their activities and mobility in the world are so different from older youth (Masten & Narayan, 2012; J. D. Osofsky, 2011). Adolescents generally are more likely to understand what is happening, are less likely to be supervised than young children, have more connections to people and organizations that can be affected by catastrophic events, get recruited or called upon more to help in war, and also simply get around more than young children do (Eisenberg & Silver, 2011; Narayan & Masten, 2012; Reed et al., 2012). Protection from exposure also can vary by sex, with females more closely supervised or sheltered from unfolding violence or destruction and males more often recruited to engage actively in the situation, especially older males. Females often experience more sexual violence whereas males experience more trauma related to active involvement in war or violent conflict. Adults also hold age-related and gender-related expectations about children, which can affect not only the level of monitoring or buffering actions by adults, but also exposures to atrocities, such as rape or torture (APA, 2010; Reed et al., 2012).

Exposure also can be related to many other geographical, community, family, or individual differences. At any given time, there are regions of the earth more or less prone to earthquakes, floods, hurricanes, and political conflict. Low-income families or communities may live in locations with greater vulnerability (e.g., to flooding) or fewer protections (e.g., warning systems or evacuation services). Personality differences could influence exposure during disasters or war and contribute to the likelihood of joining a war or taking risks during a “superstorm.” Cognitive skills and emotion regulation skills could influence behavior that affects exposure as well as coping (Eisenberg & Silver, 2011). Height, strength, or attractiveness could influence the likelihood of being kidnapped for sex trafficking or slavery as a child soldier.

### *Mediating Processes of Exposure*

There is considerable interest in the mediating processes by which mass-trauma experiences affect children. Some processes are biological, within the individual child, while others are mediated by the families, friendships, and schools. Nations and economies can be devastated by major disasters and war, with long-term consequences for employment and economic opportunities for young people. Families and whole communities can be displaced, externally or internally, disrupting many aspects of family life, cultural practices, and education.

Many models of mediating processes for children have focused on stress at the family level. *Family stress*

*theory* was developed to account for processes by which large-scale economic crises, including the Great Depression (Elder, 1974/1999) and the Iowa farm crisis (Conger, Conger, & Martin, 2010; Conger & Elder, 1994) influence child development. In these models, economic strain initially generates stress and symptoms of distress in parents, often increasing interparental conflict and disrupting normal routines and effective parenting. These family disruptions alter the quality of parenting and family life for children in a spreading cascade.

There is also rising interest in the pregnancy-related effects of mass trauma stress on the developing fetus, as indicated above. In this case the unborn child experiences many biological consequences of the mother’s physiological stress through the placenta (Hertzman, 2012; Shonkoff et al., 2012). This phenomenon, whereby biological embedding of stress may be a mediating process of parental exposure to trauma and child outcomes, has been documented empirically. For instance, fetal programming as a result of trauma could increase the risk for PTSD across the life span (Yehuda & Bierer, 2009; Yehuda et al., 2007; Yehuda, Bell, Bierer, & Schmiedler, 2008). As evidence grows for intergenerational transmission of experience-induced epigenetic changes in animal and human studies, these prenatal effects portend ominous risks.

There is rapidly increasing attention to the long-term consequences of “toxic stress” exposure, broadly defined, both prenatal and postnatal, for health and development (Gunnar & Herrera, 2013; Johnson, Riley, Granger, & Riis, 2013; Shonkoff et al., 2012). Many aspects of mass trauma experiences fit the criteria for experiences defined as toxic by many of these scholars, with the potential to affect large populations for generations.

Developmental timing and sensitive periods are central to concerns about toxic stress exposure. Compelling evidence, including data from Chernobyl research described above, suggests that biological systems in the developing child are more sensitive to stress effects during particular periods of development, both prenatal and postnatal, effectively programming these systems for the long-term. Traumatic stress may alter the organization and “tuning” of multiple stress-response systems, including the immune system, the autonomic system, and the hypothalamic-pituitary-adrenal (HPA) axis (Gunnar & Herrera, 2013; Hochberg et al., 2011; Johnson et al., 2013; Meaney, 2010; Shonkoff et al., 2012). High levels of unregulated stress can be harmful to the developing brain and neural systems important for the top-down control of emotion and problem solving. Moreover, elucidation of epigenetic

processes, where experience alters gene-expression, offers plausible explanations of how early traumatic experiences could “get under the skin” to affect long-term health or brain development (Boyce, Sokolowski, & Robinson, 2012; Hochberg et al., 2011; Johnson et al., 2013; Meaney, 2010). Genetic and epigenetic studies remain limited in the study of war and disaster but important clues are beginning to emerge on genetically mediated consequences of severe trauma exposure, which are discussed in later empirical sections of this chapter.

It is not hard to imagine how prolonged mass disasters generate enormous stress in parents and the family system, with many direct and indirect consequences for family functioning, parenting, and child development, including family disintegration and child abuse (Eisenberg & Silver, 2011; Kaniasty, 2011; J. D. Osofsky, 2011; Reed et al., 2012). Yet many families show resilience during disaster, war, and displacement, continuing under sometimes extraordinary circumstances to provide emotional security, routines, monitoring, and hope to their children. Thus, there also is great interest in the processes that may protect or promote family function in times of great upheaval and interventions to support those processes (Masten & Monn, in press). Decades of research on family resilience in diverse situations can inform these efforts (Walsh, 2011).

### *Explaining Variations in Response*

Beyond exposure dose, what predicts the responses of children to mass trauma experiences, and particularly good or better recovery? There is considerable interest in this question because the answers can influence efforts to prepare for these experiences or facilitate recovery for children. Many factors have been studied, beginning in the classic studies of war and disaster described previously. These include the presence of secure attachment figures, child sex, cognitive abilities, opportunities to play or go to school or help with the recovery, faith and religious practices, and many other features of individual child, family, and community.

Some of the factors that predict good recovery are related to positive development under any conditions, such as good caregiving, nutrition, and health care. These are usually termed *promotive factors* (Sameroff, 2000). Others, such as emergency services or good arousal-regulation strategies, are particularly important as the level of adversity or stress rises, and these are often called *protective or resilience factors* (Masten, 2013). Parents function both ways: They promote good development at all levels of risk but, in the midst of severe trauma, effective parents take extra steps to protect and buffer their children in

response to the nature of threat in the context. Protective factors moderate the impact of trauma on child function or development.

Research on children in war and disaster has considered vulnerabilities as well as promotive and protective influences on response. Moderators that increase the negative effects of exposure are viewed as *vulnerability* factors. Additionally, investigators in this area have considered the possibility that extremely traumatic experiences can *induce* vulnerability or resilience for later adversities.

Developmental timing has been implicated for both vulnerabilities and protective processes, raising the interesting question of timing with respect to sensitization versus inoculation effects of early exposure to trauma (Masten & Narayan, 2012). Some exposure to adversity (in lower doses that the organism can manage) may be essential for activating healthy defense systems for later responses to stress or infection, whereas too much exposure or exposure at the wrong time may sensitize the organism, creating vulnerability (Rutter, 2006; Seery, Holman, & Silver, 2010). Sensitization and inoculation models that clarify “the right dose at the right time” would improve understanding about how to prepare children and families for better responses to mass-trauma experiences.

Children and parents also differ in their typical reactions to experience and the resources they can draw on for adaptation. These differences are studied as moderators of adversity at multiple levels of analysis, including genetic differences and personality differences, neurocognitive function, problem-solving abilities, social support, socioeconomic resources, community resources, and religious or cultural practices, among other differences. These differences often are studied in war or disaster as vulnerabilities, or promotive or protective factors, depending on how they function.

### *Differential Susceptibility and Sensitivity to Context*

One of the most intriguing concepts in research on individual differences is the idea of differential susceptibility to experience or variations in sensitivity to context (e.g., Belsky & Pluess, 2009; Boyce & Ellis, 2005; Obradović & Boyce, 2009; Pluess & Belsky, 2013). These concepts propose that some individuals are more sensitive to experience, “for better or for worse” (Belsky, Bakermans-Kranenburg, & van IJzendoorn, 2007). These individuals, who may have distinctive biological profiles or genetic characteristics, are more reactive to their environments, including traumatic experiences and positive experiences. In the context of extreme stress, they may do poorly if unprotected, but in

good situations, they may flourish. Such children also may be more responsive to the protections afforded by parents or interventions to promote positive development. It has further been proposed that experience itself, particularly early in development, could alter these characteristics in that either very positive experiences or very negative experiences could shift the organism toward greater sensitivity (Boyce & Ellis, 2005).

### **Cascading Consequences and the Intergenerational Transmission of Trauma**

Concepts and themes presented above suggest that there are potential long-term and spreading effects of mass-trauma experiences on development, over the life span and also across generations. As noted, scholars long have expressed concern about progressive, expanding, and/or intergenerational effects of extreme trauma (La Greca, Silverman, Lai, & Jaccard, 2010; Masten & Narayan, 2012). New research on the possibilities of epigenetic transmission of trauma effects has opened a whole new dialogue on this longstanding set of questions. There are also many other processes of interest to scientists who study war and disaster, at the level of social development and parenting or cultural change.

Some children spend their entire childhoods in a context of war or in an impoverished refugee camp. What are the long-term consequences of these experiences for individual children, the global well-being of children, and hopes for global peace? Many scholars across the world, as well as global agencies concerned with children, such as the United Nations and World Bank, are raising these questions. It is important for developmental scientists to respond and contribute to this important dialogue, an issue discussed further in the concluding section of this chapter.

### **CHILDREN IN WAR, TERRORISM, AND VIOLENT POLITICAL CONFLICT**

The locations and nature of war and political violence have changed markedly over the past century, although the devastating effects of mass violence remain a global threat. In 1996, a landmark report was presented to the General Assembly of the United Nations by Graça Machel titled *The Impact of War on Children*. Machel, a well-known educator and children's advocate from Mozambique, had been charged with preparing an independent examination of the impact of armed conflict on children. The report, along with follow-up reports (Machel, 2000; UNICEF,

2009), had far-reaching effects in bringing the issues of children in war to the forefront of global attention.

The multifaceted nature of the devastation wrought by armed conflict on child development is hauntingly clear in these reports. Children suffer direct physical and psychological injuries. They lose their parents, their homes, their hopes, and their futures, often experiencing the horrific combination of atrocity and deprivation. Wars rob children of security and food. Farmers stop growing crops and soldiers burn land to starve civilians as well as combatants. Economic development, education, and the viability of land for growing food are all sacrificed in the course of ongoing conflicts. Commerce, exchange of information, and international aid are also disrupted. Millions of families with children are displaced by war and conflict, often residing for long periods in unsafe and unhealthy refugee camps.

In the initial report, Machel (1996) noted that contemporary armed conflicts killed and maimed more children than soldiers. In Mozambique alone, from 1981 to 1988, she documented that 454,000 children died from direct and indirect effects of the conflict. Children in many war-affected regions already suffer from the health burdens of malnutrition and disease, and they are vulnerable to the added threats of conflict. During the height of the conflict in Somalia, half of the deaths among children were caused by measles. The residue of conflict also includes landmines and unexploded ordinance that can cause harm years after the conflict ends.

This section highlights current empirical findings on the impact of violent political conflicts on child development. Findings on the nature of exposure and dose effects are presented first, followed by findings related to mediating processes and moderating influences, and the role of the recovery context. Results from intervention studies are discussed, as well as interest in promoting peace through child-focused activities.

#### **Variation in Exposure**

The nature and severity of traumatic exposures in violent political conflicts vary across situations. Experiences may begin and end suddenly or be prolonged with no discernible onset or offset. Ongoing conflicts can be punctuated by sudden terrorist attacks or surges in violence. Children may be held hostage for days, as in the 2004 Beslan school hostage incident in Russia, or kidnapped into an army to serve as a child soldier for years. Exposures may be direct, with physical injuries or witnessing of atrocities, or

indirect, including media exposure. Armed conflicts often generate complex trauma exposures for children, who may witness torture, lose their parents, suffer starvation, endure rape, and encounter many other terrifying experiences.

Tol, Song, and Jordans (2013) reviewed findings on children and adolescents living in areas of armed conflict, focusing on studies addressing child mental health or resilience that were conducted in low- and middle-income countries, where most children affected by armed conflict live. Of the 53 peer-reviewed articles meeting their inclusion criteria, 15 were qualitative or mixed-method studies and 38 were quantitative. They did not attempt a meta-analysis because of the inconsistencies in many aspects of the studies. They noted numerous shortcomings in the literature, particularly in measures and design. For example, validated and culturally sensitive measures were rare, most of the studies were cross-sectional, and the longitudinal studies usually had small sample sizes. Nonetheless, the authors concluded that the supportiveness of the context was equally as important if not more important for promoting resilience than individual qualities of the children. In addition, resilience-promoting influences did not fully counter the impact of severe (particularly ongoing) trauma. Therefore, interventions cannot focus solely on promoting strengths but also need to mitigate risk and/or reduce vulnerabilities. Tol et al. (2013) also emphasized the complexity of resilience processes in the context of armed conflict, and the need to tailor interventions and intervention research to the particular context.

Over the past decade, millions of children in Africa, the Middle East, Sri Lanka, Afghanistan, and other regions of the world have been affected by political violence and war; children have been massacred, orphaned, injured, separated from parents, and displaced. Studies of children in protracted conflicts in Sierra Leone, Uganda, and Sudan, for example, have documented severe and prolonged exposures to war atrocities. These atrocities include the experiences of child soldiers, discussed below, and also profound suffering brought about by death of parents, destruction of home and community, dislocation, maiming, and injuries.

Conflict in Sudan began in 2003, eventually resulting in terrifying attacks by militia (known as the Janjaweed) on civilians, including children. Morgos, Worden, and Gupta (2007-2008) documented the experiences and trauma symptoms of 331 internally displaced children from the Southern Darfur region of Sudan. Over 90% of children reported experiencing each of the following events: home invaded, witnessed homes burned, witnessed shootings,

and hidden to protect themselves. About 75% had witnessed torture, half had been threatened with death, and half had witnessed people burned alive. Over 40% had experienced death of a sibling and witnessed rape, 24% had parents die, and 22% had been forced to kill or injure members of their families.

In Uganda, even young people spared from life as a child soldier suffered many traumatic experiences. This conflict began in the 1980s, between government forces and the Lord's Resistance Army, notorious for their forced recruitment/abduction of children to be child soldiers. In a rare comparison study of child soldiers with peers from the same conflict, Moscardino, Scrimin, Cadei, and Altoè (2012) compared the rates of traumatic experiences reported by adolescents who were former child soldiers and similar youth from the same region of northern Uganda who had never been abducted as child soldiers. Youth aged 14 to 18 from four schools in the Gulu district, a region at the center of this conflict, were invited to participate, with 234 out of 238 invited students taking part. The former child soldiers ( $n = 133$ ; 57% of the sample) had much higher rates of traumatic experiences than the never-abducted youth, but exposures reported by never-abducted youth ( $n = 101$ ; 43%) were also quite high: 52% of the never-abducted were beaten (compared with 78% of child soldiers); 52% were injured (80%); 31% witnessed someone killed (69%); 7% killed someone personally (47%); 10% had to drink urine (51%); 16% had to punish other children (76%); 22% had to fight (76%); and 19% were forced to engage in sexual contact (45%; Moscardino et al., 2012).

### *Child Soldiers*

As evident in the data from Moscardino et al. (2012), child soldiers in the Lord's Resistance Army experienced severe, repeated, and prolonged traumatic experiences. They were abducted at an average age of 11.9 years (ranging from 5 to 17 years old) and held for an average of 2 years. The investigators also observed that correlations between particular traumatic experiences and mental health problems were more often found for the never-abducted sample, potentially due to the extreme range of responses in abducted children. Overall, child soldiers had more severe signs of PTSD, but mental health problems among the child soldiers were barely related to the severity and nature of specific traumatic experiences. This finding has been observed in another study of child soldiers from Uganda by Klasen et al. (2010), and is consistent with an asymptotic effect, such that exposure levels this high exceed the severity threshold for full expression of any dose-response effects.

One of the most important longitudinal studies of child soldiers was conducted by Betancourt and her colleagues in Sierra Leone (Betancourt et al., 2010; Betancourt & Khan, 2008; Betancourt, McBain, Newnham, & Brennan, 2013). Prospective studies are rare in this literature, although Boothby has followed a small cohort of former child soldiers from Mozambique for many years (Boothby, Crawford, & Halperin, 2006).

The conflict in Sierra Leone began in the 1990s in a civil war among the Sierra Leone Army, the Revolutionary United Front, and other parties. This conflict resulted in extensive harm to children, with many children forced into combat or slave service in the armies, directly assaulted and mutilated, or indirectly harmed by the consequences of this destructive and lengthy conflict. In many cases, the revolutionaries deliberately tried to break the ties of the young conscripts to their homes by forcing them to commit atrocities against their families and communities so that they could not return. By 2001, nonetheless, many child soldiers returned and the United Nations mission in Sierra Leone confronted the challenges of demobilizing and re-integrating many of these child soldiers.

In the study by Betancourt et al. (2010), 156 former child soldiers aged 10 to 18 years were assessed in 2002, with follow-up assessments after 2 years. These children had spent an average of more than 5 years with the RUF. Given this sample was comprised of survivors, the investigators noted that the children must have been particularly resourceful. The investigators examined change over time in symptoms among the former child soldiers. They found that increased hostility over time was predicted by the experiences of rape and wounding or killing others, traumas that the investigators describe as toxic for children. Their disaggregated analysis on the importance of specific experiences for distinct outcomes aligns with the goal of unpacking dose-response effects discussed above. These investigators also studied the importance of the recovery context, discussed further below.

A subsequent report by Betancourt, McBain, et al. (2013) analyzed three waves of data from this ongoing prospective study, to study trajectories of internalizing symptoms over time. Four groups were derived in this analysis: youth who held a steady low course of internalizing symptoms (41%; a stress-resistance pattern); youth who improved over time (47%; a resilience-recovery pattern); youth who had persisting symptoms (5%); and those who worsened over time (6%). Thus, about 88% of these young people showed some kind of resilience-recovery over time in this one domain of functioning. These investigators

continue to follow these Sierra Leone youth as they grow up and have their own children; their research may reveal longer-term or intergenerational consequences of severe trauma exposure.

Betancourt, Borisova, et al. (2013) reviewed the existing literature on child soldiers, using the Systematic Assessment of Quality in Observational Research (Ross et al., 2011) to identify empirical studies meeting quality standards, a system developed for psychiatric research. Of 21 studies from 10 countries, they identified only eight studies of high quality and four of moderate quality. Five were intervention studies and two were prospective. Very few had comparison groups. These studies corroborated the extreme level of violence exposure typical for child soldiers, with similar rates for boys and girls. Girls were often, though not always, more likely to experience rape as child soldiers. Girls also tended to report more psychological problems. More mental health problems were observed in child soldiers who were abducted into service, perpetrated violence, or witnessed the death of family or friends. In some contexts, including Sierra Leone and Nepal, returning girls who experienced rape received less community support and experienced more stigma. Better outcomes were associated with family and community acceptance in multiple studies. Perhaps most notable in this review was the overall paucity of research, particularly on interventions, given the scope of the problem worldwide.

### *Prolonged Political Conflict*

There is a distinct literature on young people experiencing lengthy political conflicts in the Middle East, Northern Ireland, and other “hot spots” of ethno-political conflict around the world (Barber, 2009a; Cummings et al., 2012; Dimitry, 2012). These conflicts often are deeply rooted in the history and cultures of the region. Violence may wax and wane, exposing children and youth to many forms of threat. Young children may be exposed directly to violence but also experience the stress of repeatedly being taken to shelters during bombing attacks; strain on family members; loss or separation from parents due to injury, death, and incarceration; and disruptions of family and daily routines, such as school. Adolescents, in addition, may voluntarily participate, endangering themselves physically and psychologically. They also risk arrest, incarceration, humiliation, or torture at the hands of the other side of the conflict.

There have been numerous studies published since 2000 on conflicts in the Middle East, particularly related to the Palestinian-Israeli conflict (see Barber, 2009a; Dimitry, 2012). One of the most distinctive aspects of this body

of research is the focus on adolescents engaged in the ongoing conflict, including their identity development and the meaning young people ascribe to these conflicts and their roles in it (Barber, 2009b). Many youth join these conflicts and appear to gain a positive sense of identity and agency through their engagement. Understanding these situations and how to intervene to promote peace, reduce violence, protect children, and prevent intergenerational transmission of the conflict requires great sensitivity to the historical and cultural issues involved, as well as a developmental perspective.

### ***Terror Attacks***

Over the past two decades, research on the effects of terrorism on children has been spurred by major events with global impact, including the Oklahoma City bombing on April 19, 1995, the World Trade Center attacks on September 11, 2001, and the Beslan school siege in September of 2004. The Oklahoma City bombing shocked the world, but the deaths of 19 young children from the daycare centers within the Federal building had an especially searing impact. The effects of this bombing on children have been documented in a series of publications by Pfefferbaum and her colleagues (e.g., Gurwitsch, Sitterle, Young, & Pfefferbaum, 2002; Pfefferbaum, Call, & Sconzo, 1999; Pfefferbaum, Nixon, et al., 1999; Pfefferbaum et al., 2002).

Over 3,000 children lost parents in the attacks on the World Trade Center and many more lost loved ones. It is estimated that 10% of youth in the New York City area knew someone who died. However, the scale of the impact was global: Acts of terror are intended to propagate fear over large distances and in many more people than those directly targeted. Live news coverage and replays of this attack amplified effects on people around the world, including children.

Numerous studies were conducted after the 9/11 attacks, both in New York and across the United States (Pfefferbaum et al., 2013). Many of these studies focused on internalizing symptoms including symptoms of PTSD. The New York City Board of Education commissioned a study of the mental health needs of students in the public school systems about six months after the attack on the WTC. Over 8,000 students (around 9 to 18 years of age) were surveyed across 94 schools (Hoven et al., 2005). Results suggested elevated trauma symptoms throughout the city. Risk for PTSD-level symptoms was related to personal exposure to the attacks (e.g., injured, in the smoke cloud), family exposure or death, previous trauma exposure, and

media exposure. National surveys also indicated substantial symptoms of PTSD shortly after the attacks, in adults and children (e.g., Schuster et al., 2001). Some studies also observed a correspondence between parent symptoms and child symptoms (see Comer & Kendall, 2007; DeVoe, Klein, Bannon, & Miranda-Julian, 2011; Eisenberg & Silver, 2011; Phillips, Featherman, & Liu, 2004).

A number of studies on the effects of media emerged after 9/11 (Lengua, Long, Smith, & Meltzoff, 2005; Otto et al., 2007; Phillips et al., 2004; Saylor, Cowert, Lipovsky, Jackson, & Fitch, 2003; Schuster et al., 2001). Results were mixed but generally showed that media exposure could be traumatizing or retraumatizing, and that young children, especially preschoolers, do not understand that media coverage is repeated. In their national survey 5 days after 9/11, Schuster et al. (2001) found that one third of parents reported restricting their children's television viewing, an idea that many experts on disaster response have encouraged.

Another heart-wrenching terror attack unfolded 3 years after 9/11, in September of 2004, when armed separatists (Chechens, Ingush) occupied a school in the Russian town of Beslan. Approximately 1,300 hostages were held in the school, including nearly 800 children. The children spent over 50 hours without food or water in a hot gymnasium, wired with explosives, and witnessed the murder of other hostages (Moscardino, Axia, Scrimin, & Capello, 2007; Scrimin, Moscardino, Capello, Altoè, & Axia, 2009; Scrimin et al., 2011). After 3 days of standoff, the Russian forces stormed the building, using heavy arms. Over 300 hostages died in the ensuing explosions, fire, and battle, including 186 children.

One of the post-Beslan studies (Scrimin et al., 2009) focused on emotion recognition in exposed (101) and nonexposed (102) children (Age 12 years on average) 20 months after this terror attack. Results suggested that children in both groups responded similarly to faces expressing pure emotions (e.g., anger, sadness). However, when they were asked to recognize morphed, mixed-emotion faces, they were more sensitive (accurate) in detecting anger, a bias also observed in maltreated children (Pollak, Cicchetti, Hornung, & Reed, 2000).

### **Determinants of Exposure**

Exposure to the trauma of war, terrorism and political violence in children varies by characteristics of individuals, families, communities, natural and social ecologies, and geopolitical as well as historical context. Some children

are specifically targeted in war or political violence, while others are simply more likely to be exposed. At the same time, there are some random elements to exposure, particularly in surprise attacks, when individual exposure is unrelated to any characteristics of exposed children or families.

### *Individual Differences*

Evidence continues to support observations about age differences from early research (e.g., Dimitry, 2012; Drury & Williams, 2012; Dubow, Boxer, et al., 2012; Eisenberg & Silver, 2011; Masten & Narayan, 2012; Reed et al., 2012). Older youth, compared to young children, usually have higher objective exposure to the wide scope of potentially traumatic experiences in most situations of war or conflict, for several key reasons. First, they are more likely to be out of the home or supervision of caregivers and more active in the wider community or social media, which increases exposure to many elements of war or terror. Second, they have wider social networks that expose them to greater potential for loss and concern about friends. Third, they are more capable of many actions that could lead to voluntary or involuntary involvement in the situation and thus more likely to be targeted for recruitment or rape. Finally, older youth have much better understanding of the immediate and long-term implications of an unfolding crisis, due to more advanced cognitive skills; they have more abstract and also more realistic fears about the meaning and lasting consequences of war and terrorism (Barber, 2009a; Dimitry, 2012).

Younger children may have lower objective exposure to the broad scope of a disaster due to immature cognition and limited mobility, and the direct efforts of adults to shield very young children from exposure. At the same time, young children are highly dependent on caregivers and sensitive to disturbances in parent function and family routines. Within their small scope, exposure may be profoundly mediated by the exposures or behaviors of their caregivers (J. D. Osofsky, 2011).

Studies also corroborate findings on sex differences (Barber & Schluterman, 2009; Dubow, Boxer, et al., 2012; Masten & Narayan, 2012). Girls are more often targeted for rape and forced sexual service as child soldiers, although boys are targeted as well. In some conflicts, rape is used as a tactic of war, as a weapon of terror and ethnic cleansing. Boys are more often called on to fight in wars and political conflict, either voluntarily or involuntarily, which increases exposure to combat-related violence, injury, death, and capture.

Individual differences in cognition, self-regulation, and risk-taking behavior also would be expected to influence

exposure to danger in the context of war and related violence. Young children may be protected from potentially harmful effects of such individual differences because they are monitored so closely. However, individual differences would be expected to play a larger role in exposures of older children and adolescents. Cautious or fearful youth, for example, would not be expected to engage as often in dangerous activities as bold, sensation-seeking, or impulsive youth (Belsky, 2012; Otto et al., 2007). However, there continues to be a paucity of research on individual differences as determinants of exposure.

### *The Roles of Family in Exposure*

Families, and especially parents and other primary caregivers, have many responsibilities and strategies for protecting their children from harm in the course of development, which are not unique to war and political violence. In many ways, caregivers are “gatekeepers” of exposure, to the degree that is feasible or age-appropriate (Pine, Costello, & Masten, 2005; Qouta et al., 2008). In terms of exposure to war, terrorism, and political violence, parents may actively intervene to regulate exposure in many ways, such as acting as physical shields, moving children to safer places or bomb shelters, supervising child activities, monitoring television and media use, keeping children inside, and discouraging potentially harmful peer friendships. They also may not fully inform young children as a protective strategy. Clearly these strategies will all depend on the development of the children and parents’ perceptions of dangers, as well as the personality (e.g., cautiousness or inhibition) of the parents (Belsky, 2012; DeVoe et al., 2011; Hendricks & Bornstein, 2007; Saraiya, Garakani, & Billick, 2012).

Given their exposure-moderating role, family capabilities and resources would be expected to influence how well the family can reduce exposure. These resources might include economic or social capital to get help or move to safer locations. When parents are depressed or traumatized, or they are disabled by the unfolding crisis situation, they may not be able to protect children as well from exposures. Children or youth who do not have any functional parenting figures in the caregiver/protector role (e.g., caregivers are dead, separated, or disabled) will be at much higher risk for exposure to all forms of danger in wars or conflict (Masten & Narayan, 2012; Masten & Obradović, 2008; Sagi-Schwartz, 2012). Thus, it is not surprising that the UN and many humanitarian organizations emphasize the importance of reuniting children with families or placing them with safe and protective caregiving adults when that

is not possible (Ager, Stark, Akesson, & Boothby, 2010). To date, however, there remains little direct research on the roles of family in regulating exposure during war, terrorism, and violent political conflicts (Gewirtz, Forgatch, & Weiling, 2008).

### **Media**

Concerns about media exposure continue to increase, most likely due to the general escalation in media use including social media in the midst of conflicts. Media exposure is extremely common in mass violence events and this exposure has been linked to symptoms in children as well as adults (Bonanno et al., 2010; Comer & Kendall, 2007; Dimitry, 2012; Eisenberg & Silver, 2011; Masten & Narayan, 2012; Otto et al., 2007; Saraiya et al., 2012). There has been particular attention to media exposure in very young children, although there is growing concern for older youth because they have increasingly unfiltered access to social media and global broadcasts.

To date, research has focused on television exposure. Less is known about the impact of the Internet and virtually nothing is known about the role of social media in propagating terror or vicarious violence exposure. Terrorists may exploit media to spread terror, and all sides of political conflicts utilize media to spread visual images of conflict to promote their causes or perspectives (Martin, 2013). However, emergency responders and governments use media to provide information and instructions to families to reduce fear and panic.

There are broader, international concerns about the role of violence exposure through media on child development, particularly with respect to the effects of playing extremely violent video games, using websites that incite violence, and cyberbullying (Anderson et al., 2010; Gentile & Bushman, 2012; Lam, Cheng, & Liu, 2012; Romer, Bagdasarov, & More, 2013). Data mining of social media and Internet traffic to detect emerging threats or danger zones and intercede to prevent mass violence or cyberbullying is now underway (Dinakar, Jones, Havasi, Lieberman, & Picard, 2012; Ptaszynski et al., 2010). More research is needed on the roles of contemporary media on child exposures to war and political violence and the potential of media for prevention and intervention.

### **Community, Cultural, and Geopolitical Differences**

Wars and political violence have characteristics related to the nature and dynamics of the conflict itself, the local community and cultural traditions, and geopolitical parameters. Dangers for children would be expected to vary in relation

to conflict-related features, the economic and social situation in the community, and the political situation.

The social ecology of war and political conflict in relation to the experiences of children, youth, and families is gaining more attention, though research remains limited. For example, investigators have contrasted the socioeconomic, political, cultural, and daily life experiences of Palestinian, Israeli-Jewish, and Israeli-Arab children living in Gaza, the West Bank, and other regions of Israel, and they have studied the effects of the Palestinian-Israeli conflict on children and youth (Barber, 2009b; Boxer et al., 2013; Dimitry, 2012; Dubow, Huesmann, et al., 2012). Exposures vary by region and ethnic group within region.

Based on data from their longitudinal study of Palestinian and Israeli youth, Boxer et al. (2013) suggested that differences in ethnopolitical violence at the level of social ecology influence the degree of violence exposure of youth living in those contexts and have effects over time on the development of aggressive behavior, particularly during late childhood and early adolescence. They tested a model grounded in Bronfenbrenner's (1986) ecological theory, employing a cohort sequential design where they collected data over three waves and 3 years, beginning with children who were 8, 11, and 14 years old. This study represents a unique, longitudinal analysis of multilevel dynamics linking political violence at the macro level to violence in child microsystems (community, family, school) to individual child aggression. Findings from this study are consistent with cascading effects of violence across ecological contexts. Ethnopolitical violence in children's exosystems was associated with increases in children's aggressive behavior via the negative effects on children's microsystems, including violence in community, family, and school contexts.

### **Variations in Response: Mediating and Moderating Processes**

Research published in this new millennium supports many of the classic findings about the responses of children to different forms of political violence, while also building a more nuanced database. In this section, we describe new evidence pertinent to understanding processes that may explain variations in how children respond to mass-violence exposure.

#### ***Dose-Response Gradients***

Dose remains a major determinant of response variation. Numerous studies have observed a classic linear pattern of

response (e.g., posttraumatic symptoms) rising as a function of exposure dose, although there is growing attention to nonlinear response patterns (Barber & Schluterman, 2009; Eisenberg & Silver, 2011; Masten & Narayan, 2012). The meta-analysis by Furr, Comer, Edmunds, and Kendall (2010), which included terror events (but not war) among the acute disaster studies reviewed, found that posttraumatic stress symptoms in children were related to greater overall loss of life, closer physical proximity of exposures, and death of loved ones or friends. Dimitry's (2012) review of findings from studies of armed conflict in the Middle East also found consistent evidence of dose-response gradients, with number of exposures and proximity to life-threatening experiences associated with a wide variety of emotional and behavioral problems and risk-taking behaviors in youth.

Studies also implicate the importance of context before and after mass-terror events for understanding dose. Children exposed to 9/11 with previous trauma histories had more posttraumatic stress symptoms than children with lower levels of preexisting trauma (Eisenberg & Silver, 2011). Adolescents exposed to ongoing political conflict had more PTSD symptoms, substance use, and violence perpetration if they had been maltreated in childhood (Schiff et al., 2012). These findings echo patterns from sensitization or depletion models.

Children's subjective experience of exposure or trauma also is associated with distress and other symptoms in the aftermath of conflict and terror (Bonanno et al., 2010; Comer & Kendall, 2007; Dimitry, 2012; Eisenberg & Silver, 2011). Perceptions of threat and danger in children may be influenced by many factors (discussed further on in the chapter), but caregivers may play a particularly salient role. Children "read" danger in the facial expressions and reactions of trusted attachment figures and model their behavior (Gewirtz et al., 2008; Masten, Best, & Garnezy, 1990; Muris, Steerneman, Merckelbach, & Meesters, 1996). Research on children in war zones, hostage situations, and during or after bomb and terror attacks often has found that child symptoms are related to parent symptoms. This could occur for many reasons, but partly may reflect the influence of frightened parents on child perceptions of danger.

Interest in unpacking dose-response gradients is evident in many studies of war and terror that have examined whether certain experiences have greater effects. As indicated above, studies of child soldiers suggest that killing other people (which may include being forced to kill family members or friends), violent rape, and violent injury may

be especially traumatizing. Experiences of direct violence, traumatic death, death of parents, and ongoing trauma after an acute exposure or within the recovery context also appear to be particularly traumatizing for children, across different situations of trauma in childhood, including war and terror.

### *Individual Differences and Developmental Timing*

Research continues to indicate that age, or the developmental differences across age (e.g., in comprehension or self-control skills), affect exposure severity and responses to war and political violence. However, it is difficult to interpret effects by age because exposures and protections in war and terror situations are often so different for infants and very young children compared to older children.

There are good reasons to expect that developmental timing of extreme trauma would be critical given advances in knowledge about sensitive periods for brain development and stress-related programming effects. Yehuda and her colleagues have reported such timing effects in offspring of mothers who were pregnant during traumatic experiences of war or terror (Yehuda & Bierer, 2009). Mothers who were pregnant during 9/11 and developed PTSD had lower cortisol levels, as did their infants, compared to nonexposed mothers and mothers who did not develop PTSD following 9/11. Maternal exposure to 9/11 during the third trimester, and resulting PTSD, yielded the strongest effects (Yehuda et al., 2005). This pattern is consistent with the possibility that prenatal stress exposure alters the biological systems that regulate physiological stress in children. Yehuda and colleagues (Yehuda et al., 2007; Yehuda et al., 2008) have studied children of Holocaust survivors, finding a similar pattern of lower cortisol in children of parents with PTSD compared to children of Holocaust survivors without PTSD and parents not exposed to the Holocaust. They also found that maternal (but not paternal) PTSD in Holocaust survivors was related to PTSD risk in the children. These findings are congruent with models of gene-expression (e.g., for glucocorticoid genes) related to maternal stress and its effects on the fetus, with potentially lifelong health effects (Hertzman, 2012; Yehuda & Bierer, 2009).

There also may be developmentally differentiated responses of other people to child victims of war and terror. In the study of returning child soldiers described above, former child soldiers who were younger were more accepted than older youth when they returned home (Betancourt et al., 2010).

Adolescents' intensification of identity, autonomy, spirituality, and/or ideology also may interact with exposure

to war, political violence, and terrorism. Barber and others who have studied youth participants in political conflicts in Ireland, the Balkans, and the Middle East (see Barber, 2009a) have noted the salience of meaning-making systems of belief about self and the purpose of conflict for the psychological well-being of the youth involved. Many of the youth engaged in the Intifada uprisings expressed pride and a sense of a larger purpose in their involvement (Barber, 2009b). Child soldiers, even those coerced into service, may redefine themselves as leaders in an important cause. Adults may exploit powerless youth's yearning for a sense of control and meaning, thereby promoting a sense of identity or commitment to the cause and rewarding child soldiers who fall into line with the goals of the group or its leadership.

Based on intensive and longitudinal study of former child soldiers from Mozambique, Boothby, Crawford, and Mamade (2009) noted that in the recovery center, boys who had spent 6 months or less as a child soldier viewed themselves as *victims* of RENAMO (Mozambique National Resistance), whereas boys who had spent a year or longer as child soldiers described themselves as *members* of RENAMO. Examples of comments by the latter group include: "I could have escaped but didn't because I had a good position"; "I first served as his personal servant. Then he made me chief of a group of other boys. I had power" (p. 244).

Findings related to sex differences continue to be complex in studies of violent political conflicts. It is difficult to sort out these differences when the nature of exposures and their cultural meaning vary for males and females. The most widely reported sex difference in the literature on mass trauma is the finding that females exhibit or report more internalizing symptoms including anxiety, depression, distress, or trauma symptoms, as well as PTSD (Barber & Schluterman, 2009; Furr et al., 2010). However, this finding is not universal, with some studies finding no significant differences in responses of males compared with females (e.g., El Zein & Ammar, 2011). Other studies have found no significant differences in rates of PTSD even when girls report more internalizing symptoms (McMullen, O'Callaghan, Richards, Eakin, & Rafferty, 2012; Reed et al., 2012). To complicate matters further, one study after terrorist attacks in Israel found that girls reported more symptoms of PTSD and fear, but boys reported PTSD symptoms that were more severe (Laufer & Solomon, 2009).

Evidence also continues to support the longstanding observation that males show more externalizing problems than females in extreme adversity (e.g., Dimitry, 2012).

Cultural and social roles and expectations for males in mass violence may differ from girls in ways that might increase the likelihood of aggression or violence (Belsky, 2012). Male youth also are often engaged more directly in battle, recruited and trained to fight, and expected by their cultures or families to show strength or heroism involving aggression (Dimitry, 2012; Qouta et al., 2008).

In the broad literature on child responses to extreme adversity, individual differences in child cognitive skills, personality, and coping capabilities have been studied in relation to child responses and outcomes (Cicchetti, 2013b; Masten, 2007, 2013; Zimmer-Gembeck & Skinner, 2011). Studies focused on war, political violence and terror continue to examine individual differences that may exacerbate or ameliorate child responses to severe adversity, although research in this area remains limited (Dubow, Huesmann, et al., 2012; Eisenberg & Silver, 2011; Masten & Narayan, 2012). Given rising interest in the neurobiology of resilience, there is notably limited data on possible moderating effects of individual differences at the biological level, although there are some studies of individual differences in cortisol responses before and after children's exposure to trauma (Delahanty & Nugent, 2006; Vigil, Geary, Granger, & Flinn, 2010).

Cognitive skills can be a double-edged sword, in the sense that more reflective or thoughtful children may be more aware of the scope of war or terror, perceive more direct threat, or have empathy for the victims, while at the same time they are better at problem-solving, finding help, or eluding capture. Studies of youth in Palestine have suggested that cognitive capabilities, such as creativity and mental flexibility, may be protective in contexts of political conflict (Qouta et al., 2008). Refugee children who can recruit skills of cognitive restructuring and effective emotional expression may adjust more positively to the recovery context. Furthermore, less guilt-related cognition, as well as less vindictiveness and vengefulness, were noted to be important in the resilience processes of child soldiers (Klasen et al., 2010).

Self-regulation skills hold particular interest because they play a key role in everyday management of stress and goal-directed action, have been implicated in many studies of resilience in children, and have potential as targets for intervention (Eisenberg & Silver, 2011; Masten & Coatsworth, 1998; Zelazo & Carlson, 2012). In one of the few studies with preconflict data, preschoolers were assessed in Kenya before and after a short-term, sudden-onset political conflict (beginning in December, 2007 and lasting for 3 months; Kithakye, Morris, Terranova, &

Myers, 2010). Teachers rated child adjustment before and after the conflict. After the conflict, effortful control skills (i.e., attention focusing, attention shifting, and inhibitory control) and trauma exposure were assessed in 84 children Ages 3 to 7. After statistically controlling for preconflict behavior, effortful control skills were associated with less aggression and more prosocial behavior and were protective for more positive postdisaster adjustment.

Eisenberg and Silver (2011) reviewed the evidence on coping styles and behavior in 9/11. Findings are overall sparse and inconsistent. There was some evidence that active and voluntary efforts to cope through problem-solving, positive thinking, distraction, and other strategies were associated with fewer stress symptoms than either involuntary engagement (e.g., rumination) or involuntary disengagement (e.g., numbing, avoidance).

Studies of hope, optimism, faith, and beliefs about the meaning of life in children in war and political conflict have been rare, although these indicators of subjective well-being and cultural connectedness have been included in several studies (Dimitry, 2012; Masten & Narayan, 2012). Youth who survive war, life as a child soldier, and related traumatic experiences may gain a sense of pride in their survival or activism. Positive beliefs and feelings, self-confidence, and self-efficacy often accompany positive behavior under many circumstances, including recovery after mass trauma experiences. However, it is difficult in studies with limited preconflict data to know whether positive attitudes and beliefs contribute to or stem from positive recovery.

### *Mediating and Moderating Processes in the Family*

For many decades, investigators have consistently observed that children's adjustment and recovery following exposure to war or terrorism are closely linked to the availability and responses of their caregivers. Parent-child relationships are a key adaptive system that not only shields children from the aftermath of trauma but also influences how children react to, process, and recover from traumatic events. Positive parenting practices, characterized by warmth, support, and structure, are associated with children's positive adjustment and resilience following war and political conflict (Dimitry, 2012; Gewirtz et al., 2008; Qouta et al., 2008). Additional aspects of parenting may be critical in regards to certain types of exposure. Media exposure, discussed earlier, provides an example of parenting practices that can mitigate risk, when parents actively increase their monitoring and restriction of child exposure to upsetting images on television or other media (Saraiya et al., 2012).

Parents who facilitate communication about a traumatic event, whether children experienced it directly or through media, may also help children to more effectively process traumatic reactions (Gil-Rivas, Silver, Holman, McIntosh, & Poulin, 2007; Otto et al., 2007).

Moderating effects of parenting (indicated by significant interaction effects) have been observed in some studies. Although studies on the protective mechanisms of parenting in war and terrorism remain limited (Gewirtz et al., 2008), positive parenting, including consistent praise and discipline, had a moderating effect on posttraumatic stress symptoms for Israeli and Palestinian youth exposed to political conflict who were studied longitudinally. Children who received low levels of positive parenting had more PTSD symptoms (Dubow, Huesmann, et al., 2012).

Generally, negative parenting may have damaging effects on children following exposure to war, terrorism, and political conflict. After 9/11, negative parenting, including impatience and parenting difficulties, predicted children's elevated PTSD symptoms (DeVoe et al., 2011). Other risky aspects of parenting for increased PTSD symptoms include anxious attachment between parents and children (Finzi-Dottan, Dekel, Lavi, & Su'ali, 2006) and overprotective, controlling, or inconsistent parenting (Comer et al., 2010; Hendricks & Bornstein, 2007). Such findings indicate that quality of parenting and the parent-child relationship can serve as both powerful protective factors for child adjustment and significant sources of risk.

Severe exposure to trauma can undermine the functioning of parents. It is therefore not surprising that mental health problems in parents, such as PTSD and depression, predict worse adjustment in children (e.g., Barber & Schluterman, 2009; Chemtob et al., 2010; Feldman & Vengrober, 2011). After the 9/11 terror attacks, child adjustment in some cases appeared to be more strongly influenced by parents' degree of exposure rather than children's own exposure (Hoven et al., 2005). This transmission of stress reactions within families also can work both ways. Parents have exhibited increased PTSD due to exposures their children endured alone, such as during the school hostage crisis in Beslan (Scrimin et al., 2006).

Perhaps the most extreme and compromising situation for children occurs when parents are killed or injured; however, even these situations have differential effects on children. For example, in contexts of ongoing war, maternal death directly predicted child maladjustment but paternal death indirectly predicted child maladjustment through increased vulnerability to war-related stressors (Drury & Williams, 2012).

