

Integrative, Complementary, and Alternative Therapies

Despite the advances in understanding the neurobiology of ASD, many unanswered questions remain about why ASD occurs and how best to treat it. Families often consider nutritional interventions and nonmedical therapies without a scientific evidence base to address the symptoms that conventional interventions cannot rapidly address, or there is limited access to conventional services in their community. Primary care providers are often asked about nonstandard interventions that are used in integrative practice or are promoted on the Internet, in the popular press, by other families, and by celebrities.[511–516] The National Center for Complementary and Integrative Health maintains a Web site in which current information on novel therapies in popular use for people with ASD is reviewed.[517] In the past decade, an increasing number of interventions based on theories of causation of ASD that are, as yet, unproven have been examined in clinical trials. Appropriately designed trials have provided evidence to support some interventions, such as the dietary supplement melatonin, and have disproven others, such as secretin.[518] Many interventions, although still widely used, remain unproven.

Complementary therapies are often attractive to families because they are purported to correct putative biological causes of behavioral symptoms and may be discussed with an optimism about outcome that is often not conveyed with the recommendation for conventional therapies. Between 28% and 74% of children with ASD are given at least 1, and usually more than 1, complementary therapy.[519–521] Although use of novel therapies is common among children with a range of developmental disabilities, children with ASD who are irritable or overactive or who are reported to have food allergies may be more likely to be given additional therapies.[522]

Complementary, alternative, and integrative therapies used for ASD can be grouped into 3 general areas: (1) natural products (including herbs, vitamins and minerals, and probiotics), (2) mind and body practices (including yoga, chiropractic, massage, acupuncture, progressive relaxation, and guided imagery), and (3) other therapies (including traditional medicine and naturopathy).[517]

Dietary interventions used to treat symptoms of ASD are perceived by many families as beneficial because they are natural and without adverse effects. Dietary elimination of gluten- and casein-containing foods is often implemented in an attempt to ameliorate core symptoms of ASD, not on the basis of allergy or celiac disease.[523,524] The double-blind clinical trials to date have not demonstrated a treatment effect with diet.[524,525] Whether a subgroup of children with GI symptoms might benefit from these or other dietary interventions requires additional study. Children may be adequately nourished on a casein-free diet with calcium and vitamin D supplementation. Nutritional counseling is recommended if a trial of this diet is elected.[406] It may be that improvement in unrelated conditions may influence behavioral symptoms (eg, removal of dairy products may decrease irritability attributable to lactose intolerance).

Dietary supplements are often given to children who are selective eaters by their families to compensate for a limited diet.[406] However, many children with ASD are given vitamins and minerals to treat proposed biochemical abnormalities that have been proposed to be unique to ASD. Popular dietary supplements include vitamin D,[526,527] vitamin B_{12},[528] vitamin B_6 with magnesium,[529] omega-3 fatty acids,[530] and multivitamin preparations. The literature to date is controversial with respect to vitamin supplementation as a treatment of symptoms of ASD, and at this time, no conclusive evidence exists that people with ASD require different nutrient intake than that recommended in the Dietary Reference Intakes (https://www.ncbi.nlm.nih.gov/books/NBK225472/). The long-term risks of high-dose supplementation have not been studied.[531] Although maternal folic acid status may provide biologically plausible risk for ASD, there is no evidence that supplementing with B vitamins has therapeutic benefit at this time, whether a child carries common variants in the *MTHFR* gene.[532,533] Of dietary supplements in common use, melatonin has been demonstrated to be a safe and effective intervention for sleep in children with ASD.[428]

Nonbiological interventions used for symptoms of ASD are popular and have also been increasingly studied. There has been conflicting evidence regarding the effect of music therapy,[534] yoga,[535,536] massage,[537] and equine-assisted therapy[538,539] on the symptoms of ASD in children, but evidence does not support these therapies for treatment of the core deficits of ASD at this time. Evidence to date does not support the use of auditory integration training, in which an individual listens to altered sounds through headphones in an effort to change auditory or other processing.[540] Existing studies are insufficient at this time to support dance therapy, drama therapy, and chiropractic therapy.[541]

Medical interventions used for nonstandard purposes also are sometimes prescribed for symptoms of ASD. Clinical trials do not support the use of antifungal agents, immunotherapy, or hyperbaric oxygen treatment, and concern for safety, in addition to lack of supporting data, cautions against chelation therapy for children with ASD.[516]

As with any intervention, families electing a novel therapy should work with their therapeutic team to identify target symptoms they hope to address and develop a monitoring system to track change. Interventions should be implemented in a stepwise fashion so that proper attribution of effect is possible and confounding factors can be identified. It is important that the medical home provider and family collaborate to select and monitor safe and effective interventions.[542]

SECTION 6: WORKING WITH FAMILIES

Families play a key role in effective treatment for children with ASD. Recognition that individuals who are affected and their families are partners with the professionals in all aspects of planning a personal, local, and national agenda for ASD has emerged and has shaped approaches to community services as well as research planning.[543] Provision of patient- and family-centered care requires the clinician to educate the family about the child's health and engage in respectful dialogue. Resources to support the clinician in talking to families about the diagnosis include a toolkit developed by the Autism Speaks Autism Treatment Network (https://www.autismspeaks.org/tool-kit/atnair-p-guide-providing-feedback-families-affected-autism).

Impact of ASD on the Family

The impact of having a child with ASD on other family members and on society is considerable. Parents of children with ASD report more stress[544,545] and increased costs[546] than do parents who do not have a child with ASD. More than half of families report that a parent needs to cut back on work or stop working because of the care needs of the child.[547] The largest societal costs associated with ASD are special education, residential care, and lost days of caregiver work.[4] Peer support for families of children with ASD is associated with less parental stress, less negative mood, and more positive perceptions.[548] Parents who understand more about their child's ASD can advocate for more intensive and appropriate services.[549] Best practice includes giving families contact information for a family support group at the time of diagnosis. This support may be a local group that provides face-to-face interaction and community activities or an online community.[550] Many families may not have the time or inclination at the time of diagnosis to communicate with other families affected by ASD but may find the support useful later when they are facing the transitions of preschool, adolescence, or adulthood. National support groups that address a wider community of children and youth with special health care needs (such as Family Voices and Parent2Parent), autism-specific national support organizations (such as Autism Speaks and the Autism Society), and local organizations are effective in helping families obtain information and feel supported. Clinicians should familiarize themselves with national and local sources of support and information so that families can be given Web sites or phone numbers at the time of diagnosis and again as indicated. State-specific information on services and Maternal and Child Health Bureau–supported programs are found online (https://mchb.hrsa.gov/maternal-child-health-initiatives/autism). It is important for providers to advocate for instructional material in other languages as well as be knowledgeable of other resources in their communities that can provide services or support to the culturally diverse groups they serve.

Comorbid conditions, such as intellectual disability and/or psychiatric disorders, add to the impact of ASD on family functioning and access to care.[551] Although families of older children and youth typically report fewer interactions with professionals, the stress on the parent related to the ASD diagnosis persists.[552] Primary care providers should speak with families about the stresses associated with ASD and the health of other family members and make appropriate referrals, either for supportive counseling for the caregivers or agencies that can address behavioral and respite needs of the child or to address unmet health needs in family members.

The effect on siblings also needs to be considered in the context of both anticipatory guidance and primary care. Most siblings of children with ASD do not report having a sibling with a disability to be a negative experience; however, they, too, are at risk for increased stress and subsequent emotional problems.[553]

Siblings may have precocious involvement in the care of the child with ASD, and some resent the amount of attention and resources the child with ASD requires or the family's inability to participate in activities in which they see their peers engaging. Proactively teaching siblings about ASD and providing them with peer support may be helpful (Autism Speaks Sibling tool kit: http://www.autismspeaks.org/sites/default/files/a_siblings_guide_to_autism.pdf). Many areas have groups to provide education and support to siblings. It appears that positive parental attitudes and a supportive family setting are associated with better sibling adjustment as well. The pediatrician should monitor the well-being and need for behavioral health supports of siblings as well as parents.

Medical Home

In the AAP's medical home model, primary care is envisioned as accessible, continuous, comprehensive, family centered, coordinated, compassionate, and culturally sensitive for all children and youth, including those with special health care needs. Children with ASD represent a population that has had difficulty accessing comprehensive coordinated services. The chronic care model provides the structure for clinicians to collaborate with patients and their families.[554] Parents of children with ASD perceive care to be less comprehensive, less well coordinated, and less family centered than they desire and report that they are less satisfied with their care compared with parents of children with other special health care needs.[555] Parents also perceive their providers as less well informed regarding treatments for ASD, especially complementary, alternative, and integrative therapies, than they would like them to be. Pediatricians report that they lack the knowledge to provide this support to patients with ASD[556] as well as the time and resources for specialized care.[555,557] Parents of children and youth with ASD would like better access to specialty care and report greater unmet medical and behavioral health care needs[558] and a higher financial burden for care compared with parents of children without ASD.[559]

Increasing family awareness and understanding of the medical home can promote partnership of the parents and primary care provider in planning and coordinating the child's care and advocating for their needs. National survey data reveal that family-centered and coordinated care through a medical home results in fewer unmet needs,[558] including dental needs.[560] Organizations, such as Family Voices and Family-to-Family Health Information Centers, can provide information and support as well as resources for guiding families in developing care notebooks for their child. Through their ongoing relationship, providers can help children understand their own diagnosis at their developmental level. Clinicians can remind their patients with ASD of their strengths, such as focus, memory, visual-spatial problem-solving, and others, as well as their personal accomplishments in building skills and mastering barriers to achieve goals. Recognition of achievement of milestones, whether it is toilet training or college graduation, should be acknowledged.

Shared decision-making promotes a collaborative process for planning care through dialogue among the individual who is affected, caregivers, and clinicians. It can be particularly useful when the evidence for an intervention is either controversial or if there is not a uniformly accepted approach.[561] Shared decision-making requires clarity of the question to be answered, the options to be understood, and the family context and beliefs to be respected. It is often a process rather than a single conversation. Helping children and youth with ASD understand their diagnosis within the context of their developmental level can help them understand their symptoms and participate in decision-making.[562]

Transition to Adulthood

Planning for children with ASD to understand and participate in their own health care should begin early in adolescence, with adaptation for developmental abilities. The AAP clinical report "Supporting the Health Care Transition From Adolescence to Adulthood in the Medical Home" provides guidance on the steps necessary to address health care transitions for all patients with chronic conditions.[563] Got Transition recommends 6 core elements that need to be addressed for health care transition without disruption in care, including (1) a transition policy for the practice, (2) tracking and monitoring transition, (3) assessing transition readiness for youth and/or family, (4) actively planning the details of transition, (5) transfer of care, and (6) transition completion.[564] The pediatric health care provider is also in a position to advise the family about teaching their adolescent with ASD about sexuality.[565] Planning for wellness requires considering young adult opportunities for exercise and leisure activities. Planning for medical transition for all aspects of health care should start around ages 12 to 14 years. Educational transition starts at the school level at age 14 years and should involve the student as much as possible.

As a child approaches legal adulthood, the family may need to consider guardianship, either full guardianship in cases in which an adult child cannot make health, financial, or other decisions because of cognitive impairment; limited guardianship in cases in which an individual can participate in decision-making; or conservatorship in cases in which the oversight extends only to

financial decision-making. Many young adults with ASD will be capable of independent decision-making and should be prepared for transition to adulthood like other teenagers. The young adult with ASD may be eligible for Supplemental Security Income (SSI) benefits. SSI is a federal program that provides funds for the care of individuals with developmental disabilities who will not be able to support themselves independently. Because of the strict guidelines regarding cognitive and adaptive delays, some adults with ASD may not be eligible for SSI even if their disability is a barrier to employment. Families may wish to meet with a counselor who can advise them on financial planning, with attention to the needs of an adult child with developmental disability.

Students with disabilities who plan to continue their education need to be advised of the transitioning process into postsecondary education. Students with disabilities are protected under IDEA (1990; amended 1997 and 2004); Section 504 of the Rehabilitation Act of 1973; the Americans with Disabilities Act (1990); and the ADA Amendments Act of 2008. Some colleges may provide accommodations to students with developmental disabilities with proper documentation of their needs, including recent academic testing. College students with ASD may benefit from continued supports around social skills development, medication monitoring, and mentoring on living independently.[566]

Although resources are still insufficient, attention is growing for the need to provide social skills training for youth with ASD with and without intellectual disabilities to enter the workforce in competitive employment as well as job skill development. There are insufficient group-home and supported community–living arrangements for adults with ASD to meet the demands in most communities. The clinician should initiate discussions with parents regarding their plans for where their child with ASD will progress to postsecondary school education and/or employment and their plans for where their child will live in adulthood early in adolescence so the family can plan appropriately with community agencies.

Families should work with their child's school throughout adolescence to target the skills their child will need to master to be successful in young adult programs, the workforce, or postsecondary education. Goals for increasing skills may include academic, social, communication, leisure, and self-care goals. Families need information to be as proactive as possible in planning for health, academic, job, and residential needs in young adulthood. Additional research is needed to develop and evaluate evidence-based and effective interventions for this age group.[314] The pediatric health care provider should provide anticipatory guidance to the family in the context of ongoing health supervision and communicate with identified adult providers for smooth health care transition.[567]

State Programs, Supports, and Laws

State laws related to education, social service, and insurance for individuals with ASD vary significantly. Although the federal government mandates early intervention for children at risk for developmental delay and a free and appropriate education for students aged 3 to 21 years who have specific educationally handicapping conditions, the implementation of educational services varies by state and locality. The law states that services need to be appropriate, not necessarily optimal. No legal mandate for adult services exists, although the agencies that provide residential services, service coordination, job training, and adult day services typically are funded through the states.

The social services and home- and community-based waiver services available to families whose children have developmental disabilities, including ASD, differ from state to state.[568] The clinician should be familiar with the requirements for programs in their state that might lead to a Medicaid waiver (medical assistance as a secondary insurance for children with special health care needs), service coordination, respite care, and other financial or behavioral supports afforded a family when a child has special health care needs. The clinician may need to complete a form to verify the diagnosis and needs for eligibility. Of note, some children with ASD who have typical cognitive abilities may not qualify for many special education and social service supports. However, later on, at the time of transition to adulthood, if they experience difficulty with employment and daily-living skills, they may qualify for support services.

SECTION 7: RESEARCH AND SERVICE NEEDS

More than $1.5 billion of private and public research funding was devoted to ASD between 2008 and 2010.[569] The passage of the Combating Autism Act of 2006 (Public Law 109–416) and its reauthorization in 2014 as the Autism Collaboration, Accountability, Research, Education and Support Act (CARES) Act (Public Law 113–157) continued a trend in funding to address the intervention needs of individuals diagnosed with ASD. Before this time, research funding was largely focused on the genetics and neurobiology of the disorder. However, this changed with the convening of the National Institutes of Health Interagency Autism Coordinating Committee in 2006. The committee was assembled to provide guidance to the agencies funding autism services, and the research agenda was expanded on the basis of the contributions of stakeholders, including families, individuals

affected, and federal agencies. The committee's 2009 strategic plan, updated in 2017,[570] identified 7 areas for research funding: (1) early detection, (2) underlying biology, (3) genetic and environmental risk factors, (4) treatments and interventions, (5) services and implementation science, (6) lifespan services and supports, and (7) epidemiological surveillance and infrastructure.[571] The committee recommended that multiple levels of inquiry be pursued simultaneously to inform evidence-based clinical care. These levels include the following:

- basic and translational science in the areas of genetics and epigenetics, neurobiology, and psychopharmacology to understand typical and atypical brain development and function to develop ASD-specific behavioral and pharmacologic therapies; additional research is needed to identify and understand ASD risk factors that might be mitigated to reduce ASD-related disability;
- research into the underlying neurobiology of sensory symptoms and restricted interests and repetitive behaviors to inform development of targeted interventions;
- clinical trials to test focused interventions based on the underlying biological processes involved with ASD to determine if they are appropriate for community application;
- epidemiological surveillance to gather data important for planning for current and future needs, including screening, diagnosis, and lifespan health and mental health services; and
- health services research to provide guidance for comprehensive, accessible, and culturally appropriate medical, educational, and behavioral care for children, youth, adults, and families affected by ASD.

Research in all of these areas is critical to move forward with early diagnosis, effective treatment, and evidence-based interventions at each age.

PEDIATRIC RECOMMENDATIONS

To provide appropriate care to all children and families affected by ASD, health, education, and public health systems need to collaborate and build integrated and adequately funded and staffed systems.

- Early identification and treatment: Pediatric providers should use screening and surveillance to provide accurate and early identification, cost-effective and timely diagnosis, prompt implementation of evidence-based interventions, and elimination of disparities to access to care for children with ASD. Clinicians should respond appropriately to family or clinical concerns and results of screening to avoid delays in diagnosis and treatment.
- Collaboration of systems of care: Children with ASD should be provided evidence-based services to address social, academic, and behavioral needs at home and school; access to appropriate pediatric and mental health care; respite services; and leisure activities.
- Planning for adolescence and transition to adult systems of care: Communities should build services to promote social skills appropriate for work and postsecondary education, access to appropriate medical and behavioral health services, job skills development, and community leisure opportunities. Pediatricians need to engage with families and youth to plan a transition to adult medical and behavioral health care. The medical home provider should support the family and youth in advocating for appropriate postsecondary work or schooling, residential supports, and activities to maintain a healthy lifestyle.
- Informed individuals and families: The pediatrician can educate youth with ASD and their families about the evidence for interventions, refer families for possible participation in clinical research when appropriate, refer families to support organizations, and prepare families to navigate transitions.
- Informed pediatric providers: To best serve patients and families affected by ASD, the clinician caring for children and youth with ASD should be familiar with issues related to diagnosis, coexisting medical and behavioral conditions, and the impact of ASD on the family to provide a medical home for these patients. Actively addressing capacity building to care for children and youth with ASD requires initiatives directed at provider education and practice quality improvement and public health, educational, and social programs to support families in their journey from diagnosis to service provision to transition to adult care.

FINANCIAL DISCLOSURE: The authors have indicated they have no financial relationships relevant to this article to disclose.

FUNDING: No external funding.

POTENTIAL CONFLICT OF INTEREST: MeMix LLC is a company that makes an application (for phones). Dr Levy is on the advisory board for the application's development. This application is being developed to assist in nutritional and dietary management of children with autism. Dr Levy has not received any money yet from this company. This application is the focus of a National Institutes of Health R21 grant, for which Dr Levy is funded for ∼2% of her salary. Once it is studied and marketed (if appropriate), Dr Levy will (possibly in the future) earn some money. Her years of relationship with the company are 2015 to the present. Dr Hyman has a relationship with Roche. Dr Hyman is the site principal investigator of a clinical trial of a novel agent being tested to promote social function in patients with autism. The University of Rochester (Dr Hyman's institution) was 1 of >40 sites and had 2 study participants in 2018. University of Rochester will be leaving the trial in 2019 (withdrawal submitted) because of staffing, and that reimbursement for staff time does not cover the cost of participation. Funding was for the staff to complete the assessments required for the clinical trial. Dr Hyman got no personal reimbursement from the company; the funding was for staff time for recruitment and assessment and clinical research center support for the trial.

COMPANION PAPER: A companion to this article can be found online at www.pediatrics.org/cgi/doi/10.1542/peds.2019-3448.

Supplemental Information

SUPPLEMENTAL TABLE 14 Recurrent CNVs Most Commonly Identified in Cohorts With ASD by Using CMA Analysis

CNV Region	Frequency[a]	Common Clinical Features
16p11.2 deletion	1 in 304	ASD, DD or ID, expressive language impairment, relative or absolute macrocephaly, overweight
16p11.2 duplication	1 in 396	ASD, schizophrenia, bipolar disorder, ADHD, relative or absolute microcephaly, underweight
15q11.2-q13 (BP2–BP3) duplication	1 in 494	ASD, DD or ID, epilepsy, hypotonia, ataxia, behavior problems
15q13.2-q13.3 (BP4–BP5) deletion	1 in 659	ASD, DD or ID, epilepsy, schizophrenia, cardiac defects
1q21.1 duplication	1 in 659	ASD, DD or ID, schizophrenia, ADHD, relative macrocephaly, hypertelorism
22q11.2 duplication	1 in 659	ASD, DD or ID, hypotonia, motor delay
16p13.11 deletion	1 in 791	ASD, DD or ID, epilepsy, schizophrenia, congenital anomalies
7q11.23 duplication	1 in 989	ASD, DD or ID, growth retardation, hypotonia
16p12.2 deletion	1 in 989	ASD, DD or ID, schizophrenia, epilepsy, growth retardation, cardiac defects, microcephaly, hypotonia
17q12 deletion	1 in 1978	ASD, DD or ID, schizophrenia, renal cysts, mature-onset diabetes of the young type 5
15q13.2–13.3 (BP4–BP5) duplication	1 in 1978	ASD, DD or ID, obesity

BP2 breakpoint 2; BP3 breakpoint 3; BP4 breakpoint 4; BP5 breakpoint 5; DD developmental delay; ID intellectual disability.