Other changes in the family system also can be harmful for children's adjustment, through escalating family violence or interparental conflict. In Belfast, Ireland, political violence in the surrounding community indirectly affected children's internalizing and externalizing symptoms via the effects of the violence on marital conflict and children's resulting emotional insecurity of the interparental relationship (Cummings et al., 2012). After 9/11, increased marital tension was a salient predictor of children's PTSD symptoms (DeVoe et al., 2011). Tension between two parents may further undermine the recovery context. Single parenting, however, in the aftermath of trauma also may increase vulnerability if parents are struggling to manage their own and their children's stress reactions without the support of another parent (Kaniasty, 2011).

In sum, changes at multiple levels of family systems, such as parent-child and interparental relationships, can transact and spill over to compromise parent and child individual adjustment and parenting (see Bornstein, Chapter 3, this *Handbook*, this volume). The extent of vulnerability within family systems as well as the potential for child recovery and resilience may be graded, and depend on the extent of parent and child exposure, factors influencing relational change, and resulting psychopathology.

### ***Recovery Context***

Many reviews have emphasized the crucial importance of the recovery context for the immediate and long-term well-being of children, youth, and families (Masten & Narayan, 2012). Research also continues to support the importance of *normalizing* everyday life for children and families, by resuming school, providing opportunities to play and socialize, restoring family routines, and supporting cultural or religious practices (Barber, 2009a; Franks, 2011; Masten & Osofsky, 2010). Boothby et al. (2009) described key components of the rehabilitation efforts for the 39 child soldiers brought to the Lhanguene Center in Maputo, the capital city of Mozambique, for recovery and then reintegration with relatives. Most were accepted by their communities, and all went through traditional ceremonies on their return, which cleansed them of what they may have done during the war. Boothby and colleagues described the importance of these rituals for both the individual boys and the communities in the process of rebuilding community trust and cohesion (2009). These ceremonies signified forgiveness or relief from shame. The recovery of child soldiers also appears to depend on resuming normal life. This might include going to work in the fields or to school; the essence appears to be returning

to normal life and a chance to be, in the words of one child soldier, "like everyone else" (Boothby et al., 2009, p. 248).

Similar observations have been made in refugee camps and resettlement efforts. War and political violence can lead to years of displacement either within the conflict region or other locations. For children, returning to country of origin, or, conversely, assimilating into a new culture, and feeling accepted again within the school or peer context can be critical factors in promoting positive readjustment (Fazel et al., 2012; Reed et al., 2012).

### **Refugees and Resettlement**

Refugee children represent a heterogeneous population in terms of their traumatic experiences and recovery needs, yet many have endured the dual risk of exposure to trauma and loss of their homes. Systematic reviews have summarized the experiences and needs of refugee children in low-, middle-, and high-income countries (APA, 2010; Fazel et al., 2012; Reed et al., 2012). The most typical profile of a refugee child is to have experienced a host of traumatic events pre- and postdisplacement and to be relocated for long periods of time in unsafe refugee camps in low- or middle-income countries. Only a small percentage of displaced children, approximately 0.5 of the total 18 million that are currently estimated to be displaced, are sent to high-income countries (Reed et al., 2012), including the United States (APA, 2010).

Many refugee children have been exposed to multiple types of atrocities, including exposure to violence in their countries of origin, separation from or loss of caregivers, forced displacement from their homes, and resettlement in refugee camps where levels of rape, child maltreatment, and deprivation of basic needs are high. Investigators have noted that number of lifetime exposures, including pre- and postmigration experiences, may be the best reflection of overall dose of exposure (Fazel et al., 2012; Reed et al., 2012). Experiences of continued mobility or discrimination following resettlement, even to high-income countries, influence adjustment, as do the quality of health care, schools, and community safety. Refugee children who are not accompanied by adults are at elevated risk for long-term psychological maladjustment and postmigration homelessness, delinquency, crime, and prostitution, especially if they are adolescents. Overall, findings indicate that the combination of exposure to violence and displacement has the potential to profoundly disrupt multiple levels of these children's development and ecology, especially if displacement is characterized by chronic instability,

language and cultural barriers, and recovery contexts that are traumatic and low in resources. For refugee children, pathways to risk and resilience largely depend on the quality of recovery contexts, including the quality of family support and resources (Betancourt, Newnham, Layne, et al., 2012; Fazel et al., 2012; Reed et al., 2012).

### Intervention and Prevention Research

Given the diversity of experiences that characterize children's exposure to war, terrorism, and political conflict, the challenges of implementing research in these contexts, and the array of mediating and moderating processes involved, it is not surprising to find that knowledge remains limited on how to intervene effectively. Peltonen and Punamäki (2010) conducted a meta-analytic review of the extant literature on the effects of preventive interventions for children in armed conflict. They reported that only four studies met the gold-standard criteria of random assignment to intervention versus control groups.

Two of these studies were conducted with Bosnian children, although the intervention contexts differed markedly. Dybdahl (2001) implemented an intervention to promote mother-child interactions in Bosnian families displaced or living in refugee villages. The comparison group received only medical care while the treatment group also received an intervention to promote maternal warmth and support to 5- and 6-year-old children. Maternal mental health and child physical health improved more in the treatment group than the comparison group.

Layne et al. (2008) conducted an intervention on adolescent Bosnian students. The control treatment included classroom-based psychoeducation and skills training, while the treatment group also received trauma- and grief-focused group treatment. Both groups reported significant improvements in posttraumatic stress and depressive symptoms, but those receiving the additional group therapy showed further significant improvement in grief reactions.

The other two RCT studies reviewed by Peltonen and Punamäki (2010) found effects of treatment compared to waitlist control groups. In one study, Israeli elementary school children had significantly lower posttraumatic stress symptoms in the treatment group following a school-based intervention with cognitive behavioral therapy elements (Berger, Pat-Horenczyk, & Gelkopf, 2007). In the other study, group interpersonal psychotherapy resulted in significantly fewer depressive symptoms in Ugandan adolescent

girls (but not boys) compared to the controls (Bolton et al., 2007).

Since the Peltonen and Punamäki (2010) review was completed, a number of additional school-based RCTs have been conducted. A teacher-based cluster-RCT intervention was conducted with Israeli children ages 8 to 13 randomized by classroom. Treatment included elements of cognitive-behavioral therapy (CBT) and promoting coping skills, perceived safety, and creative expression (Qouta, Palosaari, Diab, & Punamäki, 2012). Compared to waitlist controls, boys showed significant reductions in PTSD symptoms. Girls also showed substantial reductions in PTSD symptoms but only if they displayed lower levels of peritraumatic dissociation at baseline.

A classroom-based cluster RCT for Indonesian children (Ages 7 to 15 years), incorporating CBT techniques, trauma narratives, psychoeducation, and creative expression, contributed to improvements in PTSD and hope (Tol et al., 2008). Two additional school-based interventions, one in Nepal (Jordans et al., 2010) and one in Sri Lanka (Tol et al., 2012), utilized aspects of CBT and creative expression or play experiences and did not find significant improvements in primary psychiatric indicators. However, both studies reported some evidence of sex differences on other treatment indicators, including general improvements in boys' aggression and anxiety symptoms and girls' prosocial behaviors (Jordans et al., 2010; Tol et al., 2012).

Another school-based psychosocial RCT, involving cognitive-behavioral and creative expression applications, was conducted with war-exposed Indonesian children aged 8 to 13 (Tol et al., 2010). This study is unusual in its focus on positive adaptation, finding improvements among treated compared to control participants in positive coping strategies, hope, and support from peers during play. In relation to PTSD symptoms, Tol et al. also found a sex by treatment interaction: girls exhibited greater decreases in PTSD symptoms than boys as a result of the treatment. Generally, however, findings regarding sex differences should be interpreted with caution until replication studies in various contexts have been conducted.

Other RCT studies also include interventions outside of the school domain that focused on adapting evidence-based treatments. These include two RCTs conducted with former child soldiers. Ertl, Pfeffer, Schauer, Elbert, & Neuner (2011) adapted narrative exposure therapy (NET) to youth aged 12 to 25 years in Uganda. NET is a short-term treatment that combines techniques of testimonial therapy

(i.e., autobiographical narratives) and trauma exposure therapy for PTSD (Neuner et al., 2008). Compared to a group that received academic assistance and supportive counseling and the waitlist control group, children in the NET condition displayed significant decreases in PTSD symptoms. These effects were observed using therapists from the communities with no mental health or medical training backgrounds.

Also conducted in Uganda with former child soldiers, Betancourt, Newnham, Brennan, et al. (2012) randomly assigned 14- to 17-year-old youth, approximately one half whom had been abducted by the Lord's Resistance Army, to receive interpersonal therapy in a group format (IPT-G), creative play exercises, or a waitlisted treatment. They found that abduction status interacted with sex to predict treatment outcome, such that IPT-G was most effective in decreasing depression in abducted girls. Decreases in depression were also noted in abducted boys, but not in nonabducted boys.

Additional studies supported the strategies of NET for children (KIDNET), adapted from the narrative exposure therapy techniques described above (Neuner et al., 2008), and trauma-focused CBT. Implementation of KIDNET compared to a waitlist control group was effective in reducing the PTSD symptoms of refugee children exiled in Germany from organized violence in their countries of origin (Ruf et al., 2010). Finally, although not an RCT, a needs-based study conducted by the Child and Adolescent Trauma Treatments and Services Consortium (CATS Consortium, 2010) through the New York State Office of Mental Health to target 9/11-exposed children examined the differential effects of trauma-focused or brief CBT depending on children's symptom levels. Trauma-focused CBT was found to be effective in reducing children's moderate to severe trauma symptoms, and brief CBT was found to reduce children's mild trauma symptoms, which highlights the promise of interventions tailored to level of initial impairment.

Innovative strategies, incorporating a breadth of techniques, are also emerging with promising results. A teacher-delivered, manualized intervention for children, Enhancing Resiliency Among Students Experiencing Stress (ERASE-Stress) was conducted following chronic exposure to rocket attacks in Israel (Berger, Gelkopf, & Heineberg, 2012; Gelkopf & Berger, 2009). This program resulted in significant improvements in PTSD symptoms, somatic problems, functional impairments, and anxiety

levels. In addition to successful implementation during the ongoing threat, strengths of ERASE-Stress included the breadth of components, cultural adaptations, and fidelity checks during teacher delivery (Berger et al., 2012).

### *Stress Inoculation Training*

The majority of RCTs for mass violence exposures have focused on the aftermath of conflict or terror attacks. However, in regions at high-risk for conflict, it is possible to implement prevention efforts that can be subsequently evaluated in the event of an upsurge of violence or attack. These efforts are conceptualized as stress-inoculation training (SIT). An example is provided by intervention in areas of Israel characterized by frequent rocket attacks (Wolmer, Hamiel, & Laor, 2011). School-based, teacher-led training for children aged 8 to 12 included manualized exercises in coping enhancement, stress management, affect regulation, and processing of experiences. Three months later, there was a surge in shelling, Operation Cast Lead, in the region. Subsequently, PTSD symptoms among students at six schools who received the training were compared with students at six schools with the same level of exposure who did not receive the training. Students in schools that received this preventive intervention had significantly fewer PTSD symptoms.

There is considerable advancement in knowledge from the increasing number of high-quality intervention studies implemented in regions affected by political conflict. It is striking that so few of these studies have targeted the needs of parents, given the widespread agreement on the importance of positive parenting as a protective system for children. However, in light of the challenges of conducting this type of work, it is understandable that the priority has been on targeting children. There also continues to be a discrepancy between the number of children affected by war and political conflict that need interventions for mental health and the relative scarcity of sound intervention studies. Of necessity, many humanitarian interventions to help war-affected children and youth continue to be based on a combination of evidence and pooled wisdom from experience (APA 2010; Masten & Narayan, 2012).

### *Preventing War and Promoting Peace*

There is increasing attention to the broad goals of promoting conflict resolution and peace, in conjunction with preventing war and ongoing conflict, through programs or

education for children and youth (Punamäki, 2009; Smith, 2010; UNICEF, 2009). UNICEF provides teaching materials on “Peace Education” for children and video examples of activities, such as sports, intended to reduce conflict and promote understanding among children from regions in conflict. These efforts range from general attention to children’s rights or affording children and youth a voice in resolving conflicts to specific efforts to prevent youth violence by training younger children in self-control, empathy, or other qualities to reduce the probability of violence involvement. Efforts to reduce intergroup conflicts in schools among different ethnic or cultural groups or “sides” in an ongoing conflict could also be viewed as a peace-promoting strategy (Spiel & Strohmeier, 2012). An important venue for future research may be to develop and test the effectiveness of programs to promote peace and reduce intergroup violence.

## CHILDREN IN NATURAL AND TECHNOLOGICAL DISASTERS

Since the turn of the new century, millions of children and families have faced natural and technological disasters. Research and reports from the field continue to indicate that most children, given adequate protection and support, will show resilience following disasters. However, exposure to prolonged or complex disasters can result in lingering psychological effects on child development. (Kessler, Galea, Jones, & Parker, 2006; H. J. Osofsky, Osofsky, Kronenberg, Brennan, & Hansel, 2009; Weems et al., 2007). Large scale, complex disasters, such as Hurricane Katrina (2005) or the Fukushima Daiichi nuclear disaster following the 2011 earthquake and tsunami in Japan, which cause massive disturbances across many system levels, are expected to have significant impacts on children over decades, if not multiple generations. Lessons and information gleaned from the *Exxon Valdez* oil spill (Gill, Picou, & Ritchie, 2012; Wohlforth, 2010) suggest that the vulnerability of children and families, as well as whole communities, to the psychological, social, economic, and ecological consequences of these technological disasters can extend well into the future.

Some major disasters occur with very little warning but cause large scale destruction, as did the massive “megathrust” Sumatran-Andaman earthquake in Indonesia on December 26, 2004, that triggered major tsunami waves in the Indian Ocean. Over 200,000 people were killed and most were caught by surprise because there were no

tsunami-warning systems in place. In this kind of situation, the main parameters of exposure are determined by the characteristics of the disaster itself, including magnitude and the individual’s proximity to the epicenter. Magnitude can be indexed by physical characteristics (e.g., “moment magnitude” or, formerly, the Richter scale, of an earthquake; level F1 to F5 of a tornado), death toll, or scope of destruction path. By all these indicators, this earthquake was one of the worst disasters in recorded history. Parents may not have time to connect with children, resulting in separations, and lost or unidentified children.

Other natural disasters come with more warning to regions long-accustomed to these events. Exposure to relatively “expected” disasters may vary by differences in community, family, or individual characteristics, as well as the features of the unfolding disaster itself. Families make choices about whether or not to evacuate and more advantaged families may have additional options. Poverty also could relate to living in more dangerous regions or areas prone to storm surges, wildfires, or hurricanes (J. D. Osofsky, Osofsky, & Harris, 2007). Child exposure would be expected to relate to caregiver exposure and family and community affordances.

Large-magnitude disasters often trigger a cascade of catastrophic events that increase cumulative disaster dose. For instance, Katrina was compounded by the collapse of the levee system as well as human error during the response (Knabb, Rhome, & Brown, 2006). The earthquake and subsequent tsunami that struck Japan on March 11, 2011 caused a meltdown of the Fukushima Daiichi nuclear power plant, resulting in a “level 7” (highest level) nuclear disaster (Sugimoto, Krull, Nomura, Morita, & Tsubokura, 2012; Watanabe, 2012) and what has been called a “triple catastrophe” (Bromet, 2011). In this case, exposure effects are still unfolding and there are little data yet available on the effects of this complex disaster on children and families. However, long-term generational consequences are expected. Additionally, in Japan, radiation exposure carries special significance in a society profoundly affected by the nuclear bombs dropped on Hiroshima and Nagasaki (see Bromet, 2011; Lifton, 1967/1991).

Disasters, like war and political violence, can generate large numbers of displaced families and children, resulting in temporary housing, multiple moves, and permanent relocation. Many people across the world watched the media broadcasts of the relocation and recovery processes following Katrina, including emergency shelter in the Superdome, temporary housing on ships, the challenging conditions of prolonged residence in “temporary” trailer

parks, and the relocation of many families to other states (J. D. Osofsky et al., 2007). In Japan, a large area around the Fukushima nuclear power plant was contaminated with radiation, and the radius of the danger zone expanded as the crisis unfolded (Sugimoto et al., 2012). These situations pose ongoing risks, with uncertain dangers for families, children, and pregnant mothers.

Many aspects of the recovery context matter for response to natural and technological disasters, including the actions of individuals, families, communities, societies, and global agencies to respond and support recovery, discussed further below. Disasters like Katrina and the earthquake/tsunami events of 2004 in Indonesia and the Indian Ocean and 2011 in Japan elicit responses on many levels, from local to international. How children fare depends on the actions of many people and systems, as well as individual differences in the children themselves.

### Variations in Exposure and Response

Many child survivors of large-scale disasters experience adversities similar to children affected by large-scale political conflicts, including losses of parents, homes, schools, communities, friends, and overall stability and routines that are important for children's healthy and adaptive development (J. D. Osofsky, 2011; J. D. Osofsky et al., 2007). Much like children exposed to violent political conflict, the ways in which children respond and recover from exposure to disasters vary as a function of the magnitude of exposure, characteristics of the child (including age, sex, and cognitive skills), developmental timing, and the function of family and community as support systems.

### *Dose-Response Gradients*

Studies show that the combination of exposure to natural disasters and the resulting experiences of loss and ongoing stress negatively affect young children's psychological outcomes in diverse ways (J. D. Osofsky, 2011; DeVoe et al., 2011). For example, although children's symptoms of posttraumatic stress generally decrease over time, level of exposure, loss, and ongoing stressors affect the severity and longevity of children's symptoms (McLaughlin et al., 2009; H. J. Osofsky et al., 2009). As demonstrated in a study by Swenson et al. (1996), hurricane-related distress decreased over time for the majority of 2- to 6-year-old children. However, children who had lost their homes as a result of the hurricane or who experienced ongoing family stressors such as a marriage or a death were more likely to have increased levels of posttraumatic stress 14 months after the hurricane.

Proximity effects to the epicenter or areas of greatest destruction have been consistently observed in natural and technological disasters, as noted above. Dose-response gradients following natural disasters may reflect cumulative exposures to disasters, or consecutive, compounding exposures. Data gathered after the 2010 Gulf oil spill in areas previously impacted by Hurricane Katrina and subsequent hurricanes indicate that children's vulnerability to mental health problems may increase with exposure to multiple traumatic experiences and disasters (H. J. Osofsky, Osofsky, & Hansel, 2012). Analyses of over 3,500 elementary and high school students screened in 2010–2011 indicated that 25% met the cut-off for mental health services with significant differences between children living in oil spill affected areas (50% meeting the cut-off) and those living in areas that were not impacted (21% meeting the cut-off; Hansel, Osofsky, Osofsky, Reuther, & Louisiana State University Health Sciences Center Department of Psychiatry, 2011). Evidence from the same research suggests cumulative effects on many parents as well. Children may have been affected indirectly by the functioning of their parents, as well as through direct exposure to trauma. Families, in turn, may be affected by the corrosive effect of lingering devastation on their communities.

For many children experiencing disasters, their once thriving communities, including homes, neighborhoods, grocery stores and playgrounds, often are no longer functional; many children and families experience multiple moves and changes in schools, separation from friends and family members, and elevated interfamilial stress from tension, conflict, and unemployment (Kaniasty, 2011; H. J. Osofsky et al., 2009; J. D. Osofsky et al., 2007; J. D. Osofsky & Osofsky, 2013; Watanabe, 2012). For children impacted by the 2011 triple disaster in Japan, routine life became confusing and upsetting when the simple act of playing outside was either prohibited or severely restricted due to concerns about radiation exposure (Watanabe, 2012). Families may be threatened with severe economic difficulties, evaporation of traditional support systems, and loss of their identities as they must learn to thrive in other communities with fewer economic and health resources. In those communities near the water that depended on fishing for economic survival, the tsunami and nuclear disaster in Japan and the oil spills in Louisiana have threatened the tranquil fishing and wildlife areas and multigenerational ways of coastal living. Investigators of the *Exxon Valdez* oil spill have suggested that long-term effects in youth were closely tied to the broader impact of the oil spill on the

family and community identity, as well as individual identity (Gill et al., 2012; Palinkas, 2009; Picou & Gill, 1996).

### Individual Differences

Similar to the literature on children's responses to other traumatic experiences, variations in response and recovery have been observed in relation to individual differences. However, it is interesting to note that in natural and technological disasters, which are more likely to have acute onset over a large area of exposure, variations in short-term exposure could depend less on individual differences and more on relatively uncontrollable aspects of the disaster. In these sudden-onset disasters, the role of individual differences may play a greater role on response variations or the recovery context than they do in initial exposure.

Studies on response by age generally continue to be mixed. For instance, in a series of studies with children Ages 9 to 15 after the 2004 tsunami in Sri Lanka, younger children exhibited more positive adaptation, defined as more psychosocial competence and less psychopathology, than older children (Catani et al., 2010). These effects held after accounting for cumulative exposure, although generally children who were exposed to more types of trauma fared worse. In contrast, in another study that compared children of three different age groups (Ages 9–11, 12–14, and 15–18), the youngest group of children exhibited the highest levels of PTSD symptoms (Kronenberg et al., 2010). Other studies have found that older children (e.g., teens) may have more depressive symptoms after exposure to a tsunami (Thienruka et al., 2006) and higher rates of PTSD after an industrial disaster (Godeau et al., 2005).

In spite of the mixed findings connecting age and risk for psychopathology, the nature of manifested traumatic reactions may vary by development at time of exposure (Franks, 2011; Narayan & Masten, 2012). For school-age children, common reactions to disasters include anxiety, worry about family and friends, physical complaints, disruptive behaviors, aggression or extreme withdrawal, problems with concentration, mood swings and depression, posttraumatic stress symptoms, and sleep problems including nightmares. For adolescents, in addition to physical complaints, disruptive and high-risk behaviors are common, including interpersonal aggression, school truancy and academic decline, peer problems, sleep disturbances, substance use, and risky sexual behaviors. In the section on interventions, we discuss treatments found to be most helpful with children of different ages.

"Project Ice Storm" is a rare study designed to examine the effects of prenatal maternal stress on child outcomes in

regard to developmental timing of exposure. Investigators examined the birth outcomes of 172 children whose mothers were pregnant during or shortly before a major ice storm in Canada in relation to normative data and individual differences (King & LaPlante, 2005; Dancause et al., 2011). Results were consistent with the possibility of modest but complex effects of maternal stress on birth outcomes (e.g., length, weight, head circumference), depending on child sex, exposure timing, and mothers' perceived stress levels.

Sex differences also continue to present a mixed picture. In one study of an industrial disaster, girls exhibited higher rates of PTSD than boys, regardless of whether they were preadolescent or adolescent age (Godeau et al., 2005). Following a cyclone in India, no significant sex differences were noted in overall rates of PTSD, depression, or anxiety; however, sex differences in specific traumatic responses were observed, such that girls perceived more guilt, whereas boys exhibited more avoidance and intrusive memories and dreams (Kar & Bastia, 2006). In the second and third years after Hurricane Katrina, girls were also generally observed to have less adaptive recovery patterns, characterized by more symptoms of PTSD and depression than boys (Kronenberg et al., 2010; Weems et al., 2010). However, another study after Hurricane Charley, a strong Category 4 hurricane that struck Charlotte County, Florida, in August 2004, found that girls only exhibited elevated PTSD compared to boys after the first but not the second year (La Greca et al., 2010).

Other studies have further complicated the sex differences picture by finding that girls may perceive greater threats or distress than boys but not actually display different levels of symptoms (McDermott, Lee, Judd, & Gibbon, 2005; Norris, Friedman, Watson, Byrne, et al., 2002). Taken together, results suggest that although females may generally be at higher risk for PTSD and related internalizing symptoms following traumatic events, there are a host of other factors that influence variations in observed responses by sex, including cognitive and perceptual influences, parental responses, cultural influences, and biological factors (Furr et al., 2010; Proctor et al., 2007; Vigil et al., 2010).

The individual response to a disaster may vary depending on the type of disaster. For example, the majority of the literature on hurricanes indicates that children are at high risk for symptoms of depression, anxiety, and PTSD (Goenjian et al., 2001; Kessler et al., 2006; H. J. Osofsky et al., 2009; J. D. Osofsky et al., 2007). A number of disaster studies have documented symptoms of PTSD in children who have experienced natural disasters, including earthquakes, tsunamis, and hurricanes (Goenjian et al.,

2005; John, Russell, & Russell, 2007; Kolaitis et al., 2003; Piyasil et al., 2007). Many of these studies have reported comorbid symptoms of depression in children following natural disasters. Although there is overlap in PTSD and depression symptoms, including anhedonia, sleep difficulties, and problems with concentration, irritability, and restricted affect, research has demonstrated the distinct presence of each disorder following disasters (Goenjian et al., 2001; Kolaitis et al., 2003; Roussos et al., 2005). For example, a study of PTSD and depression in children ages 7 to 17 who experienced a supercyclone in India found that most children with PTSD did not meet criteria for depression, and many children with depression did not meet criteria for PTSD (Kar et al., 2007).

Individual differences in perceptions of threat may also affect rates of child psychopathology following natural disasters. One study found that children exposed to a tsunami developed higher rates of PTSD if they perceived high levels of threat, fear, or danger to themselves or their family members (Thienruka et al., 2006). Similar relations between perceived threat and PTSD symptoms were also observed after a bushfire disaster (Yelland et al., 2010).

Individual differences, such as aspects of cognitive functioning, also may be protective for postdisaster recovery. Children who perceived themselves as competent had more positive recovery patterns after Hurricane Floyd (Cryder, Kilmer, Tedeschi, & Calhoun, 2006). Similarly, a study conducted after Hurricane Katrina found that children's constructive thoughts about the event contributed to posttraumatic growth. Interestingly, negative and ruminative thoughts also were associated with more positive outcomes, perhaps because of the meaning making that occurred (Kilmer & Gil-Rivas, 2010). Another study conducted in the aftermath of Katrina found that children's strong effortful control abilities buffered them from PTSD symptoms (Terranova, Boxer, & Morris, 2009). Certain cognitive skills may also serve as protective and vulnerability factors depending on the context and the age of the child. After Katrina, children with stronger theory of mind skills had more coping skills; however, they also experienced more intrusive thoughts (Sprung, 2008).

### ***Mediating and Moderating Processes in the Family***

The recovery processes following natural and technological disasters may be similar to those following exposure to political conflict, and the same family functions appear to play a key role in mediating or moderating child adaptation. Positive parent-child relationships helped to alleviate adolescents' symptoms of PTSD and depression following a tsunami in Sri Lanka; however, increased

rates of maternal depression compromised adolescents' psychological adjustment (Wickrama & Kaspar, 2007). Aspects of parent-child relationships can also be harmful for children's postdisaster functioning, such that maternal overprotectiveness following a flood in Poland exacerbated children's PTSD symptoms (Bokszczanin, 2008).

The literature also highlights the primary role that parent-child relationships have in buffering children's responses to natural disasters. Proctor et al. (2007) assessed 4- to 5-year-old children who experienced an earthquake and found that their levels of posttraumatic stress were related to extent of exposure, including experiences of physical injury, damage to the home, displacement from home or school, loss of possessions, and financial stressors. The links between exposure and adjustment were moderated by caregiving relationships, including caregivers' levels of stress and positive and negative behaviors with children during play. At high levels of child exposure, however, the protective effects of parenting were not as strong, suggesting that even the protective systems of parenting have limitations. Nevertheless, many children, and particularly young children, are likely shielded from disasters by effective parental protection but show increased vulnerability when caregiver function or parent-child relationships are compromised (J. D. Osofsky, 2011; Proctor et al., 2007; Scaramella, Sohr-Preston, Callahan, & Mirabile, 2008).

### ***Pathways to Recovery and Qualities of the Recovery Context***

Longitudinally, studies have focused on patterns of recovery versus continued impairment and the factors that influence these pathways. H. J. Osofsky and colleagues (e.g., H. J. Osofsky et al., 2012; H. J. Osofsky & Osofsky, 2013) carried out child mental health needs assessments with over 40,000 elementary and high school students between 2005 and 2011 in collaboration with schools in heavily impacted areas following Hurricane Katrina and the Gulf oil spill. Using a modified National Child Traumatic Stress Network (2005) Hurricane Screening assessment measure, they found that self-reports of PTSD and depression symptoms in children decreased over several years, but then increased again after exposure to another hurricane and damaging effects of the Gulf oil spill. Further, Kronenberg et al. (2010) studied recovery patterns following Hurricane Katrina in 387 students Ages 9 to 18 from heavily impacted areas. The vast majority of students (72%) reported being on either stress-resistant pathways or the "breakdown and recovery" pattern. The students reporting breakdown without recovery (23%), and the small percentage (4%) showing delayed breakdown,

endorsed more consultations with mental health therapists, violence in the family and neighborhood, prior losses or trauma, and post-hurricane losses, all of which would make them more vulnerable.

The effects of relocation on symptoms were also studied by comparing 525 students from New Orleans to 270 students from Baton Rouge (80 miles from New Orleans) with matching pre-Katrina zip codes (Hansel, Osofsky, Osofsky, & Friedrich, 2013). Relocated students who had been unable to return to New Orleans had more symptoms of posttraumatic stress and depression. Younger relocated students reported fewer symptoms compared to older students. In those who returned to their same zip code, older students reported fewer symptoms. In addition to illuminating key differences in risk and recovery patterns depending on relocation circumstances and age, this study emphasized the need for school-based services not only in acute disaster areas, but also in areas where survivors are relocated.

Using 3-months post-Hurricane Andrew data of 568 exposed children and latent growth mixture modeling, La Greca et al. (2013) identified three trajectories of posttraumatic stress reactions: (1) resilient (37%), (2) recovering (43%), and (3) chronic distress (20%). Odds ratios further revealed that in comparison to children on the resilient trajectory, children on the recovering and chronically distressed trajectories were more likely to be girls and to report higher anxiety and lower emotion regulation. Further, compared to the recovering trajectory, children in the chronically distressed trajectory had greater odds of reporting high anxiety, less social support, more intervening life events, and more use of poor emotion regulation strategies.

There also is research on the recovery context of communities affected by chemical and technological disasters. Of particular relevance to understanding outcomes following the Gulf oil spill are data from the *Exxon Valdez* oil spill in Alaska in 1989. In both cases, there were deep concerns about the ability to rebuild and continue multigenerational ways of life. Reported mental health problems from qualitative interviews immediately after the Deepwater Horizon oil spill included anxiety, depression, increased use of alcohol and drugs, family difficulties, and indications of the beginning of a “corrosive community” (Palinkas, 2012). The most challenging concerns for families and communities following technological disasters as compared with natural disasters are uncertainty about the future; mistrust of information about the disaster; multiple layers of destruction to environment, property, livelihood, and economy; fears about toxic exposure and

future health problems; lingering traumatic stress from past disasters compounded by economic concerns; and psychological effects of the technological disaster on an already vulnerable community (H. J. Osofsky, Palinkas, & Galloway, 2010).

In summary, there has been progress in understanding children’s reactions to disasters, both in regard to risk factors that predict persistent, long term traumatic stress reactions and protective factors that may mitigate these reactions. There is less progress when it comes to understanding whether (and how) children’s reactions may be effectively reduced via psychological assessment and intervention. Bleaker still is our understanding about whether (and how) targeting risk factors, protective factors, or both may help prevent the development of maladaptive adjustment following disasters.

### Intervention in the Aftermath of Disaster

As discussed throughout this chapter, responding adequately to the psychological needs of children in the aftermath of disasters is challenging. Similar challenges confront investigators who plan to conduct intervention research in these contexts. For example, in the immediate postimpact phase of a disaster, when chaos and distress are intense, a priority is placed on restoring safety, helping loved ones reconnect, and returning toward some semblance of normality (McFarlane & Williams, 2012). With the passage of time, children’s mental health needs may appear on the radar of concerned stakeholders, including parents and teachers. However, addressing children’s needs in the context of RCTs and all that entails (e.g., obtaining informed consent, being randomized to a potentially less effective treatment, completing detailed protocols, and collecting long-term follow-up data) is not a priority of stakeholders seeking help for distressed children (Forman-Hoffman et al., 2013; La Greca & Silverman, 2006; Masten & Osofsky, 2010). Direct service delivery with no “experimental strings” attached is more likely to be desired. In light of these challenges, it is not surprising that the intervention literature on disasters continues to be sparse.

Rolfesnes and Idsoe (2011) conducted a meta-analysis reviewing school-based interventions for PTSD symptoms due to natural or man-made disasters and repeated war exposure, in addition to sudden death of a loved one, car accidents, community violence, or catastrophic illness/injury. Inclusion criteria required studies to use standardized instruments and to have pretreatment (not predisaster)

baseline data. Nineteen studies conducted in nine countries were found, and seven dealt with natural disasters (eight focused on war or political conflict).

Overall, a medium to large effect size (Cohen's  $d = .68$ ) was found for PTSD symptom reduction across the 19 studies, suggesting potential utility of school-based interventions in the aftermath of child trauma exposure including disasters. The promise of CBT procedures was noted, which were the most common elements in the majority of the studies. This observation has been made in earlier reviews as well (e.g., La Greca & Silverman, 2006; Stallard, 2006). Related to this point, Rolfsnes and Idsoe (2011) cited three studies that used other procedures (i.e., play/art, mind-body skills, eye movement desensitization and reprocessing), which yielded promising results. Given that all three of these studies also utilized aspects of CBT, however, more research is needed before conclusions can be reached about the efficacy of these other procedures (La Greca & Silverman, 2006; Rolfsnes & Idsoe, 2011; Stallard, 2006).

Forman-Hoffman et al.'s (2013) review focused on similar types of trauma events, referred to as "nonrelational traumatic events," and required that studies include traumatic stress symptoms or disorders among the outcomes. In addition to school-based interventions, clinic and community based studies were included, as well as pharmacological trials. The review identified 21 psychological and pharmacological trials as either low or medium risk of bias (i.e., free of methodological flaws that would otherwise invalidate the findings). The trials targeted children exposed to natural disasters (e.g., hurricane, tsunami, earthquake), car accidents, terrorism, and war. Close to half of the studies were conducted in countries other than the United States.

Forman-Hoffman et al. (2013) concluded that psychological treatment is better than no treatment following child exposure to nonrelational traumatic events and it does not seem to be associated with iatrogenic effects. The latter conclusion was drawn based on reviewing trials with low to medium risk of bias and that were grounded in theoretical, empirical, or clinical foundational principles. This point is emphasized in light of the growing evidence that critical incident stress debriefing, which encourages child expression of feelings and normalizing disaster responses (Chemtob, Tomas, Law, & Cremniter, 1997), is more likely to be harmful than helpful (Klasen & Crombag, 2012; Rose & Bisson, 1998).

The reviews of both Rolfsnes and Idsoe (2011) and Forman-Hoffman et al. (2013) acknowledged that little

effort has been made to replicate specific treatments across studies. Instead, each study has focused on evaluating a particular "brand" of psychological therapy, though most contain elements of CBT (e.g., La Greca & Silverman, 2006; Rolfsnes & Idsoe, 2011; Stallard, 2006). No positive evidence was found for pharmacological treatments. Both reviews also highlighted several methodological difficulties with the existing research base that make it difficult to draw comprehensive and valid conclusions. These difficulties include small samples; overreliance on child self-report rather than using parent or teacher reports; lack of multimethod (rating scales, interviews, observations) assessments (Silverman & Ollendick, 2005); short-term follow-ups; lack of systematic follow-ups and independent evaluators; and limited information on whether measures were validated in the target populations. Many studies also did not employ manualized treatments or assess treatment fidelity. Much heterogeneity is evident in the inclusionary criteria of studies with respect to baselines levels of post-traumatic stress symptoms and PTSD required for study eligibility. Such heterogeneity poses interpretative challenges: If baseline symptoms are low, it may be difficult to detect improvement.

Three general conclusions about interventions for children in the context of disaster should be highlighted based on these two reviews and related research. First, there is evidence of iatrogenic effects of interventions. Critical incident stress debriefing may lead to harmful effects (Bonanno et al., 2010; Wei, Szumilas, & Kutcher, 2010). In addition, these types of interventions are likely too brief to sufficiently address the multiple, complex, and cascading stressors from disasters, which may last for months or years (La Greca & Silverman, 2006).

Second, observations in the field indicate that psychological first aid (PFA) may be useful for assisting children as well as adults after disaster. PFA was developed for PTSD by the National Child Traumatic Stress Network and the National Center as a low-risk, supportive intervention for the general population following large-scale trauma exposures, and a second edition of this approach is now available (see <http://www.nctsn.org/content/psychological-first-aid>). Although this approach needs a systematic controlled evaluation, the content of PFA is widely regarded as evidence-informed and much more congruent with the literature on children in war and disaster than critical incident debriefing (Bonanno et al., 2010; Masten & Narayan, 2012). Many of the core techniques included in PFA are based on the factors described in this chapter that support children's recovery (e.g., connection with social

support, promoting effective coping strategies). There is a PFA application for cell phones and adaptations for use by schools, religious professionals, medical reserve corps, youth, and families experiencing homelessness.

Third, a number of organizations, including the American Red Cross (2013), the Federal Emergency Management Agency (2012), and the National Voluntary Organizations Active in Disasters (2012), have produced materials to assist parents, teachers, and mental health professionals in their communications with children during the postimpact disaster phase. These materials generally emphasize the importance of encouraging children to express their feelings, fears, worries, and security concerns in developmentally appropriate ways without dwelling on them. Parents, for example, are encouraged to listen to their children and make it possible for them to express feelings through discussions, drawings, storytelling, or journal writing. Emphasis is also placed on restoring children's normal roles and routines. Despite the pragmatic utility of these materials, systematic evaluation is needed here as well.

### *Randomized Controlled Trials*

There has been progress on fielding RCTs of interventions that have been conducted to address children's mental health needs in the aftermath of natural disasters. Although several of these studies were included in Rolfes and Idsoe (2011) and Forman-Hoffman et al. (2013), none were individually discussed in those reviews.

The first and one of the largest RCTs in the aftermath of a natural disaster was conducted by Chemtob, Nakashima, and Hamada (2002) in Hawaii following Hurricane Iniki, which struck the island of Kauai on September 11, 1992. After screening 4258 children in Grades 2 to 6 (around 7 to 12 years old) by self-reports, 248 children were identified as having high levels of trauma-related symptoms 2 years after the disaster. Children were randomly assigned to one of three consecutively treated cohorts (with subsequent cohorts serving as waitlist controls) and within each cohort, to individual or group treatment. Both treatments were manualized and consisted of four weekly sessions on restoring a sense of safety; grieving losses and renewing attachments; adaptively expressing disaster-related anger; and achieving closure about the disaster to move forward. Compared to waitlist control participants, children in the treatment groups reported significant reductions in trauma-related symptoms, which were maintained at

1-year follow-up. The group and individual treatment approaches did not significantly differ.

Despite the absence of a long-term comparison sample and reliance on child self-reports, Chemtob et al. (2002)'s study has high historical significance as the first to screen and intervene with a relatively large population of children two-years postdisaster. They also demonstrated the feasibility and efficacy of a brief school-based, manualized psychological intervention.

After the tsunami of 2004 struck Sri Lanka and resulted in 35,000 deaths, Berger and Gelkopf (2009) conducted a quasi-randomized control trial to evaluate the effects of a school-based intervention. The study included 166 students, Ages 9 to 15, who reported significant levels of tsunami exposure in addition to past trauma exposure. The treatment group received 12 sessions of "ERASE-Stress Sri Lanka," involving experiential group activities, psychoeducation, and coping skills training, compared to a waitlist control group that received a class on religion. Students' functioning was assessed 1 week before and 3 months after the intervention on measures of PTSD and symptoms, depression, somatic problems, functional problems, and hope. Significant improvements were found on all outcome measures for the treatment versus waitlist condition. In addition, no new cases of PTSD were found in the intervention group. Notably also, thoughtfulness was given to adapting the intervention to address the unique cultural characteristics of the community, such as including the traditions by which emotions, pain, mourning, and death are processed and expressed in Sri Lanka culture (Berger & Gelkopf, 2009).

An additional RCT conducted in the aftermath of the Sri Lankan tsunami and during ongoing civil conflict implemented KIDNET (Catani et al., 2009). Thirty-one children Ages 8 to 14 years were randomized to receive KIDNET or a treatment that combined medication and elements of relaxation techniques (MED-RELAX). After six sessions of either treatment, both groups exhibited significant and comparable improvements in symptoms of trauma, a finding that persisted over 6 months. Both forms of treatment were deemed to be effective in this sample, although the authors acknowledged that the lack of control group precluded knowing whether treatment effects were due to treatment or spontaneous remission. This is a challenge in postdisaster environments, where "no intervention" may not be an acceptable option. Under such circumstances, RCTs that include wait-list controls may

be the most practical way to at least be able to differentiate treatment effects from spontaneous recovery.

Following Hurricane Katrina, Salloum and Overstreet (2008) built on past disaster intervention efforts (e.g., by Goenjian et al., 2005) by emphasizing treatment components that targeted grief in addition to PTSD and implementing an RCT just 4 months post-Katrina. Fifty-six children Ages 7 to 12 years who reported moderate to severe levels of posttraumatic stress symptoms were randomly assigned to 10 weeks of manualized individual versus group treatment. Both treatments focused on providing psychoeducation to children about grief and trauma, and assisting children to express thoughts and feelings via drawing, discussion, and writing, and reducing trauma symptoms. Meetings with parents also were held as much as it was feasible. Children were assessed before treatment, immediately following treatment, and 3 weeks posttreatment. Statistically significant improvements were found on all measures over time with no differences found between the individual and group treatments. As in the case of the KIDNET study in Sri Lanka, described above, the absence of a no-treatment control group and the short follow-up make it difficult to rule out spontaneous remission as the reason for the observed “treatment” effects for posttraumatic stress symptoms. Of note, however, the observed effect sizes at post treatment and follow-up exceeded those found by Chemtob et al. (2002). Moderate to large effects also were found for depression and traumatic grief.

In a subsequent study, Salloum and Overstreet (2012) reported the results of an intervention to examine the differential effects of coping skills versus trauma narration in producing positive outcomes among 70 African American children (6 to 12 years). Both treatment conditions included at least one parent session, with follow-up assessments at 3 and 12 months. Results indicated significant improvements in all distress related symptoms as well as social support for both treatment groups through 3 and 12 months, leading the authors to question whether processing trauma was essential for treatment: “It may be that active coping skills to address grief and trauma, without the clinician-directed trauma and loss processing, are mechanisms of change in treatment” (Salloum & Overstreet, 2012, p. 177). This is an intriguing theoretical possibility and perhaps some preliminary mediational analyses would have shed further light on it. The study also might have insufficient power to detect significant differences. Alternatively, as the authors noted, the two conditions may not have been so different

from one another as implemented. Nevertheless, this study provides an important example of moving beyond questions of outcome to questions focused on the processes by which outcomes are produced in interventions. These are critical questions for intervention research in disasters, as well as other forms of trauma, and intervention work more generally (e.g., Kazdin & Nock, 2003; La Greca, Silverman, & Lochman, 2009).

### *Disaster Preparedness*

Many of the studies and reviews described above on disaster discuss “lessons learned” for disaster preparedness. Such recommendations are discussed below. However, there is little published research on the status or the effectiveness of disaster preparedness in regard to children and their families. Existing research is predominantly focused on whether medical facilities are equipped to handle pediatric emergencies in the aftermath of disaster (e.g., Clancy & Kacica, 2012) and on training (e.g., Fox & Timm, 2008). In 2010, the National Commission on Children and Disasters painted an alarming picture of U.S. readiness to meet children’s needs, which has spurred subsequent efforts to improve pediatric preparedness.

## CONCLUSIONS AND FUTURE DIRECTIONS

Disasters and war continue to affect millions of children worldwide as we write this chapter, and there is every reason to believe that extreme adversities will confront untold millions in the future. What have we learned from the science on children in war, terror, and disaster? What do we need to know to improve strategies that reduce risk and promote resilience in terrible circumstances? In this closing section, we summarize the state of the evidence, its translational applications, and implications for future research. We conclude by discussing the potential role of developmentally informed science in the global task of understanding and addressing the consequences of these massive-scale catastrophes for child development.

### *State of the Evidence*

The aim of this chapter was to review the science on children in extreme circumstances related to war and disaster, focusing primarily on studies conducted since the turn of the present century. On the whole, the empirical knowledge

base has advanced in important and informative ways. At the same time, there are notable shortcomings in the evidence to date.

Conclusions drawn from the five decades of research on children in war and disaster during the 20th century, beginning during World War II, have held up well in the studies published during the 21st century. The most salient general conclusions from this literature are as follows:

- Higher exposure doses, both physical and psychological, pose greater risks to child well-being.
- Cumulative risk exposure, including adversities before and after acute war- or disaster-related events, increases risks for maladaptive child function and development.
- Older children typically experience greater exposure due to their awareness and age-related activities.
- Older girls generally report more internal distress while older boys display greater aggressive or disruptive behavior.
- Loss of caregiving due to separation, dysfunction, or death of parents poses particular risks for children.
- The quality of the recovery context at the family and community level influences how well children recover.
- Restoration of routines in family, school, and community are important for recovery of children.
- Given a favorable recovery context, many children fare reasonably well or recover from mass-trauma experiences.

There also have been notable developments that have advanced the science on these themes. Methodologically, there are improvements in the design of many studies, with more longitudinal data, use of multiple methods and informants, and assessments that are more culturally appropriate. Research at multiple levels of analysis, including genetic and neurobiological studies, has expanded. More nuanced studies of exposure and response are beginning to unpack the links between particular kinds of exposure and their timing, with specific parameters of response, uncovering more leads on processes by which extreme adversities affect child development and linger over time. Studies also suggest adaptive and protective processes by which parents, communities, and the children or youth themselves influence the effects of mass trauma on development.

There is growing evidence about the toxic effects of extreme adversity on child development in war and disaster, as well as developmental timing effects, that resemble the evidence from the literature on maltreatment (Cicchetti, 2010, 2013b), poverty (Evans, Miller, Chen, & Seeman,

2012), and other severe forms of adversity (Shonkoff, Boyce, & McEwen, 2009; Shonkoff et al., 2012). Children often show greater trauma symptoms when they have experienced killing, torture, and rape, whether they are victims, witnesses, or perpetrators. Traumatic stress may alter the organization and programming of stress-response systems with long-term consequences for health and vulnerability to future traumatic stress exposures (Pluess & Belsky, 2011). Generally, studies that consider timing effects have gained ground. Such work could shed light on sensitization versus inoculation effects observed in the literature. However, this research is still in its very early stages.

There is more attention to the possibility that dose effects may not always be linear. There may be exposures so high and prolonged in severity that there is a ceiling effect, beyond which point greater exposure does not continue to predict more severe symptoms (the dose-response gradient levels off). The responses of young people to political violence also may shift as conflict increases in duration or severity, with greater engagement and commitment to the cause emerging at high levels of cumulative exposures. These possibilities suggest that nonlinear models of dose-response dynamics may be important for future research.

There is new research on individual child differences in cognitive function, biology, and personality that may influence the experiences and adaptive outcomes of children or youth. Nonetheless, research on neurocognitive and biological processes remains limited, as does research on related genetic or gene-environment interaction effects. Research on the possibility that there may be differential sensitivities to experiences of mass trauma is barely underway. Similarly, there is little study as yet on the role mass-trauma exposure may have on the development of biological sensitivity to context (another developmental timing topic). Moreover, although new studies consider the role of optimism, hope, pride, and faith in the processes that influence how war or disaster engages or affects children and youth, knowledge on belief systems and self-efficacy remains very limited, as does understanding of how neurobiological processes may be linked to these differences.

The roles of child age and sex as mediators and moderators of dose and response appear to be complex. This set of findings serves as a powerful reminder that vulnerabilities and protections are continually changing with experience and development, and they are likely to interact with biological and cultural differences related to sex.

New evidence delineated throughout this chapter corroborates the central role of families and especially parents

in the experiences and responses of children to war and disaster. Yet, given the longstanding recognition about the importance of caregivers in the exposures and responses of children, observed since the very beginning of work in this research domain, there is not as much focus on family roles and functions in this literature as one might expect, either in naturalistic studies or intervention research. These gaps extend from research on parents as role models to their mediating or moderating influences on the effects of traumatic stress exposures.

There are encouraging signs that investigators are considering cultural and community differences in their conceptual frameworks, research designs, and interpretations of the findings. This is perhaps most evident in the development of culturally sensitive assessment tools. Yet this remains an area of relative neglect, ripe for future research.

There is growing attention to the role of media in many forms in child and family experiences of war and disaster, along with recognition that research on media effects has fallen behind the rapid transformation in personalized media utilization among children and youth. For better and worse, young people are “growing up online” and using social media to experience, share, and respond to salient events in their lives. With widespread use of the Internet, social media, and a “24-7” news cycle, the potential for local and global “contagion” effects of mass-trauma events has changed, along with the potential for reaching out to help through online training and better-informed outreach. Yet, to date, little is known about the impact of these media changes on the risk and protective processes for children in war and disaster.

## Future Directions

Clearly, although there has been progress in this body of research, there is much to learn about the processes of exposure, response, and recovery that will inform efforts to prepare and protect children in the circumstances of war and disaster. It is not surprising that the quality and findings of studies in these challenging research contexts lags behind advances in less difficult research environments. We anticipate the next decade of work will bring powerful new tools and knowledge to this research environment, including more studies on neurobiology, gene-environment interactions, and developmental timing effects. We also anticipate more multicultural and multinational studies that allow for elucidation of cultural risk and protective processes, and longer-term follow-up studies of pathways and growth trajectories.

More longitudinal studies also will facilitate the examination of cumulative trauma effects, developmental cascades, intergenerational transmission, and the long-term consequences of war or disaster exposure on development. We expect greater focus on the functions of cultural and community context, as well as media. As findings accrue in the next generation of research, we expect that some of the puzzling data on age and gender effects will be clarified. And finally, we expect that even more research attention will turn to intervention studies as a strategy for illuminating risk and resilience processes for child development following war and disaster.

## State of Translational Applications

One of the most salient features of new research is the increase in intervention studies, accompanied by a broader effort to translate the growing evidence base into more effective preparedness to protect children in the wake of disaster and war. These efforts have yielded data on what works, guidelines for policy and practice, and many new questions for the future.

It continues to be challenging to field an intervention study in the midst of mass trauma or recovery. Further, although we highlighted a number of new studies of interventions in the literature, including gold-standard RCTs, we noted many limitations that characterize this body of work (e.g., small samples, overreliance on child self-report, limited follow-ups). Nevertheless, these studies indicate that systematic and controlled intervention research is feasible in the context of mass-trauma exposure, although “no treatment” controls may not be ethical or feasible. CBT procedures are included in the treatments that show the most promise, although other features of the intervention may vary. This has resulted in a lack of theoretical clarity about the specific procedures most essential for producing positive outcomes. Relatedly, although intervention research (both prevention and treatment) has the potential to serve as a platform for innovative theory testing regarding vulnerability and protective processes at multiple levels of analysis, the intervention research conducted to date has lacked this type of theory-driven orientation.

Perhaps one of the most controversial issues in this intervention literature concerns whether to intervene at all, and if so, when and with whom. Bonanno et al. (2010) have made a compelling case for caution and allowing natural recovery processes to occur before intervening. Although well intended, premature intervention or excessive intervention could undermine spontaneous adaptive processes

and even interfere with healing or recovery processes at the individual, family, or community level. Certainly, it is important to provide all needed emergency resources to meet medical, physical, and emotional needs of children and avert further trauma exposure. For example, children separated from families need to be reunited as soon as possible. However, efforts to “debrief” or provide extensive mental health services can be counterproductive and run the risk of harming rather than helping children or their families.

Concerns about “overdoing” intervention or iatrogenic treatment effects have led a number of reviewers in this literature to urge caution in emergency responses to disasters and other mass-trauma events (APA, 2010; Bonanno et al., 2010; Hobfoll et al., 2007; La Greca & Silverman, 2009; Masten & Narayan, 2012; Masten & Osofsky, 2010; NCCD, 2010). These advocates support preparedness and applying general guidelines for helping the population at large in the aftermath of disaster, followed up (as

indicated) by more targeted treatment by health professionals for children or adults who do not recover or become worse over time.

### *Guidelines for Policy and Practice*

Violent conflicts are ongoing and disasters strike frequently. As a result, there is always an imperative to prepare and respond on behalf of children. The evidence base now and at any time is imperfect, but nonetheless, the preparation and response efforts must go on. This situation has motivated efforts to develop principles and guidelines to assist emergency planners and responders in their preparations and response. In Table 18.1, we list some of the common guidelines for planning and responding with the goal of helping children weather the vicissitudes of war and disaster, delineated by a host of scholars based on the evidence. For each of these 10 common guidelines, we cite sources and provide quotations reflecting the guideline category.

**TABLE 18.1 Guidelines for promoting resilience in children exposed to war and disaster, with illustrative quotations**

<b>General</b>	
Prepare for child victims <sup>1–5</sup>	“All first responders need to know what responses to disaster can be expected at all levels of human development” (Masten & Obradović, 2008, p. 12).
Support positive adaptation at all ages <sup>2,6</sup>	“Promote a sense of safety, calming, self- and collective efficacy, connectedness, and hope” (Hobfoll et al., 2007, pp. 285–286).
Recognize that parents, childcare providers, and teachers are first responders <sup>4,5,7</sup>	“Frontline responders include police, firefighters, medical personnel, emergency service providers, teachers, and daycare providers” (Pine et al., 2005, p. 7).
Reunite children with parents and caregivers <sup>1,4,5,7</sup>	“Mobilization and mediation efforts are needed to facilitate the process of reintegrating separated children” (Ager et al., 2010, p. 1275).
Restore daily routines and reconnect children to peers and teachers <sup>1,2,4,8</sup>	“Our ‘best practices’ suggestions [acute postdisaster phase] would be for caring adults (parents, teachers and health professionals) to reassure children . . . and to help them resume normal roles and routines” (La Greca & Silverman, 2009, p. 5).
<b>School-Focused</b>	
Train school personnel as first responders <sup>3–5,9</sup>	“ . . . teacher-based resilience-focused intervention is a universal, cost-effective approach to enhance the preparedness of communities of children to mass trauma and to prevent the development of PTSD after exposure” (Wolmer et al., 2011, p. 340).
Provide students with access to mental health services <sup>4,10</sup>	“Additional services should include just-in-time training on bereavement support, psychological first aid, brief supportive services, and guidelines for referral for mental health services” (NCCD, 2010, p. 99).
<b>Community and Cultural</b>	
Restore cultural and religious practices <sup>4,11–14</sup>	“ . . . recommend the enhancement of community self-help and social support, helping the provision of appropriate cultural, spiritual, and religious healing practices, and support, particularly for young children (0–8 years) and their careers” (Reed et al., 2012, p. 262).
Build community resilience across multiple ecological systems <sup>4,5,14</sup>	“Communities must develop economic resources, reduce risk and resource inequities, attend . . . to areas of greatest social vulnerability . . . engage local people, create organizational linkages and relationships in advance of disasters, and boost and protect naturally occurring social supports” (Norris et al., 2008, p. 145).
Tailor prevention and intervention efforts to cultural context rather than “one-size-fits-all” <sup>1,15</sup>	“It is essential to not ignore or undermine existing or traditional mechanisms” (Ager et al., 2010, p. 1275).

*Note.* Guidelines are derived from recommendations in the following sources: <sup>1</sup>Ager et al. (2010); <sup>2</sup>La Greca and Silverman (2009), <sup>3</sup>Masten and Obradović (2008); <sup>4</sup>Masten and Osofsky (2010); <sup>5</sup>Pine et al. (2005); <sup>6</sup>Hobfoll et al. (2007); <sup>7</sup>Masten and Narayan (2012); <sup>8</sup>Betancourt, Borisova, et al. (2013); <sup>9</sup>Wolmer et al. (2011); <sup>10</sup>National Commission on Children in Disasters (NCCD, 2010); <sup>11</sup>Fazel et al. (2012); <sup>12</sup>International Agency Standing Committee (2007); <sup>13</sup>Reed et al. (2012); <sup>14</sup>Norris et al. (2008); <sup>15</sup>Tol et al., 2013.

### Future Directions

As other reviews have noted, there is a striking lack of research on intervention, best practices, preparedness, and related policies given the global scope of children exposed to war, terror, political violence, and disasters. There is a vast gap between international need for evidence on “what works” in situations of great threat to child well-being in war and disaster, and the current state of the research. This situation calls for a large-scale mobilization of stakeholders to support and promote more high quality, practical research on prevention, preparation, and treatment of children in war and disaster.

### A Call to Action for Developmental Scientists

Developmental scientists have much to offer the global effort to understand and address the issues of children in potential danger from mass-trauma situations (Masten, 2014). Ager et al. (2010) delineated this theme in their article in a special section on children in war and disaster in *Child Development*. They described a translational gap between the international humanitarian agencies and developmental sciences that may be due in part to the limitations in developmental science with respect to research in diverse cultural settings, particularly in low-income regions of the world. Another factor may be a communication divide. These authors urged developmental scientists to engage more fully with practitioners to conduct research in diverse cultural settings and also to provide clearer guidance based on their evidence for humanitarians involved in international relief and disaster response. A forum for this dialogue would facilitate the efforts of those who want to span this divide.

There are additional signs that a window is opening for developmental science to inform and advance global efforts to reduce harm and promote resilience in relation to war and disaster. Multinational organizations, such as UNICEF, the European Union, and the World Bank, that frequently plan and respond to mass-trauma situations have sponsored conferences and publications that include developmental science and scientists. The U.S. National Commission on Children in Disaster report in 2010 cited a special section on children in war and disaster in *Child Development* (Masten & Osofsky, 2010). Developmental science organizations and funders are expanding their support of research in low- and middle-income regions of the world more generally and disaster or war zones more specifically, through grants, meetings, membership, and publications in their journals. The 2013 Ernst Strüngmann

Forum at the Frankfurt Institute for Advanced Studies brought multidisciplinary scientists together to discuss the potential role of developmental science for building pathways to peace (see Leckman, Panter-Brick, & Salah, 2014).

Developmental science will be informed and enhanced by expanding the capacity for research on children in war and disaster worldwide, and by opening more opportunities for ongoing dialogue and collaboration of developmental scientists with experts in the field who are charged with preparing and helping large populations to respond effectively on behalf of children. Experiences of war and disaster test the limits of human capacity for change and recovery, and they may reveal entirely new processes of adaptation, risk, and resilience that enrich and challenge developmental theory. Prevention and intervention research designed to test best practices for preparation and recovery have the potential to test theories about vulnerability and protective processes, differential sensitivity, and effects of developmental timing or culture for positive change at multiple levels of analysis. Analysis of similarities and differences across distinct cultural contexts that compare effects or interventions in war or disaster with other forms of extreme adversity also may be illuminating. After seven decades of study, research on children in war and disaster continues to be a frontier for developmental science.

## CHAPTER 19

# Children and Cultural Context

JACQUELINE J. GOODNOW and JEANETTE A. LAWRENCE

### OVERVIEW 746

#### CONCEPTUAL FRAMES: SEPARATIONS AND CONNECTIONS 748

The Meanings of *Culture* and *Cultural* 748

Splits, Dichotomies, and Fundamentalist Steps 750

Levels of Influence: Low for Cultural Contexts? 751

Directionality: From Contexts to Children and the Reverse 752

#### LINES OF ANALYSIS 752

Line 1: From Universals to Situational Bases of Similarity and Difference 752

Line 2: Toward Common Units of Analysis: Place, Activities, People 754

Line 3: From Continuity to Change, From Uniformity to Diversity 760

Line 4: From Single to Multiple Cultural Contexts: Analyses of Acculturation 765

Line 5: From Theory and Research to Policies and Policy-Making 771

#### IMPLICATIONS AND FURTHER DIRECTIONS 773

Contexts and Development: Change in Either Has Flow-On Effects for the Other 773

Development: Culturally Valued Knowledge and a Sense of Belonging 774

Measures, Methods, Interpretations: Reconsidered for Cultural Meanings 778

#### SUMMARY 779

#### REFERENCES 781

Studies and analyses of children and cultural contexts have changed a great deal over a relatively short time. Over the past decade, for instance, there has been a marked increase in number and in content: in the variety of questions raised and proposals offered. Those changes have prompted several large-scale accounts (e.g., Bornstein, 2010; Cole, 2010; Rogoff, 2003; Shweder et al., 2006). They have enriched and revitalized analyses and studies in the area. They have also brought with them the danger of making analyses and studies in the area to appear like unrelated “bottles washed up on the beach” (Bornstein & Lansford, 2012, p. 26). To avoid that danger and to bring out structures and patterns within the variety of approaches, we take two steps. One consists of focusing on changes in content, with changes in

number largely set aside. The other consists of asking two central questions: What has changed? What follows?

### OVERVIEW

The chapter is in five sections. The first is an account of what the chapter covers. The second focuses on changes in conceptual frames: their separations and connections. Proposed is a shift toward considering the development of children in relation to *cultural contexts* as a way of avoiding splits and dichotomies. The third section focuses on changes, for five lines of analysis, in specific conceptual frames and topics, and in research approaches as they have progressed and might progress. The fourth section cuts across the previous two. It turns to implications for research directions that move from an emphasis on separations to emphases on connections. It also moves beyond positions that are essentially “one-way” in their emphasis: are unidimensional, unidirectional, or neglect questions

---

We gratefully acknowledge the continuing support of our universities and departments and the many colleagues who have contributed to our understanding and experience of development.

With deep sadness we note the passing of Jacqueline Goodnow prior to the publication of this chapter.

about changes over time. The summary then reviews what the chapter has covered and what has emerged for us as some specific proposals for future directions in conceptual frames and in research questions.

The approach throughout is directional rather than encyclopedic. The emphasis falls on starting points, shifts, and further directions. The work we cover and the citations we make are then necessarily selective. We have given preference to analyses and studies that bring out starting points or changes in direction, or to articles that offer reviews of these. The approach also draws from more than one discipline, primarily anthropology and psychology. Proposals often differ from one discipline to another. Those differences, however, make contributions from more than one all the more interesting and useful.

The focus on content does not mean that we regard changes in number as unimportant. They simply tell a different story. We note them only in relation to some parallels in the bases suggested for both number and content. One of these consists of changes in voice: in the power of political voice and in demands for change in what is covered. This is one of the bases suggested by García Coll and her colleagues for increased attention to development in ethnic/cultural groups within the United States (e.g., García Coll & Marks, 2012). The second base has to do with changes in the extent and immediacy of encounters with cultural contexts other than one's own. Those changes may stem from travel, immigration, displacement, or refugee status, or from the increased flow of information that comes from media changes. Attention to "remote acculturation" is one example of that suggested base (e.g., Ferguson & Bornstein, 2012; Thompson, 2012). Both bases underline the importance of external conditions. We see these as always important. For changes in content, however, we emphasize conceptual frames or research approaches that may help or hinder the exploration of unfinished work or new questions.

We divide changes in content into two kinds. One focuses on changes in conceptual models, the other on changes in both models and specific research topics or approaches. That separation may at first seem strange. Frames and research approaches are always interrelated. In the first kind of change, however, conceptual frames are expected to apply to a variety of areas. There is then no need to add attention to specific topics or procedures. In the second kind, changes in frames are anchored in and accompanied by specific topics and studies. For both kinds of change, we single out some particular forms, offering first a description of the nature of the shift and

then questions or proposals that follow or might follow. Analyses of frames are predominantly concerned with separations and connections of several kinds. We start with what is covered by the terms *culture* or *cultural*. Prompted then are moves toward clarifying what these terms mean and setting up criteria that should be met before their use. As particular sources, we turn to proposals from Cole (2010), D'Andrade and Strauss (1992), and Gjerde (2004).

Considered next are moves that seem to start from interests in order or structure but do so in ways that turn out to be limiting and restrictive. The first of these takes the form of conceptual splits, dichotomies, and fundamentalist steps. Here, for example, are splits between persons and contexts or between cognitive and social development, often made so separate that they are seldom seen as intertwined or as co-occurring. Here also are fundamentalist steps in the form of regarding one side of the divide as more "real" or "fundamental" than the other, then dismissing the other side with the assumption that the one regarded as the "real" can account for everything. As a particular base, we take analyses offered by Overton (e.g., Overton, 2010; Overton & Lerner, 2012).

The remaining changes related to separations and connections have to do with differences in the power and the direction of influence. In the first of these, the initial frame has been one of assigning a low degree of power to cultural contexts. They have often been placed at the remote ends or the outer edges of a collection of influences. Children's experiences and awareness of cultural contexts have also been seen as occurring late in their lives. The shift has been toward regarding cultural contexts as central and as part of children's lives at an early age (e.g., Diesendruck & Markson, 2011; Goodnow, 2011; Hedegaard, 2009). In the last change in frame, the shift takes the form of an expansion. Often, the directional flow of influence was seen as coming from cultural contexts to children. The shift has been toward considering the flow of influence as taking two directions, with children themselves seen as active rather than as passive, as influencing the nature of their development and of their contexts. Analyses by Kuczynski and his colleagues provide a particular base (e.g., Kuczynski & De Mol, Chapter 9, this *Handbook*, Volume 1).

The second kind of change combines conceptual models and, for research, specific content areas and procedures. Line 1, the first of five lines of analysis, focuses on shifts from an emphasis on universals—that makes cultural contexts largely irrelevant—to an emphasis on specific situations and circumstances. Emphasized, for instance,

is the occurrence of particular needs or expectations and of the experiences or resources that help people meet these needs and expectations. The research emphasis then falls on analyzing the nature of expectations and experiences, the choice of groups to compare and of measures to use, and the interpretation of similarities and differences. As a specific base, we take a study by Callaghan et al. (2011).

Line 2 focuses on change in the form of emphasizing the need for units of analysis that can be brought to bear on a variety of contexts or age groups. Without these, it is difficult to compare contexts or ages with one another, to ask how they are related, or to analyze effectively the nature of transitions from one context to another. The units proposed draw on the features of place or site, of activities and participation in them, and of people and their relationships (e.g., relationships as experts or novices, or as collaborators on joint activities). The research emphasis then falls on analyzing the nature of these features (e.g., the nature of participation in joint activities and of the ways in which people act together). We take as a base, proposals from Barker and Wright (1955), Cole (2010), Rogoff (2003), and Stone, Underwood, and Hotchkiss (2012): proposals drawn from both ecological and cultural-historical perspectives.

Line 3 focuses on shifts in the qualities seen as markers of cultural contexts, again seen as primarily in terms of one marker, with its opposite excluded. One shift is from regarding continuity over generations as the primary marker to an emphasis on change, both across and within generations. The other is a shift away from regarding cultural contexts as marked or defined by uniformity or homogeneity. Ideologies of interdependence or independence, for example, were often seen as applying to all people living in a particular context. Instead, cultural contexts are now seen as marked by diversity in ways of thinking or acting, often in competition with one another. The research emphasis then falls on exploring the conditions that favor the emergence of continuity or change, of uniformity or diversity. It falls also on the strategies people use to promote the occurrence of one rather than the other. For specific research bases related to continuity, we take work prompted by Patterson's (2010) questions about "the puzzle of persistence" (p. 139). For diversity, we focus on studies of strategies, for example, on a study by Padilla-Walker and Thompson (2005) about the strategies parents use to avoid children's serious departures from the ways of thinking or acting that parents value.

Line 4 picks up issues of continuity and change, of uniformity and diversity, and of transitions, specifically

relating these experiences to concepts and studies of acculturation. The shift is away from seeing acculturation-related changes as belonging only to immigrant and minority groups, seeing these changes as relevant to all people within multicultural societies and to all people, especially young people who are in touch with global media and changing societies. Research on development then naturally focuses on changes in young people's relations to their heritage cultures, their construction of bicultural identities, and their relationships with parents who are committed to the heritage culture.

Line 5 takes up moves away from separating "pure" from "applied" psychology, "theory" from "action." These are never separate. As a way of bringing out their links, we take up analyses of policies that affect children's lives. Those analyses may focus on variations in policies among cultural groups. We emphasize instead the need to consider not only the policies that are the end products of work but also the process of policy-making, regarding it as a joint activity that involves several players. As examples of this shift and of possible variations among cultural contexts, we turn to analyses by Beckert (2008), Shonkoff and Bales (2011), and Tisdall (2008). On the basis of those lines of analysis, in the final sections, we draw out implications and directions, and recurring messages about contexts and development that have emerged from considering the two kinds of change.

## CONCEPTUAL FRAMES: SEPARATIONS AND CONNECTIONS

We start with reexaminations of the terms *culture* and *cultural*, noting their nature, their significance for analyses of contexts and development, and shifts toward more productive positions. As we noted earlier, that concern with conceptual models is followed by concerns with conceptual splits, and by second looks at divisions related to the strength and the directional flow of influence.

### The Meanings of *Culture* and *Cultural*

Ways of defining culture have a long and varied history. The most accepted view, however, is that defining it only in terms of nationality will not be enough. It may even be misleading. Looking only at definitions of what culture is, however, may be even less rewarding. The last thing one needs, in Cole's (2010) analysis, is "to get bogged down

in disputations about ‘the one right meaning’ of the term” (p. 462). That can easily happen. Kroeber and Kluckhohn (1952), for instance, listed 160 definitions of culture. To that list, Jahoda (2012) noted, they added one more: their own.

What alternatives then might be used? One alternative is to discard the term altogether. As Cole (2010) noted, “many anthropologists have decided to chuck the concept of culture as a distraction” (p. 462). That alternative, however, Jahoda (2012) has seen as out of step with the fact that the term is already part of everyday language. His advice was to take one of two steps: either set up a single definition and stay with it, or stay closer to everyday use. People have little difficulty, for example, with being asked: What is your cultural background? They may answer in hyphenated terms: Swiss-German, Italian-American, Malaysian-Chinese. They may also answer in terms that are meaningful only to a smaller group of people (e.g., Assyrian or Transylvanian). Overall, however, people have little or no difficulty with questions about their cultural background.

A second alternative is to turn completely or in large part to the use of the adjective *cultural* rather than the noun *culture*. That alternative is in wide use, for instance, in references to cultural practices and cultural models. The adjective avoids any reification: any view treating culture as a “thing” that may vary only in whether there is more or less of it. Use of the adjective *cultural*, however, is still seen as best restricted to ways of thinking or acting that meet certain criteria. D’Andrade and Strauss (1992), for example, have offered analyses of both *cultural models* (ways of thinking) and of *cultural practices* (ways of acting). They reserve the term, however, for ways of thinking or acting that are shared by all or most people in a group, have the same meanings for them, have been maintained over one or more generations, and have some quality of commitment. People may, for example, share views of how light bulbs work. Those views, however, are held without commitment and are easily changed. Views of what marriage means are less easily changed.

Cole (2010) has provided a further part of the picture. He has used both terms (*culture* and *cultural*) but again with some particular qualifications. In his approach, the adjective *cultural* applies to ways of thinking or acting that are widely shared, have been generated in the past, and are made available to people who come to the same task or the same setting at a later time. *Cultural* then can be a way of describing not only practices and schemas but also what Cole described as tool kits: resources or artifacts that range from spades and cooking utensils to written languages and

other forms of available knowledge. *Cultural* is also a term that in Cole’s (2010) view:

applies equally to small groups of people who have engaged for some time in joint activities to achieve some common object, such as working in the same business or same office, or the same Little League team or army unit or in the same classroom. (Cole, 2010, p. 462)

That proposal certainly shakes up the meanings of the terms *culture* and *cultural* in both everyday and social scientific usage. It conveys, however, less of the sense of self and other that Gjerde (2004) regarded as a definitive feature of cultural ways of thinking or acting. Once those ways of thinking and acting are recognized, it becomes harder to weaken the significance of the cultural. They may also become more salient under particular circumstances. The sense of being Japanese and distinctive in ways of thinking or acting, to take one of Gjerde’s (2004) examples, became more pronounced during the time of American occupation. In related fashion, descriptions of oneself as from “the North” or “the South” seem to reflect, within the United States, the strength of memories of what is still often referred to there as “the war between the States.”

### *Significance and Some Further Questions*

Discussions about definitions may seem to be only of academic interest. They have, however, the positive value of indicating changed approaches to questions about the nature of contexts, of development, and their interconnections. Instead of encountering *culture*, for example, children can now be seen as encountering a world in which some ways of thinking or acting are widely shared, and held with feeling. They are then likely to receive the same message from a variety of sources, making it more likely for them to see that message as normal, natural, or right, and to be accepted without questioning. All told, children can be regarded as encountering a mix of approaches to ways of thinking, acting, and feeling. Some of these are actively encouraged: for example, use the “magic word: the word please” (Becker & Goodnow, 1992). Some are actively discouraged: for example, “never eat food with your left hand.” (Views about what is “clean” and what is “dirty” seem to vary from one cultural context to another, but the distinction appears to be made in all, and to be made with feeling). Some are left more open to negotiation, compromise, deferral, or choice: for example, “that’s possible,” “you’ll learn more about that when you’re older,” “that’s up to you.” or “which one would you like?” Development can then be regarded in terms of people—children

or adults—accepting some ways of thinking, acting, or feeling without question. It can also be seen as a process of testing the limits or rejecting what others have proposed (e.g., Kuczynski & De Mol, Chapter 9, this *Handbook*, Volume 1; Valsiner & Lawrence, 1997).

Still to be taken further are questions about the everyday use of *culture*. Its use, Jahoda (2012) pointed out, is widespread. Still unclear, however, are the meanings carried by the term, and the conditions that influence the terms used for describing one's own or other groups. The use of hyphenated terms such as German-American, or Swiss-German, for instance, is likely to vary from one social situation to another. It may also vary with age. The choice of hyphenated terms to describe oneself, for instance, may be more likely to occur at ages when young people review their identity and the names associated with it: mostly in adolescence or young adulthood (e.g., Côté, 2006; Marcia, Waterman, Matteson, Archer, & Orlofsky, 1993). Even then, however, some groups may reject hyphenated or other terms that make sense to other people. The second-generation Turkish young people in the Netherlands interviewed by Verkuyten (2004), for example, described themselves as Turkish: but not Turkish like those in Turkey, not like the segregated, traditional Turks in the Netherlands, not like their Turkish immigrant parents, not like other immigrant groups, and not like the Dutch.

Is this reexamination of terms and views among psychologists and anthropologists all that is needed? Within social science, one unfinished task has to do with taking up recommendations of the kind just mentioned. We would like to see both terms—*culture* and *cultural*—retained but used with care. For this chapter, however, we have tried using only the adjective *cultural*, and using it only to refer to ways of thinking or acting or to situations that are marked by the several criteria suggested by Cole (2013), D'Andrade and Strauss (1992), and Gjerde (2004). Still left, however, is the challenge offered by Cole (2013) about *cultural* as a term to use when we refer to groups that have met a common or shared task in ways and with meanings that have lasted over time, and that carry with them implications of identity (e.g., "I—or you—are one of the regiment, team, or working group"). We have yet to find widely accepted terms for these contexts, with some social scientists turning, for instance, to terms such as *subcultures*, *mini-cultures*, or *communities*: terms with further sets of meanings to decipher. The term *cultural context* covers the sense of ways of thinking, feeling, and acting that are shared and lasting, the sense in which people

can be said to belong to distinctive cultural groups, and the sense that there is more than one way of thinking, feeling and acting in any situation. Development, then, needs to be considered and analyzed as it is intertwined with cultural contexts.

### Splits, Dichotomies, and Fundamentalist Steps

Analyses of contexts and development, it has been pointed out, are often marked by conceptual splits. Overton (2010) offers a particularly relevant list. It includes, for example, separations between person and context, stability and change, unity and diversity, reason and emotion. The presence of such splits has often been noted. They come up in several disciplines and in analyses of a variety of content areas. Overton (2010) has added three further steps. One consists of regarding what has been placed on the two sides of the divide as completely distinct and as never coinciding (as "dichotomies"). In the second, one of the separated parts comes to be regarded as more "fundamental" than others. To take one example, "the natural (material physical, objective) constitutes the ultimate foundational real, the ultimate 'atoms' on which all else is built" (Overton, 2010, p.12). In the third, "one of the pieces of the whole is more real than the other and . . . therefore the less real must be explained (i.e., reduced) to the more real" (p.12).

Objections to these several steps are not new. From them, we single out objections to the fundamentalist steps that assign all or most power to what is on one side of the divide. One specific objection is that assigning the main role to social processes reduces the significance of internal mental processes and ignores the duality (Valsiner, 2000). A further objection is to positions that regard the genetic or the neural as fundamental, again reducing the significance of all other sources of influence on development or ignoring them: a widespread and often repeated objection (e.g., Gottlieb, 2007; Lerner, 2011; Lerner & Overton, 2008; Overton & Lerner, 2012).

In the face of these many objections, why have splits, dichotomies, and fundamentalist steps persisted? One base is certainly the simplification of conceptual or empirical tasks. Exploring interactions or interconnections can now be avoided. A second base, more specific to analyses and studies of cultural contexts, is the lack of clear alternatives. Other areas, for instance, have seen the development of "systems perspectives": perspectives in which all the components of contexts and development are regarded as parts of a dynamic system, constantly interacting with one

another. Change in one then involves changes in others. In addition, each component (a family, for instance) is regarded in itself as a dynamic system rather than as a fixed or single block, interacting only with other blocks (e.g., Lerner, Lerner, Almerigi, & Theokas, 2006).

Systems perspectives, however, are not yet a consistent part of analyses of cultural contexts. Some proposals certainly come close to including them. Acculturation changes for one person, for instance, have been recognized as having significant flow-on effects for other family members. A child's competence in a new cultural context may also bring extra family responsibilities. Immigrant young people who become competent in dealing with the mainstream culture, for instance, may become bridges for their parents' interactions with personnel from various institutions: teachers, doctors, shopkeepers (Padilla, 2006).

Emerging also as possible bases for the persistence of splits are views about "other people" in the tasks faced by social scientists and in everyday experience and everyday language. Studying other people may seem an esoteric activity, a diversion from what is seen as the important task of understanding one's own cultural group. To counter this view, it has been said that one of the greatest benefits from analyzing contexts and development in "other places" is the increased awareness of what is taken for granted in one's own views of children and of appropriate approaches to research. With new awareness, for example, we soon begin to take second looks at our concepts of intelligence, our sense of the need to know children's chronological age before making any comparative study or any developmental assessment, and our understanding of how it feels to be a "stranger," a "foreigner," or an "alien" (e.g., Shweder et al., 2006).

For the last potential basis, we have been prompted by Overton and Lerner's (2012) description of splits and fundamentalist steps as a "divide and conquer" strategy. That strategy is one often observed or advocated in many parts of life. Perhaps the approaches of many social scientists to contexts and development are in large part an extension of that experience. Divisions are certainly more prominent than interconnections or duality. Here are day and night. This is "what boys do," this is "what girls do," and mixing these is often seen as best avoided or as requiring some extra justifications: justifications, for instance, on the basis of equity, fairness, tolerance, or creativity. In related fashion, a divide and conquer strategy is thought of as fundamental or routine in many content areas. It may then be simply extended, without thought, to conceptual analyses of contexts and development.

### Levels of Influence: Low for Cultural Contexts?

Cultural contexts are often regarded as on the remote mountaintop or the outer edges of children's experience. They are to be turned to only when influences from more proximal sources have been found to be insufficient. Even then their influence may be seen as indirect. They affect child development, for example, by influencing the behavior of parents, or they trickle down to more proximal contexts. In contrast is the recognition of the relevance of cultural contexts to all analyses of development in context and to the understanding of development in general. Contributing to this position are reservations about nested or tiered arrangements.

Any nested picture of contexts attracts the perception of cultural contexts as on the far outer edge of other contexts and as having only indirect impact on children and their development. Bronfenbrenner's (1979) ecological model provides an example. There is no doubt about the value of its contribution to the recognition of contexts as more than simply proximal. The text also draws less sharp lines between contexts that succeed one another than often-cited graphic pictures of circles that surround one another. Reservations to both, however, have taken several forms, all related to some underlying concepts of children and their development. In one reservation, concern is expressed that children are seen as passive and acted upon (Goodnow, 2010; Hedegaard, 2009; Lawrence, 2008). In another, children are seen as acquiring knowledge of a remote world only through parents or other adults playing filtering or gate-keeping roles (Goodnow, 2011). A third has to do with the implication that young children will have little awareness of the world outside the family. At least in many ethnic minority groups, however, children have an early and sharp awareness of outside conditions and of what may or may not be open to them (Raffaelli, Carlo, Carranza, & Gonzalez-Kruger, 2005). In a fourth reservation, the concern is that the temporal sequence implied by the model is not in keeping with what happens in many cultural contexts. In Bronfenbrenner's (1979) model, for instance, children appear as making a late entry into contexts outside the family, doing so only when they cease to be young children or after some years in school contexts. That may be the case in the Western world. (We recognize that the term "Western" is a social construction but, for ease of reading, we omit the quotation marks here and throughout the chapter.) In many cultural contexts, however, children are expected to enter paid work and contribute to the family income at an age when children in

Western contexts are in preschool (e.g., Dachyshyn, 2007; Nsamenang, 2011; Weisner, 2002).

Are there then alternatives to separated and nested contexts? One alternative is certainly an emphasis on the immediacy of a variety of children's experiences. Diesendruck and Markson (2011), for example, see children from the start of their lives as "surrounded by norms, practices, and symbols that are mostly arbitrary and often unique to a particular community of people" (p. 189). In order to know what others expect, and how to signal what they themselves wish to have happen, they need from the start to work actively at decoding those norms, practices, and symbols. Occurring also may be not so much encounters with new ways of thinking, acting, or feeling as encounters with a reworking of some core pervasive themes. Children may always be seen as entitled to some support from adults. The supports they think they need and that others are prepared to supply, however, will vary from one context to another. Those variations present children, as they move from one context to another, with the need to think again about the nature of supports. That task in itself, however, is not completely new (e.g., Goodnow, 2010).

### **Directionality: From Contexts to Children and the Reverse**

Influences on child development have at times been seen as one-directional, with contexts given the primary role. In those approaches, the emphasis then usually falls on how others shape child development. Kuczynski and De Mol (Chapter 9, this *Handbook*, Volume 1) provide an historical review of these accounts, describing the middle of the 20th century as a "unidirectional era." The shift has been toward the recognition, especially in parent-child relationships, that influences are always bidirectional. That shift has also become a part of analyses of person-context interactions. Contexts are now seen as not only reproductive, with development taking only the form of children coming to reflect adults' ways of thinking or acting. Instead, children are increasingly recognized as affecting the nature of contexts, possibly transforming them (e.g., Shweder et al., 2006).

These conceptual frames take us part of the way toward bringing out the pattern of analyses in the area of cultural contexts and development, highlighting shifts that have occurred, the directions they have taken, and the directions that might now be considered or taken further. To them, however, we need to add an account of research studies.

These are a necessary part of the picture: often the point where interest in the area or in conceptual frames begins. They are also a check on conceptual frames, asking where they fit well and where they need some amendments or expansions.

## **LINES OF ANALYSIS**

Each of these five lines of analysis, as we mentioned earlier, involves a shift in concepts and often, in research approaches. To each line we bring a common directional frame, focusing on starting points and shifts. Each line ends with suggested further directions. From all, we have excluded debates about whether cross-cultural comparisons or within-group analyses are the optimal or the only methods. The use of either or both depends on the questions being asked.

### **Line 1: From Universals to Situational Bases of Similarity and Difference**

Questions about possible universals have been asked in relation to many aspects of development. These range from psychomotor development, mirror self-recognition, language development, stages in cognitive development, progressions in moral reasoning, and distinctions among relationships. At issue in all these areas is more than the demonstration of similarities and differences. At issue are questions about the developmental changes we regard as significant, how we can effectively compare contexts, measure similarities and differences, and legitimately draw out inferences from what we observe.

As a focus, we take analyses of psychomotor development. For many developmental psychologists, this was where interest in universals began. Analyses in this area also have a long history of challenges, changes, and new proposals, with many of these relevant to several areas of development. Our starting point is Gesell's analysis of early motor development (e.g., Gesell, 1928). It covered changes in behaviors such as sitting, standing and stair climbing, accompanied by proposals that these developmental sequences were invariant and showed little impact from efforts at direct instruction. When these progressions were incorporated into Bayley's (1969) widely used scales for infant and toddler motor development, they often came to be regarded as normative, with delays seen as indicative of difficulties in development that called for corrective measures (Adolph, Karasik, & Tamis-LeMonda, 2010).

Proposals about sequences and timing—age of onset especially—were soon followed by reports of cultural variations. These were variations in the form of “African precocity” and in the form of delayed timing (e.g., later ages of onset when infants were carried, swaddled, or strapped to a papoose board rather than being allowed or encouraged to crawl or toddle). Overall, a picture emerged of departures from the Gesell/Bayley norms and recognition of influences from a variety of circumstances: “climate, housing, terrain, man-made artifacts, parents’ expectations and naive theories, and particular childrearing practices” (Adolph et al., 2010, p. 65). Both universals and variations exclusively based on genetic differences ceased to be adequate accounts. So did any view of nurture as restricted to direct instruction.

Those shifts might seem to have been the end of interest in variations in early motor development. One contrary example is Varga’s analysis (2011) of the extent to which Gesell’s (1928) research approach shifted attention from observing children in the course of their daily lives to observing them in unfamiliar situations and in isolation from the people who usually share space with them. Varga also criticized Gesell’s view that the age norms he observed would apply to all groups, seeing that as an early example of the essentially ethnocentric or colonial quality of many Western views of development.

As a further example of continued interest, we take a study by Callaghan et al. (2011). We single it out for four reasons. It is relatively recent. Its emphasis is firmly on what cultural contexts demand and provide: circumstances that clearly might change from one situation or context to another. It displays an awareness of pitfalls and how they might be avoided. It also makes some particular contributions to questions about concepts, methods, and interpretations: contributions relevant to the analysis of other aspects of development and other contexts.

Callaghan et al. (2011) compared three groups of children Ages 1 to 3. Two groups came from traditional village settings in Peru and India, the third from a middle-class setting in rural Canada. The measures chosen were of actions labeled *social cognition*. They involved “understanding the intentions and attention of others: imitation, helping, gaze following, and communicative pointing,” together with “participating in interactive episodes of collaboration and joint attention” (p. vii). In effect, the shift was away from emphasizing actions that may be carried out in solo fashion to actions that call for the coordination of one person’s actions with those of another.

Differences in the age of onset (later onset for children from traditional villages) appeared only for skill in pretend play that called for object substitutions (e.g., treating a stick as a horse) and in the production of pictorial representations of objects or people. Parents in traditional groups may see these skills as having little or no functional value or as relevant only in relation to preparation for school. The children in all three groups, however, did develop these skills. The general interpretation of these differences is in terms of children developing “the skills they need at the times they need them” (Callaghan et al., 2011, p. 11): a proposal similar to Tomasello’s (2003) usage-based rather than nativist approach to the development of language. In effect, neither inborn readiness nor direct instruction was seen as an adequate description of how developmental changes come about.

### Questions and Directions

The study by Callaghan et al. (2011) is an example of an approach that offers both some conceptual changes and some changes in research decisions in relation to questions about the intertwining of cultural contexts and development. Conceptually, this approach emphasizes that there is more than one possible interpretation of similar ways of thinking and acting across cultural groups. One interpretation is in terms of nativist givens. Another is in terms of the kinds of experiences that various contexts provide. Similarities across cultural contexts, for instance, may arise either because these skills depend very little on environmental input, or because each environment offers sufficient experience to support similar aspects of development. A related conceptual proposal is that a particular aspect of development need not be tied to a specific experience. Several experiences may serve the same function. The basis may also lie in flow-on, cascading effects from other developmental changes (e.g., Cox, Mills-Koonce, Propper, & Gariépy, 2010; Masten & Cicchetti, 2010).

An account of development based on normative expectations, however, may seem to suggest that children play an almost dormant role, awakened by input from contexts. It may suggest also that developmental changes follow only the directions that contexts promote. Both limitations are out of line with conceptual frames that give children a more active role. The challenge lies in specifying the forms this active role may take. A study by Rakoczy, Warneken, and Tomasello (2008) provides one specification. Young children were asked to watch a puppet solve a puzzle in

order to reach a reward. The puppet made several unnecessary moves. The children, however, did not repeat these moves when they were asked to solve the puzzle. They did not indiscriminately reproduce what they had observed. Instead, they brought to what they observed an interpretive and evaluative eye.

For approaches to research, we take up two aspects. One is the use of age of onset as a primary measure. The other is the choice of particular behaviors. Age of onset is only one of many aspects of age, and requires a reason for choosing it (Adolph et al., 2010). Callaghan et al. (2011) chose onset because of the conceptual proposal that skills appear as needed. Some may appear later than others because they are seen as less significant, as not yet needed or expected. The less significant are then deferred until the more significant have been met. Pretend play, for instance, may have a low priority in many cultural groups. It did appear in all the cultural groups considered in this study. In the traditional villages, however, it seems highly likely that other forms of competence were given a higher priority.

For their selection of behaviors, Callaghan et al. (2011) chose behaviors that are not solo activities. These social cognitive tasks called for understanding the actions and the intentions of others (e.g., understanding the meanings of pointing) or for tapping into the symbolic systems of others (e.g., coming to understand that riding a stick may represent riding a horse or that particular lines on paper can represent a person or a house). One reason for this choice was to avoid criticisms of “researchers who parachute their procedures from Western labs into cultures where even asking a question one knows the answer to is considered odd” (Callaghan et al., 2011, p. 112). Criticisms of that kind have a continuing history in cultural studies (e.g., Cole, Gay, Glick, & Sharp, 1971; Serpell & Jere-Folotiya, 2008). One alternative is to choose measures that reflect the local culture. Callaghan et al. (2011) instead chose some behaviors (e.g., mutual gazing, responses to pointing) that had already been observed both in many cultures and in other primates. These were not then unfamiliar or foreign behaviors for any cultural group. The researchers then contrasted them with other behaviors that were more likely to be culturally specific.