[a] Moreno-De-Luca D et al[631]; the frequency of each CNV among 3955 probands with ASD from the Autism Genetic Resource Exchange, Autism Genome Project, and Simons Foundation Autism Research Initiative Simplex Collection cohorts.

SUPPLEMENTAL TABLE 13 Selected Genetic Syndromes Associated With ASD

Condition	Physical Findings	Gene	Confirmatory Testing	Importance
Fragile X syndrome	Long face, prominent forehead and jaw, large ears, joint laxity, macroorchidism after puberty in boys	*FMR1* (CGG repeat expansion, abnormal methylation)	Targeted mutation analysis (PCR and Southern blot)	Genetic counseling (X-linked dominant inheritance); all mothers of individuals with an *FMR1* full mutation are carriers of an *FMR1* premutation or full mutation; extended family counseling is necessary; premutation carriers are at risk for fragile X–associated tremor/ataxia syndrome and *FMR1*-related primary ovarian insufficiency in female patients; several targeted pharmacologic therapies are under investigation
Neurofibromatosis 1	Multiple café-au-lait macules, axillary and inguinal freckling, iris Lisch nodules, cutaneous neurofibromas	*NF1*	Clinical criteria; optimized protein truncation testing, sequence analysis, and deletion or duplication analysis are available but infrequently required	Genetic counseling (autosomal dominant inheritance); 50% de novo, 50% inherited; associated problems requiring investigation or monitoring (optic gliomas, other CNS tumors, peripheral nerve sheath tumors, vasculopathy, hypertension, orthopedic issues, osteopenia)
PTEN hamartoma tumor syndrome (includes Cowden syndrome and Bannayan-Riley-Ruvalcaba syndrome)	Marked macrocephaly, skin hamartomas, pigmented macules of the glans penis	*PTEN*	*PTEN* sequence analysis, deletion or duplication analysis	Genetic counseling (autosomal dominant inheritance with highly variable expression); associated problems requiring investigation or monitoring (significant risk of benign and malignant tumors of the thyroid, breast, and endometrium as well as intestinal polyps, colorectal cancer, renal cell carcinoma, cutaneous melanoma, and cerebellar dysplastic gangliocytoma)
Rett syndrome	Deceleration of head growth velocity, acquired microcephaly, loss of purposeful hand use, prominent hand stereotypies (especially hand wringing or clasping), apraxia, hyperventilation or breath-holding, seizures	*MECP2*	*MECP2* sequence analysis, deletion or duplication analysis	Genetic counseling (>99% de novo, <1% germline mosaicism); associated problems requiring investigation or monitoring and anticipatory guidance (failure to thrive, gastroesophageal reflux, respiratory problems, osteopenia, sudden death); targeted pharmacologic therapy under investigation
Smith-Lemli-Opitz syndrome	Characteristic facial features (narrow forehead, low-set ears, ptosis, epicanthal folds, short nose, anteverted nares), microcephaly, cleft palate, 2- to 3-toe syndactyly, postaxial polydactyly, hypospadias in male	*DHCR7*	7-dehydrocholesterol level (elevated); *DHCR7* sequence analysis available	Genetic counseling (autosomal recessive inheritance); potential role for treatment with cholesterol

SUPPLEMENTAL TABLE 13 Continued

Condition	Physical Findings	Gene	Confirmatory Testing	Importance
	patients, prenatal and postnatal growth retardation			
Timothy syndrome	Long QT interval, other ECG abnormalities (atrioventricular block, macroscopic T-wave alternans), congenital heart defects, cutaneous syndactyly, low-set ears, flat nasal bridge, thin upper lip, round facies, baldness for the first 2 y of life followed by thin scalp hair, dental abnormalities, frequent infections because of altered immune response, intermittent hypoglycemia	*CACNA1C*	Targeted mutation analysis, sequence analysis, deletion or duplication analysis	Genetic counseling, autosomal dominant, usually de novo, but parental germline mosaicism has been observed; treatment related to long QTc (β-blocker, pacemaker, implantable defibrillator) and avoidance of hypoglycemia
Tuberous sclerosis	Hypopigmented macules, angiofibromas, shagreen patches (connective tissue nevi), ungual fibromas, retinal hamartomas	*TSC1*, *TSC2*	Clinical criteria; *TSC1* and *TSC2* sequencing available	Genetic counseling (autosomal dominant inheritance); associated problems requiring investigation or monitoring (CNS tumors, seizures, renal angiomyolipomas or cysts, cardiac rhabdomyomas and arrhythmias); potential role for targeted pharmacologic therapy (mTOR inhibitors)

CACNA1C, calcium channel, voltage-dependent, L-type, α-1c subunit; CGG, cytosine-guanine-guanine; CNS, central nervous system; *DHCR7*, 7-dehydrocholesterol reductase; ECG, electrocardiogram; *FMR1*, fragile X mental retardation 1; *MECP2*, methyl CpG binding protein 2; mTOR, mammalian target of rapamycin; PCR, polymerase chain reaction; *PTEN*, phosphatase and tensin homolog; QTc, corrected QT interval; *TSC1*, tuberous sclerosis 1; *TSC2*, tuberous sclerosis 2. Adapted with permission from Myers SM, Challman TD. Autism Spectrum Disorders. In: Voigt RG, Macias MM, Myers SM, eds. *Developmental and Behavioral Pediatrics*. Elk Grove Village, IL: American Academy of Pediatrics; 2011:249–291.

SUPPLEMENTAL TABLE 15 Selected ASD Risk Genes Identified or Confirmed in Whole-Exome Studies

Gene	Gene Name	Broad Functional Categorization
SCN2A	sodium channel, voltage-gated, type II, α subunit	Synaptic functions (eg, ion channels, neurotransmitter receptors, cell adhesion molecules, microtubule assembly, scaffolding proteins, actin cytoskeleton)
GRIN2B	glutamate receptor, ionotropic, N-methyl-D-aspartate 2B	
KATNAL2	katanin p60 subunit A-like 2	
ANK2	ankyrin 2, neuronal	
DSCAM	Down syndrome cell adhesion molecule	
NRXN1	neurexin 1	
SHANK2	SH3 and multiple ankyrin repeat domains 2	
SHANK3	SH3 and multiple ankyrin repeat domains 3	
PTEN	phosphatase and tensin homolog	Intracellular signaling, activity-dependent synaptic protein synthesis and degradation
SYNGAP1	synaptic Ras GTPase activating protein 1	
DYRK1A	dual-specificity tyrosine-(Y)-phosphorylation regulated kinase 1A	
POGZ	pogo transposable element with ZNF domain	
CUL3	cullin 3	
CHD2	chromodomain helicase DNA binding protein 2	Transcription regulation, chromatin remodeling
CHD8	chromodomain helicase DNA binding protein 8	
ADNP[a]	activity-dependent neuroprotector homeobox	
ARID1B	AT rich interactive domain 1B (SWI1-like)	
ASH1L	ASH1 (absent, small, or homeotic)-like	
KDM5B	lysine-specific demethylase 5B	
KMT2C	lysine-specific methyltransferase 2C	
SETD5	SET domain containing 5	
TBR1	T-box, brain, 1

SUPPLEMENTAL TABLE 16 Selected Metabolic Conditions That May (Rarely) Be Associated With an ASD Phenotype

Disorders of amino acid metabolism
Phenylketonuria (untreated)
Homocystinuria
Branched-chain ketoacid dehydrogenase kinase deficiency
Disorders of γ-aminobutyric acid metabolism
Succinic semialdehyde dehydrogenase deficiency
Disorders of cholesterol metabolism
Smith-Lemli-Opitz syndrome (7-dehydrocholesterol reductase deficiency)
Disorders associated with cerebral folate deficiency
Folate receptor 1 gene mutations
Dihydrofolate reductase deficiency
Disorders of creatine transport or metabolism
Arginine-glycine amidinotransferase deficiency
Guanidinoacetate methyltransferase deficiency
X-linked creatine transporter deficits
Disorders of carnitine biosynthesis
6-*N*-trimethyllysine dioxygenase deficiency
Disorders of purine and pyrimidine metabolism
Adenylosuccinate lyase deficiency
Adenosine deaminase deficiency
Cytosolic 5′-nucleotidase superactivity
Dihydropyrimidine dehydrogenase deficiency
Phosphoribosyl pyrophosphate synthetase superactivity
Lysosomal storage disorders
Sanfilippo syndrome (mucopolysaccharidosis type III)
Mitochondrial disorders
Mitochondrial DNA mutations
Nuclear DNA mutations
Others
Biotinidase deficiency
Urea cycle defects

Identifying the Misshapen Head: Craniosynostosis and Related Disorders

Mark S. Dias, MD, FAAP, FAANS,[a] Thomas Samson, MD, FAAP,[b] Elias B. Rizk, MD, FAAP, FAANS,[a] Lance S. Governale, MD, FAAP, FAANS,[c] Joan T. Richtsmeier, PhD,[d] SECTION ON NEUROLOGIC SURGERY, SECTION ON PLASTIC AND RECONSTRUCTIVE SURGERY

Pediatric care providers, pediatricians, pediatric subspecialty physicians, and other health care providers should be able to recognize children with abnormal head shapes that occur as a result of both synostotic and deformational processes. The purpose of this clinical report is to review the characteristic head shape changes, as well as secondary craniofacial characteristics, that occur in the setting of the various primary craniosynostoses and deformations. As an introduction, the physiology and genetics of skull growth as well as the pathophysiology underlying craniosynostosis are reviewed. This is followed by a description of each type of primary craniosynostosis (metopic, unicoronal, bicoronal, sagittal, lambdoid, and frontosphenoidal) and their resultant head shape changes, with an emphasis on differentiating conditions that require surgical correction from those (bathrocephaly, deformational plagiocephaly/brachycephaly, and neonatal intensive care unit-associated skill deformation, known as NICUcephaly) that do not. The report ends with a brief discussion of microcephaly as it relates to craniosynostosis as well as fontanelle closure. The intent is to improve pediatric care providers' recognition and timely referral for craniosynostosis and their differentiation of synostotic from deformational and other nonoperative head shape changes.

INTRODUCTION

Pediatric health care providers evaluate and care for children with a variety of head shapes, some of which represent craniosynostosis and other craniofacial disorders, some of which are deformational in nature, and some of which are simply normal variants. Identifying the various types of head shape abnormalities is important for aesthetics, to identify candidates for future monitoring, and, at least in some, to prevent increases in intracranial pressure (ICP) and allow proper brain development. This report reviews several of the important head shape abnormalities and normal variants that pediatric health care providers are

likely to see, describes their salient clinical and radiologic features, and discusses the optimal timing for referral and surgical correction. The report begins with an overview of the normal development of the skull and sutures and the pathophysiology of craniosynostosis.

NORMAL DEVELOPMENT OF THE CALVARIUM AND MOLECULAR DETERMINANTS OF CRANIOSYNOSTOSIS

The skull is a complex skeletal system that meets the dual needs of protecting the brain and other sensory organs while allowing its ongoing growth during development. The calvarial vault (Fig 1) is composed of paired frontal, parietal, and temporal bones and a single occipital bone. The paired frontal bones are separated from each other by the midline metopic suture, and the paired parietal bones are separated from each other by the midline sagittal suture. The frontal and parietal bones are separated by the paired coronal sutures, the parietal and temporal bones are separated by the paired squamosal sutures, and the parietal and occipital bones are separated by the paired lambdoid sutures. There are also a number of sutures and synchondroses involving the skull base. The anterior fontanelle (bregma) forms at the junction of the paired frontal and parietal bones, whereas the posterior fontanelle (λ) forms at the junction of the paired parietal bones with the midline occipital bone.

The skull encompasses the skull base, calvarial vault, and pharyngeal skeleton.[1,2] The bones of the skull base mineralize through endochondral ossification involving the replacement of a fully formed cartilaginous anlagen with bone matrix. In contrast, the bones of the calvarial vault form by intramembranous ossification involving the mineralization of bone matrix from osteoblasts without a cartilaginous intermediate. Craniosynostosis involves the abnormal mineralization of suture(s) and fusion of one or multiple contiguous bones of the cranial vault and can include additional abnormalities of both the soft and hard tissues of the head.[3] The role of cartilage growth disturbance within the cranial base in craniosynostosis is still a matter of debate.[4–7]

The bones of the cranial vault ossify directly from undifferentiated mesenchyme.[8,9] Differentiating osteoblasts accumulate on the leading edges of cranial vault bones as the brain expands during prenatal and early postnatal growth.

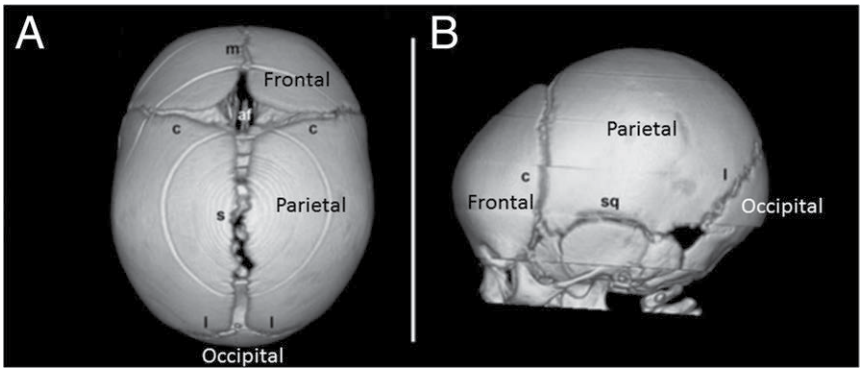

FIGURE 1

Undifferentiated cells between these osteogenic bone fronts form the cranial vault sutures, which function to keep the suture patent while allowing rapid and continual bone formation at the edges of the bone front until brain growth is complete.[10] Sutures are fibrous "joints" that allow temporary deformation of the skull during parturition or trauma, inhibit bone separation for the protection of underlying soft tissues, and, perhaps most importantly, enable growth along the edges of the 2 opposing bones until they ossify and fuse later in life.[10,11] Sutures normally remain unossified well into adolescence. When sutures mineralize (close) abnormally, growth is prevented at the fused suture and is instead redirected to other patent sutures, which, in turn, alters the shape of the skull in predictable ways.

Research has revealed multiple genetic factors, involving several major cellular signaling pathways such as wingless and Int-1 (WNT), bone morphogenetic protein (BMP), fibroblast growth factor (FGR), and others, that interact to direct the behavior of particular subpopulations of cells within the suture. In craniosynostosis, these cells receive and emit signals that stimulate osteogenic differentiation far earlier than expected,[12] resulting in mineralization and progressive ossification that unites the bones on either side of the suture. Pathogenic variants of fibroblast growth factor receptors (*FGFR*s) are the most common genetic variants associated with craniosynostosis.[13–15] *FGFR*s are transcription factors that initiate and regulate the transcription of multiple genes throughout prenatal development.[16–21] Various mouse models expressing *FGFR* pathogenic variants have been developed and demonstrate phenotypes analogous to the human craniosynostosis syndromes, including premature coronal suture closure and midface

flattening (retrusion).[22–31] Pathogenic variants in *TWIST1* (twist family basic Helix-Loop-Helix transcription factor 1) gene, another transcription factor associated with craniosynostosis,[32–34] directly affect BMP signaling of skull preosteoblasts, leading to variations in cerebral brain angiogenesis.[35] These animal models as well as studies of cellular behavior in human craniosynostosis cell lines provide the means to examine the structural, cellular, and molecular changes that occur during prenatal development.[36,37]

THE EFFECT OF CRANIOSYNOSTOSIS ON ICP AND DEVELOPMENT

Aesthetic consequences aside, there are concerns that craniosynostosis, in some cases, affects brain growth and intellectual development. A recent systematic review strongly suggests that craniosynostosis is associated with a higher risk for presurgical neurocognitive deficits compared with the population unaffected by craniosynostosis; these deficits persist postoperatively, suggesting that they may occur independent of surgical correction.[38] Generalized IQ is shifted downward with increased learning disabilities, language delays, and behavioral difficulties.[39] At least 4 mechanisms have been proposed: (1) globally elevated ICP, (2) global brain hypoperfusion, (3) localized compression and deformity, and (4) genetic predisposition. It has proven difficult to extract the exact contributions of each factor, and studies have provided conflicting data. Moreover, many studies suffer from a variety of methodologic flaws, including the inclusion of several types of craniosynostosis, varying definitions of ICP elevations (and lack of normative data), the use of different neurocognitive testing strategies, lack of randomization, inconsistent operative approaches, variations in operative timing, and small study cohorts, to name a few.

To what extent, if any, treatable causes contribute to neurocognitive deficits in craniosynostosis, and whether prompt surgical treatment can improve neurobehavioral outcomes, is a matter of debate. Elevated ICP is present in 4% to 42% of children with single-suture craniosynostosis and approximately 50% to 68% with multisutural involvement[40–44]; the incidence of intracranial hypertension is higher among older untreated individuals.[42,44] Elevated ICP correlates with developmental and cognitive outcomes in some studies[40] but not others.[39,45,46] Neither has the severity of the deformity correlated with the presence of neurocognitive deficits.[39] A few studies have suggested that earlier treatment of craniosynostosis may result in better early and late neurocognitive outcomes,[45,47] but the majority have not found such an association.[12,48–50] Finally, genes involved in craniosynostosis syndromes have recently been found to be involved in brain development,[51] and syndromic craniosynostosis syndromes having virtually identical patterns of skull fusion may carry widely different risks for neurodevelopmental deficits (see below).

THE IMPACT OF SUTURAL SYNOSTOSIS ON DIRECTED CALVARIAL GROWTH

Single sutural synostosis results in predictable changes in skull shape (Fig 2, Table 1). Persing et al[52] proposed 4 rules that govern calvarial growth and predict the head shape in cases of craniosynostosis. These rules are based on the principle that calvarial growth occurs by osseous deposition from calvarial bones lying adjacent to each suture, and this deposition is oriented perpendicular to the intervening suture:

1. Bones that are fused as a result of craniosynostosis act as a "combined growth plate," having reduced growth potential at all of the margins of the plate;
2. Bone is, therefore, deposited asymmetrically, with greater osseous deposition in the bones opposite the perimeter sutures of the combined growth plate;
3. Non-perimeter sutures that are in-line with the combined bone plate deposit bone symmetrically at their suture edges; and
4. Both perimeter and in-line (abutting) sutures nearest the combined bone plate compensate with greater osseous deposition than more distant sutures.

To use sagittal synostosis as an example, the fused parietal bones act as a single, combined growth plate with reduced growth perpendicular to the sagittal suture; accelerated bone deposition occurs within the frontal and occipital bones. The metopic suture, as an abutting in-line suture, deposits bone symmetrically at an accelerated rate. The result is an elongated head (scaphocephaly) with parietal narrowing as well as frontal and occipital bossing. A similar analysis predicts the head shape for the other sutural synostoses (Fig 2). Multisutural synostosis can be appreciated as the combined effect of fusion involving each of the individual component sutures.

SCAPHOCEPHALY (SAGITTAL SYNOSTOSIS), DOLICHOCEPHALY (NICUCEPHALY), AND BATHROCEPHALY

Sagittal synostosis is the most common form of craniosynostosis, accounting for approximately 40% to 45% of cases[53–55] and having a prevalence of 2 to 3.2 per 10 000 live births.[53,56,57] Sagittal synostosis has a distinct male predominance of 2.5 to 3.8:1.[53,55] Sagittal synostosis produces scaphocephaly, characterized by both an elongated head and biparietal narrowing that is evident at birth. The head elongation is best appreciated by looking at the infant from the side (Fig 3). Some patients have an associated saddle deformity at the vertex, giving an

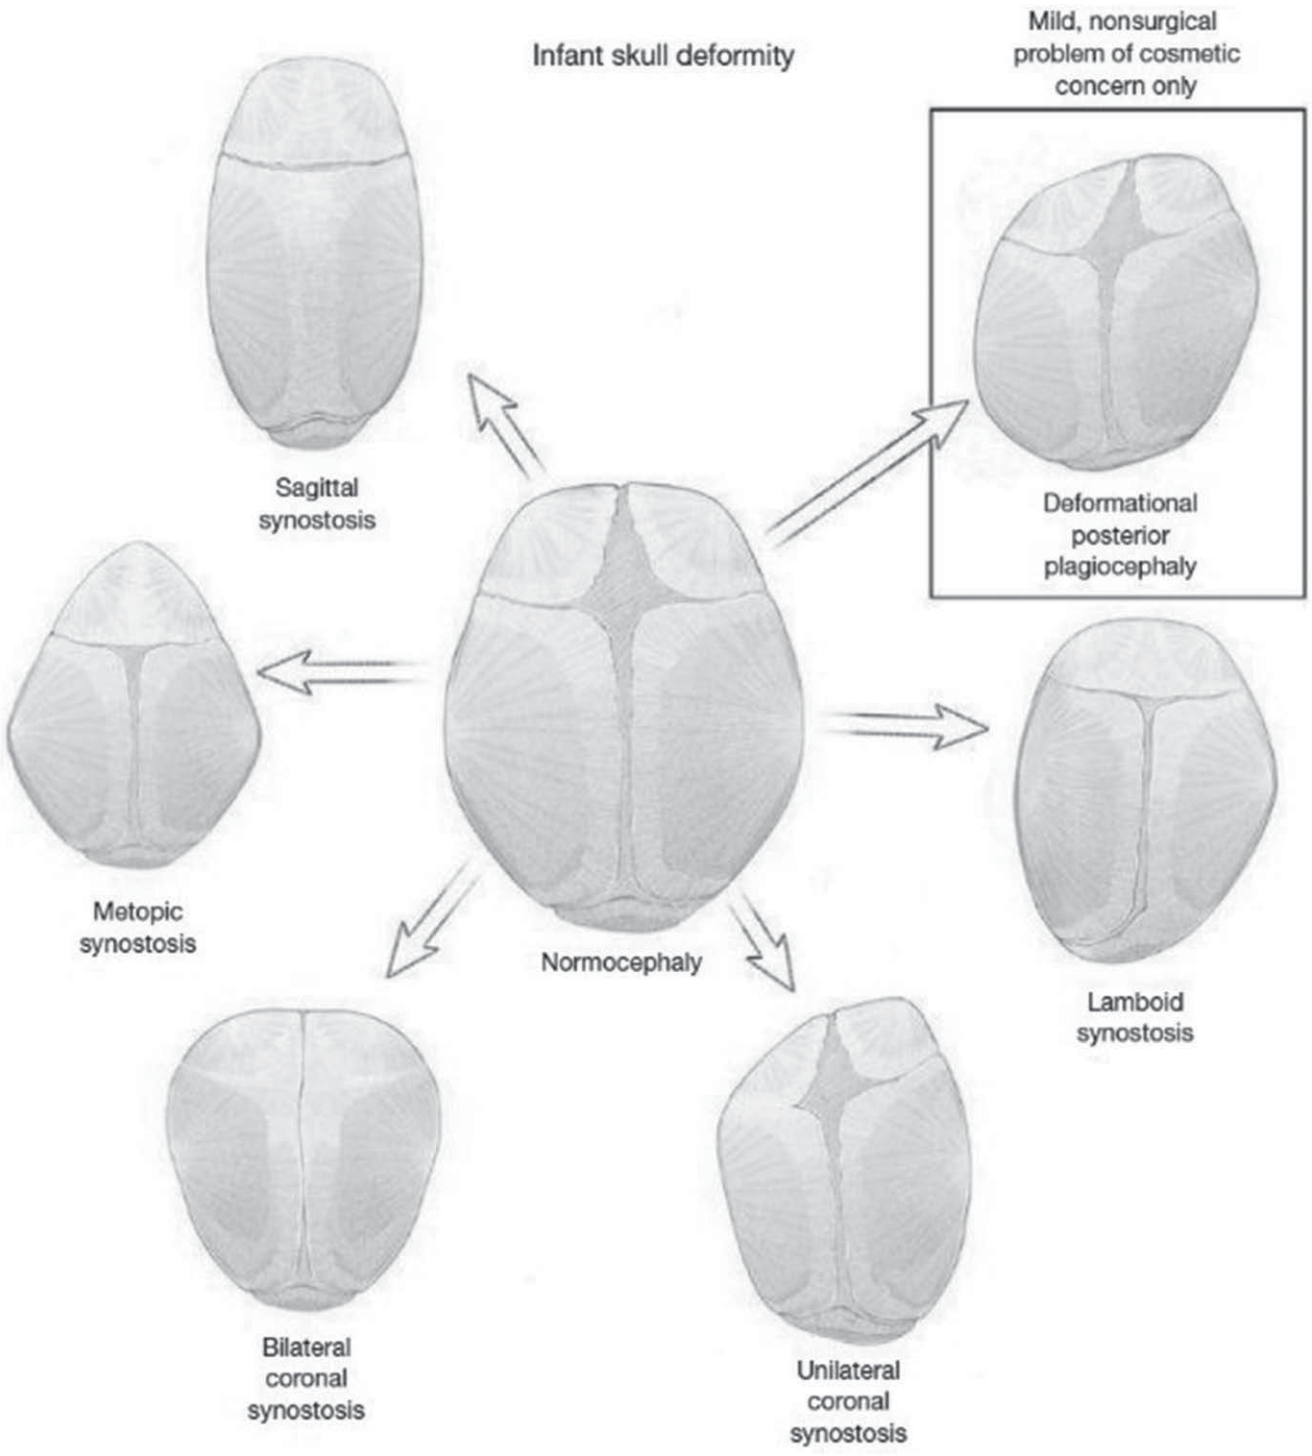

FIGURE 2

overall "peanut" shape to the head. The second consistent abnormality is the biparietal narrowing when looked at from the front or from above. Normally, the parietal bones project straight up or even bowed outward from the temporal region. Biparietal narrowing in sagittal synostosis produces a "cone-head" or bullet-shaped head when viewed from the front and a bicycle racing helmet shape when viewed from above

TABLE 1 Head Shapes Resulting From Craniosynostosis and Positional Deformations

Type	Head Shape Name	1° Change	2° Change(s)
Sagittal	Scaphocephaly	Elongated AP distance	Biparietal narrowing, frontal and/or occipital bossing, and occasional saddle deformity
NICUcephaly	Dolichocephaly	Elongated AP distance	Lack of biparietal narrowing and frontal/occipital bossing
Metopic	Trigonocephaly	Triangular forehead	Bilateral orbital retrusion, bitemporal narrowing, and hypotelorism
Unicoronal	Plagiocephaly	Trapezoid	Flattened ipsilateral forehead, retruded and elevated ipsilateral orbit (Harlequin eye), ipsilateral nasal root and contralateral nasal tip deviation, and anterior displacement of ipsilateral ear
Bicoronal	Brachycephaly and turricephaly	Shortened AP distance; flat, tall, and wide forehead	Exorbitism if associated midface hypoplasia is present
Unilambdoid	Plagiocephaly	Trapezoid	Bulge behind ipsilateral ear or mastoid and ear displaced posterior and inferior
Bilambdoid	Brachycephaly	Shortened AP distance, flat occiput	Bulge behind both ears or mastoid and both ears displaced posterior and inferior
Frontosphenoidal	Plagiocephaly	Trapezoid	Retruded and depressed ipsilateral orbit and contralateral nasal root and ipsilateral nasal tip deviation
DP	Plagiocephaly	Parallelogram	Ipsilateral occiput, ear, and forehead all displaced anteriorly
DB	Brachycephaly	Shortened AP distance	Flattened occiput with normal forehead and orbits

(Fig 3). Frontal or occipital bossing is a variable feature and tends to worsen as the infant ages. Physical examination also demonstrates a prominent midline interparietal, or sagittal, ridge that extends between the anterior and posterior fontanelles; the sagittal suture is longer, as measured from the anterior to the posterior fontanelles. Partial synostosis may cause an incomplete ridge involving only a portion of the suture. One may demonstrate the fusion of the 2 parietal bones by placing a thumb on each of them near the midline and alternatingly depressing each of them; there should be no independent movement.

Sagittal synostosis produces an elongated head on lateral radiographs and a bullet-shaped head on anterior-posterior (AP) radiographs (Fig 4A and B). The normal sagittal suture tapers toward the midline on AP radiographs; in sagittal synostosis, the fused sagittal suture may not be visible, but, more commonly, it appears to have an abrupt, more squared-off appearance (Fig 4B), paradoxically appearing to be open when, in fact, it is not. Computed tomography (CT) scans demonstrate the elongated head with biparietal narrowing (Fig 4C); the fused sagittal suture is best appreciated on coronal reconstructions by using bone algorithms (Fig 4D); three-dimensional reconstructions are particularly well suited to demonstrate the midline sagittal ridge (Fig 4E) but may involve more radiation exposure, particularly with thin slices.

It is important to distinguish scaphocephaly from dolichocephaly. Although these 2 terms have been used interchangeably by many, dolichocephaly refers to an elongated head without associated biparietal narrowing and is caused by positioning. Dolichocephaly most commonly occurs in preterm infants in the NICU: so-called NICUcephaly. Of course, there is no midline sagittal ridge as there is in sagittal synostosis, and, with the thumb maneuver described above, the parietal bones will move independently, often making the infant cry because this appears to be painful.

Infants with frontal bossing from hydrocephalus or chronic subdural hematomas or hygromas may generate confusion. However, these infants have neither an elongated head nor biparietal narrowing, and they have no midline sagittal ridge. Metopic synostosis is readily differentiated from sagittal synostosis by the presence of a prominent midline ridge that extends from the nasion to the anterior fontanelle, anterior to the sagittal suture, and is often associated with a triangular or keel-shaped forehead (trigonocephaly) with recession of the lateral orbits and narrow set eyes.

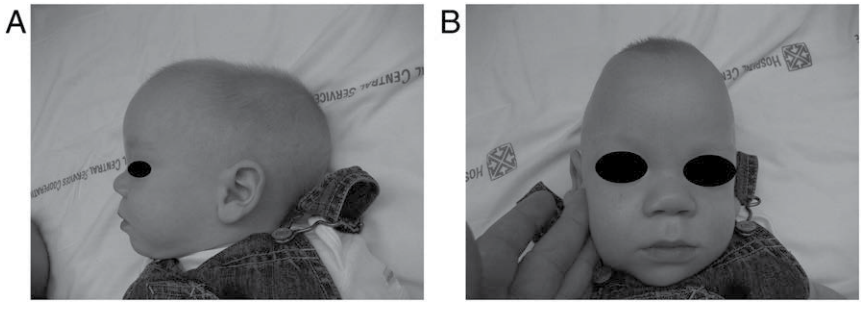

FIGURE 3
Scaphocephaly attributable to sagittal synostosis. A, Lateral view shows elongated antero-posterior dimension with modest frontal bossing and saddle deformity at vertex. B, Frontal view in same child shows parietal bones that curve inward giving a conical head shape attributable to parietal narrowing.

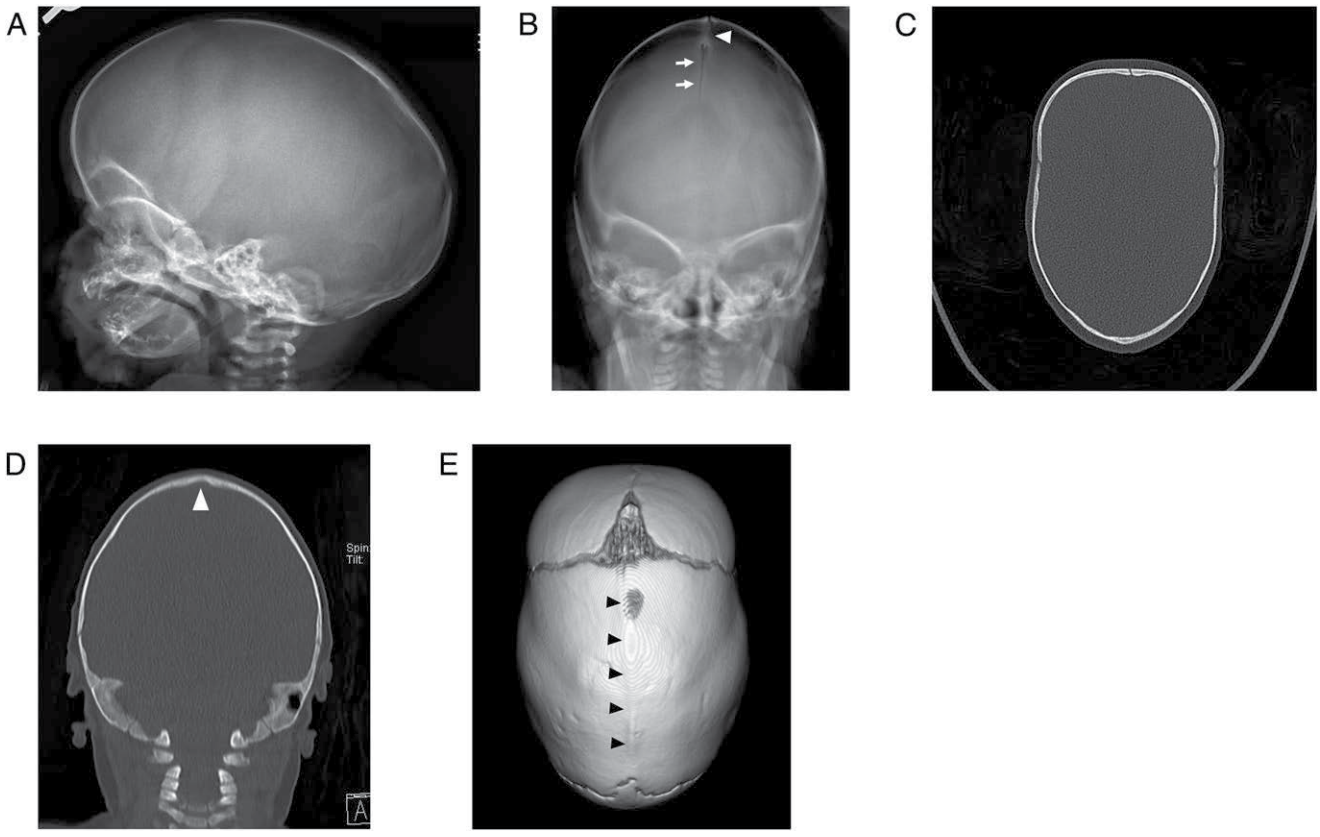

FIGURE 4
Radiologic features of sagittal synostosis. A, Lateral skull radiograph demonstrates an elongated head (sagittal suture is difficult to see from this perspective). B, Anteroposterior skull radiograph shows conical head shape. Note that part of the sagittal suture appears fused (arrowhead), whereas some appears open with sharp borders and adjacent hyperdensities (arrows). The entire suture was fused at surgery. C, Axial CT scan shows elongated head shape with prominent frontal bossing and fused posterior sagittal suture (arrowhead). D, Coronal CT scan shows conical shape of head with fusion of the sagittal suture (arrowheads). E, Three-dimensional CT scan shows prominent midline ridged sagittal suture (arrowheads); both coronal and lambdoid sutures are patent.

Bathrocephaly is another condition that can produce confusion. Bathrocephaly results in a prominent occiput that angles sharply inward toward the neck but without frontal bossing, biparietal narrowing, or sagittal ridging (Fig 5). Bathrocephaly is associated with a persistent mendosal suture, an embryonic suture that extends transversely between the 2 lambdoid sutures and, normally, is gone by birth Fig 5C.[58] Bathrocephaly does not require treatment.

Infants who have sagittal synostosis should be referred to a specialist for repair as early as possible because surgical correction is usually performed much earlier (often at 6–12 weeks of age) than for other forms of synostosis. Surgical management options include both open and endoscopic repairs; adjunctive postoperative helmet therapy is recommended for up to 1 year postoperatively, after more limited endoscopic repairs.[59,60] The importance of early recognition and referral for surgical management cannot be overemphasized because infants treated after 6 to 10 months of age increasingly require more extensive and morbid complete calvarial vault remodeling to achieve adequate correction.

TRIGONOCEPHALY (METOPIC SYNOSTOSIS)

Metopic synostosis is presently the second most common form of craniosynostosis, accounting for 19% to 28% of cases[53–55] and having a prevalence of 0.9 to 2.3 per 10 000 live births.[53,57] The prevalence of metopic synostosis may have increased over the past decades (without a corresponding increase in other synostoses) for uncertain reasons.[54] Metopic synostosis also has a distinct male preponderance of 1.8 to 2.8:1.[53,55] Metopic synostosis produces trigonocephaly with reduced growth potential perpendicular to the metopic suture, a pronounced metopic ridge, and hypotelorism; the forehead forms a keel, similar to the prow of a boat, with bilateral orbital retrusion and bitemporal narrowing (Fig 5). Reduced bifrontal and accelerated biparietal growth along the coronal

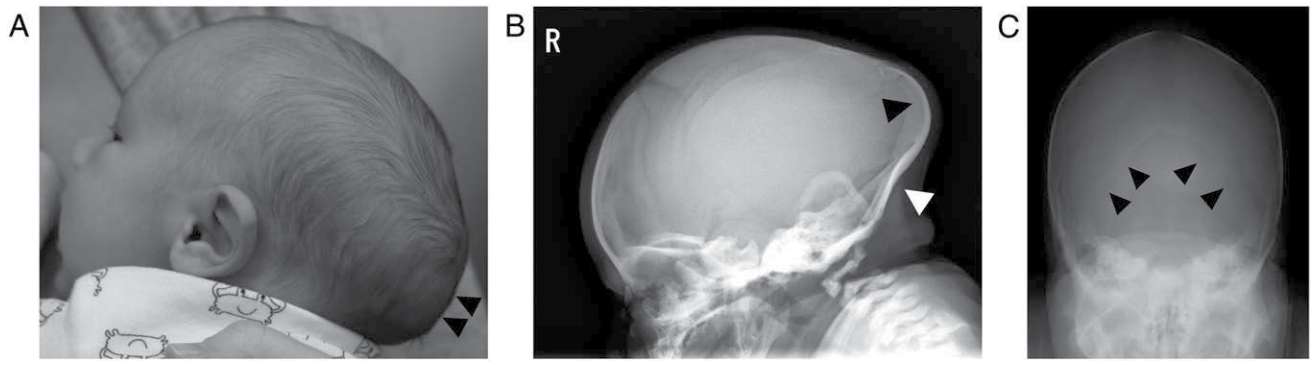

FIGURE 5
Bathrocephaly attributable to persistent mendosal suture. A, Infant with focal prominent occiput (arrowheads). Note the lack of frontal bossing. B, Lateral skull radiograph shows prominent occiput (black arrowhead) and steep angle of the posterior skull (white arrowhead). C, CT scan shows persistent mendosal suture (arrowheads).

sutures, with additional symmetrical growth along the in-line sagittal suture, results in a widened, pear-shaped calvarium behind the coronal suture (Fig 6B).

Some infants may display only a palpable (and sometimes visible) metopic ridge with little or no trigonocephaly; whether this represents a forme fruste of metopic synostosis or another distinct process is unknown. Infants with an isolated metopic ridge and minimal or no trigonocephaly do not require surgical correction.

Plain radiographs may display prominent bony fusion of the metopic suture; however, care must be taken because the metopic suture may normally begin closing as early as 3 months of age and all are closed by 9 months of age.[61] CT scans readily demonstrate the triangular-shaped anterior fossa with midline thickening of the metopic suture and hypotelorism (Fig 7).

ANTERIOR PLAGIOCEPHALY (UNICORONAL SYNOSTOSIS)

Unicoronal synostosis is the third most common form of craniosynostosis, accounting for 12% to 24%[53,55] of nonsyndromic cases and with a prevalence of 0.7 per 10 000 live births.[57] Unlike other forms of synostosis that have a male predominance, unicoronal synostosis has a female preponderance of 1.6 to 3.6:1.[53,57] Unicoronal synostosis produces anterior plagiocephaly in which growth along the ipsilateral coronal suture is reduced and results in a flattening of the ipsilateral forehead (Fig 8). Accelerated growth of the contralateral frontal bone along the perimeter (metopic) and in-line (contralateral frontal) sutures results in compensatory bossing of the contralateral forehead. Some parents and providers may focus on the contralateral compensatory bossing rather than the ipsilateral flattening on the involved side. The metopic suture is bowed toward the side of the flattening. Accelerated growth along the squamosal suture (another perimeter suture) also produces a degree of ipsilateral temporal bossing as well as posterior and inferior ear displacement. The net effect of these changes is a trapezoidal head shape with flattening of the ipsilateral calvarium (both frontally and occipitally) compared to the contralateral side (Fig 8A). This presentation stands in distinct contrast to the parallelogram head shape that accompanies most

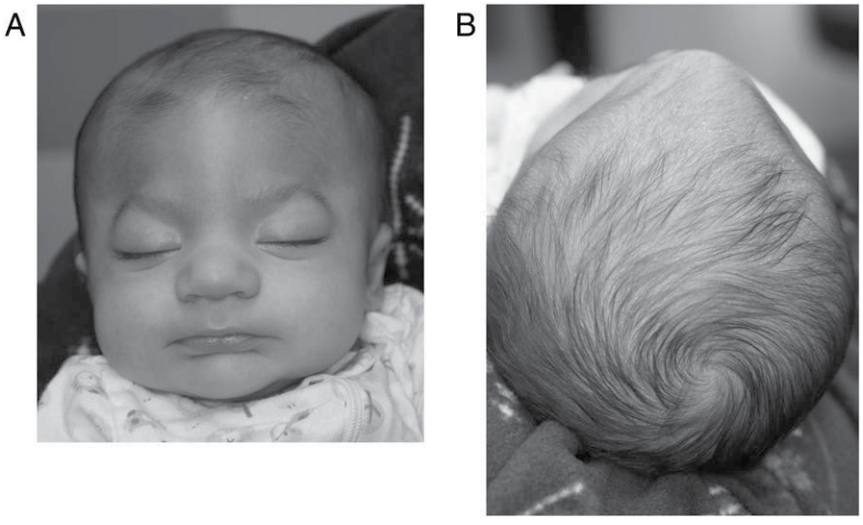

FIGURE 6
Trigonocephaly attributable to metopic synostosis. A, Frontal view of infant showing pronounced midline metopic ridge and bilateral temporal narrowing. B, Vertex view in the same infant shows triangular-shaped forehead.