Line 1 has taken us some distance toward a clearer understanding of cultural contexts and child development, together with conceptual and research questions that we shall need to keep in mind. What then is added by a line of analysis (Line 2) that focuses on contexts considered in terms of variations in place, activities, and people?

## **Line 2: Toward Common Units of Analysis: Place, Activities, People**

Line 2 presents changes in the way research and analyses have proceeded. The most visible of these changes may be a shift toward comparisons that are not always across groups differing in cultural background: the approach seen in Line 1. These comparisons are by no means abandoned. Now added, and often seen as primary, however, are comparisons between groups usually regarded as belonging to the same cultural background but varying in generation, in different kinds of experience, in needs, or in access to resources.

We now see, for example, analyses of changes over generations in the rug patterns woven by people in the same village (Greenfield, 2004). We also see studies of changes in the way Girl Scouts sell cookies as part of their annual fundraising. The goal is still the same. So also are parts of the methods used (e.g., the personalization, the sellers, the experience). There is no change in the quality of the cookies. With email access available, however, changes occur in the nature of contact, and how preferences, orders, and payments are made and recorded (Rogoff, Baker-Sennett, Lacasa, & Goldsmith, 1995).

Studies such as these may not immediately be seen as part of research on cultural contexts and development. They are, however, a major part, especially because of the search for units of analysis that can be carried from one part of the picture to another. Common units of analysis can be used to describe several contexts, to compare them with one another, to combine them into some cumulative picture, or to specify transitions between them. Without common descriptors and common units of analysis, we are in danger of working with distinct and unrelated pieces that are difficult to bring together and, especially in relation to cultural contexts, with a limited understanding of how various ways of thinking or acting evolve.

In many respects, considering various contexts in terms of tasks and resources is one move toward a common unit of analysis. More explicitly directed toward that purpose however, have been three other lines of approach. In some proposals, the emphasized common unit has to do with place or site: its demands for various forms of competence, the resources it provides, and the activities it allows, facilitates, or makes difficult. In others, the emphasized common unit is one of activities: often with an emphasis on activities where two or more people need to participate, to coordinate what they do, and to understand each other's plans or intentions. In a third, the emphasis falls on people: their expectations, their abilities, and their willingness to

promote various developmental changes, how they do so, and their relationships to one another.

Observations and proposals about these units of analysis come from several conceptual approaches, often labeled as *ecological*, *cultural-historical*, and *practice-oriented*. With one exception, we note the main proposals from these approaches as we proceed. With one exception also, we take up the three kinds of units in turn, noting interconnections as we proceed. The exception in both cases is a particular ecological approach: one that considers all three aspects—place, activities, and people—as parts of a unit of analysis.

### ***A Particular Ecological Approach***

Ecology is a term with a considerable history in both biology and psychology. It covers a variety of approaches and a variety of terms (e.g., habitats, niches, and niche construction). From psychological approaches, we single out one described as *psychological ecology* (e.g., Barker, 1968; Barker & Wright, 1955). We do so for three reasons. One is the consistency with which it considers all settings in terms of place, activities, and people, and their interconnections (*behavior setting* is the term used rather than *context* or *situation*). The second is the attention it gives to departures from behaviors regarded as ideal in children and in adults. The third is the way this approach has flowed on to others' descriptions of situations or contexts (cultural contexts included) in terms of place, activities, and people (e.g., Weisner, 2002).

The transition from home settings to childcare and school settings provides one example of attention to all three aspects together: as acting upon one another and as having cumulative effects. That transition is seen as involving shifts in site, in the kinds of activities that are expected to occur, and in the ratio of adults to children. That combination may well make the transition difficult for many children. It may also influence the behaviors of both children and teachers (Barker & Wright, 1955).

As an example of that flow of effects, we take an episode described by Barker (1968). The site is a classroom. The children are 7 years old. The activity to be organized is to be like the performance of a rhythm band. There are not enough instruments for each child, and the teacher gives red pencils to the children who miss out on an instrument. They are to wave their pencils in time with the band. One child given an instrument, however, was not cooperating, "was acting silly" (Barker, 1968, p. 171). The teacher then took away the instrument given to him, passed it to a child without one, gave the less cooperating child a red pencil to

wave, and placed him on the far side of the piano: the side away from the class.

In this and other episodes, all three aspects (place, activities, and people) are seen as contributing to what happens. In this case, the classroom site is small, with little room for alternative activities. The activity offers few alternatives. All the children in the class are expected to participate and to coordinate precisely with what the others do. The ratio of teachers to children (there is only one teacher) means that there is no extra person to provide alternative activities or encouragement for those less interested in participating. All three circumstances make it more likely that some children will be reluctant to participate, and that the teacher will develop a more authoritarian and less flexible style.

**Place.** As a way of describing contexts and development, place has been considered sometimes in terms of physical spaces, sometimes in terms of social spaces (e.g., routes to a different level of education), and sometimes in terms of social meanings (e.g., links to a sense of belonging or identity). That diversity may have both positive and negative effects. On the negative side, it may become difficult to recognize the particular aspects of place that people have in mind when they use terms such as *neighborhood* (e.g., Leventhal, Dupéré, & Shuey, Chapter 13, this *Handbook*, this volume; Nicotera, 2007). It may also make it seem difficult to consider place as a unit of analysis.

More positively, diversity in what is implied also prompts attention to what is common, for example, an interest in boundaries, barriers, routes or paths of several kinds (e.g., entry, exit, or recovery routes). Common also is interest in divisions of space in relation to people (e.g., divisions by gender or age, or provisions of sheltered niches for the more vulnerable). Prompted as well are questions about interrelationships among aspects of place. Ethnic distinctions, for example, might be expected to diminish in the course of weakened physical boundaries (e.g., as people flow out of an area once marked by most people having the same ethnic background). The reality, as Barth (1969) pointed out in a still highly influential argument, is often one in which ethnic groups seek to maintain or generate a sense of difference, regardless of the loss of other kinds of boundaries. When, why, and how this happens then become the questions to answer.

That interest in interrelated aspects of space brings together the physical and the social. The emphasis, however, may fall on one aspect rather than the other. Within psychological analyses of development, for instance, the emphasis often falls on children's knowledge of the routes

that lead from one educational level to another and on their readiness to follow those routes (e.g., Cooper, Dominquez, & Rosas, 2005). The physical aspects of place then seem to drop out of the picture. In similar fashion, it is possible to ignore the connection between place and children's competence that Labov (1972) found in African American children's ability to use completely different ways of speaking in the classroom and with peers outside school.

Those aspects, however, lead to some further ways of looking at development and some further research directions. The first is an expansion of proposals about development as a response to needs or tasks: a proposal encountered in the course of considering studies of universals (Line 1). In regions where food supplies call for travelling among islands, people develop and pass on navigational skills. When communities continue to live in the same space, particular skills and associated values are likely to be consolidated and in turn, to give rise to an increase in cultural differences and cultural diversity (Whiten, Hinde, Lalande, & Stringer, 2011).

As an example, we take a study that brings out the significance to children of learning safe ways through spaces. Children who were new to a school were asked to draw pictures of places where they felt comfortable or not comfortable. Often included in the uncomfortable and, if possible, avoided set were school areas where children felt unsafe: areas, for example, "where there are fights" (Sampson & Gifford, 2010, p. 128).

Safe/unsafe distinctions also bring out the presence of several bases to learning. One undoubtedly consists of direct encounters with open or closed access. Mountains with no clear paths restrict access to other areas. So do the restricted opening hours of schools, shops, and banks. A second is likely to be the presence of paths already established by previous generations. A third is the occurrence of direct instruction. A fourth may be an intuitive sense of what is possible or wise and what is not. Little or no experience or instruction may be required. The gloomy inner depths of forests, for example, may quickly be seen as unsafe and best avoided. A further base consists of narratives about place. Narratives have come to be given increasing attention in accounts of socialization (e.g., Miller, Fung, Lin, Chen, & Bolt, 2012). Narratives about safe and unsafe places, however, have attracted surprisingly little attention. Fiske (1991) draws brief attention to them, but leaves a great deal unexplored. We might ask what kinds of narratives are likely to be told.

Likely to be passed on when paths are not well established, for example, are accounts of people who have

managed to explore uncharted and dangerous areas and have made their way home. Passed on to children at an early age appear to be narratives that warn them about venturing into unsafe areas. Often told, for example, are stories of ghosts and ghouls, of wolves, dragons and trolls, all containing messages about the dangers of wandering away from a known base. If you do wander, the story of Hansel and Gretel adds, leave a trail behind you, even if it is only a line of crumbs. Learning about safe/unsafe areas, however, is far from confined to early ages. It is, for instance, often a major concern for parents when their adolescents do not disclose where they might go or have gone. There is much to lose when interest in contexts and development is confined to one life-phase.

**Activities.** Analyses of development in terms of activities—analyses that start primarily from what people do—have a considerable history, related to more than one conceptual position and one discipline. They have also varied considerably in the aspects of activity that have attracted attention. We focus on three. The first has to do with distinctions among activities, and the second with nonparticipation: its nature, its course, and its bases. The third has to do with principles or conventions related to joint activities: agreement, for example, on what each person involved in a joint activity should contribute and when they should do so.

Two distinctions among activities have attracted particular attention and are especially relevant to analyses of contexts and development. One singles out activities regarded as cultural practices. The other singles out activities usually described as forms of participation. These two do not exclude one another. They do, however, attract different proposals about development.

The term *practice* is usually reserved for routine ways of doing things that people come to think of as normal or natural, seldom think about or question, often find uncomfortable to change. Within analyses of practices, ways of thinking and ways of acting are also often seen as interconnected rather than separated. Ways of thinking, for example, are seen as often growing out of accumulated ways of acting, with changes needing to start from changes in practice. To take a much-used example, the first step toward changes in gender schemas and attitudes may need to be changes in our everyday ways of "doing gender": gendered separations, for example, of spaces and of tasks or occupations.

Conceptually, the starting point for an emphasis on practices comes more from anthropology than from psychology. Ortner (1984) provides a short but informative review

of its rise in anthropological analyses of contexts and of what people feel they should do. Overall, Bourdieu is the most often cited source (e.g., Bourdieu, 1990; Bourdieu & Passeron, 1977). In these anthropological sources, however, there is little reference to the lives of children. Miller and Goodnow (1995) and the several papers in Goodnow, Miller, and Kessel (1995) fill part of that gap. Helping to fill it are also studies of family routines (e.g., Fiese, Foley, & Spagnola, 2006). Family routines, however, do not always qualify as cultural practices. As we have noted, the adjective *cultural* adds the quality of being widely shared. Children are then likely to be given the same message from several sources; making some ways of thinking or acting seem all the more right or normal. That communally shared quality and its impact, may not always apply to family routines.

Within analyses of child development, distinctions among activities are often drawn in terms of the nature of participation, coordination, and collaboration (e.g., Rogoff, 2003; Rogoff et al., 2007). Within these analyses, the usual reference is to activities where people work together in face-to-face fashion. They then have direct access to each other's actions and perhaps intentions.

What further forms might analyses of activities and participation take? For one step in this direction, we turn to an observation by Lave and Wenger (1991). They noted that coordination does not always take the form of people working together in face-to-face fashion. Instead, people may be expected to develop skill in various parts of an action, with the team then needing to be sure that others will know their part well and will perform it at the expected time. A crew bringing a ship to shore provides an example. Activities calling for that kind of coordination have primarily been considered in terms of adult cognition. They are significant, however, at all ages. They also bring out a further aspect to development: the development of trust. Parents or other guides are likely to aim for coordination and trust over and above children's intellectual or physical abilities to carry out a task. In some cultural contexts, it may also be regarded as an intrinsic mark of maturity, and at times as more significant than changes in capacity (e.g., Serpell, 2011; Serpell & Jere-Folotiya, 2008).

Analyses of development are often shaped by the wish to account for approved changes or for ways to promote them. Both novices and experts have then usually appeared as willing and interested participants. In some analyses, however—mostly anthropological—experts have been described in less positive terms. They are sometimes seen as protecting their knowledge, passing it on only to a selected few (e.g., Bourdieu, 1990), or as sometimes

extending an apprenticeship as a way of prolonging cheap labor (e.g., Lave, 1991).

In analyses of childhood, however, reluctance on the learner's side has often been the focus (e.g., Kuczynski & Hildebrandt, 1997, emphasizing the need for models of both conformity and resistance). As a specific example, we take children's ideas about school. That topic has been a source of two conceptual approaches (Hartas, 2011). In one, participation is seen as an individual's choice. Teachers may describe those who choose not to participate as disaffected, as deviant, or as strugglers opting for nonparticipation as the safest way to act (Blumenfeld et al., 2005). In the other approach, nonparticipation stems from the nature of the situation that students see themselves as facing. Students in several English high schools, for instance, described their schools as offering only token forms of participation, as failing to match what students saw themselves as needing, and as concerned only with some students. In the words of one "disaffected" student: "Only the very clever or the very bad get...attention" (Hartas, 2011, p. 108).

As an addition to school settings, we turn to activities where children's presence is not compulsory (e.g., organized sports or other clubs; Caldwell & Smith, 2007). Here nonparticipation can take the form of staying away or participating only in the available social networking. Whether adolescents stay in these activities often depends on the extent to which there are opportunities for choice, control, or variation in what they do. They often drop out when these opportunities are not present, or when there is no compensation such as opportunities for social networking. These proposals, based on observations of free-time activities among adolescents in Cape Town, point to a direction that would extend developmental analyses of both participation and nonparticipation.

**People.** Like analyses of activities and participation, analyses of the role of people now have a considerable history, stretching across more than one conceptual position or discipline. We focus again on three shifts. The first has to do with the social and personal meanings that people attach to what they observe, and the second with the role of people as audiences or evaluators. The third has to do with the significance of relationships among people.

We have seen the importance of the meanings that others assign to changes in competence: not always the status that new learners expect. We now add the meanings attached to how space is divided among people. To take one example, adults often add both social and moral meanings to the way

space—sleeping arrangements especially—are divided among family members, often regarding those meanings as grounds for uneven distributions of space, shared spaces, or not using all the space available (Shweder, Jensen, & Goldstein, 1995). The meanings children attach to such divisions of space seem likely to cover both social and moral issues.

A familiar interconnection between people and activities is Vygotsky's (1978) analysis of the zone of proximal development. Development starts with a learner being assisted by someone more expert. Help then diminishes up to a point where the learner—the novice—no longer needs this kind of help. The expert then steps back. That kind of interconnection has come to be taken for granted. In contrast, there are surprisingly few developmental studies of people in the role of audience. Banerjee (2002) noted the scarcity and provided an example. Children aged 6 to 11 varied in their self-descriptions when told that the audience would be an unfamiliar peer or an unfamiliar adult, and whether those in the audience preferred “clever people” or “sporty people.” Variations were more marked at the later ages, but some were present already at Age 6.

In a different kind of study, an unfamiliar adult asked pre-school children to draw a person: a standard procedure in many tests of developmental status. The children produced images of people who were upright, not moving, and had all parts “present and correct.” Drawing for themselves, however, on paper often discarded, they played with more demanding and imaginative images: people who were, for example, often bending or moving, and with fewer standard parts. Audience sensitivity can clearly start at an early age (4 to 5 years in this case) and take some particular forms (Goodnow, 1990).

The third example we select considered changes, over the course of gaining expertise, in the audience that people kept in mind (Oura & Hatano, 2001). In the early stages of learning—learning to play the piano—the teacher was the primary audience. Learners played with this particular person in mind. His or her judgment was what counted. The significant audience changed, however, when people began to play in competitions or in concert performances. Then they began to consider what this new audience expected to hear and, at a more advanced level, how far audience tastes might be extended to a new piece or a variation on a familiar one. People as audiences remained important. What changed was who they were, their possible diversity, and the need to estimate what they might expect.

People are always part of a relationship. This aspect of people and contexts is a strong part of proposals to the

effect that all learning and all interactions among people are imbedded in specific relationships. Relationships, to repeat an earlier point, are also a major part of participation principles. Those principles are often about “*relational* rights and responsibilities” (Stone et al., 2012, p. 72, italics in original), setting limits on “how, what, and with whom conceptual and/or concrete tools are expected to be used in learning activities” (pp. 72–73).

In an innovative and more integrative move, Stone et al. (2012) made people part of a proposed four-part unit of analysis. Instead of Barker's (1968) unit of place, activities, and people, they proposed the unit of “an ensemble of relations enclosing self, tools, tasks, and others that is inter-subjectively constructed and sustained over time in formal and informal learning environments” (p. 66). Conceptually, Stone et al. (2012) described this and other proposals as influenced by Bourdieu (1990). From that work, but with reservations, they derived a strong interest in ways of thinking and acting as practices, and in the views people develop that cut across practices or situations (essentially covered by Bourdieu's term *habitus*).

The reservations that Stone et al. (2012) expressed were predominantly about what they saw as a “reproductive” bias in Bourdieu's proposals: a bias seen as overlooking the importance of agency and of intersubjective processes. They saw too little attention to the “communicative processes to coproduce knowledge and . . . to interpret, (re)shape and (re)create it for themselves” (Stone et al., 2012, p. 68). They also saw Bourdieu's account as neglecting the perceptions people develop of themselves, others, and relationships. The examples considered in detail were drawn predominantly from classrooms. The same kind of description, however, was brought to simpler activities: activities such as a mother reading a book to an infant. Here there is a combination of self, of other, and of a relationship. Here also is a tool (the book in this case) and a task: a task that calls for achieving some sense of an action to which both contribute and some coordination of actions and meanings. The participants may not necessarily achieve a shared meaning (“inter-subjectivity can . . . include disagreement and agreement, consensus and conflict”; Stone et al., 2012, p. 70), but both have a sense of contributing to whatever emerges. This is certainly a complex but provocative way of considering, as units of analysis, interconnections among tasks, tools, self, and others.

In the main, analyses of place, activities, and people focus on the development of competence. Implied then is a particular dichotomy: a separation of cognitive from social development. One move away from that separation

is a reminder that tasks and areas of competence always have a social meaning. Some, for example, are regarded as significant areas of expertise. Others are seen as trivial pursuits. No form of expertise can then be seen as “purely cognitive” or, for that matter, “culture free” (D’Andrade, 1981). The relevance of competence to social meaning and social status appears also in Lave and Wenger’s (1991) comment on the common assumption that an increase in competence will bring with it a change in social status. The end of apprenticeship, it is often assumed, will lead on to membership in a community or guild of experts. That does not always occur. Rogoff (2012) adds the important point that a change in competence alters not only social standing but also a sense of personal identity. The life course of a Mayan midwife is a prime example. Her sense of fulfilling her “destiny,” and becoming recognized as the top midwife in her community depended on more than expertise. It depended also on her commitment to a new role and her readiness to give up some other activities or to accept their disruption in order to meet the demands of a midwife role.

### ***Questions and Directions***

As we did in Line 1, we ask how Line 2 expands our understanding of the intertwining of cultural contexts and development. Conceptually, Line 2 introduces a broader set of comparisons. These are not only across cultural contexts but also within them. Line 2 also expands the descriptors and dimensions used as an interconnected set for any comparison. The set now covers places, activities, and people. The interweaving now becomes more complex and more rewarding.

The studies by Barker (1968) and his colleagues drew attention to the significance of considering all three together in any setting. As an example of how this kind of approach may be extended, we single out a study called *Children of the Land* (Elder & Conger, 2000). The diverse circumstances fed into parents’ decisions to leave or stay on a farm. These included the land’s productivity, the availability of alternate occupations or funds to help meet new demands, opportunities for children, the significance of the farm as a part of family history, and the significance of geographic closeness to other members of the family. This study also brought out the selective nature of effects on people. A sense of loss appeared to be most strong among fathers who had grown up on the farm, less strong for women who had married into farm life, and least strong for adolescents who knew some of their peers had gained access to paid work by virtue of living in town.

Making people a significant descriptor and examining their interconnections with sites and activities also highlights the social or interpersonal aspects of what is happening in any setting. Most activities have interpersonal significance. Other people are always part of the picture. They now do more, however, than present tasks and provide resources. They may be organizers, helpful experts, audiences, coworkers, or part of an accompanying social convoy. With that expansion, the active contributions by children also become salient. Their roles move further away from the role of passive child and beyond the alert observer seeking ways to solve a problem. In some situations, children take the lead and adults need to respond. When they are invited to participate in a joint activity, children also have the capacity to join or to resist, to willingly take part or to let their unwillingness show. All of these forms of participation change the activity, the relationships among people, and the provisions that the situation makes for them.

Accompanying the change in perspective is a related shift in research approaches. Comparisons may still be made across cultural contexts, directly or implicitly. Now also seen as useful, however, are comparisons across generations, across positions in a group (e.g., advantaged or disadvantaged), or across circumstances (e.g., times of large or small changes). Increased attention to tasks and measures brings out also cognitive and social aspects to the development of competence. Imitation is one such task. Children may under imitate (discarding irrelevant moves) when their goal is one of improving their problem-solving competence. In contrast, they may be less selective, or select in different ways, when the aim is to show that they admire particular people or wish to be seen as like them (Over & Carpenter, 2012). That phenomenon is obvious when older children imitate the ways in which selected others dress, speak, or communicate with one another. Over and Carpenter (2012) however, highlight its occurrence at an early age.

The social aspects to children’s participation emerge also in tasks where adults differ in the information they provide. One adult, for example, says that an unfamiliar fictional animal is called an X. Another says it is called a Y. Whose advice do children follow? This kind of study is a check on the assumption that young children place an indiscriminate trust in adults as informants. Children as young as 3 years of age turn out to be selective in their choices of whom to trust (Harris & Corriveau, 2011). In one set of studies, children based their choices on past interactions with the people offering information. In a second set, when informants were unfamiliar, children

followed the advice given by informants they saw as like themselves in appearance or as people approved by others. Overall, Harris and Corriveau (2011) conclude, “even if children are surprisingly indiscriminant in choosing *what* to believe, they are nonetheless quite selective in choosing *whom* to believe” (p. 1180). They judge the sincerity and trustworthiness of other players. Young children also emerge as being aware of shared conventional knowledge (Diesendruck & Markson, 2011). They not only know what does and should happen, but they are able to specify their own roles, and give them descriptions (Banerjee, 2002).

Like Line 1, Line 2 leads to a clearer understanding of cultural contexts and child development, and points to an expanded set of conceptual and research approaches. What then is added by a further line of analysis that focuses on changes in situations and on diversity in the ways of thinking and acting that children encounter?

### **Line 3: From Continuity to Change, From Uniformity to Diversity**

Within early analyses of culture, the emphasis often fell on continuity. Continuity, or the aim of continuity, was regarded as the defining characteristic of culture and the aim of each generation. Geertz (1973), for instance, defined culture as “a system of inherited conceptions expressed in symbolic forms by means of which men communicate, perpetuate, and develop their knowledge about and attitudes toward life” (p. 89). Shifts then took the form of increasing emphases on the occurrence of change as a marker not only of modern society, but also of all cultural contexts.

The earlier emphasis often fell also on monolithic ways of thinking or acting that all people in a social unit shared or were expected to share. That monolithic emphasis was often expressed in the form of differentiating among cultures by labels such as Christian or Islamic, collectivist or individualist. A major shift was the recognition of heterogeneity and diversity. The optimal perspective involved recognizing that in any social unit there always is more than one way of thinking or acting: more than one political view, one form of schooling, one form of worship, one approach to child-rearing. Sometimes, contest or competition among these varied ways was no problem. At other times, contest was accompanied by efforts toward maintaining hegemonic status, suppressing or keeping on a lower rung any alternatives or challenges (Gramsci, 1971). Shifts away from emphases on continuity and on monolithic views of culture are not unrelated. The presence of diverse viewpoints may make change more likely to occur. The starting points for

the two shifts, however, are not the same, and we take them up in turn.

### ***From Continuity to Change***

A shift in emphasis does not involve treating continuity and change as either/or alternatives. Both occur. For change, the challenging questions then have to do with what changes, at what rate, who is most affected by it, who pushes or resists it and why, and what resources they use to promote or resist change. A first distinction has to do with the size and predictability of change. Some changes are large and unpredictable. Others are experienced as small and predictable. We start with the large and unpredictable, with the recognition that how people respond to these changes—their sense, for example, of helplessness or of hope for the future—is also relevant to analyses of smaller changes.

Research on *large-scale changes* now covers a wide field. It has also shown a major increase in the last two decades (e.g., Elder, Shanahan, & Jennings, Chapter 2, this *Handbook*, this volume; Masten, Naryan, Silverman, & Osofsky, Chapter 18, this *Handbook*, this volume; Silbereisen & Tomasik, 2010). Considered have been large economic shifts (e.g., global economic downturns), large political shifts (e.g., the breakup or reunification of a country, or an internal revolution), natural disasters (e.g., tsunamis, earthquakes, floods), technological changes (e.g., the invention of the printing press and the computer), or as taken up in Line 4, large population flows from one part of the world to another.

Among studies of *large economic changes*, we choose as a starting point a longitudinal study by Elder (1974) on the effects of The Great Depression on family members within the United States. We single it out at this point, because it contained an early recognition that effects were not the same for all family members: a within-family variation that has increasingly become a focus of interest in analyses of all changes (Elder et al., Chapter 2, this *Handbook*, this volume). Children who were already adolescent showed fewer long-term adverse effects than did younger children, perhaps because of a difference in the opportunity to engage in part-time work. For that work, they were often paid at lower than adult rates. Those amounts, however, still made a significant and appreciated difference to the family income.

Several other studies extended that line of research. Conger, Schofield, Conger, and Neppl (2010), for example, considered the flow-on effects of the economic downturn in the United States in the 1990s. Links to development, they proposed, stemmed from two processes. One was

social causation in the sense that developmental changes were driven by the economic shift. The other was social selection in the sense that consequences differed across individuals. Those who had shown more distress as adolescents during the economic downturn also experienced later difficulties as parents of young children.

As an example of *political change*, we take the end of division between East and West Germany. Up to that point, political changes were mainly seen as increasing risk. The shift was to regarding them as a mix of risks and opportunities, especially for young people from East Germany. They now had the opportunity to move away from home at younger ages (e.g., Juang & Silbereisen, 2001). A further example comes from political changes in Turkey. After the establishment of the Republic of Turkey in 1923, the shift was toward a secular nation, compulsory schooling, the provision of family planning services, and a general change from a rural to an urban population (Ataca, Kağıtçıbaşı, & Diri, 2005). The striking outcomes were a drop in the size of families and a change in gender hierarchy. This took the form of moves away from a father's complete authority and from a marked preference for sons over daughters. Those changes were widespread, but again selective. In rural areas, a larger number of children than the advocated two per family seemed to reflect less easy access to family planning services.

There is now available a series of studies focused on children's experiences of *natural disasters*, war and violence and on procedures for intervention after their occurrence (e.g., Masten & Osofsky, 2010; Masten et al., Chapter 18, this *Handbook*, this volume). As an example, we take a study of the aftermath of the Indian Ocean tsunami of 2004 (Exenberger & Juen, 2010). Children differed in their sense of subjective security and wellbeing five years later. Children still living with one or both surviving parents often commented on their fear. Tsunami-related triggers still scared them, but they had overcome their fears of the sea and now enjoyed the seaside. In contrast, children living in out-of-home care in children's villages mentioned the orderliness of their lives and the availability of the food and shelter that the family-based children did not have.

*Technological change* provides a different set of circumstances. As a specific example, we take a study by Hansen, Postmes, van der Vinne, and van Thiel (2012). They analyzed the effects of providing a laptop to a group of children in Ethiopia: a country where fewer than 10% own a computer or have access to the Internet. In 2008, the government distributed 6,000 laptops to children in several rural and

urban schools. The 169 children in a follow-up study were in the 12-to-16 age range. They all attended the same school in a small city in Northern Ethiopia. There were 69 students who could still use their laptop, 24 whose laptop had broken down, and 76 who did not receive a laptop. At the end of the year, those who still had a laptop in use, compared with the other two subgroups, showed a stronger view of themselves as independent and a stronger endorsement of the value of individualism. Among the processes that underlay these effects were the usage of the technology (a broken laptop produced no such change), and gaining higher status where ownership of anything as valuable as a laptop was unusual.

*Conventional change* is at the opposite end of the range to large and unpredictable change. Studies of transitions to school are relevant, in large part because they have been seen in two quite different lights. In one, the transition has been seen as a small and expected change. In the other, this transition is recognized as a major change. What has been allowed or encouraged at home, for instance, may not fit with what is expected in school. In Fleer and Hedegaard's (2010) close analysis of this kind of change, for example, one boy's free use of space and "wandering" at home was sharply discrepant with the expectation at school that he would sit in one place and pay attention only to the teacher, and not to other children. He could no longer roam with either his feet or his eyes, and his skill in keeping track of events around him was not valued. In keeping with a frequent attribution, the teachers interpreted difference as deficit and sought to have him referred for help with an attention deficit disorder: a referral resisted by his parents.

A study by Entwisle and Hayduk (1978) focused on variations with social class is an example of how the transition to school is minor for some children and families but not for others. Parents of the educated middle class put effort into preparing their children for the move. They also looked for ways to maneuver around its rules: checking on any differences among teachers and on how to arrange for their children to be in classes taught by preferred teachers. In larger terms, these variations are not simply an example of differences in social class. They are also an example of differences in what has been described as cultural capital (Bourdieu & Passeron, 1977). At the far end of the scale, appear to be children with a refugee background. For them, the first day of school may be like stepping into an unknown world. There may be no advance preparation for what they are likely to encounter. For some older children, it may also be their first experience of school. For others, there may be no sense of making the transition along with others who are

at least close to them in age. In one example from ongoing research by Brooker and Lawrence, a 19-year-old refugee finds himself not only in school for the first time, but also being placed in a class where everyone else is 15 or 16 years old and has been in school since the age of 5 or 6.

### *Change and Persistence*

The focus on change has been a needed shift from the focus on continuity across generations. When that shift becomes completely one-sided, however, the challenge involves accounting for what Patterson (2010) called the “puzzle of persistence” (p. 139). The practice of female circumcision, for instance, persists in countries where, after long tradition, it has been declared illegal. It also persists when families move into a country where most people regard the practice as an unthinkable mutilation, a violation of basic human rights, a form of child abuse and, for all these reasons, a practice to be stopped, with a first step being its formal declaration as illegal (e.g., Barstow, 1999).

What then makes such a practice persist? Several proposals have been offered. One is the presence of multiple justifications: a strong indication of a practice with multiple bases. Barstow (1999), for example, lists 19 justifications, ranging from religious sanctions through to ways of ensuring virginity and chastity and being regarded as clean, honorable, beautiful, and marriageable. Another is widespread resistance to change (e.g., Shweder, 2000). Women are often reluctant to challenge or depart from tradition, driven by fear of social isolation and of being regarded as strangers in their own communities. Girls have expressed similar concerns. In their experience, uncircumcised girls are bullied or teased, excluded from activities such as the preparation of food, treated as “unclean,” and denied being recognized as a woman rather than a child (Yirga, Kassa, Gebremichael, & Aro, 2012). Objections to the practice are also often set aside as coming from outsiders who do not understand its significance and meanings (Khaja, Lay, & Boys, 2010).

From studies of persistence in all its forms come further proposals. In some, practices are seen as persisting because they suit people with vested interests and power (Bourdieu & Passeron, 1977; Gjerde, 2004). In others, persistence stems from the absence of change in the concerns or circumstances that prompted the practice in the first place (Barth, 1993). Patterson (2010) adds to these the extent to which a practice has become normalized (“this is what everyone does”) and part of people’s identity and social acceptability.

Justifications, however, are still not the final word on continuity and change. For all practices, analyses of change have highlighted the need to ask more specifically what changes and what continues, for how long, and whether those shifts are common to all social units. Fuligni (2012a) raises those questions in relation to immigrant families who have been in the United States for more than one generation. First and second generation immigrant children with Asian backgrounds, for instance, do better academically than do children with nonimmigrant or Hispanic backgrounds. By the third generation, however, their academic aspirations and performance become more like those of their nonimmigrant peers. Once again, what appeared to be a simple dichotomy—in this case, a distinction between children with and without particular immigrant backgrounds—turns out to need refinement by recognizing that persistence and change should be considered together. Whether one or the other occurs in relation to particular ways of thinking or acting depends on particular circumstances. Predicting any outcome, to take a comment from Fuligni (2012a), might best start from the view that “it all depends” (p. 305).

### *From Uniformity to Diversity*

Cultural contexts have often attracted the perception that they are marked by widely shared ways of thinking or acting, and that these do not differ greatly from one person to another. A contrasting perspective places its emphasis on diversity or heterogeneity. That perspective has a strong starting base in both sociology (e.g., Gramsci, 1971) and anthropology (e.g., Strauss, 1992). In both, it has also been accompanied by interest in how people respond to challenges or questions related to their own ways of thinking or acting, and in their strategies for achieving different outcomes to the contest. We start with how people respond to challenges or questions. Is their response, for instance, one of tolerance or an attempt at suppression? We turn then to the strategies people use to achieve their preferred outcomes and the circumstances that may prompt one strategy rather than another.

### *Levels of Tolerance for Departures From Expectations*

Some departures from conventional ideologies or practices may be regarded with amusement or interest, or even as having positive effects. Within families, for example, parents and children may see differences as an opportunity to work a problem through in ways that promote developmental change for both generations (Scabini, Marta, & Lanz, 2006). Response to a break from the norm may

also depend on the extent to which the value challenged is regarded as significant, with parental responses more authoritarian in style when the value challenged is highly regarded (Padilla-Walker & Thompson, 2005). Response may also be affected by the timing of a challenge. Parents, for example, may easily tolerate behaviors regarded as not likely to last, as “just a phase.” They may be less tolerant if the same behaviors persist when children are older (Dix, Ruble, Grusec, & Nixon, 1986). In broader terms, within families and in other contexts, “the construct of tolerance reflects a discrepancy in response from what is normative” (Brestan, Eyberg, Algina, Johnson, & Boggs, 2003, p. 12).

To that broad proposal, we add attention to what people find completely intolerable. Studies of this response have been primarily at the adult level, but these offer some guidance about what we might look for when children are involved. Some ways of thinking and acting are certainly regarded by adults as unthinkable, heretical, or taboo (e.g., Tetlock, Kristel, Elson, Green, & Lerner, 2000). One basis for those evaluations seems to be the perception that there has been a serious break in the expected nature of relationships. “This is supposed to be a family,” for example, was the horrified response to one sibling grabbing what other family members expected to be shared with them when a parent had died (Goodnow & Lawrence, 2013). In similar fashion, a marriage partner’s sense of a caring relationship disappears when the feeling arises that a partner is exploiting the relationship, taking advantage of what has been freely offered and making no attempt at reciprocity (M. S. Clark, Graham, & Grote, 2002). Questions still remain about how far a concern with reciprocity exists, or takes the same form at different ages and in different cultural contexts. At the least, expectations of reciprocity have appeared across all adult life phases (Lang, Wagner, & Neyer, 2009).

### *Strategies for Achieving Hoped-For Outcomes*

What do people do when they encounter ways of thinking or acting that they see as conflicting with their own? It is clearly not enough to say that these encounters are regarded with more or less surprise or tolerance. To be added are observations of the varieties of strategies people use and the bases for turning to some rather than others. Ogbu’s (2004) description of the history of Black America is a major example of variations. Strategies often changed from one historical period and one situation to another but all carried their own costs. In one—not an option for some—people left an area or a country. In another, people disguised the way they felt, or redefined themselves, for

example, as warriors (freedom fighters) rather than as victims. Some found ways to “pass as White,” others varied the way they acted and the language they used from one situation to another.

Those strategies are not limited to African Americans. In all cases, however, we need to ask about the circumstances that promote them. For these, we draw material from studies of four strategies: *nondisclosure*, *disguise*, *changing course*, and *negotiation*. *Nondisclosure*, for instance, may be necessary for survival. Going underground may be the only option. With less risk, being open may bring to the surface a past that is regretted, is incompatible with one’s current image, would be difficult for one’s family to accept, and is best forgotten or not discussed. Being open may also invite restrictions. Disclosure to parents, for instance, may make it impossible to maintain activities that, once known, would invite parental intervention (Stattin & Kerr, 2000).

*Disguise* is a particular self-protective strategy that can be seen in studies of the experience of family poverty. In one example, Thorne (2005) singled out school lunchtimes in a part of California with a range of income levels. Some children could qualify for free school lunch or a reduced price lunch at the cafeteria. Others could buy lunch at full price or bring it from home. Lunchtime arrangements then were a clear signal of the family’s level of poverty: one that some children avoided by not having lunch at all. A contrasting attempt to disguise poverty is described in Hamilton’s (2012) study of 30 low-income families from urban areas in Northern Ireland. The predominant strategy in that group was one of conspicuous consumption. In excess of need, mothers often bought expensive brand name products, especially for their children. Paradoxically, that strategy often led mothers to “encounter the very stigmatization that they set out to avoid” (Hamilton, 2012, p. 87).

For strategies in the form of *changing course*, we take again a study related to income. This time the concern is unpredictability rather than level. When income is erratic, for instance, family routines often become difficult to sustain. Childcare arrangements that carry financial costs may be sometimes affordable and sometimes not. In the face of unpredictability, however, parents change course and rely completely on the provision of care by family members (Lowe, Weisner, Geis, & Huston, 2005). Changing goals related to schools provides a different example. Both children and parents may seek to avoid circumstances where the children face what they see as repeated failure. Leaving the situation—leaving school—may not be an

option. Children then may turn to sport as a main interest (Eckert, 1989).

*Negotiation* is the last strategy we consider. We shall see more of it when we turn to Line 4 and change and diversity in relation to immigration and acculturation. The core issues, however, have consistently to do with what is negotiated, why, and how. Negotiated, for example, are forms of work, support or in more culture-oriented fashion, identity. People may seek to be identified as a “genuine refugee” rather than an “economic refugee.” People may also seek to be identified as someone who has been in the area long enough to be regarded as a full member rather than as a stranger or a newcomer. There may be several reasons for negotiation. A direct battle, for instance, may carry too high a cost, especially in relationships that are expected to last. The more effective strategy may then be one of compromise, of meeting others half way between what you and they want; a strategy noted in studies of Japanese adult children and their parents (Izuhara, 2004). Young children may also use the same half way approach, or search for ways that will persuade others to change their position (Kuczynski & De Mol, Chapter 9, this *Handbook*, Volume 1). This avoids the appearance of simple refusal or noncompliance but, at the same time, allows children to achieve their objectives. We may well expect that cultural groups will vary in the kinds of arguments they find to be reasonable or persuasive. In all groups, however, even young children seem to test the effectiveness of various ways forward, looking for strategies that will carry some hope of success and avoid punitive responses. In effect, the strategies people use are largely related to what they feel is the nature of the threat, to what the situation allows, and to what resources are available and accessible.

### *Questions and Directions*

Line 3 brings out the complexity of the web that interweaves cultural contexts and developing children. Early views of cultural contexts as constant and unchanging give way to recognizing that they are more often fluid and changing, presenting children with both opportunities and constraints. Early views about children encountering a world of single messages about what can or should be done give way to recognizing that cultural contexts often present them with diverse and competing messages that may be experienced as exciting, or as confusing and threatening.

To the close analysis of the changing and diverse nature of cultural contexts, we now need to add closer analyses of the parts that children play, and how the part played by the cultural context and the part played by the children

intermesh and coordinate. Children interpret what is happening. They develop strategies that may make it easier to cope with or to benefit from the shifting and competing worlds they encounter. In related fashion, people who see themselves as responsible for children develop interpretations and strategies for themselves and offer some of these to their children. Given the variety of experiences that is possible, and the variety of interpretations and strategies that people generate, it is not surprising that the significance of change and diversity may vary a great deal from person to person. The issues now needing further investigation are the nature of interpretations and strategies, the circumstances in which people change and, a point emphasized by Lerner (2011), the extent to which people’s intentions and actions are likely to have beneficial effects for both themselves and the context. Among the bases for adult strategies are likely to be their views of children and what children can and should be able to manage. Among the bases for children’s strategies are likely to be where they see themselves as standing or wishing to stand in relation to other people in the context (Over & Carpenter, 2012).

Research procedures may once again involve the choice of children to compare, taking note of the selective nature of their experiences and what has followed from them. In the face of adverse circumstances, one research choice may be a focus on those who “manage to make it” (Furstenberg, Cook, Eccles, Elder, & Sameroff, 1999, p. 1), then comparing them with those who did not do so well (Masten et al., Chapter 18, this *Handbook*, this volume). Another choice is to ask less about levels of change and more about areas of recovery or continuing difficulties (e.g., Exenberger & Juen, 2010).

In the face of diverse and competing ways of thinking and acting, the comparisons of particular interest are likely to involve the strategies that adults use to keep children within their cultural boundaries. One is to erect barriers to other experiences and interpretations. Children in highly orthodox families may be protected from knowing people with different beliefs or even reading anything but approved material (Lawrence, Benedikt, & Valsiner, 1992). Another consists of allowing children to know about other ways of thinking and acting, while encouraging them to avoid making commitments to these alternatives, or becoming like people regarded as “them” rather than “us.”

In the face of changing or competing cultural contexts, research procedures need to focus on understanding people’s various interpretations and strategies, and on the ways in which these may change or be changed. Those moves,

however, need to be governed by respect for what has been experienced and for what has developed in relation to a particular cultural context, together with an awareness of vulnerability to further harm in the course of investigations and interventions intended to be helpful (Lawrence, Kaplan, & McFarlane, 2013). How to achieve research governed by respect is still an open issue, especially given the likelihood of differences being interpreted, even by researchers, as deficits (Cole, 2013).

#### **Line 4: From Single to Multiple Cultural Contexts: Analyses of Acculturation**

To this point, we have mostly considered change, continuity and diversity in ways of thinking and acting within a single cultural context. It would be difficult in today's global world, however, to find a cultural context exclusively comprised of people from one cultural background. Cultural contexts have always been mixing, prompted by circumstances that range from war, through colonization, missionary efforts, and intermarriage (Foley & Mirazón Lahr, 2011). They jostle for space and dominance, and often "collide" (Chandler & Proulx, 2008, p. 374).

We now take up questions of change, continuity and diversity when cultural contexts are jostling against one another. The bulk of the material comes from studies of immigration (e.g., Schwartz, Unger, Zamboanga, & Szapocznik, 2010; Yoon et al., 2013) or studies of people's resettlement after displacement and trauma (e.g., Goodnow, 2014; Kaplan, 2013). In all circumstances, however, the same questions arise: How far can one term—*acculturation* in this case—cover what is experienced, what changes or persists, and what responses people make to acculturation experiences?

#### ***Acculturation and Approaches to Change***

Like the term *culture*, *acculturation* suffers from an over-supply of definitions (Chirkov, 2009). Like the term *culture*, *acculturation* also has a history of unease with its meanings and use. That unease goes back to a committee appointed by the U.S. Social Science Research Council to clarify the field in 1935 (Redfield, Linton, & Herskovits, 1936). More recently, questions have arisen about whether the term refers to a state or a process (Sam & Opedal, 2003). It may refer, for example, to some people being more acculturated than others, or it may refer to the ways in which people change in the course of double or multiple cultural experiences.

We take statements from the 1935 committee's report on meanings of the term. One of these is often quoted and used as a "modal definition" (Chirkov, 2009, p. 98):

Acculturation comprehends those phenomena which result when groups of individuals having different cultures come into continuous first-hand contact, with subsequent changes in the original culture patterns of either or both groups. (Redfield et al., 1936, p. 149)

Considered important were movements into majority populations by "cultural-carriers" from a donor (Western) culture: missionaries, traders, or administrators. Unlike many later researchers, Redfield and his colleagues were looking to discover the acculturative adaptations made by receiving populations already in place rather than adaptations made by the newcomers.

A further statement about possible outcomes for both newcomer and receiving groups, however, is rarely quoted:

either a reworking of the patterns of the two cultures in a harmonious meaningful whole to the individuals concerned, or the retention of a series of more or less conflicting attitudes and points of view which are reconciled in everyday life as specific occasions arise. (Redfield et al., 1936, p. 152)

Mason took up the possibility of a range of outcomes in 1955. He criticized the single direction that acculturation research was taking. He specified the need to examine effects on the donor (for him, American) culture as well as on the majority culture to which its members came:

Most students of cultural contact have neglected to examine critically the character of the more familiar, dominant group, with a consequent incompleteness of analysis and conclusions about the acculturation of the exotic group. (Mason, 1955, p. 1264)

In effect, Mason was foreshadowing criticisms of the unidirectional approach that came to mark acculturation research (Chirkov, 2009; Rudmin, 2009; Schwartz et al., 2010). This was the tendency to investigate the adaptation of incoming or minority "exotic" cultural groups to the dominant culture, in most cases the United States. The dominant single direction approach nonetheless persisted (Rudmin, 2003). An influential study by Graves (1967), for instance, aimed at understanding psychological (individualized) as well as cultural acculturation, but for the minority group:

When culturally distinct groups are placed in continuous first-hand contact, can changes in the world view of the

minority groups be demonstrated to occur in the direction of those of the dominant group; and if so, under what conditions is such psychological acculturation facilitated? (p. 337)

Graves investigated the conditions in a South Western U.S. town under which adults from a long-standing Spanish American group and from an American Indian tribal group came to adopt “Anglo” norms. He proposed that norms and other aspects of psychological acculturation were dependent on how much individuals in these minority groups were exposed to, could access, and could identify with the dominant (“Anglo American”) beliefs. His analyses paved the way for a long line of unidirectional analyses. They also pointed to how much individuals within the minority groups differed—a point that seems to have been largely overlooked in later concerns with group-level change.