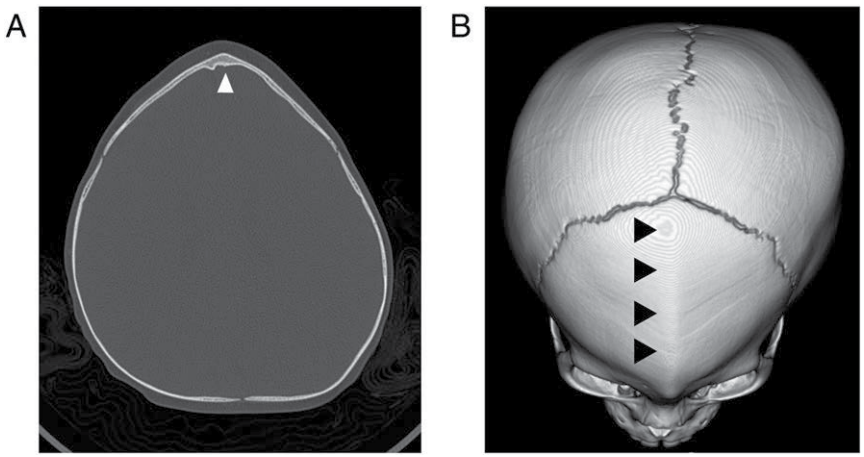

FIGURE 7
Radiologic features of trigonocephaly. A, Axial CT shows triangular-shaped forehead with fused metopic suture (arrowhead) and bitemporal narrowing. B, Three-dimensional CT scan vertex reconstructions show prominent midline metopic ridge with triangular-shaped forehead, bilateral orbital retrusion, and hypotelorism.

cases of occipital deformational plagiocephaly (DP) (see below).

Coronal synostosis additionally involves the sphenozygomatic, frontosphenoidal, and sphenoethmoidal sutures along the frontal skull base, which produces additional secondary morphologic changes involving the orbits and face. Elevation of the lateral sphenoid wing with foreshortening of the zygoma and orbit results in a characteristic elevation of the ipsilateral eyebrow, a seemingly larger palpebral fissure, and/or mild proptosis (Fig 8). The contralateral orbit may be comparatively smaller and is displaced inferiorly and laterally, sometimes leading to a vertical orbital malalignment (dystopia). Diminished growth along the ipsilateral anterior skull base deviates the nasal root toward the involved side and the nasal tip toward the contralateral side (Fig 8B), and the ipsilateral tragus is often displaced anteriorly and inferiorly. In some cases, the entire face appears to be curved with its convexity toward the involved side, leading to a "facial scoliosis" (Fig 8B).

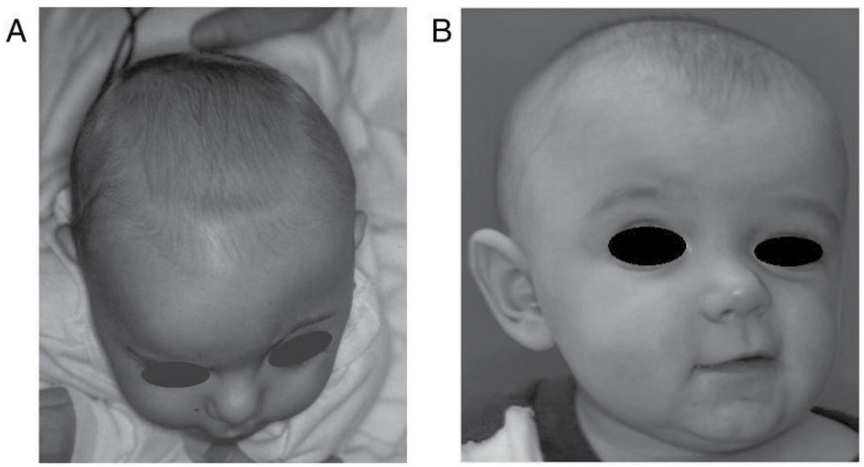

FIGURE 8
Anterior plagiocephaly attributable to unilateral coronal synostosis. A, Vertex view in a child with left coronal synostosis shows flattening of the left forehead and compensatory prominence of the right forehead, upward displacement of the left eyebrow, deviation of the nasal root toward the right and nasal tip toward the left, and trapezoidal head shape. B, Frontal view in another infant with right coronal synostosis shows elevation of the right eyebrow and misshapen orbit, deviation of the nasal root toward the right and nasal tip toward the left, and significant facial scoliosis.

Plain radiographs demonstrate poor visualization of the involved coronal suture. If visible, the ipsilateral suture is deviated anteriorly compared to the contralateral suture; one caveat is that the radiograph must be truly lateral by demonstrating that the ears and/or external ear canals are properly aligned. On the AP view, a characteristic "Harlequin" (or "Mephistophelean") orbit is visible on the involved side and is attributable to elevation of the lesser sphenoid wing (Fig 9A). The nasal bone is also askew, with its upper part deviated toward the involved side.

The findings of unicoronal synostosis are also readily apparent on CT scans. The involved coronal suture is not visible over most or all of its length, whereas the contralateral side is readily apparent on axial images. The ipsilateral flattening and contralateral bossing are also readily evident on axial images. Finally, the sphenoid wing elevation produces a distinct asymmetry to the skull base, with the ipsilateral orbital roof being visible on more superior axial images (and elevated on coronal images) compared to the contralateral orbital roof (Fig 9B). Coronal images also demonstrate the Harlequin orbit to good advantage. Three-dimensional CT reconstructions also demonstrate all of the findings.

The differential diagnosis would include occipital DP and frontosphenoidal synostosis, both discussed below. Hemifacial microsomia is another consideration, although the latter is manifest by primary underdevelopment of the

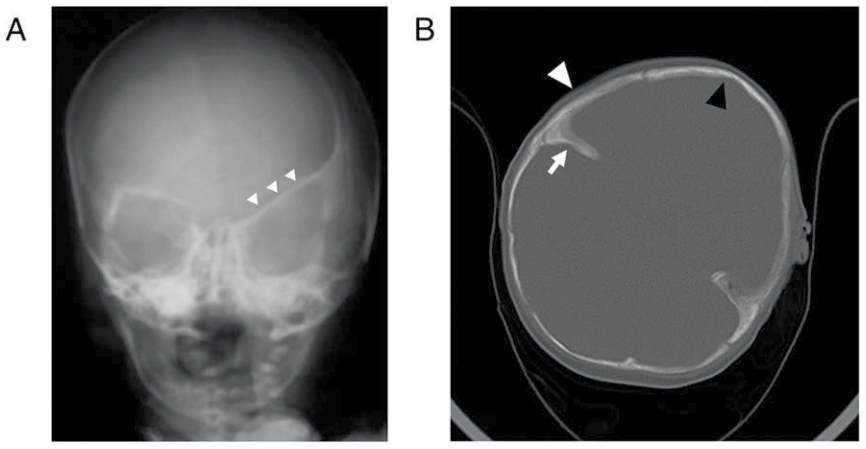

FIGURE 9
Radiologic features of unilateral coronal synostosis. A, A-P radiograph shows elevated ipsilateral sphenoid wing giving rise to the Harlequin eye deformity (arrowheads). The nasal bone is deviated superiorly toward the fused suture. B, Axial CT scan shows trapezoidal head shape with retrusion of the right forehead (white arrowhead), prominence of the left forehead (black arrowhead), and elevation of the sphenoid wing (white arrow).

midface and mandible, with relative sparing of the forehead and orbits; the ear is also malformed, and there are often preauricular skin tags.

ANTERIOR BRACHYCEPHALY (BICORONAL SYNOSTOSIS)

Bicoronal synostosis accounts for about 3% of nonsyndromic and most syndromic synostoses,[53] with a prevalence of approximately 0.5 per 10 000 live births.[57] In bicoronal synostosis, the coronal sutures are palpable on both sides, the entire forehead is flattened, the head is reduced in the anteroposterior dimension (anterior brachycephaly), and the forehead often has a towered appearance (turricephaly). The combination of frontal and maxillary foreshortening results in shallow orbits and produces significant exophthalmos; in addition, the orbits are recessed (retruded) or shallow bilaterally (Fig 10). The nasal bone is short and upturned in many cases.

On radiographs, the anterior fossa and orbits are short and both coronal sutures are radio dense or difficult to see and anteriorly deviated. Bilateral Harlequin orbit deformities are present with elevation of both sphenoid wings. Because both frontal bones are involved, the nasal bone remains midline. CT scans demonstrate brachycephaly, thickening and/or nonvisualization of both coronal sutures, a shallow anterior fossa and orbits, and bilateral sphenoid wing elevation (Fig 11). Coronal images nicely demonstrate bilateral Harlequin orbits as well.

POSTERIOR SYNOSTOTIC PLAGIOCEPHALY (LAMBDOID SYNOSTOSIS)

Lambdoid synostosis is rare; in contemporary series, lambdoid synostosis accounts for only 2% of cases and has a prevalence of 0.1 per 10 000 live births.[55,57] Older studies likely included children with DP and their prevalence rates are, therefore, higher. In one small series, male and female patients were equally represented.[55] True lambdoid synostosis is usually readily differentiated from occipital DP (see below), with which it is most commonly confused. True lambdoid synostosis is most commonly characterized by a flattening of both the ipsilateral occiput and forehead, leading to a trapezoidal or rhomboidal head shape (Fig 12). The contralateral occiput may be prominent by comparison. The lambdoid suture is prominently ridged. The ipsilateral ear is deviated posteriorly (in contrast to DP, in which it is deviated anteriorly), and the mastoid process and associated retromastoid occipital bone are unusually prominent, producing a retroauricular "bulge" (Fig 12). Bilateral involvement produces

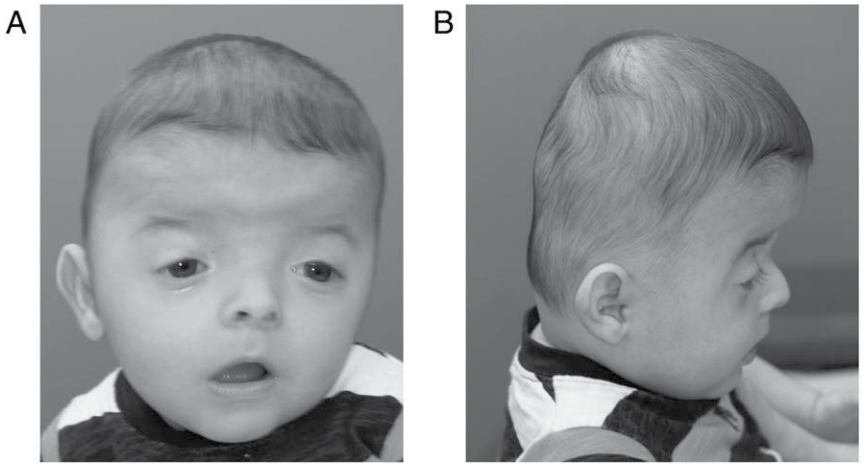

FIGURE 10
Brachycephaly attributable to bicoronal synostosis in a child with Saethre-Chotzen syndrome. A,-Frontal view shows flattened forehead, shallow orbits with bilateral orbital retrusion, a modestly upturned (beaked) nose, bilateral ptosis, and midface hypoplasia. B, Lateral view of the same infant shows flattened and tall (turricephaly) forehead, with shallow orbits and midface hypoplasia.

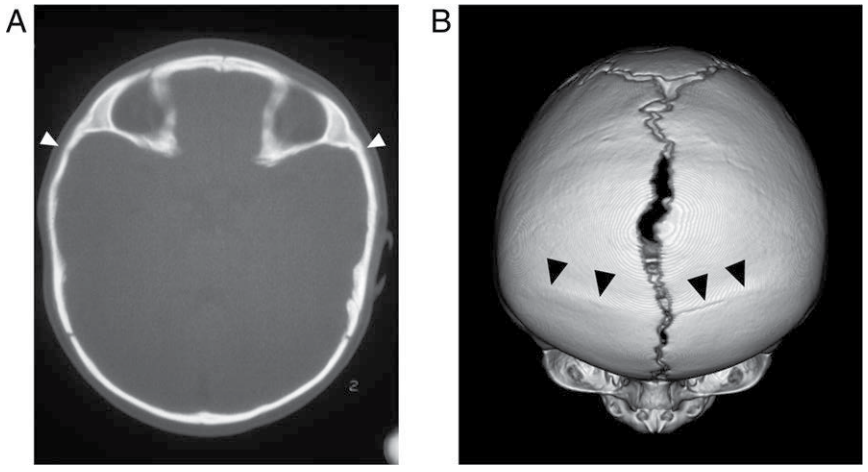

FIGURE 11
Radiologic features of bilateral coronal synostosis. A, Axial CT scan shows shallow anterior fossa and absence of both coronal sutures (arrowheads). B, Three-dimensional CT scan reconstructed vertex view shows shallow anterior fossa, bilateral superior orbital retrusion, and bilaterally fused coronal sutures (arrowheads).

a flattened occiput with ridging of both lambdoid sutures and retromastoid bulge on both sides. The posterior sagittal suture may also be involved, producing an element of scaphocephaly as well as ridging of both lambdoid and posterior sagittal sutures (the "Mercedes-Benz" sign).

Plain radiographs commonly demonstrate significant prominence and hyperostosis or nonvisualization of the involved lambdoid suture(s). CT scans also demonstrate hyperostosis or nonvisualization of the involved lambdoid suture(s). The retromastoid bulge and posterior displacement of the petrous ridge are prominent; the posterior midline and the foramen magnum at the base of the skull are also drawn toward the ipsilateral side (Fig 12C). Three-dimensional CT scans also demonstrate these findings to good advantage (Fig 12D). Treatment involves open posterior cranial vault reconstruction between 5 and 9 months of age or endoscopic repair as early as 2 to 3 months of age, followed by molding helmet treatment for up to 1 year.

FRONTOSPHENOIDAL SYNOSTOSIS

An extremely rare form of synostosis involves the frontosphenoidal suture, located at the anterior skull base and contiguous with the coronal suture and orbital roof.[62,63] Synostosis involving the frontosphenoidal suture produces plagiocephaly with ipsilateral forehead flattening that resembles unilateral coronal synostosis but differs from the latter in that the ipsilateral orbit is deviated inferiorly rather than superiorly, and the nasal root is deviated away from rather than toward the side of the synostosis (Fig 13 A and B). The coronal suture is visible on neuroimaging studies, and there is no Harlequin eye orbital deformity (Fig 13 C and D); CT demonstrates the fusion of the frontosphenoidal suture (Fig 13E). Treatment involves a fronto-orbital reconstruction.[62,63]

SYNDROMIC CRANIOFACIAL MALFORMATIONS

A number of craniosynostosis syndromes have been described phenotypically (Table 2). All of these, most commonly, include elements of bicoronal synostosis and midface hypoplasia. Ophthalmologic manifestations are also common and include shallow orbits, some degree of exorbitism, and extraocular muscle dysfunction with strabismus and resultant amblyopia and poor visual

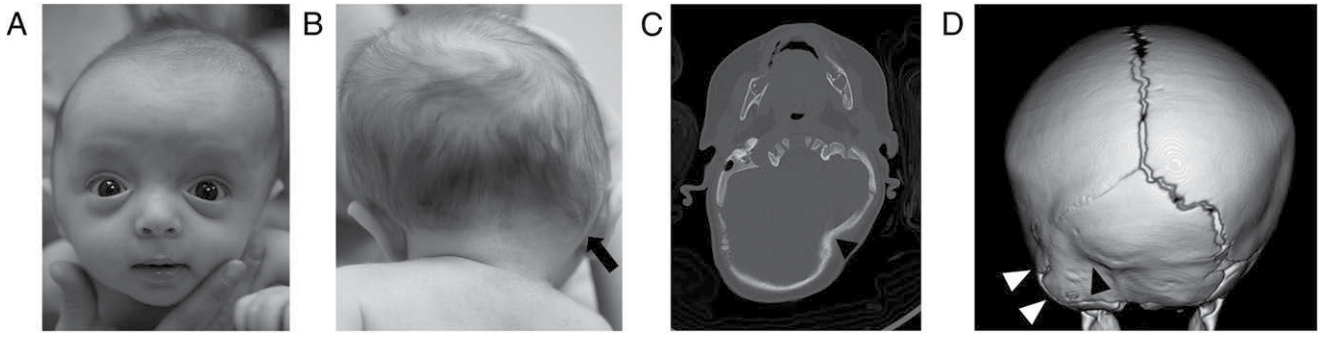

FIGURE 12
Unilateral lambdoid synostosis. A, Anterior view shows asymmetric head with calvarium deviated toward the left. Note the symmetry of orbits. B, Posterior view shows prominent curvature of the occiput toward the left with a retromastoid bulge on the right (arrow) and flattening inferior to the bulge. C, Axial CT scan shows prominent left mastoid bulge and indentation of the occipital skull (arrowhead). D, Three-dimensional CT scan posterior view shows the fused left lambdoid suture, retromastoid bulge (white arrowheads), and indentation of the occipital bone (black arrowhead).

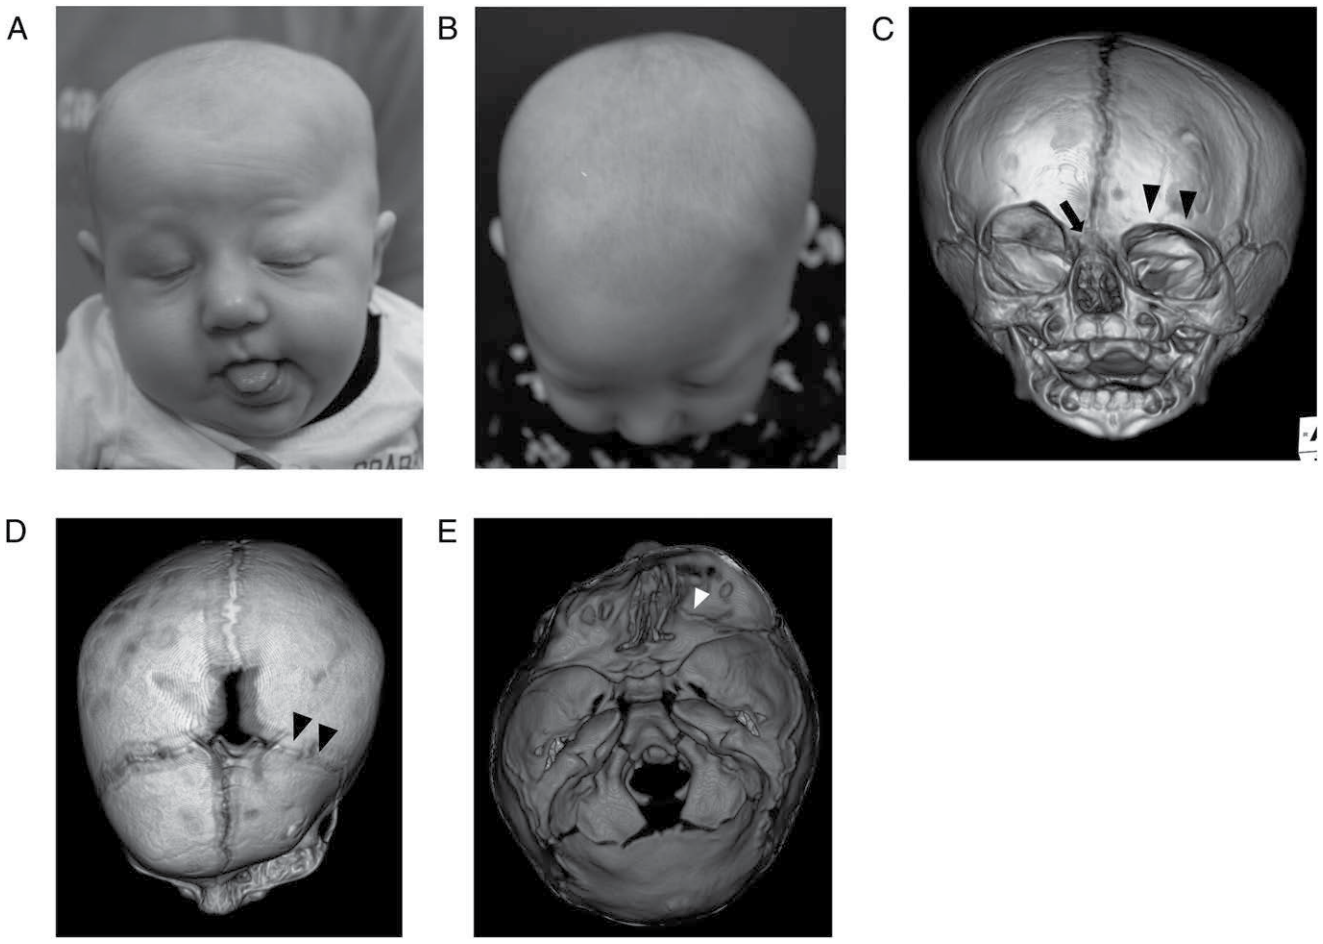

FIGURE 13
Frontosphenoidal synostosis. A, Frontal view of infant with left frontosphenoidal synostosis, with left forehead depression and retrusion and depression of left orbit. B, Vertex view demonstrating left forehead and orbital retrusion. Note in both images the deviation of the nasal root away from, and the nasal tip toward, the involved side, in contrast to coronal synostosis. C, Frontal three-dimensional reconstruction CT scan shows inferiorly displaced ipsilateral eyebrow and orbital roof (arrowheads) and deviation of the nasal root (arrow) toward the contralateral side (in contrast to unicoronal synostosis, see Fig 8). D, Vertex three-dimensional reconstruction CT scan shows left forehead flattening but open coronal suture on that side (arrowheads). E, Three-dimensional reconstruction CT scan with a view of the inside of the skull base with the calvarium digitally subtracted shows flattening of the left orbit. The right frontosphenoidal suture is patent (arrowhead), whereas the left is fused.

acuity.[64,65] More recent genetic testing has revealed significant genotypic overlap, with the same genetic mutation capable of producing distinctly different phenotypes, and a single phenotype resulting from different genetic pathogenic variants. It is beyond the scope of this report to describe all of the various syndromes in detail; brief descriptions of the more common syndromes are provided. The interested reader is referred elsewhere for more detailed information.[66,67]

TABLE 2 Genetics of Craniofacial Syndromes

Syndrome	Transmission	Identified Gene Variants
Crouzon	AD	*FGFR1, FGR2*
Apert	AD	*FGFR2*
Pfeiffer	AD	*FGFR1, FGR2*
Saethre-Chotzen	AD	*TWIST*
Carpenter	AR	*RAB23, MEGF8*
Antley-Bixler	AR and sporadic AD transmission	Uncertain (for AR) and *FGFR2* (for AD)
Muenke	AD	*FGFR3*

AD, autosomal-dominant; AR, autosomal-recessive.

Crouzon Syndrome

Crouzon syndrome is most frequently characterized by bicoronal synostosis leading to a shallow anterior fossa, a high and flat forehead (turricephaly) with reduced anteroposterior cranial measurement (brachycephaly), shallow orbits and prominent globes (exorbitism), midface hypoplasia leading to an underbite and malocclusion, and upturned (or "beaked") nose. Involvement of other sutures may

also occur, and progressive sutural fusion has been described during the first 2 years of life.[68] Craniosynostosis is a variable feature and, rarely, may be absent. Syndactyly is notably absent. Rarely, vertebral fusion, ankylosis (particularly the elbows), and acanthosis nigricans may be present. Cognitive development is often normal, and neurocognitive deficits are uncommon. Crouzon syndrome is transmitted as an autosomal-dominant condition with varying penetrance; pathogenic variants in the *FGFR1* or *FGFR2* genes are responsible for all but Crouzon with acanthosis nigricans, which is caused by pathogenic variants in the *FGFR3* gene.

Apert Syndrome

The craniosynostosis pattern in Apert syndrome is similar to that in Crouzon syndrome, although progressive fusion of additional sutures during the first 2 years occurs more commonly in Apert syndrome. Like in Crouzon syndrome, turricephaly, brachycephaly, exorbitism, beaked nose, and malocclusion are cardinal clinical manifestations in Apert syndrome. Down-slanting palpebral fissures are typical. Palatal abnormalities may be present and include narrowing, bifid uvula, and cleft palate,[69] and vertebral fusion abnormalities (most commonly involving C5-C6) may be present.[70] Structural brain abnormalities may be present, including agenesis of the corpus callosum, gyral malformations, absent or defective septum pellucidum, megalencephaly, and static or progressive ventriculomegaly. Unlike Crouzon syndrome, neurocognitive deficits are more common, with more than one-half having subnormal IQ scores. The most striking extracranial abnormality in Apert syndrome is osseous and/or soft tissue syndactyly involving fingers and/or toes, particularly the second, third, and fourth digits (Fig 14). The digits are short, and broad distal phalanges may also be present. Apert syndrome is transmitted as an autosomal-dominant condition; a mutation in the *FGFR2* gene is responsible.

FIGURE 14
Syndactyly involving the toes in an infant with Apert syndrome.

Pfeiffer Syndrome

Pfeiffer syndrome is characterized by bicoronal synostosis, and the midface is narrow but not generally retruded; there is, therefore, less significant exorbitism and malocclusion. Like Crouzon and Apert syndromes, cranial sutures in Pfeiffer syndrome may progressively fuse over time. The nose is generally small with a low nasal bridge. Partial syndactyly of the second and third fingers and/or toes are cardinal features of Pfeiffer syndrome, and the distal phalanges of the thumb and great toe are often wide. Pfeiffer syndrome is transmitted as an autosomal-dominant condition with variable penetrance; a mutation in the *FGFR2* gene is responsible.

Cohen has described 3 types of Pfeiffer syndrome.[71] Type I is characterized by typical coronal synostosis, midface hypoplasia, and digital malformations with normal neurocognitive development. Types II and III are associated with much more severe involvement, usually involving all of the sutures (and, in type II, producing a cloverleaf skull), with shallow orbits and severe exorbitism sufficient to produce corneal exposure, airway obstruction, partial syndactyly and elbow ankylosis, various visceral abnormalities, and moderate to severe neurocognitive impairment.

Saethre-Chotzen Syndrome

Saethre-Chotzen syndrome is characterized by bicoronal synostosis (with occasional involvement of other sutures) leading to turricephaly and brachycephaly with biparietal foramina but less severe midface hypoplasia and modest exorbitism. Differentiating manifestations include ptosis of the eyelids (Fig 10A), a low anterior hairline, and a prominent nose. Lacrimal duct abnormalities and a characteristic prominent ear crus may be present. Extracranial abnormalities can include partial soft tissue syndactyly, most commonly involving the second and third fingers and third and fourth toes; the digits are often short and the great toes may be broad. Saethre-Chotzen syndrome is transmitted as an autosomal-dominant condition; a mutation in the *TWIST* gene is responsible.

Carpenter Syndrome

Carpenter syndrome is characterized by synostosis most commonly involving both coronal sutures and variably others as well, with shallow supraorbital ridges and flat nasal bridge, midface, and/or mandibular hypoplasia, low-set and malformed ears and a high arched palate. A number of digital malformations may occur including brachydactyly, clinodactyly, and camptodactyly (medial deviation and flexion deformity of the distal phalanges, respectively) and polydactyly involving the toes. Cardiac malformations occur in one-half of affected individuals and include septal defects, tetralogy of Fallot,

transposition of the great vessels, and persistent ductus arteriosus. Carpenter syndrome is transmitted as an autosomal-recessive condition; pathogenic variants in the *RAB23* or *MEGF8* genes are responsible.

Antley-Bixler Syndrome

Antley-Bixler syndrome is characterized by bicoronal synostosis (in 70%) with turricephaly but with frontal bossing, midface hypoplasia with exorbitism, and a flat and depressed nasal bridge. Low-set and dysplastic ears are a consistent feature, and choanal atresia or stenosis is present in 80%. Limited limb mobility and a diminished range of motion involving virtually all joints, phalangeal abnormalities (including long fingers with tapering fingernails), radiohumeral synostosis, and femoral bowing are common features as well. Impaired steroidogenesis and genital abnormalities are associated features. Antley-Bixler syndrome is most commonly related to pathogenic variants in the *POR* gene (with impaired steroidogenesis) and autosomal-recessive transmission and pathogenic variants of the *FGFR2* gene (without impaired steroidogenesis), with autosomal-dominant transmission.

Muenke Syndrome

Muenke syndrome is characterized by fusion of one or both coronal sutures with a broad and shallow supraorbital ridge and prominent forehead (bossing). Hypertelorism and flattened maxillae are variable features. Hearing loss is present in approximately one-third of patients, and macrocephaly is present in approximately 5%.[72] Muenke syndrome is transmitted as an autosomal-dominant condition and is unusual among the syndromic synostoses in that it involves a mutation in the *FGFR3* gene.

SURGICAL MANAGEMENT OF CRANIOSYNOSTOSIS

The evaluation and management of craniosynostosis are beyond the scope of this review, but a few general comments are helpful. Imaging of suspected craniosynostosis most commonly includes either plain skull radiographs or CT scans. In general, plain skull radiographs are of limited value if craniosynostosis is strongly suspected because CT scans will likely be performed by the craniofacial team as part of surgical planning. On the other hand, obtaining a CT scan in children with low suspicion for craniosynostosis is often unnecessary. Cranial ultrasonography is used by some, and studies suggest that it is as effective as plain radiographs or CT scans in identifying a fused suture.[73] However, not all radiologists are equally experienced at identifying fused sutures on ultrasonography, so it is recommended that the provider check with the radiologist first before obtaining this study. Many craniofacial teams prefer that providers refer these children early and postpone imaging until after the child is seen by specialists. For children with occipital DP, the diagnosis is usually obvious by clinical inspection, the absence of significant deformity at birth, and the absence of a retroauricular bulge; questionable cases might require neuroimaging, but these are rare.

The timing of surgery (and, by extension, referral) is another important consideration. Traditional repairs of coronal, metopic, and frontosphenoidal synostosis are generally delayed until 6 to 10 months of age. However, the child with symptomatic increased ICP may require earlier repair. Moreover, sagittal synostosis repairs and endoscopic approaches are performed much earlier, some as early as 8 weeks of age. Delays in referral often lead to more extensive surgical repairs; early referral is, therefore, preferable, even in questionable cases of craniosynostosis.

There are many accepted surgical options for craniosynostosis that are influenced by which suture(s) are involved, the clinical indication, the experience and expertise of the craniofacial surgical team, and, most importantly, the timing of the operation. It is not the intent of this review to recommend any particular operative technique because they all have their merits.

Surgical techniques may include endoscopic suturectomy with helmet therapy, spring-assisted cranioplasty, and subtotal and complete calvarial vault remodeling. Advantages of endoscopic suturectomy include smaller incisions and less operative time and blood loss, but correction should be performed early (during the first few months of life) and followed by up to 12 months of postoperative molding helmet therapy (23 hours a day) to achieve correction comparable to open techniques. Spring-assisted cranioplasty is another surgical adjunct that can be used, in which spring-loaded devices are inserted temporarily to help distract the freed bones.

The advantages of open operative correction include more immediate and complete correction, without the need for extended molding helmet therapy. Disadvantages include a larger incision, longer operative times, greater intraoperative blood loss, and, for coronal and metopic synostosis, the need to remodel the superior orbital rim (which generally requires that the surgery be performed after the infant has reached 6 months of age so the orbital rim is thick enough to hold the surgical screws). A variety of open techniques exist, but surgical timing is important. Open sagittal synostosis repairs are performed much earlier (ideally between 2 and 6 months of

age) than are metopic or coronal synostosis. Sagittal synostosis repair includes a midline or paramedian (so-called π) craniectomy coupled with a variable degree of posterior (parietal and occipital) vault reconstruction with barrel stave osteotomies. Later surgery (generally beyond 6–8 months of age) may require a more extensive total calvarial vault remodeling. Lambdoid suture repair is also, generally, performed early. In contrast, for open coronal or metopic synostosis, in which both cranial and orbital reconstruction are performed, later surgical correction, usually between 6 and 10 months, is preferred so that the orbital rim is thick enough to hold the surgical constructs used to advance and remodel the bone. All open surgical approaches involve a full release of the fused suture and immediate surgical remodeling of the skull; postoperative helmeting is not routinely used after open repair.

The surgical management of midface hypoplasia deserves special mention because it is a frequent component of syndromic synostosis. Severe midface hypoplasia can lead to airway obstruction that requires an immediate intervention, such as a tracheostomy to secure the airway. Definitive midface correction is usually performed when the child is older (6–8 years or more) and is usually accomplished by using distraction osteogenesis, in which the midface is surgically separated from the skull base and distraction plates are applied to the maxillary bones. By using distraction screws that are turned by the patient or family on a daily basis, the midface is slowly advanced forward, and bone grows in the intervening gap, much like an Ilizarov procedure accomplishes for long bones.

OCCIPITAL (DEFORMATIONAL) PLAGIOCEPHALY AND BRACHYCEPHALY

The most common head shape abnormality is deformational (also called positional or nonsynostotic) plagiocephaly (DP) or brachycephaly (DB). The incidence of DP/DB has been estimated at 20% to 50% in 6-month-old children.[74] It is more common (approximately 60% of cases) in male children.[75] DP/DB in 80% of cases presents as an acquired postnatal condition that is most commonly noted during the first 4 to 12 postnatal weeks, although 20% of cases appear to be noted at birth, likely attributable to intrauterine forces (relative fetal restraint, such as primiparity, oligohydramnios, multiple gestation, or bicornuate uterus).[75] Eighty percent of cases are right sided, and the flattening corresponds to the side to which the infant naturally turns the head; this correlates well with observations made by Volpe[76] that normal supine infants look toward the right 80% of the time, toward the left 20%, and almost never look straight up. In addition, 15% to 20% of infants with DP/DB have some degree of neck muscle imbalance or torticollis.[75] It is now apparent that DP/DB is not synostotic but rather is caused by persistent pressure on the skull in the supine infant. The incidence increased significantly after the 1992 "Back to Sleep" campaign, which recommended supine sleep (although the decreased rate of sudden unexpected death in infancy certainly supports the continued endorsement of this strategy).[74]

It is important to differentiate DP/DB from true coronal or lambdoid craniosynostosis. The majority of cases can be readily identified by the history (as described above) and clinical examination. The infant is examined from the front, back, and, most importantly, top of the head. DP/DB is characterized by occipital flattening: unilaterally in DP (Fig 15) and bilaterally in DB. The ipsilateral ear is deviated anteriorly with respect to the contralateral side (which can be most readily identified by placing a finger in each ear and looking down from above the infant's head); the pinna may be rotated outward as well. Finally, there is often some anterior displacement of the ipsilateral forehead. The resulting deformation results in a parallelogram head shape (Fig 15A) in which the entire ipsilateral head appears to have been displaced anteriorly. In contrast, the child with unilateral coronal or lambdoid synostosis will have a trapezoidal-shaped head with ipsilateral flattening of both frontal and occipital calvarium and posterior and inferior deviation of the ipsilateral ear, as discussed above. Patients with DP may have an element of facial scoliosis (Fig 15B). Although the ipsilateral orbit in DP may be slightly misshapen, the Harlequin orbit deformity observed in unicoronal synostosis is not present. Similarly, the bulging retromastoid area in lambdoid synostosis is absent in DP and DB. In DB, the occiput is flattened bilaterally, and the head is, therefore, brachycephalic and widened in the transverse dimension, leading to a round face. However, the absence of turricephaly, orbital retrusion, Harlequin orbit, and exophthalmos differentiate DB from bicoronal synostosis.

Other abnormalities observed in some cases with DP include an element of facial scoliosis. Some have elevation and shortening of the mandible with a "hollow" space in the submandibular region, superficially resembling hemifacial microsomia. This variant seems to be more common among those whose DP is present at birth and/or those with torticollis; it is suggested that perhaps the shoulder may lie within this hollow and restrict neck rotation in utero. Another less common variant of DP is what is referred to as the "Gumby" head shape in which, when viewed from the front, the ipsilateral calvarium is flattened and the vertex slopes upward toward the opposite side (Fig 15B).

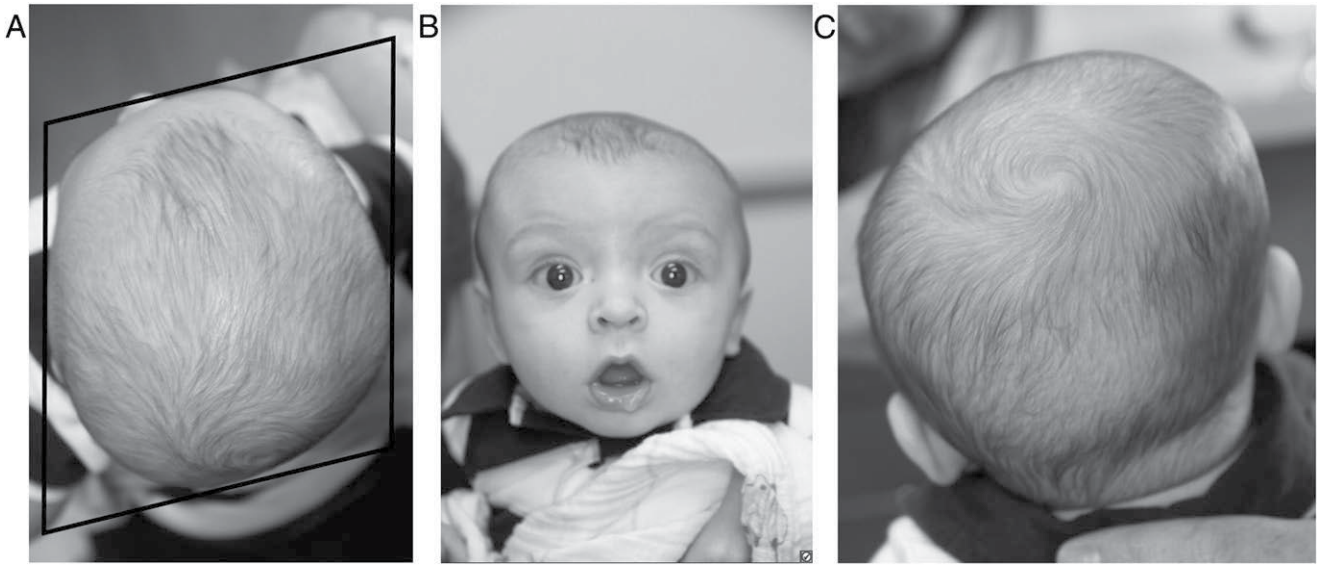

FIGURE 15
Occipital deformational flattening (plagiocephaly and brachycephaly). A, Vertex view of DP shows parallelogram-shaped head with ipsilateral flattening, anterior deviation of the ipsilateral ear, and mildly prominent ipsilateral frontal bossing. B, Frontal view shows the calvarium deviated toward the right but no elevated eyebrow and/or orbit or deviation of the nasal root or tip. Note the upward slanting cranial vault from patient's left to right ("Gumby" deformity). C, Posterior view of DP shows flattened right occiput with parietal boss.

A number of centers quantify the severity of DP and DB, both for the initial assessment and at subsequent follow-up visits, by measuring certain anthropometric indices with cranial calipers. The severity of DP is described by using the cranial vault asymmetry index (CVAI), which describes the difference between the longest and shortest head axes along the diagonal when viewed from above (Fig 16). In general, a CVAI of >3.5 is consistent with DP.[74] The severity of DB is described by using the cranial index (CI), which measures the ratio of head width to head length when viewed from above. A CI of $\geq 85\%$ is consistent with brachycephaly.[77]

The differential diagnosis of DP includes unilateral coronal and unilateral lambdoid craniosynostosis, both described above. In most cases, the diagnosis of DP or DB is readily apparent on clinical examination, and adjunctive imaging such as plain radiographis or CT scans is unnecessary and would expose the child to ionizing radiation. The use of imaging should be reserved for equivocal cases. Plain radiographs are usually difficult to interpret, except in cases of DB in which the occipital flattening is evident on lateral films. Partial nonvisualization or focal areas of calcification adjacent to the lambdoid suture may be identified on plain radiographs and CT scans but should not be interpreted as lambdoid synostosis. Axial CT scans readily differentiate DP and DB from coronal synostosis, demonstrating the parallelogram head shape, open coronal sutures, and normally formed anterior skull base with normal sphenoid wing and absent Harlequin orbit.

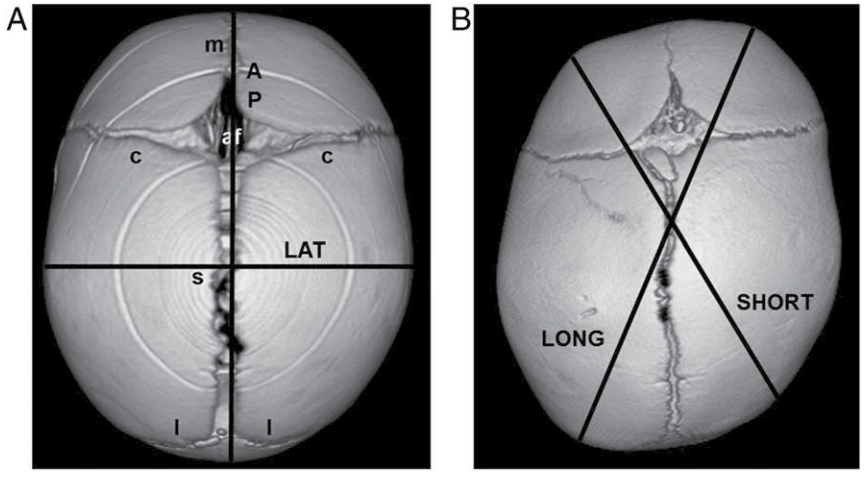

FIGURE 16
Diagram showing the calculation of the (A) CVAI and (B) CI. See text for definitions.