Subsequent research has largely neglected the earlier promises of investigating areas of change in both cultures. Berry’s (1997) description of four types or strategies of acculturation and their relative adaptive effects for immigrants has been particularly influential, although not without significant questions about the conceptual and empirical bases of the strategies (e.g., Chirkov, 2009; Rudmin, 2009; Yoon et al., 2013). These strategies of assimilation, integration, separation, marginalization identify different orientations both to holding onto a heritage culture and to taking hold of a mainstream culture. They usually focus on changes in incoming and minority groups, rather than the receiving dominant group.

Another question has to do with the distinction between acculturation and *enculturation* experiences. In most cases, acculturation refers to changes in the course of encountering a second cultural context. Enculturation usually refers to changes in the course of experiences in one’s birth or heritage cultural context. The two terms can become confused conceptually and in how they are measured (Lawrence, Brooker, & Goodnow, 2012; Oppedal, 2006; Rudmin, 2009). There are warnings, for instance, about using inappropriate measures, especially for samples of American Indians (Garrett & Pichette, 2000) and African-Americans who have always lived in multicultural spaces (Obasi & Leong, 2010). These warnings are another indication of the inappropriateness of parachuting measures across cultural groups and situational conditions. Overall, greater attention should be given to variations in people’s backgrounds, circumstances and responses to research questions (Goodnow, 2014).

### *Taking Account of Diversity*

Earlier we noted how Graves (1967) was concerned with differences among and within acculturating groups. A study from Europe also illustrates the significance of diversity across entering groups and across receiving groups. Vedder, Sam, van der Vijver, and Phinney (2006) compared patterns of acculturation change and adaptation among young people from Vietnamese refugee groups and Turkish guest worker groups in four European countries (Finland, France, Norway, Sweden). Vietnamese young people with little expectation of returning to Vietnam were more inclined to identify with the new country. Turkish young people with the expectation of possible return were less inclined to identify with the new country, and were higher on psychological adaptation but lower on social adaptation: results that fitted with their greater ethnic orientation and lower integration. Other differences in Vedder et al.’s (2006) sample, however, were related to diversity in the conditions of settlement. Members of both the Vietnamese and Turkish groups experienced most discrimination and least integration in Norway. Norwegian society was the least diverse of the four receiving countries, and this seems to have added to the discrimination/integration differences.

For diversity within a single cultural group, Abdullah & Brown (2012) reported that religiosity and adherence to African American culture had differential protective effects against alcohol use for young men and women. Women high on religiosity did not use alcohol frequently, regardless of their adherence to their culture. For men, in contrast, low alcohol use was related to being high on both religiosity and cultural adherence.

There clearly is a need for multidimensional models of the experience of double or multiple cultural experiences. Schwartz et al. (2010) offer such a model, arguing for the inclusion of multiple directions and multiple dimensions of change, particularly change in practices and values in both heritage and mainstream cultures. They recognized that acculturation cannot be treated as a single process. They also argued that only multivariate, higher order analyses would be likely to reveal the complexities of relationships among dimensions, directions and rates of change in groups and individuals. A multidimensional model also has potential to encourage new research directions. Here we single out one research interest that focuses on whether parents and children show the same patterns of change, and the effects of concordance and discordance in the acculturation experiences of families.

### *Acculturation Differences for Young People and Their Parents*

Differences in terminology and approaches once again cloud the issues. Intergenerational differences have been variously described as acculturation differences (Costigan & Dokis, 2006), acculturation discrepancy (Unger, Ritt-Olson, Wagner, Soto, & Baezconde-Garbanati, 2009), acculturation dissonance (Portes & Rumbaut, 2001), acculturative family distancing (Hwang, Wood, & Fujimoto, 2010), or intergenerational conflict (Kwak, 2003). Each of these concepts focuses on some aspect of distancing between parents and their children when their acculturating experiences fall out of step (Telzer, 2010).

We add two cautionary notes. First, Kuczynski, Navara, and Boiger (2011) suggest that we see this distancing as acculturation *gaps* centered on specific issues rather than as one, undifferentiated gap. The second is that the interpretation of parent/child discrepancies in immigrant families needs to include close comparisons with discrepancies in nonimmigrant families. There are recent findings, for instance, of greater concordance between adolescents and parents in mainstream families than was previously expected (e.g., Collins, Raby, & Cusadia, 2012). If the gaps found in immigrant families are seriously larger, then a closer look at the specific experiences that accompany immigration and resettlement is warranted. There were, for example, few culturally related differences in nominations of the personal strengths and school-related skills of elementary school children, as they were perceived by Somali and local Australian parent/child pairs. The most frequent differences were between all parents and their children and not between cultural groups (Dodds, Albert, & Lawrence, 2014). Among adolescents, Sam and Virta (2003) similarly found that intergenerational discrepancies were not greater in immigrant parent/child pairs (from Pakistani, Turkish, and Vietnamese immigrant families) than in comparable pairs from their host countries of Norway and Sweden. Across all these groups, adolescents were more concerned about their rights, but parents were more concerned about their adolescent children's obligations.

Some parent/child differences can be expected from immigrant youths and their parents, precisely because they live in different worlds and follow different pathways through mainstream institutions (Cooper, 2011). Children and adolescents experience everyday challenges to develop instrumental skills and expressive values in order to communicate and to act appropriately at school

and with peers (e.g., Dodds et al., 2010; Roer-Strier & Strier, 2006). Parents, especially house bound mothers, are under less pressure to adapt: a distinction that may become all the more important when their children need to be their cultural brokers (Cooper, 2011; Dorner, Orellana, & Jiménez, 2008). The exposure and access criteria, however, can work in two ways. Children may find themselves with little outside support for accessing traditional values, if the family has resettled in isolation rather than in an ethnic enclave (Padilla, 2006).

Intergenerational differences in practices often relate to the social behaviors of the younger generation. These range from smoking and drinking to sexual and violent behaviors, often with related mental health issues, especially youth depression (Hwang et al., 2010; Updegraff, Umaña-Taylor, McHale, Wheeler, & Perez-Brena, 2012). Studies of these behaviors also cover the measures that parents take in trying to protect their children from these negative accompaniments of acculturation (e.g., Padilla, 2006; Schwartz et al., 2012). Updegraff et al. (2012), for example, found that Mexican familism values helped keep children from depression and risky behaviors in the United States. With increasing age, however, adolescents moved further away from their families' traditional values. The protective effect then may be less.

Intergenerational differences in values also may disrupt the organization of family life and family goals (Bornstein & Cote, 2006; Raeff, 2006). That difference may prompt challenges to parents' long-held values and practices (Fuligni, 2012a), and challenges to patterns of relationships among family members (Kwak, 2003; Tardif-Williams & Fisher, 2009). Adolescence often brings challenges to parental authority (Fuligni, 2012a; Hwang et al., 2010; Kuczynski et al., 2011). Family disagreements often center around how adolescents prefer to live compared with how they think their parents want them to live (Unger et al., 2009). Those challenges then give rise to parental concerns about losing control and their traditional child-rearing orientations (Kirmayer, Fletcher, & Watt, 2009).

Once again, the issue is heterogeneity. Differences are often particularly stressful for parents whose heritage cultural structures do not socially or religiously align with mainstream institutional structures (e.g., de Haan, 2011; Ibrahim, Small, & Grimley, 2009; Kirmayer et al., 2009; Telzer, 2010). As one Somali father expressed it to us, unconscious of local influences already in his own language: "My kids are turning into bloody Aussies." It is not

young people's adoption of aspects of mainstream culture that most often prompts family discordance, but how little or how much they hold to their parents' heritage culture and the protective base it can afford against risky behavior (e.g., Costigan & Dokis, 2006). We need to distinguish families' deeply held values from specific arguments and disagreements (Fuligni, 2012a; Hwang et al., 2010).

The outcomes of acculturation gaps and discrepancies, nevertheless, may not all be negative (Lau et al., 2005). Their effects are likely to depend on some particular circumstances. Differential sensitivity to particular parent/child issues is one such circumstance (e.g., familism values in Hispanic families; achievement values in Asian families: Fuligni, 2011). Factors that may mediate conflict may include levels of family cohesion, demographics such as home ownership and parents' work experiences, and parental monitoring (de Haan, 2011; Fuligni, 2012b). We need more studies that trace parent-child relations over time, allowing us to consider continuance or decay of any acculturation gaps and their consequences. The study by Updegraff et al. (2012), for example, covered a five-year period and brought out the shifting patterns of change in traditional familism values and risky behaviors for adolescent Mexican boys and girls in the United States.

The complexity of these and other aspects of parent/child gaps in acculturation are brought out in a review by Telzer (2010) that pointed to several issues that can be confused when exploring parent/child differences in immigrant families. These include: the directions of difference (parent/child differences in retention of heritage and acquisition of mainstream culture); the levels (determining which generation is more and less oriented to each culture); and the domains of acculturation (everyday practices compared with deeply held beliefs and values). When these varied possibilities are taken into account, the evidence on gaps, discrepancies, and dissonances becomes less clear.

### *Acculturation Experiences and the Course of Development*

Acculturation changes can be expected as part of the normal course of development (Sam & Oppedal, 2003), although that specific relationship is unclear (Fuligni, 2012b). Acculturation changes may, for instance, be tacked onto or disassociated from normative experiences, or they may become an integral part of typical courses of development. They may also act as catalysts for change. These possibilities are not well explored. They are, however, an essential part of the complex net of positive and negative aspects of acculturation experiences—a point

made by Strohmeier and Schmitt-Rodermund (2008). All these possibilities take the issues of change out of analyses of groups and into analyses of individualized development.

One thing is clear. We cannot continue to assume that what is normative for Western middle-class society is normative for what Kağıtçıbaşı (2007) saw as the majority world. Developmental science needs both a broader view and finer ways of disentangling long-held assumptions about groups that focus on race and ethnicity (Quintana et al., 2006). We also cannot assume a one size fits all view of acculturation (Rudmin, 2003). We must ask then whose view of normative is appropriate in particular situations, and also what issues should be added to analyses of normative development outside North America and Europe (Goodnow, 2014).

It is possible that new norms will continue to emerge as people develop hybrid cultures, for example, as young people reinterpret norms about marriage arrangements (Kwak, 2003) or religious practices (Ketner, Buitelaar, & Bosma, 2004). What people regard as the obligations of one generation to another are often reinterpreted (Goodnow & Lawrence, 2013; Lawrence & Goodnow, 2011). Adult children in Japan, for example, have re-interpreted their obligations to provide care for their elderly parents (Izuhara, 2004). That obligation is no longer seen as automatically calling for parents to move into their child's home, although the obligation to provide other forms of care and support remains. In effect, the norm has not changed, only the ways in which it is met.

The processes of enculturation into one's heritage culture do not stop because new demands arise in the course of double culture experiences (Sam & Oppedal, 2003). Elements of novelty may be introduced into the "on-going transformations" that mark the lives of developing persons (Kloep & Hendry, 2011, p. 57), and become catalysts for change (de Haan, 2011). The catalyst may be the demand for new skills and competences (Dodds et al., 2010). It may also be the demand for adjustments or alternatives to existing beliefs, values and practices (e.g., Kwak, 2010; Lawrence et al., 1992). It may, as well, be the stress placed on families that prompts parents to review their expectations of their children's developmental pathways (e.g., Dachyshyn, 2007).

The source of change may also reside in the normative developmental transitions experienced by young people. These often bring new options for developing cultural competence (e.g., going to school, finding a life partner, caring for disabled or elderly parents). They may also close off some traditional experiences such as expectations

of competence that are tied to closeness to the physical environment (Kirmayer et al., 2009), views of intelligence as involving responsibility (Serpell & Jere-Folotiya, 2008), and rituals marking the transition to adult status (Yunkaporta, 2008).

### ***Biculturalism and Bicultural Identity***

The emphasis in studies of acculturation often falls on related stresses and difficulties (e.g., Schwartz et al., 2010). Equally important, and sometimes equated with acculturation, however, is the development of positive ways by which people come to terms with multiple cultural experiences. Among those positive ways, particular attention has been given to the development of biculturalism or a bicultural identity. Most immigrants become bicultural to some degree (Bornstein & Cote, 2006). A bicultural identity is also usually seen as more adaptive and health promoting than alternatives that involve rejection of either one or both cultures (e.g., García Coll & Marks, 2012; Schwartz & Unger, 2010; Yoon et al., 2013). More specifically, it is related to educational advancement in immigrant and refugee young people, especially as they maneuver through different challenges in their social environments (Brooker & Lawrence, 2012; Cooper, 2011).

The positive construction of a bicultural identity involves people's active transactions with two cultures: heritage and mainstream (or national) cultures. In the specifics of their life situations, these transactions involve exploring and making commitments to both (Phinney & Ong, 2007). In Côté's (2006) terms, the construction of a bicultural identity is "a special form of the individualization of the life course" (p. 31). The processes involved are closely tied to the construction of a sense of personal identity. Skandrani, Taïeb, and Moro (2012), for example, asked young women from the Maghreb living in France how they constructed identities as Muslim women in a society often hostile to their cultural practices (e.g., wearing the hijab). Although these young women varied in their religious affiliations and practices, they expressed a reappropriation of their Muslim identity. This novel "hybrid Muslim identity," however, was also tied up with their French identity. As one explained: "Euh, being Muslim and French, that's connected for me. . . . I can even say, that the French part of myself doesn't go without the Muslim one. Both parts live together" (p. 87).

These processes of individualized constructions are marked by open possibilities. One set of possibilities, for example, involves switching back and forth between cultural frames in response to situational demands (Mistry

& Wu, 2010; Oppedal, 2006). Another related possibility is the construction of a blended or hyphenated identity (Bhatia & Ram, 2001). Some young people are able to articulate the blending or hybridization with hyphenated labels for themselves: labels, for example, such as Australian-Sudanese or Australian-Vietnamese. Young people with these different forms of bicultural identity are usually seen as being comfortable with themselves, and at home in both their heritage and mainstream cultures (Lawrence et al., 2012; Schwartz & Unger, 2010). That sense also was associated with less depression and hopelessness than alternative forms of cultural identification in the LaFromboise, Albright and Harris (2010) study of American Indian young people. Bicultural identities gave these indigenous young people more protection against adolescent problems than identities that were mainly either traditional American Indian or mainstream "White."

There is, nevertheless, some evidence contrary to that rosy picture. Identifying with two cultures is not always associated with better mental health. Separatist identities may actually be more protective of young people faced with discrimination and prejudice (e.g., Hernandez, Denton, Macartney, & Blanchard, 2012; Schwartz et al., 2010). The difference again largely depends on a variety of circumstances (historical time, social environment, pressures on people), and on the variety of positions individuals may take in their reactions and opposition (Bisin, Patacchini, Verdier, & Zenou, 2011; Ogbu, 2004; Portes & Rumbaut, 2001).

The contrasting experience to a sense of belonging may be a sense of "cultural homelessness," a sense of not fitting into either cultural context and of not belonging anywhere. That sense of homelessness may start with an awareness of there being other ways of thinking and acting and, for some people, a move out of the heritage cultural context (Lawrence et al., 1992; Valsiner & Lawrence, 1997). The culture one turns to, however, may also feel alien. The end result may then leave people marginalized and in opposition to both (Portes & Rumbaut, 2001).

Cultural homelessness is increasingly being recognized among "third culture kids": children in families that, for reasons that are often occupational, shift from one country to another (Hoersting & Jenkins, 2011). It has also been reported among ethnic repatriates from the former Soviet Union in Finland, Germany, and Israel (Jasinskaja-Lahti, Liebkind, Horenczyk, & Schmitz, 2003). Returning to what ideally should be their cultural home gives rise to a sense of not belonging there, as well as not belonging in the countries from which they came.

Biculturalism, alternatively, can be seen as a continuing developmental experience of coming to feel at home in two cultures. It is constructed in a complex intertwining of cultural frames, situational activities and personal preferences. It is also relational. Changes for one person can have significant effects for other family members. A child's bicultural competence, for example, may bring extra family responsibilities, specifically the role of family or community broker and bridge to the mainstream (Padilla, 2006). In turn, this can add to a young broker's self-esteem and increased standing in the community (Dorner et al., 2008).

### *Questions and Directions*

Overall, this line of analysis extends our understanding of the diversity of cultural contexts and the significance of that diversity in how cultural contexts intertwine with the lives of developing children. Line 4 has brought into sharp relief the diversity that marks out children's worlds as contexts that come into contact and continue to exist in the same space. Within these contested spaces, cultural contexts undergo many changes. Developing children live through those changes in experiences of immigration, repatriation, and minority status in relation to the experiences of normative development. Analyses of change then need to cover changes in each cultural context, regardless of whether it is the dominant, mainstream culture or another. They also need to cover the multiple dimensions of cultural life that can change in the process (e.g., values and practices) and the multiple directions that change may take across and within people's mainstream and heritage cultures.

The central concepts of acculturation and enculturation need to be reexamined in the light of at least 80 years of this line of research. Acculturation processes can no longer be regarded as one-dimensional or one-directional (Schwartz et al., 2010). Neither can they be seen as experienced only by members of immigrant and minority groups nor in uniform ways. Parents and their adolescent children are likely to experience acculturation processes differently, and in different areas of their lives. For the children, pathways through changing patterns of behavior and values will be complex and interwoven with different forms of experience and allegiance (e.g., religion, family values, mainstream behaviors).

Within contested cultural environments, the possibilities that evolve bring new levels and new ranges of skill into the repertoires of children (e.g., digital information-gathering and networking). Children of Latino immigrants in the United States, for instance, aim for previously unknown educational achievements, and their goals become more

attainable as their community embraces the possibilities that open up to them to support their children (e.g., Cooper, 2011). The restrictions imposed either by one's heritage or by the mainstream cultural context also impact on young lives (e.g., Vedder et al., 2006). Misunderstanding, discrimination, prejudice, or fear can hedge young people into situations where they find for themselves alternatives or exit routes out of either or both cultural contexts. They may construct identities that are either flexibly adaptive (Oppedal, 2006) or thoroughly oppositional (Bisin et al., 2011; Portes & Rumbaut, 2001).

Among new directions for research then is the challenge to take up Sam and Oppedal's (2003) call to understand more about how the children of newcomers blend their experiences within their heritage and mainstream cultural contexts. Perhaps more challenging is understanding how any developing person can take up Moghaddam's (2012) imperative that we all should become "omnicultural" and rise above local cultural allegiances to give human similarities priority over cultural differences. Many young people, for instance, create hybrid identities (e.g., Bhatia & Ram, 2001; Lawrence et al., 2012; Skandrani et al., 2012) and hybrid life styles (e.g., Kwak, 2003, 2010).

Developmental processes are intertwined dynamically with the cultural interactions that identify life in particular places. Connections between developing children and each cultural context are likely to have some flow-on effects from the connections that are occurring between cultural contexts. When one cultural context is dominated by another, the opportunities and possibilities for children born and raised in it will be constrained by the boundaries incurred within that heritage cultural context. Even if the children are developing within the dominant cultural context, their opportunities and possibilities will be constrained by changing expectations in a global world where all people are looking for a better place for their children.

These complex, interacting and multidirectional connections demand multidimensional analyses that can account for the various connections between children and their several cultural contexts. We have few models or accounts of how the agency and cultural participation of children and young people reaches beyond the confines of family and school to the wider community and the world. There are indicators, however, of diversity in the areas and directions involved in interactions between acculturating children and their parents. This diversity encourages us to press for analyses of wider networks of connections for children developing with the experience of multiple cultures. A more comprehensive understanding of those

connections and of children's experiences and participations in cultural contexts also must have a flow-on effect on policy-making to assist their development in complex cultural experiences. Line 5 addresses that issue.

### **Line 5: From Theory and Research to Policies and Policy-Making**

This last line of analysis again focuses on shifts and what these contribute to conceptual and procedural issues. We single out two of these shifts. One is a rise of interest in policy that is accompanied by a variety of rationales. The other is a shift toward regarding change-oriented regulations or policies as a form of joint activity that involves several players. Their actions may possibly be collaborative. At the least, each makes some contribution and their actions are inherently interwoven and influence each other.

#### ***The Rise of Interest in Policy***

This changing interest requires little documentation. Its bases, however, call for comment. One proposed base is a general decline in distinctions between what were once called "pure" and "applied" research (e.g., D. A. Phillips & Styfco, 2007). Another is the view that considering change-oriented action is an intrinsic part of all developmental analyses (e.g., Bornstein, 2010; Goodnow, 2008; Jensen, 2011). A third is the view that when children are disadvantaged, a concern with change-oriented action is a moral imperative (e.g., Gouveia, 2010): one coupled with obligations for respect and for avoiding any further harm to vulnerable people (Lawrence et al., 2013). The state's interests are a fourth. Change-oriented actions are often seen, or presented, as having investment value. They make it more likely that people will be competent, in good physical and mental health, at home in the context in which they live and, over time, will contribute to the health and wealth of the nation and to the shaping of social policies (e.g., Shonkoff & Phillips, 2000).

Not all policies, however, have positive outcomes, prompting a fifth base for a closer look. School systems provide an example. Curricula or organizational schemes may be imported without change from Western countries and middle-class districts. For those imports to be effective, there needs to be a reasonable fit with the daily lives, learning styles, and goals of the cultural community (e.g., for Zambia, Serpell, 2011; for Western Samoa, Watson-Gegeo, 1992). A good fit, however, may not even be part of the original planning for new imports. The reasons for the importation then become matters for concern and research.

### ***Policy-Making Is a Joint Activity***

It is easy to compare cultural contexts in terms of their current or past policies and regulations. Those comparisons, however, tell us little about how policies are shaped, responded to, implemented, changed, or discarded. Without attention to those dynamics, it is argued, policy-making for change is not likely to be understood or to be effective (e.g., Shonkoff & Bales, 2011; Shonkoff & Phillips, 2000). How analyses of those dynamics might proceed is far from clear. One major step forward lies in regarding policy-making as an activity that always involves two or more players. In this sense, it is a joint, rather than solo activity, prompting once more questions about who are the players, what each contributes, when and where they agree, and how they deal with points of difference.

As a first example, we take a study by Beckert (2008) on parliamentary debates that preceded the establishment of laws specifying what children should inherit in Germany, France, and the United States. Currently, whether children must receive a direct share, and how assets are distributed among them, largely are matters of a parent's choice in some countries. Arrangements are largely prescribed by law in other countries (e.g., equal division among a spouse and children, or among children, or both). How such differences evolve is an area where concepts and methods are still largely uncharted. Beckert's (2008) unusual step was to use archival data on parliamentary debates leading to the passing of laws. Three principles were mentioned: the rights of individuals, the protection of children, and the protection of spouses. Priorities and relative weights, however, varied by country. Within the United States, the principle of the rights of individuals was emphasized. Individuals should have the right to decide whether family members would receive any assets and, if so, who would receive various shares. Protection of children and spouses were qualifications related to circumstances such as their needs as dependents, or the motives of the bequest-maker. In contrast, French and German debates gave priorities to protection of family members or to equity in distributions. The rights of individuals would then be respected by some qualifications, for example, the right of bequest-makers to make their own decisions but only for a specified small proportion of assets. In each system, nevertheless, people find ways around restrictions or negotiate departures (Goodnow & Lawrence, 2013, provide examples).

Inheritance laws may seem remote from analyses of opportunities or resources for development. We do not think that is the case. The same kind of approach could

well be used for the analysis of other regulations or policies related to children. Shonkoff and Phillips (2000) provide an example, again considered in terms of joint activity. For policy-making, they saw two parties as the minimum cast. On the one hand were researchers. On the other were the politicians or bureaucrats who make decisions about funding. These two parties would often negotiate over the management of a trial. Shonkoff and Bales' (2011) Strategic Frame Analysis added other parties to the cast. "Concerned citizens" and "communication specialists" now enter the picture, with a closer specification of what and when each person should contribute. The advocated sequence starts with interviewing concerned citizens to identify their ways of thinking about the chosen issue. Communication specialists come next with the task of translating the citizens' concerns into a simplified but shared story. This story is then tried out with politicians, exploring whether they regard it as likely to be told easily, to be understood and approved by voters. Only by using this talkback chain in a collaborative process, it is argued, are effective and acceptable policies likely to emerge. Questions still remain, we believe, about the choice of concerned citizens and the extent to which they are involved both in the planning phase and in later evaluation of the story that is developed. At the least, however, all players have some role in the development of a shared story or a common view of what is happening, what needs to be done, and what can be done.

A different approach comes from the United Kingdom. Again the goal was to broaden the decision-making group, seeking especially the involvement of people beyond researcher/practitioner or politician/bureaucrat groups. Particularly relevant to analyses of development was the mandatory inclusion of children in the process of developing, implementing, and evaluating research and policies that impacted on their lives. Government departments were required to have action plans for including children and young people in decision-making. Other groups were funded in ways designed to ensure their compliance.

One immediate outcome was an increased interest in children's involvement. "Children and young people's participation has never been such a popular demand" (Tisdall & Davis, 2004, p. 131). Not surprisingly, reservations and questions also arose (Tisdall, 2008). Young people saw some invitations to participate more as tokens than genuine interest or willingness to alter existing ways of decision-making or to ensure truly representative participation in decision processes (Hartas, 2011). Tisdall (2008) observed that "the broad umbrella of children's

participation" may need to be replaced by more "nuanced terms" (pp. 27, 28). Over several decades, however, the legislative move has certainly brought greater attention to children's views.

It is tempting to see the two approaches (U.K. and U.S.) as representative of each country's general style. The U.S. style might be seen as a marketplace approach. Policies are not put in place until the market—politicians and public—has been sold on them. The U.K. style might be seen as involving government intervention at an earlier point, with reservations left to arise and be dealt with at a later time. That kind of inference, however, would ignore what we have learned so far about avoiding dichotomies. A dichotomy, in this case, would identify one cultural context as exclusively market driven and the other as exclusively legislation driven. Both styles are likely to be present in all cultural contexts. Where differences occur is in the situations to which each style applies. Australia again provides an example. It is legally compulsory to provide, in all road vehicles, special forms of protective seating for young children. Older children, like adults, must wear seat belts. In contrast, parents can choose whether children should be immunized or not. Most parents do so (around 85%–90%), but concern is now arising about the percentage that does not, with potentially wide adverse effects. A law-driven approach clearly is not always taken, raising questions about when and why this occurs. Questions also arise about the place in these joint activities of two further players. One consists of the people who are meant to implement any policy and are potentially given various degrees of support by the other players. The other consists of the players expected to evaluate the effects of any policy. Who chooses these evaluators? Are they the same people who developed the program in the first place? Are they seen as disrupting a worker/client relationship that is already tenuous? More significantly we may ask, following the English experience, what is the most appropriate form of participation in policy-making for children?

### *Questions and Directions*

In the course of considering the lines of analysis, we have asked several times how various concepts and perspectives might be translated into the choice of methods and measures. That same question applies to views of policy-making as a joint activity. Clearly we need to promote awareness of the appropriate rights and responsibilities of each player in the collaborative process. One way of doing so consists of watching what happens in the course of meetings. To be watched, in particular, are

advisory boards for research or intervention projects that involve two or more members from different cultural groups or different vested interests. Another is to promote collaborative activities in any research project where the initial research group has one cultural background but the project's working group and target group come from another.

We have not found available and useful records of how this joint activity proceeds or is expected to proceed. One way forward, however, is illustrated by a meeting called by the U.S. National Research Council (NRC, 2008). The NRC's official policy is one of international collaboration on projects where there are differences in cultural background among the researcher planners, the research staff on the ground, and the target group. The NRC brought together researchers from several countries and asked them to comment on how collaboration had worked out for them. A variety of issues emerged. These ranged from definitions of childhood, to control over the choice of staff or sample, the interpretation or ownership of data, and the identification of what counted as a common cultural background. It is a mistake that breeds resentment, for example, to homogenize groups that regard themselves as distinct. Lumping together groups such as North and South Sudanese, or a variety of groups as "Asian" (Thorne, 2005) is a poor beginning. Policy decisions from which target groups are excluded appear to be more strongly resented (Goodnow, 2008). In effect, some translation from concepts of policy-making into research methods and measures is possible. We have some distance to go, however, before we can see more clearly how to proceed. One way to do so involves focusing less exclusively on the content of a policy—the end product—and more on the players involved, what each contributes, and what each sees as the rights and responsibilities of others and of themselves.

## IMPLICATIONS AND FURTHER DIRECTIONS

In the previous two sections, we considered the nature of conceptual frames and of frames combined with specific research topics and approaches. As we proceeded, we drew out several implications for changes in concepts and in research studies. We now draw these together. The central concern remains one of moving beyond separations: separations between contexts and development, among contexts, and among aspects of development. Cutting across a variety of analyses and studies, however, are

several recurring proposals. The first is related to contexts and development: change in either one has flow-on effects for the other. The second takes the form: individuals are never solo. Activities are always joint, even though the forms of joint may vary. The third takes the form: skills and capacities always have a cultural meaning. In effect, aspects of development that are often treated separately and regarded as distinct—as cognitive and social, for instance—need always to be considered as interrelated. The fourth takes the form: Measures, methods, and interpretations need always to be reconsidered for their cultural meanings. All four are expressions of the general view that cultural contexts and developing children cannot be disassociated from each other.

### **Contexts and Development: Change in Either Has Flow-On Effects for the Other**

It is easy to recognize that changes in development alter contexts for children. When children reach puberty, for instance, changes occur in opportunities, obligations, and relationships with parents. Less clear are the ways in which views of contexts and views of development are related. To bring these out, we consider four changes in views of contexts and the changes that follow in views of development.

#### ***Cultural Contexts as Fluid, Marked by Change and Continuity***

Analyses of cultural contexts have often emphasized continuity in ways of thinking and acting, and people as actively working to pass on these ways from one generation to another. Only individuals are seen as changing. Moves away from this one-dimensional view place more emphasis on contexts as fluid. They also see change and continuity as interrelated. A focus only on change or only on continuity is a return to the dichotomies we are trying to avoid. For views of development, the interesting questions then relate to the extent to which continuity or change are anticipated, are seen as risks or opportunities, and give rise to particular strategies.

#### ***Cultural Contexts as Marked by Diversity and Competition***

In one-dimensional views of cultural contexts, ways of thinking and acting are bundled together under a single descriptor, and that descriptor is used to characterize a context as, for example, collectivistic or individualistic, as embracing interdependence or autonomy. Any ongoing

dialogues and debates already happening within the cultural context are ignored. In moves away from this position, Strauss (1992) advocated dropping these bundling terms altogether, and Kağıtçıbaşı (1994) argued against treating collectivism and individualism as extreme ends of a single scale. More moderately, Kağıtçıbaşı (2012) and Raeff (2006) both argued that all cultures value both interdependence and autonomy. All cultures display some evidence of both collectivism and individualism. They vary, however, in the situations where people are expected to adopt one orientation rather than the other. In any cultural context then, development does not consist only of becoming more independent or more interdependent. Instead it has to do with how people constantly test for the appropriateness of some general alternatives. People may often say, "You can never stand in the same river twice." They may maintain, however, some default ways of categorizing or grouping rivers. When in doubt, they may use those groupings to identify new situations by recognizing "this is like that". The interesting questions then have to do with the ways in which people test alternatives and the ways in which they move toward any generalizations across situations. People clearly do not go through life regarding every situation as unique. How children or adults come to develop and use differentiations and groupings of situations, however, are topics calling for further exploration.

#### ***Cultural Contexts Are Marked as Directive and Demanding***

In line after line of analysis, contexts emerge as presenting tasks and expected orientations to children and adults. These are not simply about what *can* be done, but also what *should* be done, together with evaluative judgments about what is completely unacceptable, and whether people fail to act as they should because of ignorance or deviance (Shweder et al., 2006). Cultural contexts, nevertheless, do allow some loopholes where members can apply distinctive strategies: ways to avoid complete compliance with what is conventionally proposed as what they should do. People may acceptably fudge their performance so that it looks closer to the directives (Wikan, 1982). They may push out the boundaries, constraining back on constraining norms (Valsiner & Lawrence, 1997). Development then needs to be seen in terms of coming to accept directives and also to avoid or minimize compliance. It needs also to include questions about how children respond to competing demands. Faced with the demands of adapting to a mainstream cultural context, for instance, young immigrants may focus their major efforts on their own normative

developmental needs rather than on the expectations of either heritage or mainstream cultures.

#### ***Cultural Contexts Are Marked as the Core of Experience***

Cultural contexts have sometimes been placed only on the remote (distal) outer edges of influences that make a difference to development, and as having only indirect effects on the proximal contexts. Placing them at the core calls then for a change not only in views of contexts but also in views of development. Development may need to be seen, for example, as the acquisition of general orientations that are reworked when changes in contexts occur. Kwak (2010), for example, described her move from Korea to Canada as shifting from a "we" world to an "I" world. The core concern remained one of relationships to other people but now she needed to make a distinction about when and how often the emphasis should fall on "we" or on "I." That we/I distinction, however, may not always suggest there is a need to change one's own view of the world. Pattel (2007) provides an example. In her description of Australian Aboriginal views of their world, culture is always central. When Aboriginal people describe circumstances or events, they do not simply refer to themselves as being present and involved. It is always the collective "we": the kin or others who are intimately connected to the person speaking. In effect, culture is carried as an intrinsic part of their ways of thinking and acting. People who hold Western hierarchical views of contexts, Pattel (2007) argues, are then unable to understand the holistic, integrated structure of the Aboriginal universe.

#### ***Development: Culturally Valued Knowledge and a Sense of Belonging***

From the five lines of analysis emerge not only a sharpened sense of how views of context are related to views of development, but also a sense of the productive directions that analyses of concepts and research are beginning to take or might take. Among these possible directions, we take for granted the significance and appeal of considering children as active agents from an early age, and the significance of exploring the strategies that children and adults use in various situations. We focus here on one direction that offers a sharp contrast to the more usual emphasis on development as increasing skills and capacity, instead focusing on the development of both culturally valued knowledge and a sense of belonging.

Competence and belonging aspects of development have several features in common. Both involve more than

once-off changes. They are instead lifelong processes where norms and practices change with people's relationships and roles. Both involve negotiating departures from what other people regard as the norm. For both also, children are active participants rather than passive receptacles into which cultural practices, meanings and values can be poured. Children interpret and either accept or reject what the cultural context holds out for them and expects of them (Shweder et al., 2006). Their initiatives and responses together with their growing competences then hold out new possible directions of change for the cultural context.

### ***Highlighting Aspects of Cultural Competence***

We single out three aspects: participating in joint activities, negotiating in situations where one's own expectations differ from those of others, and navigating pathways from one place or social situation to another. For each of those aspects of proficiency, we need to ask: What gives rise to some proficiencies being valued more highly than others? Value may come, for instance, from relevance to survival (e.g., coming to distinguish between safe and unsafe areas) or from relevance to ways of fitting in (e.g., learning how to speak to various others). For each also, it is not only the skills that matter, but also the meanings attached to them (e.g., their being regarded as significant or trivial; D'Andrade, 1981). Cultural contexts may vary in what they regard as significant, but they all expect their children to acquire what is distinctive of their cultural life. How cultural meanings become attached to specific competences is a question warranting further research. So also are questions about the strategies people employ when departures from the culturally significant occur. A high school student, for example, announces that as a college major he will concentrate on Celtic Studies and that he will now drop most of the subjects that could lead in other directions. That area of knowledge is of some interest to historians and archeologists. It is not, however, an area that most people would regard as significant or that is likely to lead easily to any paid work in the United States. What then, if anything, do parents do and what prompts their choice of strategies for their interactions with their children?

*Participation in joint activities* is a part of any context. Children and newcomers need to learn how to participate in activities that involve other people. Participation is expected of them and sought by them. Learning how to participate, however, is not a single skill. One aspect consists of competence in calling on the "social convoy"

(Antonucci & Jackson, 2007), choosing and enlisting people who will make the task easier and safer. Another has to do with differences among forms of participation. Competence when people work together on the same task in face-to-face communication can be quite different from competence when they are physically separated from one another but are expected to reliably contribute and in the process, to deserve other people's trust. Children who are given a small part of harvesting work, for example, or are asked to deliver a message, are participating even though other people are not constantly at their side. That kind of participation has mostly been investigated in adults. Its extension to children, however, offers a way of exploring the development of reliability in children's participation and the development of parents' trust. Of interest also are questions about when the development of reliability in participation is a particular goal for parents. It may well be a major goal, for example, when children's maturity or intelligence is defined in terms of social responsibility as well as their capacity to solve problems by themselves or to act appropriately when they work side-by-side with others (Serpell, 2011; Serpell & Jere-Folotiya, 2008).

Understanding participatory rules is a further part of becoming competent in joint activities, along with being willing to participate within the parameters of those rules. Being an effective contributor to conversation, for instance, calls not only for the ability to express oneself in language, but also for the shared understanding of rules about when each person should speak, for how long, and what they should or should not say (H. H. Clark, 1996). Learning these kinds of rules is expected of children in relation to all activities. How they come to distinguish between major and minor departures from the rules is an issue whose investigation would add considerably to our understanding of development in all participation activities.

Differences need to be *negotiated* in acceptable ways. What happens when children find the tasks presented not to their liking, or when others hold different or even negative views of them or their skills? They wish to avoid rebukes, further pressures to comply, or negative assessments. At the same time, they wish to achieve their own objectives. Like adults, children seek out strategies that will allow them to operate with "acceptable ignorance, negotiable disagreement" (Goodnow, 1996, p. 345). What does the development of those strategies involve, and what do we already know about them? We know, for instance that children become proficient in searching out the weak points of adult authority and the loopholes to try. Even very young children learn shortcuts that subvert ordered

procedures (Flynn, 2008). They quickly develop specific strategies for bargaining and for resisting adult directives (e.g., Kuczynski & Hildebrandt, 1997). They seem as well to learn quickly when negotiation is not likely to be productive. When a child volunteers to take on a task but after completing it suggests that it warrants a money reward, for example, the child is likely to find that way of proceeding is “just not on” for most parents. Children rarely repeat such suggestions (Goodnow, 2004). We still have a great deal to learn about the development of negotiating skills. We know that children may take the lead and structure the negotiation process, and that parents respond to their initiatives in a variety of ways. We know little, however, about how parents signal in advance whether a particular matter is negotiable or nonnegotiable, or when they praise or rebuke a child for moving into negotiation mode.

*Pathways* within and between social situations may be geographic or social and educational. From one kind of path to another, there may well be differences in the skills needed to recognize or follow them. Some geographic paths, for example, seem to be so well worn by previous generations that children recognize and use them at an early age (e.g., safe places to play). That may or may not be the case when it comes to social or educational paths. Some children may become expert at navigating through the multiple worlds that cultural contexts offer (Cooper, 2011; Mistry & Wu, 2010). They may also become adept at taking advantage of the social institutions that can guide progress through life (Hedegaard, 2009). In the best of circumstances, however, all children and young people quickly come to recognize the value of some paths and the destructive nature of others. They learn, for instance, that they need to weigh the opportunities and risks involved when deciding to join or to leave certain strictly defined gangs and groups (Lightfoot, 1997).

Questions to ask then become: When do children find navigating difficult? What happens after they experience difficult pathways? Children and young people entering a new cultural context, for instance, may find moving between its distinctive social situations especially difficult. They need to do more than just drift in and out of new situations. They need to find ways that allow them to explore and to make choices and commitments that give them a place and some social standing in those situations (Bhatia & Ram, 2001; Phinney & Ong, 2007). In Oppedal’s (2006) terms, immigrant children find places for themselves by learning how to switch cultural codes just as they switch language codes. Switching cultural codes allows them to take part in the activities of the situations in which they

find themselves. They can, for instance, follow the heroes of the local football team with their peers and observe their family’s religious rituals at the church or mosque, and do both using different concepts and gestures.

Becoming competent at code switching, however, is not simple. One source of complexity is that children need to anticipate how their switching, if observed, will change how other people see them. Children also need to develop skills for estimating what others will regard as the worst possible errors. For adults, that kind of question is implied in Fiske’s (1991) analysis of relationship errors. Among children, it is part of learning what have been called “boundary disturbances”: actions that are close to or beyond the limits of acceptability (Bascoe, Davies, & Cummings, 2012). Children’s recognition of the worst errors to make (and their opposites, the best ways to act) offer ways of exploring how they come to recognize the most useful paths to follow. Once again, however, it is not only the level of competence that matters, but also the ways in which that competence is displayed and the inferences that others draw from the display.

### ***Highlighting Aspects of Cultural Identity and Belonging***

Throughout we have emphasized the close relationship between the development of cultural competence and the development of a sense of belonging in the cultural context. That sense of belonging has a personal orientation that is part of a sense of self, a constructed cultural identity. Like the personal identity of which it is a part, it is not easily or quickly attained, and the processes involved in its construction continue throughout the whole of life (Schwartz & Unger, 2010). It does not automatically come with one’s cultural heritage. The construction also is not the work of only one person. Instead, parents, other adults, and other children are all active in contributing to the thoughts, feelings, and activities that give a young person a sense of belonging to a cultural context. In terms of life periods, identity formation is predominantly seen as occurring in adolescence and young adulthood, with the sense that from this time, people review their initial formations (Côté, 2006; Marcia et al., 1993). The processes begin, however, in feelings of personal distinctiveness and affinity—of wanting to be able to say, “I am like you”—as Over and Carpenter (2012) found in young children’s imitative behaviors. Later reconstructions may occur not only with changes in age but also in the course of experience with others: experience, for instance, with people who are felt to be different and who confirm or deny a person’s own sense of identity (Gjerde, 2004).

Cultural identity is not one-dimensional. Among children and young people of the 21st century, the sense of self will increasingly have referents in more than one way of thinking and acting. The cultural identities they claim for themselves are increasingly likely to be bicultural, hyphenated (e.g., Malaysian-Chinese), or hybrid (e.g., being both Muslim and French; Skandrani et al., 2012). They may alternatively involve active rejection of any assigned or national identity (Bisin et al., 2011). Even that rejection, however, displays awareness of more than one possibility and of one's own cultural distinctiveness. People are able to assert their distinctiveness in detailed ways, it turns out, covering both geographical and generational differences (Verkuyten, 2004).

Cultural identity is also not restricted to what people construct for themselves. It has to do with the identity they present to others. Those two aspects of cultural identity may be quite different from one another (Ogbu, 2004). The experience of a Chinese student in the United States provides an example (Hsieh, 2006). We single it out because it involves both the recognition of a cultural difference in assessment and a personal response to that assessment. In the United States, she encountered a totally new view of her character and ability. In Hong Kong, she had been recognized as competent and smart. Her new classmates, however, considered her "stupid and weird" (Hsieh, 2006, p. 8) because she did not speak up in class. Her instructors also interpreted her silence as incompetence. With the realization that her silence was the problem, she changed her behavior in class to shore up her identity as intelligent and competent: a strategy that she herself fortunately recognized as needed in the new environment.

Negotiating cultural identity is most often considered in terms of people moving from one cultural background or one country to another. It can also occur, however, within people who see themselves as having maintained a cultural identity, and expect others to see them in that light. Young people who reenter their home culture after living abroad may have to renegotiate acceptance and belonging (Hoersting & Jenkins, 2011). Ethnic repatriates returning after longer absences often encounter the need for still more negotiation of identity. They come back to a cultural context that they think will be the same as when they or a previous generation left it. They may have assumed that they would be recognized as belonging, but find they are effectively regarded as strangers (Jasinskaja-Lahti et al., 2003). Unless they can negotiate some form of hybrid or blended identity acceptable to themselves and to others, they may find themselves culturally homeless or, in the

words of one Somali refugee after 20 years in Australia, "emotionally stateless."

Navigating a way through identity-assailing situations often involves carrying possessions from the past, not only in physical terms, but also in terms of core values. Moving successfully between mainstream school and heritage home, for example, involves choosing which values and practices are core to one's sense of self and cannot be easily set aside, and which mainstream values and practices can be taken up into one's new self-descriptions (Dodds et al., 2010). Immigrant young people seem to encounter particular navigational difficulties when their self-perceptions are out of step with how their parents see them (Telzer, 2010).

The navigational strategies of young immigrants also may be complicated by the need to find paths for others as well as for themselves: a further example of exploring occasions and sources of a sense of difficulty, ease, or satisfaction with the transition. Many immigrant young people, for example, need to be pathfinders in knowing how to present their own carefully constructed identities as people who now belong in the community. Their self-presentations may take on extra dimensions when they also need to act as pathfinders and cultural brokers for their parents (Padilla, 2006), with the responsibility of introducing their parents into and guiding them through puzzling mainstream situations (e.g., meetings with teachers or government representatives).

Overall, it is not possible to analyze the intertwining of cultural contexts and developing children without seeing children as active, sentient agents. That impossibility applies both to the development of competence in the knowledge and skills required for life in relation to the cultural context, and to the construction of a cultural identity that connects them to the cultural context and is an acceptable definition of self that others can also accept. This active role may take several forms. Children, for example, interpret what adults say, responding with agreement or disagreement (Grusec, Goodnow, & Kuczynski, 2000). Children may also take a leading role. They may, for instance, choose their own models to follow when seeking to gain specialized skills (e.g., Henrich & Broesch, 2011). Even at a young age, they may take an evaluative, critical view of what they observe or are told of the cultural rules they are expected to follow, and of what they are expected to become (e.g., Lawrence et al., 1992).

We noted earlier several studies exploring that kind of agentic action at an early age, asking whether and when children imitate or pass on all or only part of what they see a model do (Flynn, 2008; Over & Carpenter, 2012).

We also explored the choices children make when they are presented with conflicting advice from two sources and then are asked which advice they will follow (Harris & Cariveau, 2011). To those, we now add a set of studies by B. Phillips, Seston, and Keleman (2012). In these, children from 2.5 to 3.5 years old, under minimal sighting conditions and without any overt modeling, noticed which of two relatively similar tools tried by an adult effectively turned on a bell (conditions that the researchers labeled as “eavesdropping”). Even under these restricted conditions, children remembered over the course of the following days the tool that worked and could serve other functions (e.g., crush a cracker). The results were seen as “underpinning children’s striking accomplishments as cultural learners” (B. Phillips et al., 2012, p. 2071).

### **Measures, Methods, Interpretations: Reconsidered for Cultural Meanings**

Most research involves judgments or assessments of what is observed or experienced. Those judgments may be about individual people, groups of people, or about relationships. When judgments need to be made about people from other cultural backgrounds, the easiest and most reasonable solution may seem to be the use of measures that work well in one’s own cultural context. The assumption is that care needs to be taken in translating from one language to another, but that taking care should be enough. This parachuting, however, is in error on several grounds. One is that parachuting procedures are based on tacit assumptions about what is reasonable: what questions one may reasonably ask; the people of whom one may reasonably ask them; the people one would reasonably expect to answer; and the settings and tools that one may reasonably use to elicit their answers. Another ground is that the assumption of any culture-free task or question is almost always an illusion. The most likely outcome will be an assessment of children in other cultures as “doing less well” or of parents as strangely underprotective or overprotective. A third ground especially relevant to children, is that judgments—in research, in courts, and in everyday life—are based on views of developmental sequences and timetables related to chronological age. In other cultural contexts, however, there may not be any record of birth. Even when a record once existed, chronological age may not be a matter of concern, or may be better left ambiguous in dealings with authorities.

The challenge then is to explore the bases to assessment errors and to find ways of avoiding them. The main basis

to error is thinking that what we see most people do in our own cultural context is normal or right. The alternatives to parachuting currently being explored are varied. One is that we take measures from the nature of people’s daily lives. Another is to ask people from other cultural backgrounds to make judgments about our cultural practices and values: judgments, for example, about styles of parenting or what may be seen as healthy or unhealthy intergenerational interactions. There are still relatively few studies using this useful reverse approach. A third is to ask people what they find surprising, difficult, or reassuring. Explored, for instance, may be parents’ views of when they think relationships are “going well” or “could be better,” and when they feel they and their children are concerned with the same issue or activity even when they take different views: an approach currently being explored by Stone et al. (2012).

Analyses of contexts and of children often focus on changes over time. Prompted then is a series of questions. These start with a question about the time intervals being considered. Are these over historical periods, over generations, or from one time to another in an individual’s life? Are the same questions relevant to each of these time frames? Likely to be asked next is a question about what changes with time. Are there, for instance, changes over time in contexts, in individuals, or in their interconnections? Does a change in one, for instance, promote a change in the other, and does that, in turn, promote a further change? That pattern could be continued in cyclical fashion, with perhaps special attention to cyclical or cascading patterns within families. Why are effects often selective, even within families? That question as we have seen in the five lines of analysis, has attracted particular attention and is still not answered. Is change seen, for example, as a new risk, a new opportunity, or a mixture of both? Who perceives change in these ways or is there agreement by all? What happens when there is not agreement—when parents and young people, for instance, do not have the same views of changing life circumstances (e.g., of safe or unsafe places)?

Connections over time between contexts and development clearly take many forms and are still far from being fully explored. To take them further calls for a selection of changes to consider and a rationale for why we choose some rather than others. Changes in information technology, for instance, offer some particular opportunities. In Cole’s (2013) terms, there also has now been a change in conceptual tool kits, raising questions about who has access to a particular tool kit, who uses it, and for what

purpose? Here also is an opportunity to regard these tool kits as not always coming from past generations and for recognizing that information about the use of tools does not always flow from adults to children. They often flow from children to parents or teachers. Here then is a form of generational reversals that may take a different form from what is usually considered and that may alter our interpretation of what reversals involve. How in fact do parents and teachers respond to their children being the providers of information, in practice becoming cultural brokers?

## SUMMARY

We started from the view that development is always development in context. We have focused on contexts of the kind usually referred to as *cultural*. To the analysis of cultural contexts, we have added observations and proposals from other contexts, primarily family contexts.

We started also from the view that changes—changes made or still needed—reflect the need to move beyond two limitations in many analyses. One is the occurrence of splits that, as Overton (2010, 2013) emphasized, limit any analysis of contexts and development. These may be splits between contexts and development, among particular pairs of contexts, or among different aspects of development. The other limitation is the occurrence of views that are essentially one-sided or one-eyed. The emphasis falls then on contexts or development as unidimensional. It falls also on connections between contexts and development as unidirectional, primarily in the form of contexts influencing or shaping development, and as fixed in time. A particular direction of influence, for example, is observed at one time and then not followed by observations at later points or by questions about the forms that change may take or the circumstances in which they arise.

Those comments on limitations and changes point to the directional approach we have taken throughout the chapter. The starting points and shifts have led to further directions that are beginning to occur or might now be productive. To bring out the nature of those directional steps, we turned first to an analysis of conceptual frames and then to lines of analysis that combine conceptual frames with specific research studies or research approaches. Frames and research studies we see as always interrelated. Conceptual frames, however, are usually intended to apply to a variety of content areas. The lines of analysis focus on specific content areas, often turning to these as ways of testing the

validity or the limits to some particular proposals about the general nature of development.

We identified four conceptual frames. The first of these had to do with the meanings of the terms *culture* and *cultural*. Issues of meanings have prompted debates about whether to continue using the term *culture* at all. They have also led to proposals to use it—and the less debated term *cultural*—only for ways of thinking, acting, or feeling that are widely shared, have lasted for some time, and are held with some degree of commitment or some sense of links to a sense of identity (some sense of what distinguishes “us” from “others”). With those debates in mind, we have chosen in this chapter to use one term *cultural* and to combine it with the term *contexts* (the plural as a recognition that people usually encounter more than one).

With that basic frame settled, we turned next to frames that start from an emphasis on splits, dichotomies, and fundamentalist steps (steps that regard one side of the divide as the more “real” or “basic” and then reduce or explain away everything else by reference to what is “real”). Needed, we pointed out, are not only alternatives to those divides but also questions about why they continue to be used after many objections. For those questions, we have turned especially to analyses by Overton (2010) and to his view of all these steps as part of a “divide and conquer strategy.”

The remaining frames have to do with the relative position of cultural contexts. In one of these, position is considered in terms of levels of influence. The restrictive starting view has been one of allocating cultural contexts a low position. They have been seen, for example, as influencing child development only by influencing parents or other immediate caregivers. The shifts we emphasize give cultural contexts a central place in any collection of influences, and regard them as early rather than late parts of children’s experiences. In contrast, when it comes to directions of influence in the fourth frame, cultural contexts have often been seen as far stronger than the influence of children on contexts. The shifts then have to do with closer attention to the ways in which children influence contexts and, in a major move away from interactions in the form of control, the ways in which they make sense of and make use of what they observe.

We turned next to lines of analysis that combine questions about frames with specific research topics and approaches. Each issue was set out as a shift. The first of these was a shift from similarities being regarded as a sign of nativist universals to an emphasis on both similarities and differences as based on the kinds of demands and the

kinds of helpful experiences that children encounter. The research questions prompted then have to do with what is expected of children, what they experience, and the resources they can draw on. Prompted also is a recognition of the need for care in selecting groups to compare and measures for assessing development (measures that are often parachuted in from the researcher's own context) and the need to avoid further forms of cultural bias. Differences from what we regard as normal, for example, have a long history of being interpreted as deficits.

To that starting point, we added moves toward analyses that provide not only ways of describing particular contexts but also ways of comparing contexts, combining them, and specifying the nature of transitions from one context to another. We proposed descriptors focused on the nature of places, of activities, and of people: dimensions often considered in combination. For place, we noted the need to consider not only social settings but also physical settings. These are often neglected in current psychological analyses. From them, however, stem questions about demands and resources, constraints and opportunities and, at an early age, the first learning of what is expected. For activities and participation in them, researchers can then draw on a variety of psychological and anthropological analyses. We drew out from these the need to consider development not only in terms of forms of collaborative activity, but also in terms of children learning about participatory rules and of minor or major departures from those rules. We drew out also the significance of children's nonparticipation and how other people may respond to the several forms that their nonparticipation may take. For the parts that people play, we considered their number, the extent to which they are willing or reluctant helpers, their presence in body or in mind (e.g., as audiences or judges), and—an aspect especially warranting increased exploration—their relationships to each other and to the developing child. Overall, the emerging message is that all forms of competence need to be considered not only in terms of skill but also in terms of personal and social meanings and significance.

What more needs to be brought out? Contexts, we emphasize, can never be described as one-dimensional. They are fluid, marked by change. They are also often marked by continuity. One of those features may be more marked than the other (we emphasize their fluidity), but both need to be included in any analysis. We need to consider the meanings that people give to change or continuity, and the strategies people use when they need to cope with change that is unexpected or difficult (even the expected and largely unavoidable transition to school). Again, the

need is to consider both diversity and uniformity and to ask when one is more the case than the other. Immigrant children and young people, for example, have to manage changes to some deep-seated practices and expectations as they live through the continuing meetings and possible clashes between their heritage cultural context and a new, mainstream and dominant one. Often it is the young members of a family who bear the burden of adjusting to the old and the new at the same time. With Oppedal (2006), we have suggested that the cultural switching of immigrant and minority young people is a feature of developmental adaptation warranting further attention.

The final division in our analysis of changing views of contexts is perhaps unexpected. We have sought throughout to extend analyses of cultural contexts to other contexts and to several aspects of development. Unexpected, however, may be an extension to analyses of policies and approaches to intervention. These also need to be considered in more than one-dimensional, one-directional, or once-off terms. Interventions by way of law—declaring some ways of acting illegal, for example—may have little effect on actions that are based on more than legal considerations or have little effect on people who see laws as always ignorable or flexible. We would, however, shift the emphasis to a less explored area: to the activities involved in making policy and law rather than to only their final products. Those procedural aspects of policy or law may again be regarded as a form of collaboration or competition, involving variations in the people concerned, their views of what is needed or possible, and their relationships to one another.

All told, what would we choose as areas or perspectives highlighted by analyses of cultural contexts and as appealing for further research directions? For those choices, we return to our recurring proposals. The first of these is certainly the need to ask how contexts and development are always interconnected, in terms other than how much influence one has on the other. With that recognition come research questions about the nature of change: about what changes, the ease with which it occurs, and who changes, when and why.

The second recurring proposal has to do with a further form of interconnection: Individuals are never solo, self and others are always together. Research questions follow from the nature of joint activities and participation in them. These questions cover the understanding of participation rules, the nature and significance of nonparticipation, and the strategies children use when they wish to avoid expected ways of thinking or acting. Research questions also flow about the use of collaborative activity as a way of describing how

policies that affect the lives of children come to be made and implemented.

The third recurring proposal has to do with an extension in the nature of what development covers and, again, the need to avoid unproductive and arbitrary divisions. We need to start, for instance, with recognizing that development covers both culturally valued knowledge and a sense of belonging, with research questions about the social meanings and the significance that people attach to various kinds and levels of skill. More broadly, the cultural and the social can never be separated from the skills with which people think or act and those in turn can never be separated from what is interpersonal or from what is social and cultural. Just as the development of children cannot be separated from cultural contexts, changes in cultural contexts are always intertwined with changes in developing children.

### OVERVIEW

The foundation for the historical exploration of childhood and children, and for paying attention to historical research in the area, centers on the recognition that conditions for children can and do change, often quite substantially. This point must not be overdone: Elements of childhood reflect biological or psychological continuities, and any effort to portray current childhood as entirely different from the past would be a gross exaggeration. But change is quite real. Historical research can highlight how children in various past periods differed from each other, and from their contemporary counterparts, and it can seek to explain why key changes have occurred. Applied explicitly to the most contemporary historical period, historical research can also explore more specifically how present conditions and features of childhood have emerged, for some truly fundamental shifts in children's roles and expectations are quite recent.

This chapter first more fully defines the basic purposes of a history of childhood, including complexities such as the obvious fact that key historical trends interact with regional conditions to create a variety of specific patterns of change. The chapter then turns to discuss several distinctive challenges in historical work on children—some

of them, like the nature of evidence, involving enduring issues, others, like the geographic imbalance of existing research, highlighting what is hopefully a more current limitation that is being corrected.

Historians are obviously not the only disciplinary group situating children in time and place (Overton, 2010). But historians do have particular responsibility for exploring aspects of children's lives in particular past periods and then linking resultant studies to a wider sense of patterns of change. In some cases, as this chapter suggests, the effort to capture change has reflected larger conceptual frameworks, for example as in emphasizing the impact of modern structures such as urbanization and the rise of mass education in differentiating children's experiences from those in agricultural societies. Research on changes *within* modern societies may also be conceptualized. For instance, particularly in the United States, emphasis on strict manners, characteristic of the 19th-century middle class, gave way to looser habits in a process sometimes described as *informalization* (Wouters, 2007). Comparison also helps organize findings, as in juxtaposing patterns of illegitimacy in Latin American history with family structures in Western Europe.

Beyond overarching conceptual frameworks, historians are interested not only in portraying key aspects

of childhood in the past, but in determining particularly important points of change and in analyzing the effects of regional cultural and institutional factors in shaping the evolution of childhood.

In this effort, major stages in the history of childhood—what historians call *periodization*—clearly help organize a subsequent discussion of the ways historians seek to manage the phenomenon of change over time, often amid considerable debate. At what points do substantial shifts in direction occur? This then follows up on periodization by discussing specific markers, like the advent of agricultural societies or the impact of the major world religions. Modern, industrial societies began to emerge essentially in the 19th century, and with them a host of significant shifts in the ways children were viewed and treated. Elements of these trends gained more global purchase in the 20th century, although under different specific auspices such as communism. Each period, including the contemporary era, requires a balance between basic features—and, sometimes, the impact of new interregional contacts—as well as distinctive regional approaches; comparison remains essential.

The chapter ends with a discussion of ongoing opportunities in the history of childhood, including opportunities for interdisciplinary audiences and interactions. This is a field with considerable achievement to record, but many unanswered or incompletely answered questions, and it is exciting to consider what is still to be achieved.

### Emergence of the History of Childhood

The history of children and childhood is a relatively new field. Antiquarian historians, talking about daily life in the past without much analytical structure, often included descriptive information about children and childrearing, sometimes offering valuable data. But the emergence of social history as a more formal subdiscipline, effectively in the 1950s and 1960s, provided the framework within which attention to children could emerge more systematically. Even here, however, there were hesitations, as targets for other topics, such as the working class, ethnic and immigrant groups, and then women, commanded pride of place. The social history movement promised new attention to inarticulate populations in the past, and children certainly qualified on this count, but other targets long seemed more attractive (Gardner & Adams, 1983). It was revealing, for example, that a major specialist journal devoted to children's history—the *Journal of the History of Childhood and Youth*, now widely recognized—emerged only in 2008.

As early as 1960, however, French scholar Philippe Ariès came out with what, in English translation 2 years later, was titled *Centuries of Childhood* (Ariès, 1962). His conclusions that ideas of childhood were, to some extent, a modern invention helped stimulate a flurry of work, much of it bent on expanding the claims about significant differentials between modern and premodern childhood in the West. A half-decade later, a number of studies of colonial New England (Demos, 2000; Greven, 1995; Zuckerman, 1970), which in many ways launched the new social history movement in the United States, focused strongly on family life including parent-child relationships. Turmoil in the 1960s also helped generate, somewhat separately, a number of important historical projects on adolescence and youth (Fass, 1997; Gillis, 1981; Kett, 1978; Scales, Benson, Leffert, & Blyth, 2004). A new subfield, or a cluster of subfields, seemed to be off and running.

Yet interest faltered rather quickly, although without disappearing entirely. Two reasons can be suggested for this pause, and both of them continue to condition work on children's history. First, the idea that young people were going to be the leading protest group of the future, widely trumpeted amid the turmoil around 1968, faded after 1973. Young people might continue to fuel protest efforts, but protest organized around youth specifically trailed off dramatically. Second, at least in industrial societies, the demographic base for youth protest was eroded by the return of rapidly declining birth rates. One insistent reason for attention at least to the later periods of childhood diminished considerably. Women and other groups claimed more scholarly energy, because of their continued position in the public eye. Social historians have their own susceptibilities to current fads and fashions.

More intriguing still was the extent to which some of the initial scholarly flurry turned out to be a bit of a false start. Ariès' work still deserves attention, but it was based excessively on upper-class evidence, rather than more representative data. And, his position was exaggerated, even misrepresented, by some enthusiastic adepts (deMause, 2006). A number of historians began claiming huge gaps between modern and premodern childhood, around issues as diverse as discipline and affection. One leading British historian, for example, argued that affection for children was essentially a modern invention, at least in Western society, and that in considering premodern families one would expect to find about the same level of emotion as is present in a bird's nest (Shorter, 1976; Stone, 1983). This kind of analysis—although it generated a number of interesting specific findings about premodern parent-child

relationships—roused a storm of protest from experts in medieval and early modern history (Hunt, 1970). Many of these revisionists were bent not only on insisting on the humanness of parents in the past, but on arguing further that there was no essential difference between premodern and modern family contexts for children (Pollock, 1983). Here too, debate prompted some important new discoveries, but it ultimately proved counterproductive in downplaying the significance of change—however nuanced—in the history of children. After the burst of initial work, and the ensuing countersalvo, the field went largely silent for several years.

### Redefining the Scholarship

Obviously, there are lessons in this somewhat unusual scholarly episode, and as historians now consider research on children and childhood they largely define the purposes of their work with these lessons in mind. First, the reasons for work on childhood rest broadly on the importance of using history to better understand the forces—both old and new—that shape the experience of being a child and the vital role that caring for and dealing with children play in any society. We understand the past better if we actively include children in the historical record, and we understand children better if we see them, in part, as products of an often complex and interesting history. More transient themes, like youth as a protest group, take a back seat to these larger purposes.

Second, we cannot cast our history in terms of stark divides between modern and premodern systems. Changes and variations occur well before modernity, and modernity does not contrast entirely with what went before. But change is real, as against undue assumptions of continuity in, say, parent-child relationships, and modern conditions, carefully explored, played a role in the process of change during the past two centuries plus. There is abundant opportunity now for a new and more sophisticated look at these key changes in childhood caused by modern conditions.

Third, work on the history of childhood, particularly during the resurgence of interest in the past two decades, focuses on two kinds of topics that help further define the purpose of historical inquiry. Many historians concentrate on institutional or structural features of childhood, where clear data repositories often exist and/or where reasonably precise measurements are possible (Laslett, 1966; Seccombe, 1993; Wells, 1985). Another category of research addresses more qualitative aspects of children's lives or parent-child relationships, ranging from issues of

discipline to patterns of psychosomatic illness to efforts to probe children's emotional expectations and experiences (Brumberg, 2000; Greven, 1991). Ultimately, the two kinds of topics need to be combined, and their trajectories are never entirely separate. But some sense of both domains helps introduce the range of possibilities currently being explored.

On the more structural side: Scholars dealing with the 19th century have devoted considerable energy, for example, to the study of reform institutions and orphanages, as significant to the actual children involved (not always large numbers) and more broadly revealing of wider social attitudes to children (Grossberg, 1988). Legal structures receive attention, for example the late-19th-century "invention" of the concept of juvenile delinquency (and its rapid spread to places like Japan from initially Western origins). Schooling offers an extensive historiography, although more often framed in terms of the history of education, as a subfield, than in terms of children's experiences per se. Religious or political policies also enter into the exploration of structures, for example in approaches to understanding or regulating children's sexuality or in stipulations about child labor or school attendance (Binder, Geis, & Bruce, 2000; Lasonde, 2005; Schlossman, 2005; Staff, Mont'Alvao, and Mortimer, Chapter 9, this *Handbook*, this volume; Vinovskis, 1985).

Another category of essentially structural research focuses on demographic materials broadly construed. A huge development in the modern history of childhood involves the installation of the demographic transition—that is, the now-widespread contemporary regime in which both child death rates and per capita birth rates drop substantially. The demographic transition occurred, historically, in a number of Western societies, where gradual birth rate declines in the 19th century coalesced with the more sudden advent of lower child death rates between 1880 and 1920—from 20% or more among all infants born, in the former date, to 5% or less by the latter (Wrigley, 1969). This new demography brought direct changes for children themselves in terms, for example, of experiences and expectations surrounding death, or the number of siblings available for interaction. It also both reflected and caused changes in adult thinking about children, in terms for example of attachment to the individual child or new beliefs in the possibility of limiting disease (Zelizer, 1958).

In part because of Western example and influence (sometimes translated as well through international agencies such as United Nations population conferences),

somewhat similar patterns have developed in other regions of the world during the 20th and early 21st centuries. But not only has the precise timing differed from that of Western Europe and the United States, but so have the changes themselves. In many cases, for example, such as post–World War II China, dramatic reductions in child death rates have preceded significant shifts in birth rates—almost the reverse of the Western combination. Here is a case, clearly, where ultimately widespread structural changes also have continued to reflect distinctive regional policies and precedents, generating broadly similar trends but considerable complexity around specifics.

Efforts to probe the experience of being a child or the more intimate aspects of parent-child relationships more directly have drawn wide attention as well, both in the first phase of childhood history—for example, around the claims about family affect—and also more recently. Work on Chinese family patterns, from at least the classical period until modern times, has plausibly speculated about unusually intense bonds formed between mothers and sons. The Chinese system of patriarchy emphasized female inferiority with unusual vigor—illustrated, for example, in the extensive practice of foot binding—but in so doing created a situation in which mothers could both express and protect themselves by forming strong emotional links with their sons (Baker, 1970; Chan & Tan, 2004; Hsiung, 2005; Kinney, 1995, 2003; Loewe, 1968; Raphals, 1998). The result could be a considerable assurance of support for older mothers, particularly in widowhood, along with opportunities for informal assertions of power; but the implications for children themselves deserve attention as well, potentially contrasting to some degree with looser mother-son relationships in other agricultural societies such as Greece and Rome.

An intriguing study, now a generation old, examined friendships among male teenagers in the 19th-century middle class in the United States, extending into early adulthood. In a situation where males realized that marriage opportunities and even courtship must be delayed, in the interests of economic establishment before family formation, surprisingly (by contemporary standards) intense emotions went into male-male friendships (Rosenzweig, 1999; Rotundo, 1994). Letter writing suggested deep affection. Physical contacts and embraces—although not necessarily actual sexuality—were common (in a society in which, when traveling, for example, men often slept together). But these relationships began to change substantially by the end of the 19th century—far more than was true for somewhat similar intimacies among

young women—in part because of increasing emphasis on courtship opportunities including, by the early 20th century, the advent of the new practice of dating and in part because of concomitant attacks on the dangers of homosexuality.

A final qualitative example, also from the United States, is just opening up for more extensive inquiry. The idea of boredom began to emerge in the 18th century, a counterpart to growing Enlightenment interest in happiness and this-world rewards (Stearns, 2003). People may have been bored before, but it was significant that, in English, they lacked a word until that point—and arguably were, therefore, far less likely to have the experience. Boredom began to apply to children in the later 19th century, but mainly in terms of character injunctions: Children should be brought up with sufficient initiative and internal resource not to be bored, because boredom was offensive to others, a real discourtesy. By the second half of the 20th century, however, the concept and its association with childhood had slipped, and now a bored child was a criticism to those around him or her—parents, teachers, whoever should be keeping the child entertained. Children, quick to see a new advantage, began correspondingly to learn that complaints of boredom served a useful purpose in galvanizing adult attention (but also, possibly, in helping children to evaluate their quality of life). Change is complicated, and relatively quick from one generation to the next.

Shifts in structure and in qualitative experience often intertwine, although figuring out priority is not always easy. Did the modern decline in birth rate generate more attention and, possibly, affection from parent to child given the possibility of greater focus on individual children and the greater assurance of child survival (Zelizer, 1958)? Or, did new ideas about the emotional as well as economic investment owed to children by good parents help cause the decision to cut the birth rate, the better to live up to new expectations? Clearly a relation can be explored, but equally clearly its dimensions have many layers.

The history of childhood already has many dimensions, from structural features to emotional experiences, and more are opening up as scholarly interest expands. Whether the goal is a fuller picture of the past—the nature of Chinese culture and society in the classical period, with some of the special features of mother-son relationships now actively included—or an understanding of connections between past and present, as in exploring the several specific patterns and outcomes of the ongoing demographic transition, history provides both evidence and analytical challenge.

## FROM EVIDENCE TO GEOGRAPHY: CONSTRAINTS IN THE FIELD OF CHILDHOOD HISTORY

Several problems constrain historical work on children, and one at least is distinctive and intractable. Issues of evidence are paramount. Social history, from the outset, deliberately focused on groups that rarely left the most obvious records—groups in various ways out of power, not in command of the mainstream channels of communication. Children, however, pose a special case within this general spectrum, and although social historians have been imaginative in generating evidence that allows comments on the behaviors and attitudes of “inarticulate” adult groups, children, historically, raise special barriers because virtually all of the obvious information about them is filtered through some kind of adult lens.

Of course, there is some direct behavioral evidence, at least in modern times, as in statistical data about children in the workforce or school attendance rates or delinquency. Historians have also sought to make use of material artifacts, but even these, for younger children at least, often require some adult provision, as in the crafting of toys (Baxter, 2005; Crosnoe and Benner, Chapter 7, this *Handbook*, this volume; Gutman & de Connick-Smith, 2008; Wileman, 2005). But lots of the questions one would like to ask children—what was the experience of school like, or what was it like to be an apprentice to an uncle—simply lack direct accounts. We have to hear from adult observers, or recallers (like Ben Franklin in his autobiography, excoriating his printer-uncle-master), or prescriptive recommenders. The frequent blurring of topics—between histories of children and of childhood—restates the problem: Childhood is based on adult definitions and perceptions, whereas children ideally ought to be more directly approachable.

There are, in sum, evidentiary limits, even though historians have been imaginative in dealing with the constraint, and surely additional efforts will emerge in the future. One of the causes of the sometimes-disproportionate interest in institutions, such as reform schools or orphanages, is that at least there are sources to consult, even though they convey children's behaviors and reactions only indirectly and for atypical populations. The challenge is pervasive.

A second constraint is more familiar, but again quite difficult. It is considerably easier to study the history of children and childhood for middle- and upper-class groups than it is for the various popular classes. In the United States, for example, a number of studies of children's

history have focused on prescriptive literature that spells out expectations and standards. The literature is often interesting and revealing, and it is fairly readily accessible; but it also disproportionately reflects attitudes current in European American, Protestant, and middle- and upper-middle-class families. Similarly, it is usually easier to get historical evidence about children in urban settings as opposed to rural, for literary rates and government record keeping are better developed in cities. Many of the most innovative approaches to childhood history, probing topics like emotional standards, not only begin but also sometimes end with the middle- and upper-class audience. This bias was, as we have seen, a problem with the great study by Ariès, and it continues to affect the field.

A number of historians have explicitly attempted to probe lower-class situations, or with minority clusters such as (in the United States) Catholics or Jews. In many cases, it proves easier to deal with the more structural features of childhood in this expansive effort than with more qualitative issues. Thus, we can get a fair idea of birth and death rate patterns by social class, at least from the 18th or 19th centuries onward. Court records may suggest certain kinds of behaviors for lower-class children, as well as social expectations that were brought to bear on the lower classes (A. Platt, 1977; Wegs, 1989). One of the several reasons for the popularity of institutional studies, applied to orphanages or reform schools, is that they open some window onto lower-class situations, even though the institutions themselves typically reflected primarily middle- or upper-class values (A. Platt, 1977; Wegs, 1989). Lower-class families often used institutions for their own purposes to help with certain aspects of childhood, and institutional records, however unintentionally, help chart these patterns.

The history of childhood is not, in sum, hopelessly compromised by class bias. In some cases—Latin America is an example, with work on historical patterns of illegitimacy (Hecht, 2002)—attention to lower-class childhoods has preceded a more systematic historical approach to the subject. Still, class issues are not always easy to resolve, and some of the most common generalizations in the field do not necessarily cover as wide a social spectrum as might be desired.

Gender factors, by contrast, are more often accommodated. The history of childhood, particularly in the past two or three decades, has grown up with assumptions about the importance and relevance of female history. Whereas records on boys are in some cases more accessible than those on girls, reflecting disparities in patriarchal societies

of the past, the evidence issue is much less troubling for gender than it is for social class. Many childhood histories aim specifically at gender factors as part of their purview. Awareness of gender is obviously a vital component of the history of children, but it does not constitute a systematic limitation on the field as it has developed in recent decades. Geography represents the final hurdle in the subdiscipline of childhood history as it has thus far emerged. Here, even more than with social class, one hopes that existing disparities are temporary, for there is no fundamental reason that geographic disparities should burden the field in coming decades. It is a fact, nevertheless, that the history of childhood first emerged with attention to North America and Western Europe (including, for the classical period, Greece and Rome), and the richest historiographies still apply to these regions. Topical innovations in Western studies of children in the past have not uniformly spread to work in other parts of the world, which means that more global generalizations are often impeded and/or that they are offered disproportionately on the basis of Western findings and evidence (Shorter, 1976). There are some opportunities here—in the modern period, many key changes in childhood first occurred in the West, which means that Western topics may reasonably trigger at least certain kinds of inquiries elsewhere—but also some real dangers, if Western patterns are assumed to be paradigmatic.

### Geography

And the other fact is that, whereas interest in the history of childhood is spreading fruitfully, regional disparities remain stubborn, and in some cases not easily explainable. Important works on the history of childhood have emerged for China (Hsiung, 2005), applying to a number of different historical periods. Slightly short of this standard, but still reflecting scholarly progress, are efforts for Latin America and Russia (Hecht, 2002; Kelly, 2007). There is also some interesting research on Sub-Saharan Africa (Carton, 2000). The subfield of childhood history is much less well represented, however, for Islam and for South Asia, and attention to Japan is less extensive than might be expected—aside from important studies on schooling (Fass, 2003).

Geographical disparities reflect the relative newness, still, of the history of childhood, along with important regional differences in topical expansion. (Social history, in general, for example, is less well developed for the Middle East than for many other regions, and gaps in the history of childhood reflect this wider disparity.) Other fields may help compensate: Work in anthropology or religion can apply to children in past periods in places

like India (Kakar, 1978; Scharfe, 2002; Vats & Mugdal, 1999). The geographical unevenness of formal historical research continues to bedevil the field. Not surprisingly, as one result, only one or two projects have even tentatively ventured a global history of childhood (deMause, 2006; Stearns, 2011).

The result also, finally, constrains comparative work. Most interested scholars have deployed their talents on single regions, challenged enough to deal with the issues of evidence and analysis these targets involve. Only brief comparative ventures have been sketched. One intriguing article, for example, utilizes the Ariès thesis for an inquiry into Japan, and the findings suggest how a fuller commitment to comparative history might pay off in future (B. Platt, 2005). However, this ambition remains for a next generation of scholarship, and certainly some of the residual regional disparities need to be repaired before comparative work can be widely undertaken.

Overall, the history of childhood, still fairly new, reflects some characteristic growing pains. Issues of evidence and social range are still being worked out. Geographic gaps reflect some issues common to other innovative areas in historical research. Awareness of these challenges should guide further work in the field. The challenge of listening to what children themselves said and experienced in the past is the most distinctive ingredient, and it will legitimately command ongoing and imaginative attention in the future.

### PERIODIZATION

As a discipline history deals with change, and although many individual historians are more interested in the characteristics of one particular society in one point in time, or in stories that may or may not highlight change, there is an overall goal of capturing how and why change occurs and of what continuities accompany even fundamental shifts.

Some very ambitious agendas about change have been ventured, as we have seen. Ariès's idea, embellished by a number of scholars, is the most prominent: that there was, at least in Western society, a fundamental divide between premodern and modern approaches to childhood, with premodern attention riveted on seeing children as little adults, not clearly distinguishable from adults at least after a period of infancy, modern approaches far more attached to defining and often celebrating childhood as a distinct phase of life. Embellishments to this argument, to be explored more fully later, included attention to the contrast between high infant death rates in premodern societies,

compared to explicit efforts to reduce death in the modern context. Some arguments, as well, contrasted a purely utilitarian approach to children in premodern conditions, mainly as sources of labor to be disciplined as severely as required, with the more celebratory modern approach that tended to see children as desirable for their own sake, with emphasis on mutual love and affection, and that reconsidered many traditional approaches to childrearing, such as physical discipline (deMause, 2006; Zuckerman & Koops, 2003). The fact that revisionists have prompted significant modifications of these modernist arguments, particularly toward recognizing a greater complexity in premodern childhoods but also in noting some drawbacks to modern approaches, has not entirely eliminated the premodern/modern analytical structure.

Indeed, additional components can be suggested, as we learn more about modern patterns of change, although they too complicate any facile celebration of the modern approach. Another European historian, Johann Huizinga, called attention to what he termed a decline of play in the childhoods that began emerging in Western Europe from the late 18th century onward (Chudacoff, 2007; Huizinga, 1995). A medievalist, who was also interested in anthropological accounts of children's play in Africa and other societies, Huizinga emphasized the opportunities for play as a set of spontaneous, creative activities by children as individuals and in informal groups in contexts such as preindustrial villages. Huizinga stressed the importance of play in ultimately developing adult capacities, although he saw growing adult intervention against spontaneous play beginning in the later 18th century, with increasing focus on formal education and on monitoring children's activities and artifacts in the interests of adult-prescribed developmental norms. This pattern of adult intervention would simply get worse with time. Other historians, dealing for example with the rise of supervised playgrounds in the early 20th century, or the development of educational toys even earlier, have picked up on some of these themes (Cross, 1997). Here is another case, then, in which a large scheme about traditional versus modern childhoods, although not really dominant in current historiography, still hovers around the edges, inspiring certain specific projects and more limited interpretations. On the face, Huizinga and Ariès would seem at odds in their particular analyses of what the modern involves, but they might in fact overlap to some degree: Ariès was willing to argue that the traditional lack of defined childhoods gave actual children considerable space of their own, whereas more modern approaches, if in theory more accepting of children, often justified and motivated increasing intervention.

A few scholars, finally, have sketched a possible distinction between characteristic modern childhoods and a post-modern shift (Postman, 1994). A number have contrasted the glorification of children's innocence, which was part of the modern trends that opened up in the 18th and early 19th centuries in the West, with a more ominous contemporary pattern in which young people are no longer protected against various forms of adult-sponsored corruption, such as modern representations of sex and violence (Gurstein, 1999; Jolivet, 1977; Postman, 1994). Here too, most historians of childhood have not picked up on such a challenging chronological framework, but there has been some spillover into specific research projects on the later 20th century as a time of renewed change.

The big theories about a modern "discovery" of childhood continue to exercise some influence, but in the main they have been overtaken, in the expanding body of recent historical work on children, by more limited schemes. Many historians, devoted to innovative work on children in the past, are content to use established markers, defined by political regime or high culture, assuming that conventional periods are at the least a convenient target for their research and, possibly, that they correspond to definable features of childhood itself. Thus, a great deal of work has focused on the Roman Republic and Empire as a valid unit for the study of children (Cohen & Rutter, 2007; Dixon, 1992, 2001; Eyben, 1993; Nathan, 2000; Patterson, 2001; Pomeroy, 1997; Rawson, 1991, 2003). The scholars involved in this period trace internal trends during the Roman era, and they assume that Roman conditions differed from those that would describe the subsequent Middle Ages in Europe, but they do not pretend explicitly to carve out patterns of change based on internal dynamics of childhood. Some recent efforts on China essentially adopt the same tactics, focusing, for example, on the Han Dynasty and its conventional demarcation of political change, and assuming that the result is an acceptable framework for examining childhood. Studies that use "Renaissance" or "early modern" to describe the chronological boundaries of their subject adopt essentially the same approach (Ozment, 1985).

There is tension between some of the pioneering efforts to take out a chronology based on major features of childhood in society—such as the identification of childhood itself, or a distinctive approach to play—and recent efforts to probe more deeply into various aspects of childhood but within largely conventional chronological dimensions, based on factors external to children themselves (Fass, 2003). To be sure, some important work skates in between the two poles. Several studies of the 19th century have

explicitly justified the chronological framework in terms of factors directly linked to changes for children—such as the Industrial Revolution or new claims by the state to intervene in childhood (Cunningham, 2005; Heywood, 1988, 2001; Maynes, 1985). The chronological markers may seem familiar—the use of the 19th century as a period is hardly an invention of historians of childhood—but the actual focus is squarely on larger changes in children's contexts.

## AGRICULTURAL SOCIETIES

Most of the time periods historians of childhood work on fall within the framework of agricultural societies and economies, from the river valley civilizations that began with Sumeria after about 3500 BCE, to the great colonial and land-based empires of the early modern period. Important changes in childhood surely accompanied developments before the advent of agriculture, including the various phases of human evolution and tool use and the great migrations out of Africa that spread human populations widely around the globe. But it is with agriculture that most focused historical scholarship begins to be deployed.

Settled agriculture first developed on the southern shores of the Black Sea, from about 9000 BCE onward. It spread gradually to other regions, including south Asia, Africa, and Europe. Agriculture was separately invented in East Asia, around 7000 BCE, and again in parts of the Americas after 5000 BCE. In these cases it spread gradually, although hunting and gathering and also nomadic economies long remained important.

Agriculture had important impacts on childhood, in contrast to the systems of hunters-gatherers. We have scant direct records of children in hunting and gathering societies historically, although contemporary remnants provide some cues. The most salient points were the limits this original human economy posed on numbers of children per family. Resource constraints and the demands of recurrent travel strongly affected the desired birth rate, and prolonged lactation by mothers—breastfeeding for up to 4 years—provided a key mechanism for birth control. Children were not particularly useful, at least until the teenage years. Indeed, there was more: Contemporary studies of hunter-gatherers suggest that when mothers take their children with them, to forage for nuts and berries, their productivity drops. Children in hunting and gathering societies have abundant opportunities for play, but by the same token having too many children, per family or per

band, risked straining resources (Arden & Hutson, 2006; Burguière, Klapish-Zuber, Segalen, & Zonabend, 1996; Hanley, 1999). The demands of frequent migration in search of game also militated against high birth rates.

Agriculture changed much of this by providing opportunities for children to be more useful and by creating the family as a clearer economic unit in which child, and particularly youth, labor would be a key component (Staff, Mont'Alvao, & Mortimer, Chapter 9, this *Handbook*, this volume). With more abundant food supplies, on average, the means existed to expand the birth rate per average family, and this along with the new uses/needs for children produced the expected result. In most agricultural societies families sought an average birth rate of sixth to eight children, sufficient to provide adequate labor but not overwhelming available family property for surviving adults to inherit and maintain when coupled with normal reductions in numbers through high infant mortality. Obviously, some families were devastated by unexpected fertility, others harmed by infertility; some sharing of children among families was a characteristic response. Agricultural societies also highlighted the link between resources and birth rates through the common pattern in which upper-class families had much higher birth rates than peasant and artisanal classes.

But even ordinary people had many offspring, save for the 20% or so of families where one or both partners were infertile (Wrigley, 1969). Villages flocked with children, normally over half the total population. Not only for parents but also for extended families and entire communities, coexistence with, and oversight of, children was a central feature of daily life. The importance of children in defining a successful marriage was high. In early civilizations like Egypt, childless couples were regarded with suspicion and, at the least, urged to adopt (Feucht, 2001).

Agricultural societies confirmed the essential purpose of children—again, in contrast to hunting and gathering traditions—in providing labor and training for future work. This was the goal that guided family decisions about birth rates, and this was the purpose around which many other aspects of childhood were organized. Gender distinctions, which had been considerable in hunting and gathering societies, in many ways intensified. Girls and boys trained for, and did, different kinds of work; but beyond these role distinctions, agricultural societies introduced much more formal patriarchal systems, with girls impressed early on with their inferiority. Traditional Chinese society offers an illustration, in placing girl infants at the foot of the parental bed, boys at the side (Ebrey, 2002). Many children, although

expected to work from Age 5 or so onward, also had considerable periods of play—the rigor of family labor should not be exaggerated, although work demands on teenagers were frequently intense.

Nevertheless, work requirements organized many other features of childhood in agricultural economies. Most obviously, all agricultural societies placed great emphasis on the importance of obedience. Obedience could seem essential simply in providing order in fairly large broods of siblings, but it also helped orient children for the often-menial tasks they would begin to perform. Disobedience, correspondingly, was severely reprov'd; in ancient Israel, parents could in principle order that a rebellious son be stoned to death. Many agricultural societies differentiated strongly between a first few years of infancy, where children were indulged, and a passage between Ages 5 and 7 into the more serious stuff of life, including work service; this pattern was seen both in India and in Japan, for example (Stearns, 2012c). Agricultural families also sought to assure continued work from their children into their late teens and beyond. Although young children could help their parents, their work did not cover the resources needed to sustain them. Only continued service allowed children to pay off in economic terms. Agricultural villages usually organized some opportunities for teenagers to blow off steam, in various games and rituals, but they also assumed continued labor in the family economy. Some agricultural families also deliberately conceived a final child when parents were in their early 40s to provide available assistance when the parents reached old age. On another front, marriage arrangements, with parents actively picking out spouses for their children, reflected the primacy of economic factors over individualized choices by young people (Gillis, 1985). Family economies in agricultural societies, finally, dictated a great deal of legal attention to issues of inheritance. Rules varied with the case, in terms of allocations among children of different ages and genders, but in general, the importance of clarity was obvious, both for family continuity and in terms of providing motivations for children themselves as they contemplated their futures. Children commonly accepted parental choices for marriage because of ingrained obedience but also their understanding of the inheritance that would ensue.

Death rates remained high in agricultural societies, with 30% to 50% of all children born dying before Age 2 (Wrigley, 1969). Infectious diseases caused part of this high mortality, but digestive ailments were also common. Children themselves lived amid frequent death of siblings,

and at least in some cultures, the fear of death was actively invoked as a disciplinary mechanism to keep children in line (Delumeau, 1990). Against the assumptions of some early historians of childhood that agricultural families dismissed child death readily because it was so common, we know that deaths of children were commonly mourned. But medical help was less often called for children than for adults, reflecting some sense of inevitability, and markers for children's deaths were far simpler than those for adults (Stannard, 1979). Efforts to prevent accidents—for example, children falling into wells—were often surprisingly casual. For agricultural families not only had to expect high death rates among children, but to some degree depended on them to align birth rates with available resources and inheritance possibilities. Finally, in many agricultural societies, infanticide was frequently practiced, particularly among baby girls, as a means of population control (Eyben, 1993). Many agricultural societies also condoned killing deformed children (Milner, 2000).

Different agricultural societies introduced different ideas and practices around children and childhood. Ancient Egypt, for example, emphasized gender distinctions among children less than neighboring Mesopotamia did, to the amazement of Mesopotamian travelers. Infanticide was not practiced initially in Egypt, perhaps because of more assured resources in the fertile Nile valley. All agricultural civilizations generated economic and social distinctions among children depending on social class, but the Mayan practice of elongating the skulls of elite members by wrapping infants' heads in tight bands was obviously distinctive, creating a visual testimony to social status for lifetimes. More generally, in all the early agricultural civilizations, depending as they did on the introduction of writing, a few elite children had opportunities for formal education that were not available to the masses (Arden & Hutson, 2006; Duncan, Magnuson, & Votruba-Drzal, Chapter 14, this *Handbook*, this volume).

The more elaborate cultures created by the classical civilizations between 600 BCE and 600 CE set some wider distinctions among childhoods by region, some of which would prove quite durable. The significance of these civilizational differences must be compared with the features widely shared by children in all agricultural societies, and there is opportunity here for further analysis as we build up a wider store of historical case studies.