It is not our intent with this report to discuss treatment options for DP and DB. However, the parents of infants with DP or DB should be reassured that since the infant does not have

craniosynostosis, surgery is not indicated; they should be counseled that DP and DB are solely aesthetic conditions, with no credible medical evidence suggesting that DP and DB affect brain development or cause any other medical condition. The head shape often improves as the child gains developmental milestones and lies less frequently on the flattened side.[74] Supervised "tummy time" as well as varying head positions while holding the child can help; alternating head positions for sleep can be attempted, but, to reduce the incidence of sudden unexplained death in infancy, it should be emphasized that the infant should sleep alone, on his or her back, and in a crib (the ABCs of safe sleep). A recent study noted a correlation (not necessarily causal) between DP and poorer cognitive outcomes[78]; children with DP should, therefore, be monitored for possible developmental delays. The child with muscular neck imbalance or torticollis may be referred to physical therapy to teach the parents stretching and muscle strengthening exercises to reduce the tension of the sternocleidomastoid muscle and improve the strength of contralateral muscles. Use of a molding helmet may be considered for the infant with a moderate or severe deformity but is not required; a detailed evidence-based review of DP and DB treatment options can be found in a recent publication by the Congress of Neurological Surgeons and is endorsed by the American Academy of Pediatrics.[79–84]

EARLY FONTANELLE CLOSURE AND MICROCEPHALY

Two other common referrals to craniofacial clinics are concerns about early closure of the anterior fontanelle and microcephaly. Although the anterior fontanelle most commonly closes at approximately 12 months of age, there is a wide variation in the timing of fontanelle closure, with the fontanelle closing between 4 and 26 months.[85] Moreover, it is important to note that closure of the fontanelle does not mean that the sutures are closed, nor does it mean that further calvarial growth is not possible. Rather, closure of the fontanelle simply reflects the apposition of the 2 frontal and 2 parietal bones in such a manner that a gap cannot be palpated, although sutures are still present. In fact, even after normal fontanelle closure, significant head growth continues throughout childhood. As long as appropriate head growth is occurring along the normal head growth curve and the head shape is normal, there should not be concern for craniosynostosis. However, other medical conditions can be associated with premature fontanelle closure, including hyperthyroidism, hyperparathyroidism, hypophosphatasia, and rickets.

Microcephaly is defined as a head circumference below the fifth percentile for age. There are numerous causes for microcephaly, some of which are listed in Table 3. Primary microcephaly may be genetic; multiple pathogenic variants with both autosomal-dominant and recessive inheritance patterns have been described. Other conditions are usually identified by history, physical examination, and/or neuroimaging. Important considerations include a family history of microcephaly, the presence or absence of developmental delays or cognitive impairment, and a past history of pre- or postnatal brain injury. Infants with normal developmental milestones, no past history of brain injury, and a normal head shape most often have constitutional microcephaly. Single-suture craniosynostosis virtually never causes significant microcephaly, although multisutural synostosis can. Craniosynostosis is rarely a cause of microcephaly in infants whose head circumferences, although low, are running parallel to the normal curve and who have both a normal head shape and no family history of craniosynostosis.[86]

TABLE 3 Conditions Causing Microcephaly

Primary microcephaly
Chromosomal disorders
Anencephaly
Encephalocele
Holoprosencephaly
Agenesis of the corpus callosum
Neuronal migration disorders
Microcephaly vera
Secondary microcephaly
Intrauterine infections
Intrauterine toxins
Intrauterine vascular insufficiency
Hypoxic-ischemic brain injury
Intracranial hemorrhage
Neonatal infections (meningitis and encephalitis)
Neonatal stroke
Chronic cardiopulmonary or renal disease
Malnutrition
Craniosynostosis

CONCLUSIONS

Single-suture craniosynostosis produces consistent head shape abnormalities that should be readily identifiable by the pediatric health care provider. Sagittal synostosis produces an elongated head (scaphocephaly), and metopic synostosis produces a triangular-shaped forehead (sometimes with hypotelorism). Unilateral coronal and lambdoid synostosis as well as occipital DP all produce an asymmetric head shape (plagiocephaly) but are readily differentiated by the shape of the head (parallelogram versus trapezoid or rhombus), the position of the ears (anterior or posterior), and secondary features such as nasal deviation, orbital asymmetry, or bulging of the retromastoid region. Bilateral coronal and lambdoid synostosis produce a short head (brachycephaly) and are differentiated by the presence or absence of associated midface hypoplasia or bilateral retromastoid bulging.

DP and DB are the most common head shape abnormalities encountered by primary care physicians; they are readily identified by conducting a history and clinical examination and do not usually require adjunctive imaging. Early detection and positional changes (with physical therapy for those with torticollis) suffice for most infants; referral at 5 to 6 months of age is considered for helmet therapy for those who have moderate or severe deformities that have not responded to treatment.[87]

Because both single-suture craniosynostosis and DP/DB can usually be diagnosed on clinical examination, routine imaging for the initial evaluation of infant head shape is not recommended to avoid exposing the child to unnecessary radiation. Instead, timely referral of infants with craniosynostosis and those with moderate or severe DP/DB to an experienced craniofacial team (including both a pediatric neurosurgeon and craniofacial surgeon) will allow sufficient time for the team to help the family cope with the diagnosis, obtain any necessary imaging for surgical planning, discuss treatment options, and plan a timely correction.

Anticipatory guidance for parents of children with craniosynostosis should include monitoring for symptoms of elevated ICP or developmental delays, especially for those with multisutural synostosis, and a discussion about the importance of early and timely referral to specialists. Parents of children with DP or DB should be encouraged to initiate positional changes early and, for those with torticollis, should be taught neck stretching exercises and/or referred to a physical therapist. For those with moderate or severe deformities, consider a referral to craniofacial specialists to discuss molding helmets.

KEY POINTS

Children with craniosynostosis most commonly present with stereotypically shaped heads, each associated with particular sutural fusions:

long (scaphocephaly: sagittal);

short (brachycephaly: bicoronal or bilambdoid);

anteriorly pointed (trigonocephaly: metopic); and

asymmetric (plagiocephaly: unilateral coronal or lambdoid).

DP and DB are the most common head shape abnormalities, recognized by their parallelogram-shaped head, lack of retroauricular bulge, and, in 80%, absence of deformation at birth.

Syndromic craniosynostosis most commonly manifests with bicoronal synostosis, midface hypoplasia, and shallow orbits with exorbitism and strabismus.

Surgery is often performed within the first 8 to 10 weeks for sagittal synostosis repairs, endoscopic procedures, and raised ICP. Orbitofrontal advancements for coronal and metopic synostosis are most often performed between 6 and 10 months.

Early referrals to craniofacial teams are encouraged to allow early identification and repair.

Long-Acting Reversible Contraception: Specific Issues for Adolescents

- *Clinical Report*

CLINICAL REPORT Guidance for the Clinician in Rendering Pediatric Care

American Academy of Pediatrics

DEDICATED TO THE HEALTH OF ALL CHILDREN®

Long-Acting Reversible Contraception: Specific Issues for Adolescents

Seema Menon, MD, COMMITTEE ON ADOLESCENCE

Long-acting reversible contraceptives are the most effective methods to prevent pregnancy and also offer noncontraceptive benefits such as reducing menstrual blood flow and dysmenorrhea. The safety and efficacy of long-acting reversible contraception are well established for adolescents, but the rate of use remains low for this population. The pediatrician can play a key role in increasing access to long-acting reversible contraception for adolescents by providing accurate patient-centered contraception counseling and by understanding and addressing the barriers to use.

INTRODUCTION

The safety, efficacy, and long-term cost-benefit factors of long-acting reversible contraception (LARC) use in the adolescent population have been well established.[1–4] The noncontraceptive benefits, especially treatment of heavy uterine bleeding and dysmenorrhea, are also well accepted.[5–7] Available LARC methods include 1 progestin subdermal implant and 5 intrauterine devices (IUDs) and are all appropriate for use in the adolescent population.[4] The progestin subdermal implant works by suppressing ovulation, whereas the copper intrauterine device (Cu-IUD) and the progestin-releasing levonorgestrel intrauterine devices (LNG-IUDs) prevent fertilization.[2] LARC methods are the most effective forms of contraception, with less than 1% of users becoming pregnant during the first year of use.[3] The availability of effective contraception has been associated with declines in unplanned pregnancy, yet rates of LARC use among sexually active adolescents remain low at 2% to 3%.[8–10] Limitations in patient knowledge, availability of trained providers, and concerns over cost and confidentiality have been recognized as barriers contributing to the relatively low rate of use.[11–18] The American Academy of Pediatrics (AAP) previously published a policy statement and technical report on contraception for adolescents summarizing the full range of available methods.[1] This clinical report serves to improve the pediatrician's comfort level when providing LARC services and highlights specific adolescent populations that may especially benefit from the

noncontraceptive medical therapy provided by LARC methods.

LARC AWARENESS AND ACCEPTABILITY

A wealth of easily accessible online resources including evidence-based guidelines from the Centers for Disease Control and Prevention (CDC), US Medical Eligibility Criteria for Contraceptive Use (US MEC), and statements from the AAP, American College of Obstetricians and Gynecologists (ACOG), and Society for Adolescent Health and Medicine, all endorse the safety of LARC methods in the adolescent population.[1,3,4,19] This information has not effectively reached the adolescent population, with only 20% to 50% of this age group able to recognize LARCs as birth control methods.[12–15] Among adolescents aware of LARC methods, unsubstantiated safety concerns related to permanent loss of fertility, misconceptions about the insertion process, and general fears of pain and of having a foreign object in the body contribute heavily to the low use of these methods.[11,12,14,15] Counseling from a health care provider has been found to effectively improve knowledge in the adolescent population and can significantly impact LARC use.[13,15,17] Many pediatricians working with adolescents approach contraceptive counseling with the predetermination that this population is neither interested in LARC nor will they tolerate the irregular bleeding pattern that can be associated with these methods.[13,18] Data have suggested otherwise, as results from the 2011 Contraceptive CHOICE Project reported that 70% of the adolescents surveyed chose LARC when cost was removed as a barrier and accurate counseling was provided.[20] In this study, the authors also found continuation rates of LARC to be higher than those of other contraceptive methods at 12 and 24 months of use among adolescents and young adults, suggesting relatively high acceptability.[20–22]

LARC SAFETY

The US MEC provides an evidence-based summary assigning a level of safety to each contraceptive method when used in women with various medical conditions (Table 1). The CDC classifies the contraceptive subdermal implant as category 1 regardless of age group or parity status.[4] Although safe, IUD use in younger and nulliparous women still requires more caution (category 2) than does use in their adult counterparts (category 1) because of concerns related to higher expulsion risk and sexually transmitted infection (STI) rates.[4] Newer, well-conducted studies have refuted previous concerns associating IUD use and infertility.[4] A few absolute contraindications to LARC use have been defined but are uncommonly encountered in the adolescent population (Table 2). All LARC methods may be safely used at any point in the postpartum period, although IUD expulsion rates vary depending on the timing of placement relative to delivery.[2,4,23] Observational studies suggest that LARC does not interfere with lactation, although long-term data used to evaluate the effects on lactation are limited.[2,23] Given the dearth of evidence, ACOG recommends patients be counseled that hormonal LARC products may theoretically affect breastfeeding, acknowledging there is a lack of supporting data.[2] The Cu-IUD, LNG-IUD, and subdermal implant are all safe for immediate placement in a woman who is breastfeeding, with the Cu-IUD classified as a US MEC category 1 and the latter 2 classified as US MEC category 2.[4,23] There are free resources and tools available online from the CDC and other professional societies to assist in counseling adolescents on the safety of LARC use (Table 3).[24]

Adolescents with chronic medical conditions have a particular need for in-depth contraception counseling. The importance of providing safe and effective contraception to those with medical comorbidities associated with higher morbidity and mortality rates during pregnancy cannot be overstated. In a 2010 survey of 536 women with congenital heart disease, researchers found that 20% of participants were using a contraindicated contraceptive method and 28% of participants were not using any form of contraception despite stating pregnancy was not desired.[25] Although data used to guide contraceptive options are limited for adolescents with significant congenital heart defects, the safety of LARC use has been established in those with cardiomyopathy as well as for those at increased risk for a venous thromboembolic event (either from a known thrombophilia or underlying medical condition).[4] In a study of 30 adolescents with significant cardiovascular dysfunction, the authors found no complications related to LARC use.[26] Drug interactions are also an important

TABLE 1 Medical Eligibility Criteria

Category	Description
1	A condition for which there is no restriction for the use of the contraceptive method
2	A condition for which the advantages of using the method generally outweigh the theoretical or proven risks
3	A condition for which the theoretical or proven risk usually outweighs the advantages of using the method
4	A condition that represents an unacceptable health risk if the contraceptive method is used

Adapted from Curtis KM, Tepper NK, Jatlaoui TC, et al. U.S. medical eligibility criteria for contraceptive use, 2016. *MMWR Recomm Rep.* 2016;65(3):3.

TABLE 2 Conditions Presenting an Absolute Contraindication to LARC Use

	LNG-IUD	Cu-IUD	Subdermal Implant
Distorted uterine cavity	Placement and continuation contraindicated	Placement and continuation contraindicated	Not contraindicated
Current breast cancer	Placement and continuation contraindicated	Not contraindicated	Placement and continuation contraindicated
Untreated cervix cancer	Placement only contraindicated	Placement only contraindicated	Not contraindicated
Endometrial cancer	Placement only contraindicated	Placement only contraindicated	Not contraindicated
Malignant gestational trophoblastic neoplasia with intrauterine disease	Placement only contraindicated	Placement only contraindicated	Not contraindicated
Unexplained vaginal bleeding before evaluation	Placement only contraindicated	Placement only contraindicated	Not contraindicated
Active pelvic infection (pelvic inflammatory disease, current purulent cervicitis, pelvic tuberculosis, or active gonorrhea and/or *Chlamydia* infection)	Placement only contraindicated	Placement only contraindicated	Not contraindicated
Immediate postseptic abortion, puerperal sepsis	Placement and continuation contraindicated	Placement and continuation contraindicated	Not contraindicated

Adapted from Curtis KM, Tepper NK, Jatlaoui TC, et al. U.S. medical eligibility criteria for contraceptive use, 2016. *MMWR Recomm Rep.* 2016;65(3):5

consideration when providing contraception counseling to adolescents with complex medical conditions. Again, the US MEC provides guidance with virtually no significant drug interaction concerns associated with IUD use.[4]

Safety concerns related to the relationship between the relatively high prevalence of STIs, IUD use, and upper genital tract infection (pelvic inflammatory disease) have historically limited use of this method in adolescents. With new data reflected in the CDC recommendations, researchers have found that the IUD is not significantly associated with upper genital tract infection.[4] Therefore, screening tests for STIs are not required before placement of an IUD in a woman without risk factors.[4,27] Testing for STIs can be performed at the time of placement for adolescents requiring screening.[4] Delaying IUD placement is only recommended if purulent cervicitis is noted on examination or if a known gonorrhea or *Chlamydia* infection has not been treated (US MEC category 4).[4] If an STI is diagnosed after placement, the IUD may be left in place while initiating antibiotic treatment.[4]

The relationship between LARC and condom use has also generated interest. Using data from the Youth Risk Behavior Surveillance System, researchers found that condom use was significantly lower in adolescents using a LARC method (16.4%) compared with those using combination oral contraceptive pills (37.3%).[28] Theories as to why condom use may differ when using LARC include adolescents feeling more secure about the efficacy of these methods and pediatricians not routinely recommending condom use to adolescents using LARC.[28] Condom use is a complex behavior that changes over time in a relationship. The use of a particular contraceptive method is only one factor that may influence current condom use. Regardless of the reason, it is important to note the trend of reduced condom use among LARC users when providing contraception counseling to adolescents.

TIMING OF LARC PLACEMENT

Offering same-day LARC placement to adolescents has been shown to increase the use of these contraceptives.[2,29] Despite this benefit, it is common practice to have multiple unnecessary visits for counseling and testing before LARC placement.[29–31] The 2 major considerations determining if LARC placement can be performed safely are pregnancy and infection. As mentioned previously, delaying IUD placement is recommended if there is an active, untreated infection.[4] It is also recommended that LARC placement be delayed if pregnancy cannot be excluded with reasonable certainty (Table 4).[4] Urine pregnancy tests have been shown to detect

TABLE 4 How To Be Reasonably Certain That a Woman Is Not Pregnant

A Health Care Provider Can Be Reasonably Certain That a Woman Is Not Pregnant If She Has No Symptoms or Signs of Pregnancy and Meets Any 1 of the Following Criteria
Is ≤7 d after the start of normal menses
Has not had sexual intercourse since the start of the last normal menses
Has been correctly and consistently using a reliable method of contraception
Is ≤7 d after spontaneous or induced abortion
Is within 4 wk postpartum
Is fully or nearly fully breastfeeding (exclusively breastfeeding or the vast majority [≥85%] of feeds are breastfeeds), amenorrheic, and <6 mo postpartum

Centers for Disease Control and Prevention. How to be reasonably certain that a woman is not pregnant. When to start using specific contraceptive methods. Available at: https://www.cdc.gov/reproductivehealth/contraception/pdf/When-To-Start_508Tagged.pdf. Accessed September 24, 2019.

100% of pregnancies when performed 11 days after expected menses.[24] Determining the date of the last menstrual period is important for pregnancy evaluation and to guide whether back-up contraception is needed after LARC placement (Table 5). A short-term contraception method can also be used before LARC placement if pregnancy cannot be reliably ruled out. This is particularly important when an adolescent selects an IUD. In the case of the subdermal implant, same-day placement is possible even when pregnancy cannot be excluded because the benefits of starting the subdermal implant likely exceed any risk. In this case, the chance of pregnancy and need for pregnancy testing in the next few weeks are important points to discuss.[32] Regardless of the timing of LARC placement, review of the patient's medical history is fundamental to selecting the appropriate and safe contraception method. Similarly, providing expedited LARC services does not preclude the importance of discussing healthy relationships, providing education and screening for intimate partner violence, and facilitating use of resources if a coercive sexual relationship or sex trafficking activity is suspected.

NONCONTRACEPTIVE USES OF LARC

Using contraception to treat menstrual cycle concerns is well established in clinical practice. An estimated 82% of adolescents use the combination oral contraceptive pill for noncontraceptive reasons.[5] The LNG-IUD is particularly important in the treatment of heavy menstrual bleeding.[5,7] Studies involving adolescents have revealed promising results but are limited by small size.[5,33] In studies that are focused on adult women, researchers have found a reduction in menstrual blood loss of up to 80% using the LNG-IUD.[5,33]

Adolescents with physical and/or cognitive disabilities and their primary caregivers often seek options to reduce menstrual blood flow.[34] Policies surrounding consent and confidentiality often require review when working with this population of adolescents. Although confidential contraception counseling is often not feasible in this special population, including the adolescent in the discussion when possible is important. Medical therapy has greatly replaced surgical options to treat menstrual concerns in this population because of ethical questions related to consent as well as significantly higher morbidity and mortality risks compared to those of the general populaiton.[34,35] Depot medroxyprogesterone acetate is a commonly used therapy for menstrual suppression in adolescents with physical and/or cognitive disabilities. However, concerns surrounding weight gain and bone mineral density loss have likely contributed to the increased use of the LNG-IUD in this population.[6,36,37] Data regarding LNG-IUD use among young women with physical and/or cognitive disabilities are growing and are overall positive. Authors of a 2013 cohort study reported that 26 adolescents with disabilities (95% with cognitive impairment and 5% with physical impairment) undergoing LNG-IUD placement had an amenorrhea rate of 100% after 1 year of use.[38] The acceptability of LNG-IUD use in this population is also supported by limited data as authors of another study involving 56 adolescents with developmental disability reported a premature IUD removal rate of 7.4% secondary to pain and irregular bleeding comparable to adults.[37]

Adolescents with severe anemia attributable to heavy menstrual bleeding often require hormone therapy to limit menstrual blood loss. Although options have been traditionally focused on combination oral contraceptives and depot medroxyprogesterone acetate, the

TABLE 5 Back-up Contraception After LARC Placement

Type of LARC and Timing of Placement	Need for Contraception Backup for 7 d After LARC Placement
LNG-IUD inserted after 7 d of the start of menses	Yes
LNG-IUD inserted within 7 d of the start of menses	No
Subdermal implant inserted after 5 d of the start of menses	Yes
Subdermal implant inserted within 5 d of the start of menses	No
Cu-IUD insertion (anytime)	No

efficacy of using the LNG-IUD to treat heavy menstrual bleeding has been recognized.[3] Acceptance of this method is growing, with the National Hemophilia Foundation now recognizing this as a treatment option.[39] In a small study of adolescent girls with known bleeding disorders, the authors found that 100% experienced an improvement in heavy menstrual bleeding and 60% experienced amenorrhea after LNG-IUD placement.[33] These findings are consistent with studies conducted in the adult population with reported LNG-IUD associated bleeding pattern satisfaction rates ranging from of 68% to 100%.[40–43] The role of the subdermal implant as a treatment option for adolescents with bleeding disorders is unclear given the higher rate of prolonged irregular bleeding and lower rate of amenorrhea as compared to the LNG-IUD. No studies investigating the efficacy of using the subdermal implant in this population have been reported.