Classical China, for example, widely introduced practices that emphasized familial hierarchies more formally than was common elsewhere. Chinese culture, articulated further through Confucianism, emphasized deference of

children to their parents. Etiquette governed relationships among siblings themselves, with pride of place of course to the eldest son. Children were taught to bow to their parents and other elders, but younger children also bowed to their older siblings. Parents were routinely supported by courts of law, in case of any disputes with children: A widely quoted saying held that “no parents in the world are wrong.” Shortly after the classical period hierarchy was also enforced by another distinctive practice, which spread gradually but inexorably in the upper classes and cities: the practice of foot binding for young females, whereby girls and women would be permanently constrained in their movements although also, in principle, distinctively beautiful (Baker, 1970; Chan & Tan, 2005; Hsiung, 2005; Kinney, 1995, 2003; Raphals, 1998).

Confucianism also encouraged education, although opportunities varied greatly by social class. Parents were urged to take responsibility for their offspring’s educational progress. In a famous case, when the philosopher Mencius was young, he turned in some mediocre assignments, and in response his mother deliberately spoiled a day’s worth of weaving to show him that lost time could never be regained.

Childhoods in classical Greece and Rome differed from those in China in at least some respects. There was less emphasis on intense emotional bonds between mothers and children, a comparative point suggested earlier in this chapter. Women had a slightly firmer position in Roman than in Chinese families, which along with other factors may have prompted a bit less focus on bonding with sons as a means of expression and protection. Mediterranean art represented children more realistically than was the case in China, possibly reflecting a greater interest in children as individuals. Youth also received more attention in Mediterranean culture—as targets of education, as symbols of beauty and athleticism, but also as potential sources of turbulence that required careful controls. Sexual liaisons between elite males and adolescent boys, particularly common in Greece, differed from Chinese practice (Cohen & Rutter, 2007; Dixon, 1992; Eyben, 1993; Nathan, 2000; Patterson, 2001; Pomeroy, 1997; Rawson, 1991, 2003).

At the same time, however, similarities between Rome and China are striking, reflecting perhaps some common imperial themes but even more the basic relations between an agricultural economy and childhood. Both societies experienced frequent infant death, and both generated comments on how high mortality created instability in adult relationships with children. Both societies used infanticide, particularly female infanticide, with rates

rising as high as 20% of all girls born (despite some efforts to regulate the practice). Gender distinctions were strong in both cases, although upper-class girls might nevertheless acquire some education. Education itself, in both societies as well, emphasized rote learning and memorization, with a strong literary bent. Importance of parental authority and obedience were obvious but fundamental common features, along with work obligations for the majority of children. Neither society, finally, exhibited much appreciation for childish qualities, nor generated much esteem for childhood itself. Memoirs rarely mentioned childhood, and the exceptions usually noted the sternness of fathers. Children who were particularly mature and adult-like came in for particular praise: Romans often praised the *puer senex*, or “old child.” These general characteristics were not uniform: Different personality and family settings could play a role, for example, in degrees of indulgence for infants.

We know far less about childhood in classical India than for the other two big classical civilizations, which constrains comparison. Indian parents may have been somewhat more indulgent of young children, but then stricter discipline, including Hindu religious training, entered in as early as Age 8. Infanticide may have been less common, but it was practiced. Work obligations, predictably, were extensive.

Overall, the classical period highlights the tension between the importance of regional forces and features in shaping distinctive versions of common experiences, and the larger requirements of agricultural economies and their resulting social and gender inequalities.

## THE ROLE OF RELIGION

The advent of major world religions, although not tidy chronologically, introduces some additional themes and comparisons into the history of childhood if not at the level of the impact of agriculture. Basic features of the agricultural societies continued to shape childhood, but the religions provided some interesting innovations within this framework, and generated important new comparative issues.

World religions—defined as religions with a strong missionary impulse and the capacity to spread over political and cultural borders—did not emerge all at once. Hinduism, as it gradually evolved in India, had some characteristics of a world religion. However, Buddhism was the first to meet the criteria fully. Christianity emerged

later, and Islam, rising after 600 CE, was the newest of all. It was only in the centuries after 300 CE that the world religions began a period of particularly active spread, in part because of the decline of the great classical empires.

All the religions placed considerable emphasis on children and on the duties of parents, including duties of providing religious and moral instruction. All continued to stress obedience, adding reinforcement from the need to obey God or the divine order to more conventional injunctions about heeding parents. All attempted to provide some guidance in dealing with death, including the death of infants.

The world religions placed great emphasis on the soul or divine element present in each child. Partly on the strength of this belief, all the religions, but particularly Islam and Christianity, moved strongly against the practice of infanticide, now termed sinful, and some real results accrued. Religious shelters for abandoned children, although often minimally maintained, provided some new options for new parents. Other protections emerged. Buddhism for example attacked arranged child marriages, urging that people must be old enough to provide informed consent. Islam provided elaborate guidance for the kindly treatment of orphans (Browning, Green, & Witte, 2006; Cabezón, 1992; Chakravarti, 1987; Gernet, 1995).

The world religions, like Judaism and Hinduism before, placed growing emphasis on education and schools, if only to teach skills needed for religious instruction. Islam was most active in the centuries after 600 CE, and religious schools spread widely even in rural areas, undoubtedly bringing a larger percentage of children into at least brief contact with education than had occurred ever before. Boys tended to be favored for religious schools, but girls had some opportunities as well. Both Quranic schools and individual tutors were available to Muslim girls, although their attendance was usually shorter than that of boys. Islam explicitly encouraged schools in a new movement beginning in the 10th century, as leaders argued that group exchange and competition promoted more learning than did individual lessons (Berkey, 1992; Nakosteen, 1984; Reagan, 2000). A considerable literature on educational methods emerged in Islam, where literacy may have risen as high as 30% by the 11th century. In Christian Europe, including Russia, education advanced more slowly, but churches and monasteries did provide new outlets.

Islam also generated critiques of excessive physical discipline, urging that parents avoid anger. It also promoted elaborate discussions of grief and condolence on the deaths of children, in contrast to Christian Europe where

this genre was essentially unknown and where people were urged more simply to bow to God's wisdom.

A key question involves what differences the major religions may have encouraged in parenting and in children's experiences more generally. Comparative historical work here is limited, and there is great opportunity for further analysis particularly by extending inquiries into relevant aspects of Islam and Buddhism.

Even in advance of systematic comparison, however, certain aspects of Christianity raise important issues. Islam emphasized the purity of infants: They were too young to have sinned, and if they died they would go straight to paradise. Christianity, however, introduced a quite different concept through the idea of original sin: Each infant was tainted with the sins of Adam and Eve and would be relieved only through some combination of rituals, beginning with christening, and God's mercy. Emphasis on children's natural sinfulness resulted, although it would be more marked in Protestantism than in most versions of Catholicism. Sinfulness certainly highlighted the need for strong parental discipline and oversight. Larger European imagery often suggested animal-like qualities to young children—their voraciousness at the mother's breast often drew comment. A key reason given for swaddling infants—wrapped them tightly to inhibit motion—was the displeasure at watching infants crawl, another reminder of their animal state. Better to release them only when they could directly learn to walk. Despite the prevalence of imagery and emotion around the Christ child, larger Western notions of childhood tended to be rather severe (Classen, 2005; Immel, 2006; Kertzer & Barbagli, 2001; Lynch, 2003).

Whether ideas about sin led to systemic differences in the treatment of children, as opposed to intellectual discussions, is not fully clear. Certainly, many parents justified the use of fear and anger in disciplining children on the basis of their offspring's sinfulness and the need to correct by whatever means. Invocations that children should fear death and damnation were common. European harshness startled some other societies when encounters occurred. North American Indians commented adversely on the spankings and physical discipline that European intruders visited on their children (Erikson, 1993). But we do not in fact know if Christian children were disciplined, emotionally and physically, more than children in other civilizations—it simply remains a possibility awaiting more ambitious comparative research, but deriving from the undeniable peculiarity in those aspects of Christian doctrine that bore on children at least in theory.

Overall, major religions introduced some important changes in the attitude toward and treatment of children, with a mixture of results. Doctrines specific to particular religions invite further exploration.

## THE EARLY MODERN CENTURIES

Historians, whether dealing with world history or the history of particular societies such as Europe or Latin America, commonly mark off the centuries from roughly 1500 to roughly 1800 as a distinctive period, beginning to modify traditional patterns in important respects but not yet in revolutionary fashion. This periodization may have some bearing on childhood, although as always additional research will be welcome.

Three changes are particularly significant, although two are regional rather than global. In the first place, a number of historians have suggested that, worldwide, children's work burdens may have gone up between 1500 and 1800 (Maynes, Søland, & Benninghaus, 2004; Pomeranz & Topik, 2006). Child labor was not new, but there may have been new pressures (Staff, Mont'Alvao, & Mortimer, Chapter 9, this *Handbook*, this volume). In several societies, the need to produce larger volumes of goods for sale on the market or even for export, rather than concentrating on purely local subsistence needs, may have generated new pressures on children. Certainly children in the new Atlantic slave system were often expected to put in considerable work effort, and the same may have applied to apprentices in Europe, serf families in Russia, or families producing export goods for the growing trade flowing out of China. Evidence is not conclusive, except for particular systems like Atlantic slavery, but the larger point is that even more global changes may have developed and that, if so, they formed an interesting preface to modern times in placing new pressures on children.

Children's lives were disrupted in many ways in the New World, the second major point of change. European settlers were widely critical of "native" practices toward children. Spaniards, for example, routinely claimed that punishments in local Central American villages were too harsh. We know that this was not the only side of pre-Columbian tradition; local societies, for example, carefully crafted toys for children, expressing a more sympathetic side. It is not clear whether colonial masters exaggerated problems to make their own rule seem beneficent, but there is no question that, through regulations and missionary endeavor, they interfered widely with established practices, sowing confusion

in the process. Children of slavery, whether shipped from Africa or born of parents who survived the terrible crossing, faced other pressures. Not only was their work regime demanding, but they also faced the possibility of sales that would disrupt their families again and potentially separate them from one or both parents (Bartell & O'Donnell, 2001; Corsair, 2005; Hecht, 2002; Hoerder, 2002; Hsiung, 2005; King, 1991).

In Latin America a high rate of illegitimate births was a final consequence of the new colonial regimes. Many Spaniards fathered children by native or mixed-blood parents. Percentages of illegitimate children could range between 30% and 50% of all children born, in places like Brazil. Some illegitimate children were ill treated; at the other extreme, a few maintained close contacts with their fathers. The principal result, however, was to prompt further innovations to help mothers cope with single parenthood. Many illegitimate children "circulated" among families, performing labor service (sometimes under harsh discipline) and distributing obligations for support. Latin American elites expressed great concern about rates of illegitimacy, seeing this as a condemnation of lower-class morals despite their own frequent complicity in the process. But the results were not temporary, and would continue to mark Latin American family patterns even in more recent times (Hecht, 2002; Laslett, Oosterveen, & Smith, 1980).

A final area of change in the early modern centuries was largely cultural, with Western Europe as focus. Thanks in large part to the new discoveries of the Scientific Revolution, and the partial decline of some of the stricter versions of Christianity, new interest in children's potential emerged by the late 17th century. John Locke, the English philosopher, led the way in attacking ideas of original sin and urging instead that children constituted a "blank slate" that could be positively filled by education. School opportunities in fact expanded, thanks partly to Protestantism and partly to the needs of a more commercial society. Attacks, at least in principle, on some traditional disciplinary measures resulted from the new thinking. There were also changes in practice as well. By the 18th century Europeans began to stop reusing names of children who had died, introducing new names for new offspring instead—a sign that they were thinking of each child in more individualistic terms. Practices of swaddling children began to decline, meaning that parents or at least mothers began putting more time into childcare. Developments of this sort were hints of wider changes to come, but they reflected new ideas and some impact of economic change even in a society that was, at best, still largely agricultural (Trumbach, 1978).

## MODERN, INDUSTRIAL CHILDHOODS: THE 19TH CENTURY

Without falling into the trap of excessive emphasis on change, a number of innovations began to affect children, initially in Europe and North America, in particular, from the late 18th century onward, reflecting above all the new needs and opportunities of nascent industrial, urban societies. Changes were structural in part, beginning with children's functions and basic demography. They also involved further developments in adult assumptions and expectations about children, partly relating to structural change. They involved as well some measurable shifts in more qualitative aspects of children's lives and their relationships with parents and other adults.

Structure first: Two related developments began to alter the nature of childhood, and childrearing, from the late 18th century onward in many parts of Western Europe and North America. Families in the growing middle class began to send their children to school (Crosnoe & Benner, Chapter 7, this *Handbook*, this volume), and for increasing periods of time, in preference to putting them to work before their mid-teens. Education was seen as important to ultimate careers (or in the case of girls, successful families). Schooling was particularly vital for professional groups, but applied widely to the business sector also. At the same time, as children began to become costs rather than assets to the family economy, the middle class began cutting its birth rate well below traditional levels, relying mainly on sexual abstinence to effect the change (Mintz, 2004; Ryan, 1981).

Birth rate reduction began to be picked up by other social groups, although with varying timing. American land-owning farmers, for example, began to participate by the early 19th century, to assure that there would be enough land to provide suitable inheritance. More gradually, urban workers began to pick up the pattern—in Britain, for example, by the 1870s if not before.

The substitution of schooling for child labor proceeded as well, and the two phenomena were linked. Child labor was widely utilized in the early industrial factories, but by the 19th century concerns began to grow. Working-class families valued children's earnings, but they were concerned about putting their offspring under the direction of strangers; they proved to be amenable to some new regulation. Middle-class reformers trumpeted the evils of factory work versus the benefits of schooling. Headed by Britain, a number of countries, and American states, began to pass laws limiting child labor in factories (Weissbach,

1999). The laws were initially not well enforced, but by the later 19th century governments began to hire inspectors. School attendance laws completed the legislative side of the picture. By the 1870s children in most Western countries regularly attended school, as even traditionalist peasants began to realize the importance of education (Weber, 1976). Although the greatest changes involved children at the primary school level, secondary schools also began to expand, and child labor laws extended to cover nonfactory work and the early teenage years. By the early 20th century—between 1910 and 1920 in the United States—child and adolescent labor began to drop rapidly, in favor of school attendance (Crosnoe & Benner, Chapter 7, this *Handbook*, this volume).

Two other changes ultimately accompanied the transformation of children from workers to students, and the reduction in birth rates. First, national and regional governments began to oversee aspects of childhood for the first time to any wide extent in human history. They partially displaced both religious and family authority in the process. Governments regulated work, required school attendance and organized school curricula, began to produce materials aimed at improving parental practices including hygiene, provided medical care for pregnant women and young children, and offered nutritional support for poor families. Governments began to assume some responsibility for children's health as well as education, hoping among other things to support population size through better public health measures even as birth rates dropped (Heywood, 1988).

Finally—and government actions played a direct role here—child mortality began to decline rapidly. Beliefs that parents, and society more generally, should be able to prevent many infant deaths began to spread during the 19th century, as part of a more progressive vision of society; topics of this sort became staples in the new genre of women's magazines. However, big changes occurred throughout the West from 1880 to 1920, with mortality rates dropping from 20% or more of all children born (dying within 2 years of their birth) to 5% or less; and rates would continue to drop thereafter. In combination with the falling birth rate, this change clearly installed the demographic transition throughout Western Europe and the United States. Corollaries included a smaller overall cohort of children in society at large, compared to the adult segment. Sibling life changed, with fewer siblings to interact with but also fewer sibling deaths to experience. Indeed, the separation of children and death was a first in world history, and had a number of interesting implications for parents and children alike, including the reduced

experience of grief in childhood (Coales & Watkins, 1986; Haines, 1989; Seccombe, 1993).

Overall, in the span of little more than a century, childhood in the West changed from work to education. Birth rates dropped to unprecedented lows, but so did death rates, creating important changes in context. By the late 19th century, the introduction of pediatrics as a medical specialty reflected growing attention to children's health (Colón, 1999; Cone, 1985; Prescott, 1998; Zuckerman & Keder, Chapter 15, this *Handbook*, this volume). Government intervention with children and parents constituted another important innovation.

Along with these fundamental shifts in structure and framework, Western society introduced a number of other changes. Some of these related closely to the structural trends, others reflected particular features of an evolving Western culture. Many continue to challenge historians of childhood, in terms of assessing their significance and impact, and some spark ongoing debate.

Did parents, for example, develop new attachments to individual children once the birth rate dropped and mortality began to decline? In many middle-class households, by the early 20th century, employment of servants declined, and grandparents became less available (because of separate residence), so it is possible that parent-child contacts increased, at least, and possibly (on average) certain kinds of emotional attachment as well. Unquestionably the Western world began to generate an imagery that centered on a loving family, often pictured with parents and children gathered together. In this imagery, at least, emotional bonds and shared pleasures replaced economic contributions in cementing the family unit (Lasch, 1977).

Was there new confusion about what children were for, now that their economic functions declined and birth rates dropped? Compounding the issue was the fact that chores around the house also declined, as children had school obligations and as machines took over some conventional housework. The number of deliberately childless couples unquestionably went up, suggesting that adults generated new levels of variety around the question of whether to have children (Stearns, 2003).

Age segregation of children increased. Urbanization reduced the traditional village phenomenon of groups of various-aged children participating in recreation. Schooling and, probably, the decline in the number of siblings focused more attention on same-age peers (Davidoff, 2012; Hemphill, 2011; Rubin, Bukowski, and Bowker, Chapter 5, this *Handbook*, this volume).

At the same time, Western societies continued to emphasize gender differentiation among children. School curricula for girls stressed domestic topics. Differences in dress and toys were if anything exaggerated. Actual roles, however, increasingly converged, with the growing interest in school success. Gradually, coeducational experiences spread, further complicating gender issues among children by creating new interactions (Tyack, 1995).

Traditional disciplinary tactics were revisited, although change in actual adult practices came slowly. The decline in beliefs in original sin helped prompt growing attacks on the deliberate use of fear or anger in disciplining children. If children were in fact innocents, adults should learn new restraint in dealing with them, lest they introduce needless emotional tension and corruption. This theme was prevalent in most American childrearing manuals from the 1820s onward. Some of these changes coincided also with the growing maternal role in caring for children. With work increasingly located outside the home, many fathers—called upon to be “breadwinners” for the family—saw their contacts with children reduced. Sometimes they were invoked as the disciplinarians of last resort—the phrase was, “Wait till your father gets home.” This same approach encouraged mothers to emphasize gentler emotions in dealing with children, although individual practices varied greatly (Griswold, 1994; Stearns, 1990, 1998a).

Reconsideration of discipline and adult goals for children even called the traditional emphasis on obedience into question (see Figure 20.1).

Recent research on masses of published books in the United States and Britain, during the 19th century, now allowing the application of data mining techniques, shows increased discussion of obedience early in the century, when new standards for children were being earnestly discussed, but then a pronounced decline in references, with the United States taking the lead. Obedient children were still convenient in some respects, and safety concerns ran strong when handling young children. But obedience increasingly took a back seat to the desire to have more cheerful and creative children. Again, American childrearing manuals by the 1870s reflected this intriguing reevaluation, as too much obedience and docility might now be regarded as unfortunate (see Figures 20.2 and 20.3) (Stearns, 2012a).

In contrast, interest in individualism in childhood increased. Where space permitted, by the later 19th century, parents were encouraged to have infants sleep in

separate rooms, and gradually the idea of separate bedrooms for each child spread as well. The introduction of cribs, to allow young children to learn to sleep on their own but surrounded by protective devices, was a crucial innovation. New attention was given to children's birthdays, as an opportunity to mark their importance. At the other end of childhood, adult supervision over youth courtship declined. The introduction of the practice of dating, in the United States in the second decade of the 20th century, ushered in still further freedom for romantic activities among teenagers and young adults; chaperonage declined steadily (Bailey, 1989).

Change would continue in the Western world into the 20th century, as the implications of the structural shifts were further assimilated and as new levels of consumerism applied to children. It is also important to note that, around the turn of the 20th century, new thinking was also being applied to real or imagined problems of deviance.

Toleration of youthful pranks began to decline. Many young people in the urban working classes had increasing encounters with the police. Boys were most likely to face such issues, but attention to real or imagined sexual offenses among girls intensified as well. At the same time, Western societies increasingly moved toward the separate treatment of youthful offenders, under the heading of juvenile delinquency, to avoid contagion from adult criminals (Cauffman, Shulman, Bechtold, & Steinberg, Chapter 16, this *Handbook*, this volume). More broadly still, and aside from outright deviance, the introduction of the word and concept of adolescence marked a growing uncertainty about the teenage years, as schooling spread and, thanks to improved overall nutrition, the age of puberty dropped (Kett, 1978; Odem, 1995).

Individual societies introduced further specific changes. For example, growing concern about immigrants in the United States encouraged new types of testing in the early 20th century. Amid widespread assumptions about the inferiority of certain ethnic groups, it seemed vital to sort children by intelligence. Many children were tracked through IQ tests and similar measurements into separate educational programs, while encountering other forms of discrimination. European countries actually tracked children more rigorously, but they relied on achievement examinations more than assumptions about innate aptitude. Differences of this sort could have deep effects on children's lives.

### CHANGES IN NON-WESTERN SOCIETIES

The spread of industrialization outside the West, by the end of the 19th century, plus growing awareness of Western patterns, brought important changes to many other societies. In general, the structural changes that were developing in the West won wide attention, but many regions sought to introduce or maintain a different cultural balance in the area of qualitative change.

Japan provides an important case in point. As Japan embarked on its important reform era, the Meiji era, after 1868, it was immediately attracted to enhanced public health measures that would, among other things, cut into the traditional infant death rate. It also moved quickly to provide, and require, elementary education for both girls and boys, with a major act in 1872. Full implementation took some time, and there was (as had been the case in the West) important resistance to government requirements from some rural communities. But by the 1890s universal schooling was a reality, and further reform measures, limiting child labor, encouraged the transition as well (B. Platt, 2005; Stephens, 1991; Uno, 1999).

Reduction of the birth rate came somewhat more slowly, as families took some time to realize the implications of the new structures for childhood and as the government remained interested in abundant population resources. By the mid-20th century, however, Japan had completed the demographic transition, with low birth and child death rates, as well as the substantial conversion from work to schooling as the staple for childhood. The government began paying attention to children in other ways, from the early 20th century onward. It sponsored a series of publications designed to improve the quality of childrearing, holding that traditional methods were inadequate.

It introduced the concept of juvenile delinquency, ending longstanding practice of including children with adult criminals, another sign of a new recognition of childhood (B. Platt, 2005).

With all this, however, Japanese leadership also wanted to make sure that childhood remained Japanese. After a brief flirtation with Western ideas of individualism in the 1870s, the government introduced new emphasis on the importance of family and community, along with nationalism and a new level of emperor worship, in the 1880s. Already in 1879 an imperial memorandum for teachers insisted on "loyalty to the Imperial House, love of country, filial piety toward parents, respect for superiors, faith in friends... constitute the great path of human morality." Western individualism was explicitly attacked. Western nations were also preaching nationalism in their new mass education systems, but the Japanese did manage to infuse childhood with a different, more community- and peer-oriented set of values, along with the more standard changes introduced for children (Stearns, 1998b, p. 123).

From the 1920s onward, communist systems in various parts of the world experimented in different ways with combinations of structural changes and distinctive value systems. Very quickly after the 1917 Revolution, Russian communists expanded educational systems and requirements, including a network of nursery schools and kindergartens. Direct contact between government and children was a vital part of building a new society. Child labor was curtailed, although some work service requirements accompanied the formation of communist youth groups. The government also worked hard on public health, quickly driving down the infant death rate, which reached alarming proportions amid the chaos of war and revolution. By 1960 infant mortality had dropped 900% from 1918, to 3.5% of all children born (Balina & Dobrenko, 2009; Creuziger, 1996; Kelly, 2007; Kiaer & Naiman, 2006; Kirschenbaum, 2011; Pearson, 1990; Riordan, 1989; Vishneva-Sarafanova, 1984; Weaver, 1992).

As in Japan, birth rate reductions came a bit later, as the government wanted to encourage population growth. But individual Soviet families began reaching their own conclusions, by the 1930s, and family size dropped rapidly. Scarce housing added to school costs and the reduction of children's earnings to promote this facet of the demographic transition.

These structural changes were accompanied by a real effort to frame a childhood suitable for a communist society, combining new pressures (parental and governmental) for school success with, for example, a mastery of Marxism

and devotion to the state. Youth groups aimed similarly at indoctrination and solidarity. This case was not the conservatism of the Japanese approach, but it differed widely from Western models.

Communism in China, after the late 1940s, moved in similar directions. Schooling expanded rapidly. Public health measures, including the messages delivered by “barefoot doctors,” began to reduce child mortality, to 3.7% by 2003. In this case, the government famously moved in to reduce birth rates, from 1978 onward, with the “one child” policy and its rigorous enforcement. Here, again, was a case in which a revolutionary regime fairly quickly transformed agricultural childhood into a modern, industrial model. Like their Russian counterparts, the Chinese were also eager to make sure that children were freed from what they saw as the hand of backward tradition—notably Confucianism. Emphasis on science and technology, and Marxism, in the schools was part of this effort hand in hand with a wider attempt to teach children to dispute traditional etiquette and other markers of the past. Again, as in Russia, the result could be some significant tensions between children and their parents. Other measures added in, like a 1950 law that allowed young people to choose their own spouse, without parental consent (Bernstein, 1977; Chan, 1985; Chin, 1988; Hooper, 1985; Kirby, 1966; Lau, 1996; Nan, 2006; Power, 2005; Saari, 1990; Xu, 2002).

These structural changes were real and measurable—school attendance and literacy did rocket up—but some other measures met with less complete success. Schools might teach the importance of devotion to the communist struggle, but as one former student put it, “To tell the truth, we did not yet quite know what communism was.”

Changes were not confined to Japan and the communist societies. Turkey’s revolution from above, from the 1920s onward, emphasized the basic importance of schooling, and many other societies moved in the same directions. Ultimately, both structural changes and key aspects of regional distinctiveness in childhood folded into a larger pattern of global contacts and standards, particularly toward the later 20th century and thereafter.

## GLOBALIZATION AND CHILDHOOD

The variety of children’s situations remained considerable in the most recent historical experience. In many rural areas, particularly in societies where industrialization was not well advanced, children’s conditions continued in many

ways unchanged from agricultural patterns. Even basic schooling might be inaccessible, and even where inroads on child mortality occurred almost everywhere save amid war or famine, deaths rates might remain quite high.

Military conflicts continued to involve many children, both as victims and, through the phenomenon of child soldiers, as participants. Both wars and civil strife increasingly blurred boundaries between civilians and military. Deliberate attacks on children, to vent ethnic hatreds, were not uncommon. Many children also were displaced by conflict, filling refugee camps amid poor conditions. As many as 4% of all the world’s peoples have had to flee at some point during the past century, including at least 20 million children (Brett & Specht, 2004; Garbino, Kostelny, & Dubrow, 1991; Goodenough & Immel, 2008; Machel, 2001; Marten, 2001; Masten, Narayan, Silverman, & Osofsky, Chapter 18, this *Handbook*, this volume; Rosen, 2005; Schlemmer, 2000; Singer, 2006; St. John, 2008; Vincent & Sorenson, 2001).

Working conditions also deteriorated for some children. Global competition might put pressure on pay levels and safety, particularly on the part of local firms trying to withstand pressures from more modern corporations. At the end of the 20th century many governments also scaled back welfare measures, to save on taxes, which again affected children disproportionately. Many illegitimate children in Latin American slums had an increasingly difficult time hanging on. In some cases, as in some rug-making establishments in India, child workers were essentially kidnapped outright, forced to work 15 hours a day. Begging and street entertainments drew many children in the cities, and sexual exploitation almost certainly increased (Hecht, 1998; Seabrook, 2001). Other aspects of globalization prompted different types of change. By the later 20th century most governments were attempting to expand the core components of the modern structure of childhood, by extending schooling, working on public health measures that would press infant mortality down still further and, in some cases, promoting falling birth rates as well (Stearns, 2010). Globally, rates of child labor declined dramatically. By 2012, 44 million children under Age 14 were still at work worldwide, and for a time use of children actually increased in South and Southeast Asia, bucking the larger trends. Overall, however, children had comprised 6% of the total workforce in 1950, but by 1990 children represented only 3%. By 2004, 88% of all children of primary-school age were attending schools. In India itself, the 20 million children at work in 1999 had dropped to 12.6 million by 2008 (Larson, 2002; Larson, Wilson, & Rickman, 2009).

Many of these trends were further bolstered by the growing attention of international agencies to children's conditions, and a fledgling movement to define children's rights on a global scale. United Nations conferences worked to promote women's education and other measures that might improve care for children and also lower the birth rate (the correlation with women's education here was well established). The International Labor Office even as early as the 1920s sought to define rights to education and protection from work abuses. Communist countries took a lead in defining education as a children's right, but Western leaders like Franklin Roosevelt picked up similar rhetoric by the 1940s. Many nations signed pledges to end capital punishment for children, regardless of the crime. And although the United States held out against this measure, the Supreme Court in 2005 actually imposed a ban, citing international standards as one key motivation. Attempts to define children's rights more generally encountered heavy going. The United States worried that a ban on child labor would impede its use of migrant farmers. India also held out. Nevertheless a Convention on the Rights of the Child was issued in 1989, and most nations signed on: Its main provisions involved basic health standards, avoidance of abuse, access to education, and elimination of the harshest kinds of child labor. Global standards for children were rudimentary in some ways, and often violated, but there were some important areas of agreement, particularly on education, at least in principle (Guggenheim, 2005; Scheper-Hughes & Sargent, 1998).

Children's consumerism was another area reflecting new global influences, although amid great variety depending on rural versus urban residence and basic standards of living. Adults had purchased or offered items for children for millennia. Elite children in hunting and gathering societies were frequently buried with extra jewelry; Mayan toys for children showed great ingenuity; special adornment for children was a common part of social hierarchies in agricultural societies (Stearns, 2006). The more modern surge of consumerism in 18th-century Europe included new levels of purchasing for children, including books specially written for child audiences.

But it was in the later 19th century that spending on children really took off, initially in the advanced industrial societies of the West. Even infants were surrounded by purchased items, such as the teddy bears that made their debut early in the 20th century. Acquisitions at Christmas and for birthdays escalated steadily. Some concerns surrounded this new pattern—worries about making children too materialistic and greedy, or insufficiently creative. But

the push continued unabated. It was furthered as well by the new practice of giving children allowances, initiated in the United States in the 1890s. Various producers began to target children directly as consumers—for example, with cheap books and then comic books. Advertisers by the 1920s, using new technologies like the radio, also addressed children, both for items they might purchase directly and for more expensive items for which they could press their parents (Cross, 1997; Goodman, Peach, & White, 2003; Nightengale, 1995; Skelton & Valentine, 1998; White, 1994).

By the 1920s elements of this consumer pattern began to go global. Japanese consumers joined their Western counterparts in seeking special goods for children. By this decade the Japanese, along with Americans, provided a disproportionate number of new toys and games for children in the world market (Cross & Smits, 2005). Corporations like Disney, bent on selling entertainment to children and their parents, began to develop global outreach, although activities here became more extensive after World War II. By the 1960s fast-food restaurants with special appeals to children began their international ascent.

More than mere consumerism was involved in some of this outpouring. The idea began to develop that children and childhood should be happy. American childrearing literature, and some similar material in Britain, began to emphasize the importance of cheerful children during the 19th century, as part of the idealized picture of family life. Cheerfulness became a desirable character trait that good parents should both model and instill. But by the 1920s discussion in the prescriptive literature turned to happiness directly. Some authors argued that children were naturally happy, so all parents and educators had to do was avoid spoiling their positive outlook. But many materials expressed greater doubts about "natural" happiness, and urged that parents had a more active role to play. The sad child became a target of concern, possibly needing psychological intervention and certainly a reproof to parents. The urge to make children happy, promoted by purveyors of toys, foods, and entertainment, spread widely (Kotchamidova, 2005; Stearns, 2010).

Although the United States almost certainly developed this emphasis on children's happiness most widely, it proved exportable. Global commerce, touting goods made for children including, by the later 20th century, electronic games from Japan and masses of youth-oriented music, helped advance the concept. But as more societies emphasized schooling, and the desirability of rewarding children with happiness treats, and as more families

limited their birthrate and concentrated attention on one or two offspring, structural changes encouraged attention to happiness as well. Again headed by the United States, the movement even affected teaching styles, with schools urged to make learning fun, reducing conventional drudgery.

An interesting symbol of the new approach was the song “Happy Birthday,” which increasingly accompanied this special celebration of the individual child. The words were written in the United States in 1926, and became standard practice by the 1930s. After World War II the ditty was translated into most major languages. The idea of birthday parties, correspondingly, spread widely, particularly among middle-class families open to international influences. Shopping malls in Dubai sponsored birthday parties, promising “a truly memorable day for their children.” The birthday idea spread widely in Latin America and also in China, where the whole notion of calling attention to the child, rather than expressing gratitude to parents, was quite new. More widely, polls in India suggested that a growing minority of parents were coming to the belief that children can and should be happy (Miller, 1999; Riley, 2001; White, 2006). To some extent, then, elements of a new approach to children became global, or at least middle-class global, along with the structural changes in childhood that were spreading steadily.

As always, regional responses combined with global influences. A study in Lebanon showed how parents tried to combine some international messages about developing the individual child—pushed by United Nations agencies and also translated childrearing literature—with older emphases on the importance of the family unit and solidarity over individual interests (Christina, 2009; Cross & Smits, 2005; Fler, Hedegaard, & Tudge, 2009). Many families sought to balance some bows to children’s consumerism with more distinctive regional values. Japanese families embraced Disney parks, but used them differently from their American counterparts.

Changes in specific industrial societies were important as well. The huge influx of married women into the labor force, in the United States and Europe in the 1950s and 1960s, created new tensions for parents and children alike, particularly in the United States where daycare arrangements were less extensive and less acceptable than in Europe. While parental attention did not uniformly diminish—there were some impressive countermoves in many families, there is no questions that some older children were left to their own devices more often than before, and that peer cultures and media influences gained ground in this new context (Hernandez, 1995).

The importance of combining local and global in the recent history of childhood must be joined with attention to the downsides of some of the global patterns themselves. A number of societies, for example, began to face issues in the interaction between children and schooling. Children with attention problems began to draw notice as early as 1856, with a comment in Germany (Stearns, 2003). Research intensified in the 1920s, and full-blown definitions of attention deficit disorder followed, with American teachers and parents particularly eager to identify the condition and provide compensatory medication. Schooling raised different problems in Japan, where by the early 21st century several thousand schoolchildren were suffering from an ailment called *hikikomari*, or an inability to leave home and function adequately. In many countries, including the United States, Japan, and South Korea, youth suicides increased at an alarming rate, reflecting school pressures, family disorders including frequent divorce, and possibly the difficulty of expression sadness in cultures that emphasized the importance of good cheer (Stearns, 2011).

Obesity was another growing global issue among some children (Zuckerman & Keder, Chapter 15, this *Handbook*, this volume). With the United States well in the lead, growing minorities of young people became noticeably overweight, as they combined the ready availability of foods, and usually highly caloric snacks, sodas, and fast foods, with increasingly sedentary lifestyles not only in school but also in many video-based recreational pursuits (Vandell, Larson, Mahoney, & Watts, Chapter 8, this *Handbook*, this volume). Middle-class children in countries like China and India began to evince the problem, which called forth growing concern among agencies such as the World Health Organization. The classic problem of undernourishment for children had not ended, as massive child poverty persisted in many societies and new income inequalities raised issues even in affluent settings like the United States for a growing minority of children. But for the growing middle classes, the classic problem was virtually stood on its head, with changes in eating and activity patterns. Again, global changes in childhood were complex, the results clearly mixed (Bray, 2009).

## FUTURE OPPORTUNITIES IN THE HISTORY OF CHILDHOOD

Historians of childhood have covered considerable territory: We know a lot about various aspects of childhood in

the past and about connections between recent changes and current patterns. But of course there is more to do, in what is still a new field of inquiry.

The most obvious target involves the host of unresolved debates and uncovered topics. When the birth rate drops, do parental patterns of attachment change? Can we aspire to more than tentative historical work on patterns and changes in sibling relationships (a really important field, with one exception virtually untouched to date)? The list here is considerable, and there is every reason to encourage compensatory research.

A special aspect of the gap-filling effort involves more concerted efforts to deal with children's experiences directly, rather than concentrating so much on adult evaluations and perceptions. Wider attention to the use of artifacts and other materials emanating directly from childhood should pay off in future. A new approach to the history of education that focuses on evidence and activities from the child point of view is conceivable, at least for the modern period. Use of criminal and legal records—already underway with some of the histories of delinquency and “deviance”—is another way to get at inarticulate groups more directly. There also have been some interesting efforts in using oral history, although the filter of adult memory is very much involved in this genre (Hawes & Hine, 1991; Nelson, 2010; Prout, 2005). Newer techniques like data mining, suggested above, may also have some applicability to the effort to get at children more directly, although again most of the obvious data collections will come from adult authors (Stearns, 2012a). But the main point is clear: The history of childhood has a unique problem of sources, which should galvanize the imagination of historians in response.

The geographical invitation is obvious. Historians and researchers simply need to make more pioneering efforts to tackle regions and cultures vital in world history but dramatically underserved where studies of children and childhood are concerned. Further opportunities in comparative analysis will follow from a fuller set of regional studies. How different, in crucial past periods, were Islamic and Christian childhoods—overall, and around special topics, such as childhood sexuality, where in principle the two kindred religions had quite different approaches? A lot of open terrain remains here, in virtually every historical period including even the ramp-up to contemporary times (Zuckerman, 2010). More broadly, the combination of globalization and childhood, a natural topic for current history, involves the persistent need to balance wider trends and regional distinctiveness (based often in part on past

culture and institutions), and a wide geographical range in the history of childhood is essential here.

There is also a surprising gap between the excitement even of existing work on the history of childhood, and conventional history more generally. Most historians have not decided where to put the history of childhood or how to relate it to more common topics such as political history. Open a world history textbook and one will find, in the index, either no reference to children at all, or a single point about new educational measures in the 19th century. Yet, given the importance of children and childhood to individual and social life in the past, historians should be able to do better than this, to work children's history more directly into standard historical accounts rather than treating it as an esoteric offshoot. For example, can't the history of childhood be used to reach student audiences more directly, with historical issues and methods that touch them directly and that might draw them more readily into exposure to historical analysis? These represent some major discussions, and opportunities, for the future.

Historians must insist on the importance and ultimate relevance of many chronological phases of childhood history, and some of the great gaps and challenges certainly involve periods in the earlier human past. But the opportunity to deepen our understanding of modern changes and continuities, as a means of using the past to understand present patterns and complexities, remains vivid as well. Modern shifts in childhood, including the impact of new global connections, have been both fundamental and, in historical terms, quite recent, even in the societies the pioneered the first versions of modern childhood. It is small wonder that difficult adjustments continue, that adults and children alike continue to debate what childhood should entail, and that further change is inescapable in children's lives and in perceptions of childhood alike. The beauty of the history of childhood, for all is its debates, gaps, and complexities, is that it provides a roadmap of where human experience is coming from, as it barrels through the present on the way to the future.

Finally, there is the clear desirability of rekindling discussions about childhood's history and its uses with other disciplines. Some of the issues in childhood history—for example, the use of artifacts—can clearly be addressed more fruitfully through interdisciplinary conversations, some of which have already proved quite productive. Attention to the complex modern history of concerns about children's happiness, and their impact on actual children, invite discussions between developmental scientists and historians. And the list, here too, goes on. Historians are

interested in the history of childhood to improve their grasp of the past, but also to contribute to the wider understanding of what childhood is all about (Fass, 2007; Stearns, 2012b). For this purpose they need a wide audience, beyond the conventions of the discipline, but wide participation as well.

## INTRODUCTION

In its broadest sense, *ecology* is defined as "the science of the relations of the organism to the environment" (Stauffer, 1957, p. 140). A similar term, *context*, often used by developmental scientists, refers to: "any event or condition outside the organism that affects or is affected

by a person's development" (Bronfenbrenner & Crouter, 1983, p. 359). Common to both terms is the assumption that conceptualization and assessment of the environment (broadly conceived) is necessary if we are to understand development. Within this broad framework a number of modern contextual-ecologically based theories of human development have been formulated (e.g., Bronfenbrenner & Morris, 2006; Lerner, 2002; Magnusson & Stattin, 2006; Overton, 2010; Sameroff, 2009; Super & Harkness, 1999). These theories converge on a core of specific principles (Wachs & Shpancer, 1998). Core principles can be traced

---

Special thanks are due to the editors of this volume, Marc Bornstein and Tama Leventhal, for their detailed and thoughtful reviews on the initial version of this chapter.

to a common intellectual history, rooted in the work of prior generations of ecologically or contextually oriented developmental researchers and theorists such as Roger Barker and Kurt Lewin (Bronfenbrenner & Crouter, 1983; Magnusson & Stattin, 2006), and include:

- The child's environment is complex, multidimensional and structurally organized into levels that are linked with each other.
- Development is multidetermined such that the contributions of person and environment, while necessary, are by themselves not sufficient when attempting to explain or understand development. Rather than studying individual and environment in isolation there needs to be simultaneous consideration of both person and environment.
- Person and environment are functionally linked: Environment influences children's characteristics, and children's characteristics, perceptions, and actions influence their environment. In this way children play an active role in their development.
- Change over time in the individual, the environment and the relation between individual and environment is the norm.
- Because of continuing bidirectional change over time in relations between individuals and their environment, development is probabilistic in nature.

While there is convergence across existing contextual-ecological theories on this core of key principles one distinct conceptual difference involves the question of whether the most appropriate unit of analysis for studying development is variable centered or person centered (Magnusson & Stattin, 2006). *Variable-centered* ecological theories (e.g., Bronfenbrenner & Morris, 2006; Elder & Shanahan, 2006), while emphasizing that development occurs *only* through the integrated contributions of person and ecological characteristics, view linkages between specific person and environmental elements as the fundamental unit of analysis for understanding development. In contrast, *person-centered* contextual theories (e.g., Brandstetter, 2006; Overton, 2006), view the holistic synthesis of person and context into an indivisible system as the fundamental unit of analysis. Comparisons of these two approaches have concluded that while holistic models are theoretically more elegant, variable-centered models are more easily translated into specific assessment tools or functional methodological procedures for studying development (Lawton, 1999; Van Speybroeck, 2000). Given that

a major emphasis of this chapter involves the application to development of the core principles specified above a variable centered ecological model was chosen as the conceptual framework for this chapter with specific reference to Bronfenbrenner's bioecological formula defining development as a *joint function of process  $\times$  person  $\times$  context  $\times$  time linkages* (PPCT; Bronfenbrenner & Morris, 2006).

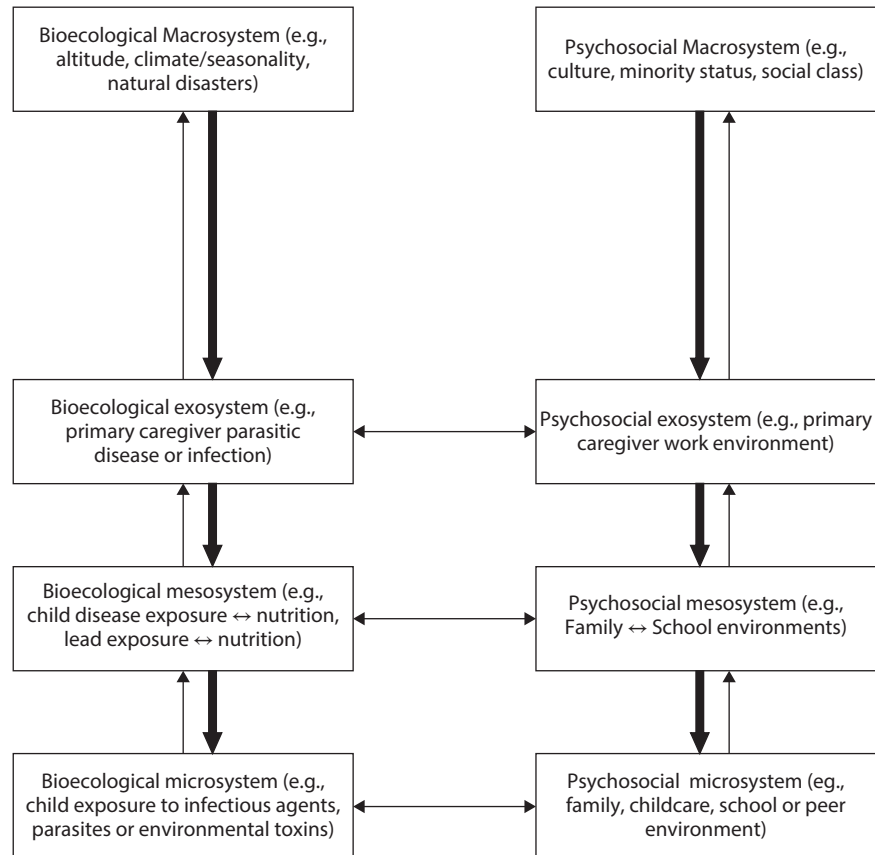

Using a PPCT conceptual framework five major issues will be considered: (1) the structure of the human ecosystem; (2) the major methodological implications of an ecological perspective in studying development; (3) how ecological characteristics influence development; (4) strategies for integrating process with person, context, and temporal characteristics; (5) applications of an ecological approach to promote development.