Dysmenorrhea is the most common gynecologic complaint during adolescence and is associated with a relatively high rate (12%) of monthly school absenteeism.[44] Dysmenorrhea is classified as primary or secondary; the latter is associated with a wide range of anatomic abnormalities. Treatment of dysmenorrhea in the adolescent population is primarily medical, with either nonsteroidal antiinflammatory drugs (NSAIDs) or hormonal contraceptive methods as initial agents.[44,45] The LNG-IUD and the subdermal implant have been shown to provide effective treatment.[44,45] Evaluation for causes requiring surgical treatment such as obstructive Müllerian anomalies or ovarian cysts is warranted if medical management is suboptimal, risk factors for congenital anomalies are present, or pain is acyclic.[44] Even in cases of secondary dysmenorrhea attributable to endometriosis, fibroids, or adenomyosis, the LNG-IUD and subdermal implant have been found to be effective treatment options.[44–46]

UNDERSTANDING LARC SIDE EFFECTS

Regardless of the reason for use, pediatricians report discomfort counseling adolescents on expected side effects and answering the multitude of questions surrounding LARC.[19] This discomfort improves after attending formal LARC training sessions.[18] Reviews of US Food and Drug Administration package insert information for the LNG-IUDs reveal that the absolute risk for an adverse event is low: ectopic pregnancy (1 in 1000), upper genital tract infection (0.5%–0.6%), uterine perforation (up to 0.1%), expulsion (3.5%–4.5%), and symptomatic ovarian cysts (3.5%). A large study including 4592 adolescents between 15 and 19 years of age found irregular bleeding to be the only significant side effect of LARC use.[47] Of note, there was no association with weight gain or mood changes.[47] Counseling about potential changes in bleeding patterns has been associated with higher LARC continuation when done prior to insertion.[48] Unscheduled spotting or light bleeding is expected during the first 3 to 6 months of LNG-IUD use and is common with subdermal implant use; this bleeding is not harmful and decreases over time.[49] Review of LARC package information provides detailed information related to expected bleeding patterns. A total of 35% of LNG-IUD (Mirena) users report 4 or more bleeding episodes or 1 episode lasting more than 10 days within the first 3 months of use. These patterns persist in only 4% of users after 1 year of use. Approximately 50% of women using the Mirena IUD report amenorrhea after 2 years of use. Amenorrhea rates after 2 years of Liletta use, another LNG-IUD with similar dosing as Mirena, is reported to be 26%. Review of packaging information for the lower-dose LNG-IUDs (Kyleena and Skyla) report prolonged or irregular bleeding patterns in 14% to 20% of users at the 90-day mark; this pattern persists in 6% to 18% of users by 1 year of use. Early discontinuation rates for unacceptable bleeding associated with the LNG-IUDs ranges from approximately 1.5% to 5%. Unlike the LNG-IUDs, heavier bleeding may persist after Cu-IUD placement. A discontinuation rate of approximately 12% is reported to be attributable to bleeding or pain concerns. Among subdermal implant users, 17.7% report prolonged bleeding and 6.7% report frequent bleeding, but 75% of women using the implant report fewer days of bleeding and spotting compared to their bleeding pattern before placement.

Bothersome irregular bleeding associated with LARC can be effectively treated with a short course of NSAIDs or oral hormonal therapy.[24,49,50] Smaller studies suggest that tranexamic acid is associated with reduced blood loss after placement of either the Cu-IUDs or LNG-IUDs.[50] Because of its ability to suppress metalloprotease activity, doxycycline may also be an effective option for irregular bleeding treatment.[50] Using this method to treat unscheduled bleeding has been associated with lower LARC discontinuation rates.[50] The CDC Selective Practice Recommendations for Contraceptive Use provides guidance to providers managing irregular bleeding associated with LARC (Fig 1).[3] It is important to consider that persistent bleeding may be attributable to pregnancy, infection, IUD displacement, or new pelvic organ pathology in LARC users.

INCREASING THE NUMBER OF TRAINED PROVIDERS

Although LARC placement is increasing in pediatric primary care clinics, adolescent medicine clinics, and school-based clinics, the lack of trained pediatricians is still a major

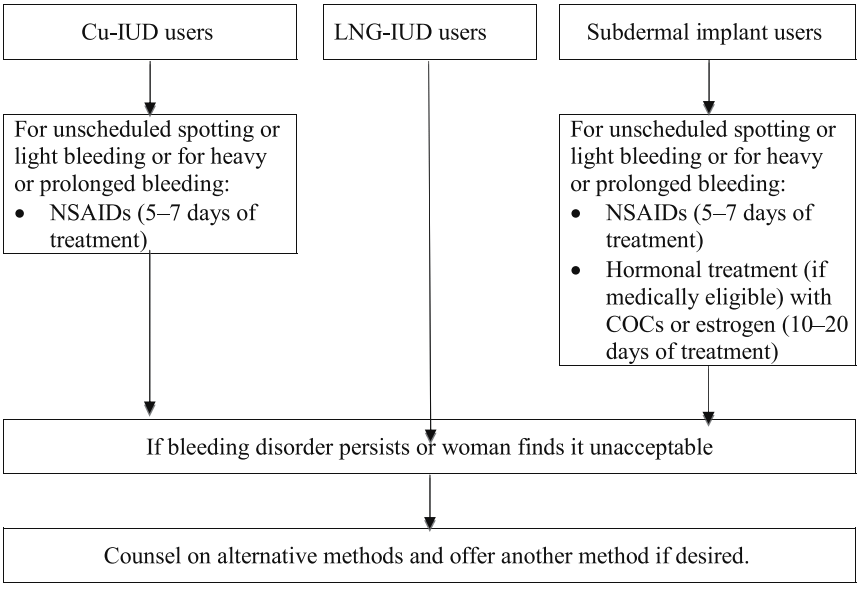

FIGURE 1
Management of women with bleeding irregularities while using LARC. COC, combined oral contraceptive. Adapted from Centers for Disease Control and Prevention. CDC contraceptive guidance for health care providers. US selected practice recommendations for contraceptive use, 2016: implants. barrier to LARC availability within the adolescent population.[17,18,51] Physicians not trained in LARC placement have concerns that IUD placement may cause emotional or physical trauma to the adolescent.[18,52] These concerns significantly wane after training and successful placement of these devices.[18] The first attempt of IUD placement in nulliparous adolescents reveals success rates (96%) similar to their parous counterparts.[53] Similarly, the duration of the IUD placement procedure does not vary between adolescents and adults.[54] Methods used to improve pain and ease of insertion have been investigated and include preprocedure administration of misoprostol, NSAIDs, paracervical block by using lidocaine, and anxiolytic medication including nitrous oxide.[55–57] Although a few studies have found some benefit in pain reduction associated with paracervical block with lidocaine use, general review of current data do not support the routine use of these strategies during IUD placement.[24,55,57,58] In special circumstances, IUD placement under sedation is appropriate, most commonly in adolescents with physical limitations or cognitive challenges, and can be combined with other procedures requiring sedation, such as dental care.

Placement and removal of the subdermal implant requires a free in-person training session sponsored by the manufacturer of the product.[59] Frequency of these training sessions varies geographically, and for some clinicians, training can be difficult to access. To improve access, training sessions are often incorporated into clinical meetings held by professional societies that are focused on adolescent and reproductive health. The contraceptive subdermal implant may only be ordered by a licensed physician after completion of the manufacturer-sponsored training.[59]

IUD training is less formalized than that for the subdermal implant. Unlike the subdermal implant, insertion and removal of IUDs does not require the completion of a specific training program. Although this skill has historically fallen under the domain of the gynecologist or family physician, increased acceptance by both individual pediatricians and professional societies has led to more training opportunities ranging from training sessions at annual clinical meetings to on-site support from pharmaceutical representatives. Access to LARC training for a pediatrician remains a challenge despite the increase in opportunities. Both the ACOG-initiated LARC program (https://www.acog.org/programs/long-acting-reversible-contraception-larc/activities-initiatives) and the National Clinical Training Center for Family Planning (http://www.ctcfp.org/larc/) provide a list of training opportunities open to all physicians regardless of specialty and professional society affiliation.

COST, CONSENT, AND CONFIDENTIALITY CONCERNS

Adolescents and pediatricians express concerns over cost and confidentiality related to LARC. Adolescents also report uncertainty about how to obtain LARC services.[13,16] Specific concerns from pediatricians over accurate billing and in-office stocking of LARC and the supplies required for both insertion and removal have had a negative impact on LARC availability.[13,17,18] Billing for LARC services is complex and multilayered, requiring a *Current Procedural Terminology* code for the placement or removal procedure charge, a Healthcare Common Procedure Coding System code for the actual LARC device charge, and an *International Classification of Diseases, 10th Revision* code for the diagnosis (Table 6). Importantly, there are codes for failed placement that can help with device replacement from pharmaceutical companies if malfunction occurs. Resources to guide LARC billing practices have been compiled by

TABLE 6 Common Billing Codes for LARC Services

Procedure Code (CPT)	Medication Code (HCPCS)	Diagnosis Code (ICD-10)
11981 insertion of implant	J7307 etonogestrel implant	Z30.018 encounter for other contraception (implant insertion)
11982 removal of implant	J7298 LNG-IUD (Mirena)	Z30.49 check, reinsert, or removal of implant
5300 IUD insertion	J7297 LNG-IUD (Liletta)	Z30.430 IUD insertion
53801 IUD removal	J7301 LNG-IUD (Skyla)	Z30.432 IUD removal
	J7296 LNG-IUD (Kyleena)	Z30.433 IUD removal and reinsertion
	J7300 Cu-IUD (Paragard)	Z30.431 IUD routine check

multiple agencies and are widely available (Table 7).

Although the Patient Protection and Affordable Care Act contains provisions designed to expand coverage of LARC and other contraceptives, gaps in access still exist. The Title X Family Planning Program is important and may help fill these gaps. This program, established in the 1970s, provides family planning for anyone desiring services, with priority given to individuals from low-income families. State government public health programs (eg, the New York State Family Planning Benefit Program and the California Department of Health Care Services Family Planning, Access, Care, and Treatment [PACT] program) and cost-assistance programs administered by pharmaceutical companies may also help cover costs.[60] Potential cuts to the Title X Family Planning Program and the uncertainty of the Patient Protection and Affordable Care Act make it difficult to forecast future coverage of LARC.

An adolescent's ability to provide consent for LARC services is dependent on state law. A minimum age of consent for reproductive health services, which includes LARC placement and removal, is explicitly defined by some states. Other states follow the mature minor principle, by which an adolescent under the age of majority and still dependent on parents or guardians can independently consent to reproductive health care services if cognitive maturity is demonstrated.[61] The Guttmacher Institute provides a helpful online resource for issues of consent.[62]

The right to consent does not guarantee confidentiality. The goal upheld by various professional societies such as the AAP, Society for Adolescent Health and Medicine, and ACOG is to consider the medical record as confidential when caring for minors able to consent for reproductive health care services, including LARC.[1,61] Breaches in confidentiality often stem from standard practices surrounding electronic health records. The electronic health record has posed multiple challenges that have yet to be adequately addressed, ranging from inability to limit sensitive health information when parents or guardians request medical records to the automated creation of discharge summaries, appointment notifications, and medication lists, which include contraception.[63] These concerns may affect the ability to provide LARC services confidentially even when state laws allow for confidential reproductive health care for adolescents.

The complexity of consent and confidentiality is amplified when working with adolescents in the child welfare and justice systems. These adolescents experience unplanned pregnancies at a higher rate than their peers, suggesting that these are special populations with higher rates of unmet reproductive health care needs.[64,65] The AAP and the National Commission on Correctional Health Care recommend that these groups of adolescents have access to appropriate reproductive health care services including contraception.[65,66] Disclosing reproductive health information is inevitable when obtaining consent for LARC services for adolescents who are unable to provide independent consent. Pediatricians may find themselves navigating between a state law that allows an adolescent to provide independent consent and a welfare agency regulation that restricts this.[64] In addition to questions of consent, incarcerated adolescents may also face an additional cost barrier because state-funded health insurance may be suspended during incarceration.[65]

Billing for LARC services also limits the ability to provide confidentiality. Groups advocating for better confidential care practices have suggested a more generic insurance bill be generated when adolescents are using parent or guardian insurance to cover reproductive

health care services.[63] The Title X Family Planning Program is unique in that a detailed bill of services is not generated and sent to the parent or guardian. The Title X Family Planning Program improves confidential care by allowing the adolescent to provide consent for reproductive health care independent of a parent or guardian. However, consent policies for procedures set by an individual health care facility may still need to be considered in some cases.[67]

TABLE 8 Steps for Patient-Centered Approach to Contraception Counseling

Patient-Centered Contraception Counseling
Review the patient's general thoughts, fears, and questions related to birth control methods
Understand the patient goals for contraception: when pregnancy is desired, whether reduction of menstrual bleeding or cramping is desired
Present all birth control options with information on efficacy, mechanism of action, safety of use, administration details, and side-effect profile
Review medical eligibility criteria and clearly discuss whether there is a contraindication to a specific birth control method
If the patient is ready to make a selection, encourage questions on the safety, efficacy, administration details, and side effect profile to ensure comfort with all aspects of the chosen method
Counsel on expected changes in bleeding
Assess need for back-up contraception and provide STI prevention education

PATIENT-CENTERED LARC COUNSELING

Pediatricians may unintentionally engage in directive counseling leading patients to select LARC methods when providing contraception care because of the overwhelmingly favorable attention these methods have received from multiple professional societies.[1–3,19] Resisting coercive counseling practice is essential when providing reproductive health care. The reproductive justice movement is focused on the human right to maintain bodily autonomy, to have and not have children, and to raise children in safe and sustainable communities.[68] Although this report endorses the demonstrable safety of LARC and supports providers caring for adolescents to incorporate LARC counseling, placement, or referral services into practice, the importance of counseling within the framework of reproductive justice is clear. Focusing contraception counseling on the priorities of the adolescent patient helps keep the discussion patient centered and the decision-making shared (Table 8). Efficacy of pregnancy prevention may not be the sole factor, or even the most important factor, influencing a patient's choice of contraception.[69,70] Cultural beliefs surrounding future fertility or bleeding patterns and side-effect profile may heavily influence the patient's contraceptive choice.[69,70] Just as cultural beliefs held by patients may impact LARC use, cultural beliefs held by providers may impact LARC availability to adolescents. The AAP and ACOG support conscientious objection by the provider as long patients receive complete information of all services (even those the health care provider is not willing to deliver) and a timely referral to another provider.[71,72]

Proponents of setting LARC within a reproductive justice framework do not discourage use of these methods. Rather, this framework advocates for active prevention of reproductive right abuses. Programs involving the previously available subdermal implant (Norplant) reflected aggressive marketing to poor women, women of color, and young urban women, and in some cases, offered cash incentive programs.[69,73] A recent survey of 100 LARC leading experts found that 77% of participants opposed incentive programs surrounding LARC. The majority of participants commented that incentive-based programming is coercive and described this type of policy as "wrong" and "very disturbing."[51]

The disparity of pregnancy incidence between adolescents from different socioeconomic and racial groups is clear. Pediatricians working with adolescents may feel compelled to deliver clear, directive counseling especially with the growing acceptance of LARC.[74,75] When pediatricians acknowledge that women in particular socioeconomic and racial groups have been the target of unethical contraceptive marketing or campaigns in the past, there is a natural recognition of the critical importance that patients choose their contraception free of coercion.[69,74] LARC counseling within the reproductive justice framework enables women to have equal access to LARC methods and allows for the removal of these devices when desired. Structuring LARC counseling within this framework focuses providers on enhancing the well-being of adolescent patients by increasing LARC availability and not on simply increasing LARC use.

RECOMMENDATIONS

In an effort to increase access to LARC by adolescents, pediatricians should do the following:

1. Recognize LARCs as safe options for adolescents. The US MEC can help clarify questions related to safety of use in a variety of complex medical conditions.
2. Have a clear discussion of expected side effects with their adolescent patients, including expected changes in bleeding patterns, as part of LARC counseling. Providing this type of information and understanding the short-term options to control abnormal uterine bleeding are associated with higher LARC continuation.
3. Recognize LNG-IUD as a promising option for reducing menses, particularly in those

with cognitive or physical disabilities or those with a diagnosis of anemia attributable to heavy menstrual bleeding.

4. Seek and obtain the required training for placement and removal of LARCs.
5. Understand that LARC placement does not need to be delayed for STI screening. IUD placement should be delayed if purulent cervicitis is noted or if an untreated gonorrhea or *Chlamydia* infection is present.
6. Emphasize dual therapy with condoms in LARC users to prevent STIs.
7. Be aware that confidentiality can be compromised when delivering LARC services during the consent process and inadvertently by insurance billing and various automated features of the electronic health record. Understand state laws surrounding reproductive health and the financial options available to cover LARC services.
8. When providing same-day LARC services, care must be taken to ensure all available contraceptive methods are reviewed, medical eligibility is considered, side effects are discussed, and personal safety related to intimate partner violence and coerced sexual activity is assessed.
9. Provide LARC counseling within the reproductive justice framework to prevent directive and potentially coercive counseling.
10. Focus on an end goal of improving the availability of LARC services to adolescents and not on increasing adolescent use of LARC methods.

Neonatal Opioid Withdrawal Syndrome

Stephen W. Patrick, MD, MPH, MS, FAAP,[a] Wanda D. Barfield, MD, MPH, FAAP,[b] Brenda B. Poindexter, MD, MS, FAAP,[c] COMMITTEE ON FETUS AND NEWBORN, COMMITTEE ON SUBSTANCE USE AND PREVENTION

The opioid crisis has grown to affect pregnant women and infants across the United States, as evidenced by rising rates of opioid use disorder among pregnant women and neonatal opioid withdrawal syndrome among infants. Across the country, pregnant women lack access to evidence-based therapies, including medications for opioid use disorder, and infants with opioid exposure frequently receive variable care. In addition, public systems, such as child welfare and early intervention, are increasingly stretched by increasing numbers of children affected by the crisis. Systematic, enduring, coordinated, and holistic approaches are needed to improve care for the mother-infant dyad. In this statement, we provide an overview of the effect of the opioid crisis on the mother-infant dyad and provide recommendations for management of the infant with opioid exposure, including clinical presentation, assessment, treatment, and discharge.

INTRODUCTION

The United States has experienced a surge in opioid use and opioid-related complications. From 1999 to 2009, there was a quadrupling of opioid pain reliever prescription sales nationwide.[1] By 2015, 3 times as many prescriptions for opioid pain relievers were filled than in 1999,[2] reaching >37% of US adults using opioid pain relievers in 2015.[3] The rapid increase in opioid pain reliever use in the early 2000s was associated with a parallel increase in opioid pain reliever–related treatment facility admissions and overdose deaths.[1] Since 2011, however, deaths from opioid pain relievers have plateaued, whereas deaths from heroin and fentanyl have grown exponentially.[4] In 2017, >47 600 Americans died of opioid-related overdoses (including opioid pain relievers, heroin, and fentanyl), outnumbering deaths from car crashes and firearms.[5]

As the opioid crisis grew in scope and complexity in the population at large, opioid use[6] and opioid use disorder (OUD)[7–9] among pregnant women also increased. Opioid use in pregnancy can lead to a withdrawal syndrome in the newborn shortly after birth. The syndrome has been traditionally called neonatal abstinence syndrome but more recently has been called neonatal opioid withdrawal syndrome (NOWS) by federal

agencies, including the US Food and Drug Administration.[10] Although neonatal abstinence syndrome is a more general term for neonatal withdrawal that, in the literature, may include nonopioid exposures (eg, benzodiazepines),[11] evidence suggests that the recent growth of neonatal drug withdrawal has been primarily from in utero opioid exposure either in isolation or in combination with other substances.[8]

The recent increase in OUD in pregnancy and NOWS reveals deficiencies in the continuum of care for the maternal-infant dyad in clinical and public systems. The child welfare system, for example, reported an increase of >10 000 infants in foster care from 2011 to 2017, most because of parental substance use.[12,13] Systematic, enduring, coordinated, and holistic approaches are needed to improve care for the mother-infant dyad. Optimizing the health and well-being of a pregnant woman gives her infant the highest likelihood of an ideal outcome. Care for the mother-infant dyad should be comprehensive and should consider the needs of both the mother and infant, as is outlined in the American Academy of Pediatrics (AAP) policy statement "A Public Health Response to Opioid Use in Pregnancy."[14] This statement builds on previous AAP-released clinical recommendations, including "Recommendations to the Indian Health Service on Neonatal Opioid Withdrawal Syndrome,"[15] and focuses primarily on the clinical presentation, assessment, and treatment of infants with opioid exposure and those with NOWS. The statement also discusses how the discharge process can be used to connect infants to important postdischarge services.

OUD IN PREGNANCY AND NOWS

Use of opioids, even as directed, can heighten risk of developing OUD, defined as a problematic pattern of opioid use that leads to clinically significant impairment or distress.[16] Rates of OUD in pregnancy grew substantially from 1999 to 2014,[7] with disproportionally higher rates in rural areas of the country.[9] Untreated OUD in pregnant women can result in dire consequences for the mother-infant dyad, including overdose death, fetal loss, and preterm birth. As highlighted by the recent report from the National Academies of Sciences, Engineering, and Medicine, "Medications for Opioid Use Disorder Save Lives,"[17] optimal care for pregnant women with OUD includes treatment with methadone or buprenorphine. Methadone is a full μ-opioid receptor agonist, which is dispensed from federally licensed opioid treatment programs. In contrast, buprenorphine is a partial μ-opioid receptor agonist and partial κ-opioid receptor antagonist that can be obtained from an opioid treatment program or from a provider who has obtained a waiver to prescribe through the Drug Addiction Treatment Act of 2000. Despite literature to support the use of medications for OUD in pregnancy, there remain substantial barriers in obtaining medications for OUD among pregnant women.[18,19] These barriers may, in part, be why the majority of pregnant women who are able to obtain treatment of OUD do not receive medications for OUD, despite evidence of their benefit.[18,20]

Opioid use typically does not occur in isolation and frequently involves other substances. In a recent study, using data from the National Survey of Drug Use and Health from 2005 to 2014, authors found that 5.1% of US pregnant women reported nonmedical use of an opioid pain reliever in the last year. Compared with pregnant women who did not report nonmedical use of an opioid pain reliever in the last 30 days, pregnant women who reported nonmedical use of an opioid pain reliever were more likely ($P < .001$) to also report last-30-day use of alcohol (49.2% vs 8.6%), tobacco (59.3% vs 15.6%), and marijuana (41.6% vs 3.3%).[21] Importantly, use of other substances (eg, tobacco)[22] or prescription sedatives (eg, benzodiazepines)[23] along with an opioid may increase risk and/or severity of NOWS. In addition, alcohol use in pregnancy is particularly problematic because alcohol, a teratogen, can cause fetal alcohol spectrum disorders and is the leading cause of preventable intellectual disability in the United States.[24] It is difficult for clinicians to disentangle the short- and long-term effects of exposure to opioids from other substances. Finally, social and economic factors,[25] systemic racism,[26] maternal physical and mental health, genetic and/or epigenetic, nutritional, and environmental factors may adversely affect infant development independent of maternal substance use disorder.[27]

Increases in maternal opioid use were accompanied by a parallel increase in NOWS.[8,9] From 2000 to 2016, the incidence of NOWS increased from 1.2 to 8.8 per 1000 hospital births.[8,28–30] These increases have been steeper in rural and tribal areas[9] and among infants enrolled in the Medicaid program.[29] In addition, there is remarkable state-to-state variation in NOWS. For example, West Virginia has the highest reported rate of NOWS at 33.4 per 1000 hospital births, compared with Hawaii at 0.7 per 1000 hospital births.[31] American Indian and Alaskan native populations have been disproportionately affected by NOWS. In 2016, American Indian and Alaskan native infants had the highest rate of NOWS at 15.9 per 1000 hospital births, compared with white infants at 10.5 per 1000 hospital births, Black infants at 3.4 per 1000 hospital births, and Hispanic infants at 2.5 per 1000 hospital births.[32]

ASSESSMENT AND CLINICAL PRESENTATION

Assessment of infants with opioid exposure by the health care team should include a thorough maternal history, including information gathered on substance use, additional medication use (prescribed and unprescribed), adversities experienced in childhood, cultural beliefs, trauma and violence exposures past and present, mental health disorders, and infectious diseases (including HIV and hepatitis C virus [HCV] infections). Ideally, clinicians should also assess the needs of the family, including the status of significant others and children as well as food and housing insecurity. When evaluating an infant with clinical signs consistent with NOWS, it is also important to consider other diagnoses that present similarly (eg, sepsis, hypoglycemia, hypocalcemia, and neurologic injury).

CLINICAL PRESENTATION OF NOWS IN NEONATES

NOWS occurs after chronic exposure to opioids (Table 1); therefore, exposure to opioids around the time of delivery, including opioids in an epidural or intravenous agonist and/or antagonist therapies (eg, nalbuphine, butorphanol), does not cause NOWS. The clinical presentation or risk of NOWS varies by opioid type (eg, immediate release, sustained release, maintenance),[22] the maternal drug history (including timing of the most recent use of drugs before delivery), maternal metabolism, net transfer of drugs across the placenta, placental metabolism, infant metabolism and excretion, and other factors.[11] In addition, maternal use of other substances, such as cigarettes, benzodiazepines, and gabapentin, may influence the onset, severity, or duration of the withdrawal syndrome.[22,23,33] Higher cumulative opioid exposure may increase the risk of NOWS among infants exposed to immediate-release prescription opioids[22]; however, studies of the relationship between maternal methadone[34,35] and buprenorphine[22,36] dosage and risk or severity of NOWS have generally found no relationship.

Because opioid receptors are concentrated in the central nervous system and the gastrointestinal tract, the predominant clinical signs reflect these systems (eg, tremors, loose stools; Table 2). Onset of clinical signs of withdrawal tend to reflect the half-life of the opioid involved. For example, withdrawal from heroin often begins within 24 hours of birth, whereas withdrawal from methadone usually begins at ~24 to 72 hours of age.[11] Withdrawal, however, may be delayed until 5 to 7 days of age, which is typically after hospital discharge for uncomplicated term infants.[11] Subacute signs of opioid withdrawal may last up to 6 months.[11,37]

SCREENING

Screening for substance use is distinct from testing for substance use. Screening generally refers to the use of a validated instrument to assess substance use, whereas testing refers to the use of a diagnostic test (eg, urine toxicology). Ideally, screening for substance use occurs in the first trimester by a prenatal provider (eg, family medicine, obstetrician, midwife) using a validated screening tool, as endorsed by the American College of Obstetricians and Gynecologists (ACOG). The ACOG recommends early universal screening for substance use at the time of the first prenatal visit.[38] During this time, other risks should be assessed, including HIV, HCV, and syphilis infection, and, if identified, appropriate planning for treatment (eg, HIV antiviral therapy) should occur in the perinatal period. An ACOG committee opinion mentions that screening tools include the "4 P's" for adults and the "CRAFFT" tool for adolescents (Table 3).[38] Clinical guidance from the AAP for screening

adolescents for substance use can be found in the clinical report on substance use screening, brief intervention, and referral to treatment.[39] Prenatal clinicians can also use their state's prescription drug monitoring program as a resource for filled prescriptions because it may capture some high-risk patient behaviors, such as patients seeking controlled substances from different clinicians.[40] A complete summary of ACOG-recommended screening is beyond the scope of this statement but can be found online (https://www.acog.org/Clinical-Guidance-and-Publications/Committee-Opinions/Committee-on-Obstetric-Practice/Opioid-Use-and-Opioid-Use-Disorder-in-Pregnancy). Ideally, pediatric clinicians should work collaboratively with obstetric colleagues to obtain relevant clinical information (eg, screening results) to minimize care duplication. Pregnant women with OUD should also receive antenatal counseling by a pediatric health care provider to assess infant risks of NOWS and provide education on the clinical signs of withdrawal and need for nonpharmacologic and pharmacologic interventions.

SCREENING AND TESTING: MOTHER AND INFANT

Given the challenges in identifying infants at risk for NOWS with maternal screening, some have advocated for universal urine toxicology testing of mothers at the time of delivery. In a recent cohort study from a single center, the efficacy of a universal testing protocol for all mothers was assessed in a community hospital setting. In this study, 5.4% of pregnant women had a positive drug test result at the time of admission (3.2% were positive for opioids). Of the pregnant women with a positive urine drug test result for opioids, 20% had a negative risk-based screen result.[41] However, screening and testing processes are complex and have potential legal ramifications, and the AAP endorses informed consent for toxicology testing of pregnant women.[14] Notably universal testing has resulted in disproportionately higher child protective services referrals for Black women compared with white women[42,43] Pediatricians should be aware of and reduce institutional biases in implementing universal toxicology testing for infants, which could result in unequal consequences for mothers and infants on the basis of race, ethnicity, and/or socioeconomic status.

Toxicology testing for an infant can occur from multiple modalities, including urine, meconium, and umbilical cord tissue.[11] A urine sample should be collected as soon as possible after birth if the clinician is concerned because many drugs are rapidly metabolized and eliminated.[44–46] For example, after in utero exposure, opioids and their metabolites may no longer be detectable in an infant's urine after the first few days of life. Similarly, a positive urine screening result may only reflect recent exposure for most substances and may not reflect previous, more remote in utero exposure. Drugs that are excreted in the hepatobiliary system as well as drugs excreted by the fetal kidneys into the amniotic fluid are concentrated in meconium. Meconium testing provides a longer window of time throughout the pregnancy, beginning as early as 20 weeks' gestation, and is generally considered the gold standard for infant toxicology testing.[47–49] Meconium collection, however, can be labor intensive, requiring collection for several days, and does not reflect periods of abstinence close to delivery. Meconium must be collected before it is contaminated by nonmeconium stools (ie, after the infant receives colostrum or transitional milk, mature human milk, or formula). More recently, umbilical cord tissue testing has emerged as an alternative to meconium collection; given that umbilical cord tissue is readily available at the time of birth, it has logistic advantages to meconium collection.[49–53] Although some studies have suggested equivalence between meconium and umbilical cord tissue testing,[53] others studies have found the paired testing of meconium and umbilical cord tissue to be discordant.[54] Clinicians should be mindful of the differences in testing modalities when considering their needs for testing and work with their laboratories to determine the best testing modality in their setting.

Infant toxicology testing should be completed when it will inform clinical management. In some instances, testing of the infant provides no additional clinical information and would not be recommended. For example, for women in treatment for OUD who are closely monitored with frequent toxicology testing, meconium and/or umbilical cord tissue testing would not likely provide any additional clinical information if this information is readily available to the pediatrician. Testing can be helpful, however, when clinical details are lacking (eg, late or

Screening for Substance Use
4 P's[a]
Parents: Did any of your parents have a problem with alcohol or other drug use?
Partner: Does your partner have a problem with alcohol or drug use?
Past: In the past, have you had difficulties in your life because of alcohol or other drugs, including prescription medications?
Present: In the past month, did you drink any alcohol or use any other drugs?
Any "yes" answer indicates that additional assessment is needed.
CRAFFT[b,c]
C: Have you ever ridden in a car driven by someone (including yourself) who was high or had been using alcohol or drugs?
R: Do you ever use alcohol or drugs to relax, feel better about yourself, or fit in?
A: Do you ever use alcohol or drugs while you are by yourself or alone?
F: Do you ever forget things you did while using alcohol or drugs?
F: Does your family or friends ever tell you that you should cut down on your drinking or drug use?
T: Have you ever gotten in trouble while you were using alcohol or drugs?
Two or more "yes" answers indicate that additional assessment is needed.

no prenatal care, placental abruption) and should be considered.

DIAGNOSIS, ASSESSMENT, AND TREATMENT

In the 1970s, several scoring systems were developed to guide the diagnosis and treatment of neonatal abstinence syndrome.[55,56] Still today, however, there is not one agreed-on scoring tool, and each scoring tool is prone to challenges of interrater reliability because each contains clinical signs that can be subjective or related to infant adaptation to extrauterine life.

The most commonly used scoring tool in the United States today is a modification of the original Finnegan score, developed in the early 1970s by Dr Loretta Finnegan.[55,57] Another commonly used score is a Finnegan scale modification created from the Maternal Opioid Treatment: Human Experimental Research (MOTHER) Neonatal Abstinence Measure trial (Fig 1).[58] Similar to other tools, the MOTHER modification includes common central nervous system, gastrointestinal tract, and autonomic clinical signs. Clinical signs are weighted to reflect severity; for example, sleeping <1 hour after feeding reflects a score of 3, whereas sleeping <3 hours after feeding reflects a score of 1. The score is used for initiation, advancement, and weaning of pharmacotherapy for NOWS on the basis of severity. The MOTHER modification suggests initiating pharmacotherapy if there is a consistent score of 9 to 12 or a single score of 13.

More recently, a new scoring tool has emerged, called Eat, Sleep, Console (ESC), which aims to guide treatment of NOWS.[59] The tool is guided by the infant's clinical signs of withdrawal through evaluation of an infant's ability to eat ≥ 1 oz or breastfeed well, sleep undisturbed ≥ 1 hour, and be consoled. If these criteria are not met, the medical team meets, assesses the environment and nonpharmacologic approaches, and considers initiating or escalating pharmacotherapy. ESC is appealing because of its ease of use and simplicity but has not been studied outside of quality improvement initiatives. It remains somewhat unclear, for example, if improvements in length of hospital stay are attributable to the ESC approach itself or to better adherence to nonpharmacologic approaches, which can also reduce length of stay.[59]

Despite challenges presented by scoring tools, data suggest that standardizing institutional scoring processes (ie, by using the same tool the same way with each patient) and training to improve interrater reliability improves clinical outcomes, including decreasing length of hospital stay.[60] For example, during the 2-year Vermont Oxford Neonatal Abstinence Syndrome Collaborative, standardized scoring processes were associated with a shorter length of stay (–3.3 days; 95% confidence interval [CI], –4.9 to –1.4).[60] The AAP does not endorse one scoring system over another because there is not significant evidence to support one tool's superiority. However, given evidence to suggest that establishing a consistent protocol and approach to scoring improves outcomes, every hospital should have a written protocol and optimize provider adherence. More research to support the optimal assessment of an infant with opioid exposure is needed.

CLINICAL MANAGEMENT OF NOWS

Observation

All infants with chronic opioid exposure should be observed for at least 72 hours to monitor for the development of withdrawal. Although

Appendix Figure 2. Maternal Opioid Treatment: Human Experimental Research (MOTHER) Neonatal Abstinence Measure

PATIENT ID#_____

Dose given q 3-4 hrs with feeds; do not exceed 4 hrs between doses

SCORE Morphine (0.04mg/0.1ml) DOSE FOR INITIATION

0-8	0	
9-12	0.04	mg/dose
13-16	0.08	mg/dose
17-20	0.12	mg/dose
21-24	0.16	mg/dose

25 or above 0.20mg/dose

Morphine Initiation:

- If neonate scores 9-12 re-score after feeding or within the hour and if re-score is 9-12 start treatment based on highest score. If re-score is 0-8, do not initiate treatment.
- If initial score is 13 or greater, start treatment immediately without reassessment.

Morphine Maintenance

- Maintain dose if score 0-8
- Increase dose by 0.02 if score is 9-12 (rescore before dosing)
- Increase dose by 0.04 if score 13-16
- Increase score by 0.06 if score 17-20

Weaning Instructions:

- Maintain on dose 48 hrs before starting weaning
- Wean 0.02 mg morphine every day for a score is 0-8
- Defer wean for score e 9-12

Re-escalation

- If neonate scores 9-12 re-score as described for initiation .
- If second score is in 9-12 increase morphine 0.01 mg q3-4 hrs
- If 2 consecutive scores 13-16, increase 0.02 mg q3-4 hrs
- If 2 consecutive scores in 17-20, increase 0.04 mg q3-4 hrs etc

Timing of Scoring: Hospitalized infants scored every 3-4 hrs **before** feeds. Reassessment Occurs immediately **after feeds** or within 1 hour.
Discharged (e.g., in GCRC) infants scored twice a day scores must be separated by 8 hrs)
NOTE: Discharged infants are to be admitted to hospital if the infant receives a single score of 9 or more

SIGNS AND SYMPTOMS Please note **presence (pr) or absence (ab)** of items where indicated. Include observations for the past 4 hour period.	Score	Date/time	Date/time	Date/time	Date/time	Date/time	Date/time	Date/time	Date/time
Crying: excessive high pitched Crying: Continuous high pitched	2 3								
Sleeps < 1 hour after feeding Sleeps < 2 hours after feeding Sleeps < 3 hours after feeding	3 2 1								
Hyperactive Moro Reflex Markedly Hyperactive Moro Reflex	1 2								
Mild Tremors: Disturbed Moderate-Severe Tremors: Disturbed	1 2

MOTHER Trial Modification of the Finnegan Score. (Reprinted with permission from Jones HE, Kaltenbach K, Heil SH, et al. Neonatal abstinence syndrome after methadone or buprenorphine exposure. *N Engl J Med.* 2010;363(24):2320–2331.)

there is increasing evidence that multiple factors may increase an opioid-exposed infant's risk of withdrawal (eg, gestational age, specific genotypes, cigarette use, benzodiazepine and gabapentin use), there remains insufficient evidence of how to use these exposures to tailor an infant's postnatal observation period. Institutions should consider observing infants exposed to immediate-release opioids for at least 3 days, infants exposed to buprenorphine and sustained-release opioids for 4 to 7 days, and infants exposed to methadone for 5 to 7 days. Notably, however, there remains limited evidence to inform observation periods, and excess observation could result in separation of the mother-infant dyad. Additional research is needed to inform appropriate hospital observation periods for infants with opioid exposure.

Setting

Traditionally, NOWS in the United States has been managed in the NICU[61]; however, many infants at risk for or with NOWS do not need NICU-level care. Depending on the physical design of the unit, care in a NICU may result in separation of the mother-infant dyad, which can further exacerbate infant clinical signs of withdrawal and can be traumatic for mothers during this vulnerable postpartum period. In addition, for infants going through withdrawal, the NICU environment, which can be loud and overly stimulating, may not be optimal. Recently, models of care have emerged that are focused on enabling the new mother to "room-in" with her newborn (in many cases, outside the NICU environment).[62] In a recent meta-analysis, it was found that rooming-in was associated with lower rates of pharmacotherapy for withdrawal (relative risk, 0.37; 95% CI, 0.19 to 0.71; I^2, 85%) and shorter lengths of hospital stay (weighted mean difference, –10.41 days; 95% CI, –16.84 to –3.98 days; I^2, 91%).[63] Keeping the mother-infant dyad together may promote bonding and facilitate breastfeeding, and rooming-in should be considered the preferred model, including in the NICU, for infants with opioid exposure. In addition, the environment and infant handling should be modified so that it is not overly stimulating, which can exacerbate clinical signs of withdrawal (eg, loud noises, bright lights). In addition, it is important that care clinicians (eg, nurses, nurse practitioners, physicians) cluster care interventions together temporally so as not to unnecessarily disturb the infant, which may also aggravate signs of withdrawal.

Nonpharmacologic Care

The literature to support specific nonpharmacologic approaches is sparse; however, evolving evidence suggests that effective nonpharmacologic care that engages the mother is an essential foundation to the care of an infant with opioid exposure. Nonpharmacologic care that is individualized should be applied beginning at birth for all infants with substance exposure and continued throughout hospitalization and beyond, regardless of the need for pharmacotherapeutic intervention. Engaging and coaching caregivers in nonpharmacologic care promotes bonding and may improve outcomes, beginning with education about the infant-specific signs of NOWS and helping the family to interpret what triggers the clinical signs the infant is experiencing and education about how to support his or her regulation. Clinical features of NOWS, such as irritability, uncontrolled movements, and fragmented sleep, can be challenging for the new mother. Providing support to the mother as she responds to these clinical features is important. Mothers frequently experience overwhelming feelings of guilt and anxiety in response to the dysregulated neurobehaviors associated with NOWS, and pediatricians are uniquely positioned to support mothers to manage their emotions while supporting the healing and development of their infants.[64] Nonpharmacologic care should also include a thorough assessment of the hospital environment and infant handling and adaptations by the infant to each to minimize NOWS expression.

Nonpharmacologic treatment may include a variety of supportive care approaches. As described by Velez and Jansson,[64] approaches to nonpharmacologic care should be tailored to the clinical behavioral and physiologic signs the infant is experiencing. Velez and Jansson[64] note 4 specific domains: (1) reactivity to sensory stimulation and regulatory issues, (2) behavioral states and state control, (3) motor and tone control, and (4) autonomic signs of stress. For example, an infant experiencing overreactivity to visual stimulation may benefit from a dimly lit environment, whereas an infant with hypertonia may benefit from swaddling (Fig 2).

Breastfeeding

Perhaps the most studied nonpharmacologic intervention is breastfeeding.[65] In general, breastfeeding is safe for mothers who take methadone or buprenorphine and may reduce clinical signs of NOWS and length of hospital stay; thus, in many settings, breastfeeding has become a critical foundation in care for the mother-infant dyad. Methadone and buprenorphine are excreted into human milk at low concentrations. The Academy of Breastfeeding Medicine has published consensus breastfeeding guidelines that suggest that breastfeeding should be encouraged if the mother has not had a relapse in >90 days but discouraged if there has been a relapse in the last 30 days.[66] Being HIV-positive is a contraindication to breastfeeding in high-income

countries, such as the United States, and HCV-positive mothers with bleeding or cracked nipples should also consider abstaining from breastfeeding.[67] Clinicians and patients should be cautious with sudden discontinuation of breastfeeding because some have reported signs of infant withdrawal.[68]

In a recent survey of women in treatment of OUD, it was found that although most mothers desire and attempt to establish breastfeeding, they encounter significant challenges (eg, long NICU stays, lack of support and education) that compromise their success. For these reasons, rates of breastfeeding initiation, exclusivity, and duration remain low among mothers with OUD. In addition, some mother-infant dyads may have difficulty with latching because of withdrawal and may require fortification of milk because of infant weight loss, which can lead to fewer breastfeeding attempts and lower sustainment of breastfeeding. Lastly, breastfeeding counseling and support should be trauma informed because mothers with OUD report high rates of trauma, including sexual trauma, which may influence their desire to breastfeed.[69–71]