## STRUCTURE OF THE CHILD'S ENVIRONMENT

In both his initial (Bronfenbrenner, 1979) and later theorizing (Bronfenbrenner & Morris, 2006) Bronfenbrenner viewed the child's environment as a "nested" set of organized linked multidimensional elements (i.e., a system). An organized, linked set of elements possesses specific inherent properties (von Bertalanffy, 1968), one of which is that any system element has the potential to influence both the structure and impact of other elements in the system (Wachs, 2000). Hence, although the environmental structure described by Bronfenbrenner can be viewed as hierarchical in nature (see Figure 21.1), with lower-level elements nested within higher-order elements, no one level is predominant (Ungar, Ghazinour, & Richter, 2013). Rather than individual system elements what is most salient for understanding development is the nature of linkages, both within and between the different environmental levels described next.

### The Microsystem

At the lowest or innermost level, the *microsystem*, are patterns of interaction (*proximal processes*) between the child and his/her immediate physical (e.g., objects, inanimate stimulation) and social environment (e.g., parents, siblings, teachers). The microsystem also can encompass mass media such as TV or the Internet, given that information contained in these sources can promote children's cognitive and social-emotional development (e.g., *Sesame Street*: Mares & Pan, 2013) and help children conceptualize the nature of their world (Garbarino, 2001; also see Calvert,

**Figure 21.1** Integrated model of the bioecological and psychosocial environments.

*Source:* Adapted from "Expanding Our View of Context: The Bio-ecological Environment and Development, T. D. Wachs, 2003, in R. Kail (Ed.), *Advances in Child Development and Behavior*, Vol. 31, pp. 365–411, edited by R. Kail, New York, NY: Academic Press. Reprinted under STM permission guidelines.

Chapter 10, this *Handbook*, this volume). Structurally, the microsystem is heterogeneous in nature and the various dimensions of the microsystem are functionally linked. For example, the home environment of the child has both physical and social components (Wachs, 2000) and the nature of proximal parent-child interactions (the social microsystem) can vary depending upon the level of physical microsystem dimensions such as home chaos (Wachs & Corapci, 2003) and physical resources (Bradley, 1999).

### The Mesosystem

The microsystem is nested under the *mesosystem*, which is defined by linkages between different microsystems (Bronfenbrenner, 1979). While an analysis based on measurement of separate microsystems would reveal if there was an additive impact of multiple microsystems upon development such an analysis would tell us little about mesosystem influences. Understanding mesosystem

influences requires understanding the nature of mesosystem linkages (Ungar et al., 2013), which can be defined by four classes of linkage patterns (McIntosh, Lyon, Carlson, Everette, & Loera, 2008).

### Implied Linkages

The weakest form of mesosystem characterization involves implied linkages, as can occur when the same individual participates in two or more settings. Peer group and school characteristics can be viewed as an implied mesosystem link if the child and their peer group attend the same school (Card, Isaacs, & Hodges, 2008). Implied linkages can also be defined by statistical covariance between different microsystem settings. For example low-income families are more likely to have connections to other low income families than to high-income families (Jarrett, 1998). While implied linkages place the individual in multiple settings this placement tells us little about the nature of interconnections between the settings.

### Functional Linkages

The operation of functional linkages can be inferred when a child's presence in one microsystem is related to events in a second microsystem. A child's membership in a gang may be viewed as a functional mesosystem link to the family when gang membership weakens the influence of positive parental childrearing practices (Tolan, Gorman-Smith, & Henry, 2003). Research on child labor in low- and middle-income (LAMI) countries also illustrates functional linkages in terms of documenting how work conditions influence the child's attendance and performance in school (Dawes, Streak, Levine, & Ewing, 2012).

### Cognitive Linkages

Mesosystem linkages also can be cognitive in nature, as seen when the individual refers to events or information obtained from a different microsystem. One example of a cognitive linkage occurs when mothers discuss information received from people in their social-support network (McConnell, Breitreuz, & Savage, 2010). The Internet can also exemplify a cognitive mesosystem, as seen when adolescents refer to health related information obtained from web-based sources (Ybarra, Emenyonu, Nansera, Kiwanuka, & Bangsberg, 2008). To the extent that individuals describe specific events or knowledge cognitive linkages can highlight mechanisms underlying mesosystem influences.

### Structural Linkages

For structural mesosystem linkages to occur the extent and nature of cross-microsystem linkages must be specified. One example of a structural linkage is seen when parents report the extent of their involvement with various school activities such as attending a school event, or discussing their child's school progress with the child's teacher (McIntosh et al., 2008). Other examples include adolescent reports of the extent and nature of parental knowledge of their child's activities with peers (McIntosh et al., 2008) or parent reports on the amount of time spent on work related activities while at home (Schneider, 2009). At the neighborhood level structural mesosystem linkages may also be inherent in the operation of "collective efficacy" (Sampson & Raudenbush, 1997), when neighbors report working together to promote neighborhood improvement.

### The Exosystem

The *exosystem* is characterized by linkages between aspects of the environment the child does not directly encounter,

but which influence development through influencing lower level microsystem and mesosystem characteristics. Much of the research on exosystem influences has been carried out in western countries and is focused on three dimensions: parental social support networks, parental work environment, and neighborhood characteristics (for detailed reviews of neighborhoods as exosystems see prior reviews by Nicotera, 2007, and Sampson, Morenoff, & Gannon-Rowley, 2002; also see Leventhal, Dupéré, & Shuey, Chapter 13, this *Handbook*, this volume).<sup>1</sup> The exosystem also can include both actual and virtual settings, as seen when parents use computer technology to work from home rather than at their work place (Golden, 2012). In low and middle income (LAMI) countries there also has been study of bioecological exosystem influences such as access to or costs associated with public health care, schooling, electrification, sanitation facilities and caregiver exposure to environmental toxins or infectious agents (Engle, 2012; R. Mistry, Galal, & Lu, 2009).

When analyzing exosystem- microsystem linkages it is particularly important to recognize the *bidirectional* nature of this relationship. For example, in the interplay between parent work conditions and family functioning a standard exosystem analysis would involve assessment of the degree of work→family conflict, where work demands impinge on family functioning (e.g., Hsueh & Yoshikawa, 2007). However, there also is a bi-directional linkage pattern, as manifest in family→work conflict, when family responsibilities impinge on parent's work performance (Buehler & O'Brien, 2011).

### The Macrosystem

At the outermost level (the *macrosystem*) are overarching organized patterns of beliefs, values, customs, and living conditions (e.g., culture, social class). Macrosystem characteristics can be defined using broad unidimensional criteria such as the distinction between *individualistic cultures*, which emphasize individual autonomy, personal independence and personal goals, versus *collectivistic cultures*, which emphasize group goals, social harmony and a sense of obligation to others (Oyserman, Coon, &

---

<sup>1</sup>As children get older and more involved in neighborhood activities there is conceptual justification for also viewing neighborhood as a microsystem. However, in this chapter, *neighborhood* is classified as an exosystem dimension given that neighborhood influences such as collective socialization function as aggregates rather than as specific proximal processes (Brody et al., 2001).

Kemmelmeier, 2002). A major concern with categorizing macrosystems using unidimensional criteria is that oversimplified conclusions can occur if there is significant intramacrosystem heterogeneity in the defining trait (Super & Harkness, 2010).

Alternatively, macrosystem patterns also can be defined based on theoretically based multidimensional categorizations that provide a detailed picture of underlying macrosystem processes, while simultaneously allowing for intra-system heterogeneity. An example of a multidimensional framework used to explain cultural influences is the “developmental niche” which encompasses three functionally linked domains: characteristics of the child’s physical and social *settings*; childcare customs and strategies for *rearing* children; parental *beliefs* about the nature of children, for example, what are desirable traits for a child to have, and what are the best ways to rear a child of a given age (Super & Harkness, 1999).

### The Chronosystem

Cutting across all of the four levels described above is the dimension of time (the *chronosystem*). In developmental research, the chronosystem is often viewed either in terms of the comparative salience of proximal processes occurring at different ages (e.g., critical or sensitive periods (Bornstein, 1989) or in terms of persons encountering macrosystem events at different ages (Elder & Shanahan, 2006). Bronfenbrenner and Morris (2006) also have emphasized that stability of facilitative proximal processes over time is essential for establishing long-term positive developmental trajectories. Chronosystem-macrosystem links can be seen when developmentally facilitative proximal processes are disrupted in families where there are high levels of income instability across time (Hill, Morris, Gennetian, Wolf, & Tubbs, 2013).

### Going Beyond Bronfenbrenner’s Ecological Structure

In understanding the structure of the environment it is important to recognize that the multiple levels described by Bronfenbrenner primarily describe the child’s *psychosocial environment*. Children and their caregivers also live in a *bioecological environment*, which is defined by multiple dimensions such as climate, natural hazards or disasters, environmental toxins, and available food sources (Wachs, 2003; also see Masten, Narayan, Silverman, & Osofsky, Chapter 18, this *Handbook*, this volume). As seen in Figure 21.1, the bioecological environment can be

described using the same multidimensional linked nested structure seen for the psychosocial environment (Wachs, 2003). Reflecting the person-environment link noted earlier Lawton (1999) also has proposed that there is a structured *subjective environment* that is parallel to and resembles the structures shown for the psychosocial environment. Taken as a totality the combined psychosocial, bioecological, and subjective environments comprise the child’s *ecosystem*.

### Ecosystem Structure: Summary and Conclusions

An important consequence of multiple linkages between different ecosystem levels is the probabilistic nature of development, given that the impact of influences from one level can be moderated by characteristics found at other linked levels. For example, childrearing by multiple caregivers (microsystem) may or may not adversely impact on the child depending upon cultural-macrosystem values (Weisner, 2010). Similarly, the impact upon children of work conditions for one parent (exosystem) may depend on how the other parent or partner deals with this situation (microsystem; R. Barnett & Gareis, 2007). Other examples of the probabilistic nature of development, resulting from *both* the hierarchical linked ecosystem and PPCT mechanisms, will be presented in later sections of this chapter.

## METHODOLOGICAL IMPLICATIONS OF A PPCT-BASED ECOLOGICAL FRAMEWORK

Besides serving as a theoretical foundation, the core principles presented earlier have three major implications for the formulation of research designs to study development.

### Studying Children in Real-World Situations

There is a long-standing emphasis in human ecological studies of conducting research in the real-world situations within which children and their families live (Bronfenbrenner, 1979; Wohlwill, 1973a).<sup>2</sup> Underlying this emphasis on conducting research in everyday settings is the issue of *ecological validity*: the degree to which the research setting incorporates essential ecosystem features normally encountered by the child (Schmuckler, 2001).

<sup>2</sup>A notable exception to the emphasis on real-world settings are studies coming from the Gibsonian ecological approach to understanding the contributions of perception to the emergence of basic skills, most of which are carried out under controlled laboratory conditions (e.g., Gogate, Walker-Andrews, & Bahrick, 2001).

### *The Ecological Validity of Laboratory Settings*

A common practice in research on microsystem proximal processes, such as parenting behaviors, is the use of laboratory-based assessments as the research setting (Kerig, 2001). The ecological validity of laboratory-based measurement of parenting can be assessed through comparing patterns of parent-child interaction in the home and in the laboratory. Comparisons typically show that while there are moderate correlations between home and laboratory assessments there also are more positive and fewer negative interaction patterns in the laboratory setting (Gardner, 2000; Goossens & Melhuish, 1996; Lindahl & Malik, 2001). In addition, relations between child age and parenting behaviors reported when out-of-home-assessments are used are not found when observations are done in the home (Zevalkink & Riksen-Walraven, 2001). One explanation for this pattern of findings is that the laboratory setting may not be representative of the totality of microsystem conditions in the child's home (Kerig, 2001). As a result mother-child interactions assessed in controlled laboratory settings may be measuring maternal or caregiver *competence* (what the mother or caregiver is capable of doing), whereas assessments done in naturalistic settings are more likely to reflect maternal or caregiver *performance* (what the mother or caregiver is normally doing when interacting with the child) (Goossens & Melhuish, 1996; Zevalkink & Riksen-Walraven, 2001).

### *Can the Real World Be Brought Into the Laboratory?*

Attempts have been made to design laboratory settings so they more closely represent real-world conditions. Reviews of both behavioral and biological evidence on the ecological validity of laboratory simulations of real-world situations either report inconsistent or limited relations between laboratory and naturalistic findings (Mori & Armendariz, 2001), or significant relations primarily when multiple laboratory assessments are utilized (Zanstra & Johnston, 2011). Given the complex multidimensional nature of the child's proximal environment this pattern of findings is not surprising. Representativeness of laboratory microsystem research findings will be limited by the degree to which interactions are setting dependent and the degree to which proximal processes and conditions that influence development in the child's natural ecological setting are missing or cannot be simulated in laboratory assessments (Lerner, Dowling, & Chaudhuri, 2005).

### *Do Studies Carried Out in Real-World Settings Guarantee Ecological Validity?*

Doing naturalistic observations of the child's ecosystem does not necessarily guarantee ecological validity given that the ecological validity of real-world assessments can be compromised by the methodological procedures used. The most obvious threat to ecological validity is the presence of an observer changing normally occurring behaviors, particularly when using overt recording procedures such as videotaping (Gardner, 2000) or when observations are carried out in cultural settings where it is not common to see strangers (Super & Harkness, 1999). The ecological validity of naturalistic observations also can be compromised when observational procedures disrupt normally occurring microsystem conditions, such as asking that the television be turned off during the observation (Masur & Flynn, 2008) or requiring that all family members be within camera range when observations are videotaped (Lindahl & Malik, 2001). Representativeness of naturalistic findings may also be questioned when a single brief observation period is used, given that findings can vary depending on when during the day an observation takes place and who is present (Leyendecker, Lamb, & Scholmerich, 1997; Raudenbush & Sampson, 1999).

Ecological validity also can be compromised when statistical control procedures such as covariance are used to allow identification of the "unique" predictor. By holding multiple predictors constant covariance procedures eliminate any role for existing complex configurations of predictors or the possibility that the impact of a specific predictor may vary depending on higher order ecological features (Gorman-Smith, Tolan, & Henry, 2000; Sampson et al., 2002). One consequence when statistical controls are used is that overly parsimonious predictor models may result, which will not yield a true picture of how existing ecological conditions translate into developmental variability (Jaffee, Caspi, Moffitt, Polo-Tomas, & Taylor, 2007).

### *Issues in the Use of "Social Address" Assessments*

Historically, initial approaches to conceptualizing the role of the ecosystem in developmental research were based on comparing the performance of children living at different social addresses (e.g., different socioeconomic status [SES] groups, different cultures, rural versus urban settings; Bronfenbrenner & Crouter, 1983). From a

developmental-ecological viewpoint there are two major problems with the use of social address measures.

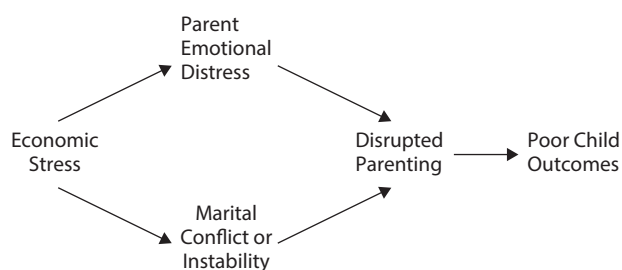

### *Social Addresses Do Not Identify What Influences Development*

Social address measures such as poverty or low SES summarize a host of covarying bioecological and psychosocial developmental influences into a single term (J. Chen, Hetzner, & Brooks-Gunn, 2010; Engle & Black, 2008). All too often this leads to the oversimplified conclusion that the social address itself produces the adverse developmental consequences. In contrast, within a developmental-ecological framework, multiple proximal psychosocial and bioecological characteristics, nested under the social address label are the primary drivers (mediators) of development (Bradley & Corwyn, 2002; Conger & Donnellan, 2007; Huston & Bentley, 2010). For example, differences between cultures in the number of school grades completed may reflect the influence of cultural values about education, availability of schools or the level of gender discrimination. To understand what underlies social address differences it is necessary to go beyond comparing outcomes associated with social addresses, such as poverty or culture, and focus on identifying proximal mediating mechanisms linked to the social address (J. Chen et al., 2010; Super & Harkness, 2010).

Illustrating this point is evidence from both high income (Bradley & Corwyn, 2002; Evans, 2004; Hackman, Farah, & Meaney, 2010) and low- and middle-income (LAMI) countries (Wachs & Rahman, 2013; S. Walker et al., 2011) documenting that two major consequences of growing up under the social address of poverty are (1) higher levels of exposure to biological and psychosocial risk factors that act to inhibit development; and (2) lower exposure to promotive influences that can enhance development or to protective factors that can promote resilience for children exposed to psychosocial or bioecological risks. By breaking down the social address label of poverty researchers have identified specific bioecological and psychosocial mediators in high-income and LAMI countries through which poverty translates into compromised child development. Identified risk mediators include (but are not limited to):<sup>3</sup>

- Preterm birth or intrauterine growth retardation (Hackman et al., 2010)
- Reduced cognitive stimulation (Bradley & Corwyn, 2002; Chen et al., 2010; S. Walker et al., 2011)
- Reduced access to preschool programs or schooling (Engle, 2012)
- Insufficient nutrition (S. Walker et al., 2011) or household food insecurity (Metallinos-Katsaras, Gorman, Wilde, & Kallio, 2011)
- Exposure to environmental pollutants crowding and physical dangers (Evans, 2004)
- Reduced neighborhood cohesion (Gorman-Smith et al., 2000)
- Maternal depression (Wachs & Rahman, 2013)
- Exposure to infectious agents (S. Walker et al., 2011)
- Lack of access to clean water or sanitation (Sheuya, 2008)
- Social exclusion (Engle, 2012)

An example of the process through which multiple risk factors mediate the impact of social addresses is shown in Figure 21.2. The pathways shown in this figure are based on a consistent set of findings involving European American and ethnic minority families living in the United States (Conger & Donnellan, 2007), which document that two major consequence of family economic hardship are increased parental stress (Evans & Kim, 2013; McConnell et al., 2010) and parental emotional problems such as depression (Conger & Donnellan, 2007). Both increased parental stress and increased parental emotional problems result in reductions in effective parenting, emotional involvement with offspring and quality of the marital

**Figure 21.2** Impact of economic stress on families and children.

<sup>3</sup>Listings of PPCT factors that produce resilience in children are found in Masten and Obradović (2006), and Ungar et al. (2013).

relationship, which in turn adversely impact on offspring development.

In interpreting the above findings there are two important caveats. The first is that no single mediator offers complete explanatory power (Hackman et al., 2010; Wachs, 2000). The second, consistent with the *specificity principle* (Wachs, 2000), is that the contribution of specific predictors varies depending on what outcome is assessed (e.g., different mediators are found for cognitive versus social-emotional outcomes: Yeung, Linver, & Brooks-Gunn, 2002).

### ***Social Addresses Cannot Easily Explain Intra-Address Variability***

Because they homogenize multiple developmental influences into a single term, social addresses often are not reflective of actual ecosystem variability. Even when different neighborhoods are classified as being at the same SES level they can vary significantly on extent of neighborhood violence, availability of resources, degree of social organization, parental childrearing strategies, and levels of social cohesion (Gorman-Smith et al., 2000; Jarrett, 1998; McGroder, 2000; Odgers et al., 2009). Similar concerns about intra-address ecological variability have been raised for other social address domains such as ethnic group membership (Leyendecker, Harwood, Comparini, & Yalçinkaya, 2005) and culture (Super & Harkness, 1999). Intra-address variability makes it difficult to explain significant outcome variability among children living at a given social address.

### ***The Role of Social Addresses in a Developmental-Ecological Framework***

The above findings emphasize the need to go beyond social address as explanation and identify the specific ecosystem mediators that define pathways linking social addresses to development. However, going beyond social addresses does not necessarily mean ignoring the measurement of social addresses. Linking social addresses to outcomes can be a useful starting point for identifying potential proximal causal influences when information is available on specific risk or protective factors associated with a given social address (Kraemer, Stice, Kazdin, Offord, & Kupfer, 2001). Further, macrosystem social addresses are important for answering public policy questions, such as whether government funding for nutrition programs reduces the level of food insecurity in lower income groups. Finally, as discussed later in this chapter, social addresses can function as an important moderator of proximal processes. (Also

see Duncan, Magnuson, & Votruba-Drzal, Chapter 14, and McBride Murry, Hill, Witherspoon, Berkel, & Bartz, Chapter 11, this *Handbook*, this volume.) For example, normally effective developmental intervention strategies may have only limited utility in highly disadvantaged resource depleted countries (Wachs & Rahman, 2013). Other examples of moderation processes are seen in the following sections.

### **Considering Both Environment and Experience**

Developmental-ecological theorists differentiate the objective (actual) *environment* (measurable external stimulation encountered by the individual: environment as it is) from subjective *experience* (how the stimulation is viewed or interpreted by the individual: environment as perceived (Bronfenbrenner, 1979; Lawton, 1999; Magnusson & Stattin, 2006). Illustrating this distinction, neighborhood can be studied as “environment” (defined by objective physical-structural features) or as “place” (defined by how residents view or experience their neighborhood; Nicotera, 2007). Although these terms are often used interchangeably, and the individual’s experience often reflects the nature of their environment, they are not necessarily the same. For example, adolescents’ reactions to social exchanges with peers (environment), varies depending on how they interpret social cues (experience) (Fontaine & Dodge, 2009).

Within a PPCT framework a major implication of the distinction between environment and experience is that studying proximal and contextual contributions to development requires going beyond the objective environment. At the microsystem level children’s perception or interpretation of proximal processes in their family or school may be a particularly critical and unique influence on their behavior and development (Brody et al., 2001; Bronfenbrenner & Morris, 2006; Dodge & Pettit, 2003). At the exosystem level child and adult perceptions of their neighborhood have been shown to mediate the influence of objective measures of neighborhood characteristics (Brody et al., 2001; Shumow, Vandell, & Posner, 1998; Tolan et al., 2003). Similarly, the belief that social support will be available when needed may be a particularly salient protective exosystem influence (Coventry, Gillespie, Heath, & Martin, 2004; B. Gottlieb & Bergen, 2010). The distinction between environment and experience is critical when conceptualizing mechanisms underlying the role of person characteristics in a PPCT framework, as discussed later in this chapter.

## THE PPCT MODEL: BRINGING HIGHER ORDER CONTEXT INTO THE STUDY OF PROXIMAL PROCESSES

Proximal processes are defined as direct transactions between the child and microsystem elements (Bronfenbrenner & Morris, 2006). There is a large body of evidence relating children's development to a variety of microsystem proximal processes including parenting practices, child-care characteristics, school experience and peer group interactions (for reviews of these areas see Bornstein, Chapter 3; Rubin, Bukowski, & Bowker, Chapter 5; Burchinal, Magnuson, Powell, & Soliday Hong, Chapter 6; and Crosnoe & Benner, Chapter 7, this *Handbook*, this volume). Given this degree of coverage direct connections between proximal processes and development will not be reviewed here. Rather, the focus in this chapter will be on developmental implications of links between proximal processes and the dimensions of context, person, and time.

Proximal processes are considered to be the primary driving force for development (Bronfenbrenner & Morris, 2006). However, because all ecosystem levels are interconnected the contributions of microsystem proximal processes cannot be fully understood without taking into account contributions from other ecosystem levels (Bronfenbrenner & Morris, 2006; Lerner et al., 2005). There are four potential mechanisms through which the linkage between higher-level contextual dimensions and lower-level proximal processes translates into developmental outcomes (Wachs, 2000). The first, *mediation* of the influence of higher level contextual characteristics by microsystem proximal processes, has been discussed earlier in the section on use of social address models. The three remaining mechanisms are (1) *higher levels structuring* the nature of lower level ecosystem characteristics; (2) *higher levels moderating* the extent and nature of influences from lower ecosystem levels; and (3) *influences from lower levels moderating* the extent and nature of higher-level contextual influences.

### Top-Down Structuring

Through structuring the nature of lower order proximal processes higher-order ecosystem dimensions *indirectly* contribute to development. Much of the available research involves higher-order psychosocial structuring by two macrosystem contexts, *culture* (including ethnic group membership) and *poverty* and by two exosystem contexts, *work conditions*, and *neighborhoods*. Other higher order

dimensions that have been shown to influence microsystem characteristics include:

- Societal violence (S. Walker et al., 2011)
- Natural disasters (Engle, 2012)
- Built structures such as new roads in rural regions (Axinn & Yabiku, 2001)
- Increased urbanization (Grimm et al., 2008)
- Mass migration of parents from rural to urban areas (Wen & Lin, 2012)

In addition, as seen in Figure 21.1, higher order levels of the bioecological environment, as manifest in climatological change, can structure lower level bioecological characteristics such as level of child exposure to parasites, disease agents, or food availability (Sheffield & Landrigan, 2011).

Going beyond higher order structuring of the microsystem, and consistent with a PPCT framework, there also is suggestive evidence that being reared in an urban environment may alter individual person biological characteristics such as neural structures and connections underlying individual differences in stress reactivity (Lederbogen et al., 2011). In addition, culture also provides expectations of ages when specific developmental transitions or behaviors should occur ("cultural scripts"; Brandstetter, 2006). Societal violence can disrupt the individual's ability to meet culturally defined chronosystem-linked activities, such as marriage or forming a family by a certain age (Barber, 2013).

### Cultural Structuring

Characteristic belief systems of a given culture are used by parents to construct ideas of what is appropriate parenting and how children develop (*ethnotheories*). Parental ethnotheories in turn structure parenting behaviors (Super & Harkness, 2010). Evidence shown in Table 21.1 illustrates the various ways in which culture influences parental beliefs, expectations and childrearing practices (also see Goodnow & Lawrence, Chapter 19, this *Handbook*, this volume). Cultural characteristics also can structure non-family microsystem and exosystem characteristics in ways that can adversely influence development. One example illustrated in Table 21.1 is culturally driven ethnic or racial discrimination (also see by McBride Murry, Hill, Witherspoon, Berkel, & Bartz, Chapter 11, this *Handbook*, this volume). The impact of discrimination may be particularly strong in cultures where racial or ethnic discrimination has been institutionalized (Cueto, Guerrero, Leon, Seguin, & Munoz, 2012) or for ethnic groups that have been forced into refugee status (Mann, 2012).

TABLE 21.1 Structuring of lower-order ecological features by higher-order contextual characteristics

Higher-Order Contextual Dimensions	Lower-Order Ecological Dimensions	Structuring
Culture	Parental rearing	Culture influences parental beliefs, expectations, childrearing practices, and involvement (Bradley, 2004; Leyendecker et al., 2005; Parke et al., 2004; Super & Harkness, 1999). Culture influences the nature of parental and peer reactivity to child temperament characteristics (X. Chen, Yang, & Fu, 2012).
Ethnic discrimination or social exclusion	Availability of resources	Ethnic minority children and/or their families are more likely: <ul style="list-style-type: none"> <li>• To be living in poverty (Hill &amp; Witherspoon, 2011).</li> <li>• To encounter barriers to upward mobility (Engle, 2012; Roscigno, 2000).</li> <li>• To be concentrated in low-income/low-resource neighborhoods with reduced access to affordable goods and services (Leventhal &amp; Brooks-Gunn, 2000; Roscigno, 2000; Sampson &amp; Raudenbush, 1997).</li> <li>• To attend lower-quality schools (Roscigno, 2000).</li> </ul>
Poverty	Nonfamily resources	Low SES/poverty: <ul style="list-style-type: none"> <li>• Increases the probability of children attending low quality schools (Leventhal &amp; Brooks-Gunn, 2000; Huston &amp; Bentley, 2010; Roscigno, 2000).</li> <li>• Increases the concentration of children with low literacy skills in schools in low-income neighborhoods (Aikens &amp; Barbarin, 2008).</li> <li>• Weakens mesosystem connections between parents and schools (Hertzman, 2010).</li> </ul>
Poverty	Neighborhood characteristics	Low-income families are more likely to live in neighborhoods with higher levels of risk and lower resource levels (Leventhal & Brooks-Gunn, 2000; Roscigno, 2000; Sampson & Raudenbush, 1997). Economic recession can change community characteristics through population migration (Hertzman, 2010).
Poverty	Parenting and family characteristics	Low-SES/poverty increases the probability of children being reared in homes characterized by: <ul style="list-style-type: none"> <li>• Less-positive parenting (Conger &amp; Donnellan, 2007; Simons, Johnson, Conger, &amp; Lorenz, 1997).</li> <li>• Lower cognitive and language stimulation (Bradley &amp; Corwyn, 2002; Huston &amp; Bentley, 2010).</li> <li>• Higher levels of marital conflict (Conger &amp; Donnellan, 2007; Parke et al., 2004).</li> <li>• Parents who are less likely to help their children make appropriate educational choices (Lucas, 2001).</li> </ul>
Poverty	The bioecological environment	Poverty is associated with increased exposure to bioecological microsystem risk conditions such as: <ul style="list-style-type: none"> <li>• Inadequate nutrition.</li> <li>• Exposure to disease agents and/or environmental toxins, poor sanitation, and unsafe drinking water.</li> <li>• Inadequate housing (Bradley, Chapter 12, this <i>Handbook</i>, this volume; Evans, 2004; Sheuya, 2008; S. Walker et al., 2011).</li> </ul>
Neighborhood violence	Parenting	In high-violence neighborhoods: <ul style="list-style-type: none"> <li>• Parents are more likely to use harsh restrictive discipline and/or more monitoring (Leventhal &amp; Brooks-Gunn, 2000).</li> <li>• There is an increased risk of violence and verbal aggression in the home (Leventhal &amp; Brooks-Gunn, 2000; Pettit, Bates, Dodge, &amp; Meece, 1999).</li> <li>• There is greater preparation of ethnic minority children to expect and prepare for bias (Hughes et al., 2006).</li> </ul>
Neighborhood violence	Schools	School educational climate is compromised when schools are in high crime-delinquency neighborhoods (Roscigno, 2000).
Neighborhood disorganization/disorder	Parenting	In highly disorganized neighborhoods there is a higher probability of: <ul style="list-style-type: none"> <li>• Harsh discipline and child abuse (Fauth, Leventhal, &amp; Brooks-Gunn, 2007; Leventhal &amp; Brooks-Gunn, 2000).</li> <li>• Lower levels of parental monitoring and effective parenting (Barber, 2001; Fauth, Leventhal, et al., 2007; Simons et al., 1997).</li> <li>• “Spillover” effects when risk factors from one neighborhood impact on children and families living in a geographically adjoining neighborhood (Leventhal &amp; Brooks-Gunn, 2000; Sampson et al., 2002).</li> <li>• Mothers being less likely to take their children to parks and playgrounds or read to or play with their children (Frech &amp; Kimbro, 2011).</li> </ul>
Neighborhood resources	Child out-of-home activities	Greater accessibility of neighborhood resources related to more child involvement in nonschool neighborhood activities (Urban, Lewin-Bizan, & Lerner, 2009).

**Figure 21.3** Living in poverty increases exposure to cumulative bioecological and psychosocial risks.

### ***Economic Structuring—Poverty***

As shown in Figure 21.3 and Table 21.1, poverty conditions can increase the chances of children being exposed to proximal microsystem psychosocial and bioecological risk factors (also see Bradley, Chapter 12, and Duncan, Magnuson, & Votruba-Drzal, Chapter 14, this *Handbook*, this volume). As also shown in Table 21.3 living in poverty can reduce the chances of exposure to protective factors such as high resource schools.

### ***Exosystem Structuring by Work Characteristics***

Maternal employment outside of the home is associated with maternal childrearing styles (Buehler & O’Brien, 2011; Hadzic, Magee, & Robinson, 2013). Job characteristics such work overload, work stress, and variable or nonstandard work shifts have been linked to disruption of family functioning (Strazdins, Clements, Korda, Broom, & D’Souza, 2006), increased marital tensions (Hsueh & Yoshikawa, 2007; Repetti & Wang, 2010) increased hostile parenting (Strazdins et al., 2006) and reductions in parental school involvement (Waanders, Mendez, & Downer, 2007; G. Wright & Smith, 1998). In addition, work characteristics such as complexity and need for self-direction can influence parental value systems (Repetti & Wang, 2010).

### ***Exosystem Structuring by Neighborhood Characteristics***

As also seen in Table 21.1, neighborhood risks and resources can structure the nature of the child’s microsystem (also see Leventhal et al., Chapter 13, this *Handbook*, this volume). Illustrating the role of the subjective ecosystem (Lawton, 1999) structuring of parenting practices or child peer network can occur as a result both of objective neighborhood characteristics (e.g., crime rate) and/or subjective parental perceptions of neighborhood problems or neighborhood safety (Card et al., 2008; Tolan et al., 2003). Low neighborhood resources (e.g., lack of public transportation), disorganized and disorderly neighborhood conditions, or concerns about neighborhood safety also can reduce the extent of mesosystem connections such as parental school involvement (Barber, 2001; Waanders et al., 2007) and parental social support networks (Simons et al., 1997).

### ***Higher-Order Moderation***

Moderation occurs when the association between a specific ecosystem feature and development varies, depending on the presence or level of another ecosystem feature. Conceptually, moderation can be viewed as a fundamental

process underlying development (Magnusson & Stattin, 2006); empirically moderation is traditionally defined by a statistical interaction between two or more predictors (Whisman & McClelland, 2005).

### *Moderation by Culture*

Developmental-ecological theorists have hypothesized that cultural characteristics can moderate the impact of lower-level proximal processes (Bronfenbrenner & Morris, 2006; Weisner, 2010) through providing the meaning systems and symbols by which individuals interpret their everyday experiences (J. Mistry & Wu, 2010). At present evidence on the validity of the cultural moderation hypothesis is mixed. Some studies have shown that the contributions of proximal processes to child cognitive or social-emotional development varied depending on *cultural background* (e.g., Feldman & Masalha, 2007; Slone, Shechner, & Farah, 2012) *country of origin* (e.g., Cabrera, Shannon, West, & Brooks-Gunn, 2006) or *family ethnicity* (e.g., Burchinal, Peisner-Feinberg, Pianta, & Howes, 2002; Dodge & Pettit, 2003; Halgunseth, Ispa, & Rudy, 2006; Whaley, 2000). Consistent with a PPCT framework there also is evidence suggesting that ethnic group membership (Latino/a versus European American) moderates adolescents level of neural activation in response to having to choose rewards for themselves or for their family (Fulgini & Telzer, 2013).

In contrast, other studies report similar cross-cultural patterns of associations between:

- Child behavior problems and parental use of physical discipline (Gershoff et al., 2010), parental rejection (Rohner & Britner, 2002) or level of home chaos (Shamama-tus-Sabah, Gilani, & Wachs, 2011).
- Early cognitive stimulation and children's cognitive development and academic achievement (Bradley & Corwyn, 2005).
- The impact of *Sesame Street* on children's cognitive and social-emotional competence (Mares & Pan, 2013).
- Developmental risk or protective factors and child outcomes across different ethnic groups (Evans, Lepore, & Allen, 2000; Parke et al., 2004).

It is unclear if inconsistent or nonsignificant cultural moderation effects reflect insufficient statistical power with multiple groups, the heterogeneous nature of social addresses such as culture or the operation of specificity processes. Exemplifying specificity processes Deater-Deckard et al. (2011) have reported that a positive

association between child adjustment and measures of *parental warmth* is seen across multiple cultures whereas patterns of association between child adjustment and *parental control* strategies vary depending upon culture.

### *Moderation by Neighborhood Characteristics*

It has been hypothesized that in higher resource neighborhoods the adverse developmental impact of children's exposure to high-risk proximal processes will be reduced (Tolan et al., 2003). Studies supporting this hypothesis illustrate how the negative impact of proximal risk factors such as association with antisocial peers, lack of after-school adult supervision, insensitive parenting or being a victim of child abuse are *attenuated* for children from neighborhoods higher in:

- Collective socialization (Brody et al., 2001)
- Safety (Pettit et al., 1999)
- Social cohesion and informal social controls (Jaffee et al., 2007)
- Supportive social networks (Gorman-Smith et al., 2000)

The findings in this list come from studies done in high-income countries. The buffering effect of positive neighborhood characteristics also occurs in LAMI countries, as seen in evidence that the postconflict depression of children forced into combat as child soldiers was lower for those whose communities were more accepting of such children (Betancourt et al., 2010).

In contrast to these supportive findings other studies on the hypothesized neighborhood buffering of proximal risk factors have shown either *nonsignificant findings* (DuMont, Widom, & Czaja, 2007) or *complex patterns of findings* with no clear interpretation (Fauth, Roth, & Brooks-Gunn, 2007; Sheidow, Gorman-Smith, Tolan, & Henry, 2001). In evaluating the overall inconsistent pattern of findings it is important to consider the possibility that definitions of what is a proximal risk factor may vary depending on neighborhood characteristics. Illustrating this possibility is evidence that high levels of harsh parental control (traditionally considered as a risk factor) may promote adolescent adjustment in high-risk neighborhoods but have the opposite effect in low risk neighborhoods (Leventhal & Brooks-Gunn, 2000). In addition, there is evidence suggesting the operation of specificity, with level or patterns of neighborhood moderation of proximal processes varying depending on outcomes assessed (Gorman-Smith et al., 2000). Finally, there is evidence illustrating higher-order moderation of neighborhood  $\times$  proximal process interactions by

chronosystem characteristics such as child age (Odgers et al., 2009).

Based on evidence that high levels of exposure to developmental risks can swamp protective influences (Sameroff & Rosenblum, 2006; Ungar et al., 2013) a second hypothesis is that *high-risk neighborhoods will overwhelm interventions designed to positively influence development*. Although there are fewer studies the evidence in support of this second hypothesis is more consistent. Studies have shown that the positive impact of facilitative microsystems such as quality parenting, high parental involvement, cognitively stimulating homes, school-based interventions, or availability of child-centered community activities were significantly weaker when neighborhoods were characterized as:

- More disorganized (Gorman-Smith et al., 2000)
- More disadvantaged (Leventhal & Brooks-Gunn, 2000; Metropolitan Area Child Study Research Group, 2002)
- Higher in crime and violence (Fauth et al., 2007)

#### Moderation by Lower-Order Proximal Processes

Evidence cited above illustrates that neighborhood characteristics can moderate the influence of proximal processes. The *bidirectional* nature of moderation processes is illustrated by studies showing how proximal family or parental characteristics can moderate the detrimental consequences for children living in disorganized, disadvantaged or violent neighborhoods (Brody et al., 2001; Huston & Bentley, 2010; Leventhal & Brooks-Gunn, 2000; Pettit et al., 1999; Roosa, Jones, Tein, & Cree, 2003; Shumow, Vandell, & Posner, 1999). Family or parenting characteristics identified as attenuating the detrimental impact of living in a high-risk neighborhood include:

- Maternal mental health
- Parental disciplinary strategies
- Restricting who the child is allowed to play with
- Active parental monitoring of the child's activities
- Choosing what school the child is enrolled in
- Consistent family routines
- Involvement with kin networks rather than neighbors

However, moderation of neighborhood risk by proximal processes may not be total given that positive family influences can weaken but not eliminate the negative impact of living in a high risk neighborhood (Gorman-Smith et al., 2000; Leventhal & Brooks-Gunn, 2000).

Proximal moderation of higher-level ecosystem characteristics is not restricted just to the neighborhood. Positive

or negative parental and family characteristics also can accentuate or attenuate the detrimental impact of: *economic adversity* (Kim-Cohen, Moffitt, Caspi, & Taylor, 2004), *exposure to societal violence* (Barber, 2001; Lustig et al., 2004; Slone et al., 2012) or *ethnic discrimination* (Brody et al., 2006).

#### Summary Conclusions: Context and Proximal Processes

Higher-order ecosystem dimensions can both structure and, in the case of neighborhoods, moderate the impact of lower order proximal processes. However, moderation is *bidirectional* in that proximal processes can, in turn, moderate the impact of a variety of higher order ecosystem dimensions. The operation of bidirectional moderation between different ecosystem dimensions highlights the importance of viewing ecosystem influences as a relational synthesis of multiple elements rather than as isolated contributions from different dimensions (Overton, 2010). Major tasks for future PPCT based research are (a) accurate mapping of the various pathways linking multilevel ecosystem dimensions; and (b) identification of the specific mechanisms underlying cross-level shaping and moderation.

### THE PPCT MODEL: INTEGRATING PERSONS INTO THE STUDY OF PROXIMAL PROCESSES

In the developmental sciences person characteristics such as personality or intelligence are traditionally viewed either as an outcome or as a main effects predictor, as in studies relating individual differences in person characteristics to development. In contrast, developmental-ecological approaches stress the fundamental interdependence of person and ecosystem. Within a PPCT framework interdependence is manifest in three ways: (1) person characteristics can influence the nature of the individuals proximal environment; (2) individuals can select into settings with certain characteristics; (3) person characteristics can moderate the influence of proximal processes upon development (Bronfenbrenner & Morris, 2006; Wachs, 2000).

#### Person Structuring of Ecosystem Characteristics

The term *person demand characteristics* has been used by Bronfenbrenner & Morris (2006) to describe the process whereby children's individual physical (e.g., birth weight, gender) and behavioral characteristics (e.g., shyness,

aggressive behavior, agreeableness) can help to shape the intensity and nature of reactions by parents, peers, teachers and other significant figures in the child's life. A similar process is referred to by behavioral geneticists as reactive covariance (Plomin, DeFries, & Loehlin, 1977). Multiple reviews have documented the linkage of child characteristics to patterns of parenting behaviors (Dodge & Pettit, 2003; Sameroff, 2009) and peer relationships (Fontaine & Dodge, 2009). Illustrating developmentally facilitative person demand processes, Werner and Smith (1992) have documented that one of the characteristics of "resilient" children growing up in high risk environments is their ability to elicit adult nurturance and support. Going beyond the microsystem it has been shown that individuals can influence characteristics of their neighborhood through actions such as the degree to which they maintain their property or are involved in community action (Roosa et al., 2003).

### Person Ecosystem Selection

The specific processes through which persons play an active role in their development have been labeled by Bronfenbrenner & Morris (2006) with the term "*generative dispositions*" and by behavior genetic researchers using the term "active person-environment covariance" (Plomin et al., 1977). Both terms refer to individuals actively structuring the nature of their proximal environment by selection into or avoidance of specific situations. The operation of active microsystem selection processes is illustrated by a consistent body of evidence documenting that temperament characteristics, such as effortful control/self-regulation and high-intensity pleasure, can influence the level of the child's exposure to deviant peers and to negative life events (Lengua & Wachs, 2012). Going beyond the microsystem there is evidence that parental characteristics can influence what neighborhoods families move into (Roosa et al., 2003; Simons et al., 1997) and that adolescents with a history of behavior problems are likely to continue to maintain ties with peers in their previous neighborhood even after their family moves away (Tolan et al., 2003).

### Person Characteristics Moderate Ecosystem Influences

Individual differences in reactivity to similar environments is illustrated by evidence that not all individual's growing up in the same family, neighborhood, or culture, or receiving the same intervention program show similar patterns of development or similar outcomes (Obradović & Boyce, 2009; Wachs, 2000). Individual differences in reactivity to ecosystem conditions also is inherent in the concept of resilient children who develop unexpectedly

well even in the face of exposure to multiple risks (Masten & Obradović, 2006; Werner & Smith, 1992).

### Specific Child Characteristics as Moderators

Whereas some studies have shown moderation of ecological influences by child *gender* (e.g., Dodge & Pettit, 2003; Hamre & Pianta, 2001) other studies have reported either inconsistent or nonsignificant findings (e.g., Criss, Pettit, Bates, Dodge, & Lapp, 2002; Odgers et al., 2009). One explanation for this inconsistent pattern is that males and females may be equally sensitive to ecological influences but the pattern of sensitivity differs as a function of gender (Booth, Granger, & Shirtcliff, 2008; Jaffee et al., 2007; Wen & Lin, 2012).

More consistent evidence for person moderation of ecosystem influences comes from research involving child cognitive or social-emotional behavioral characteristics including (but not limited to):

- *Cognitive ability* (Hamre & Pianta, 2001; Qouta, Punamäki, & El Sarraj, 2008)
- *Social cognitive processing mechanisms* (Dodge & Pettit, 2003)
- *Child-temperament characteristics* such as adaptability, emotional reactivity, sociability, and self-regulation or effortful control (Lengua & Wachs, 2012; van IJzendoorn & Bakermans-Kranenburg, 2012)

Although the overwhelming majority of studies on individual moderators of ecological conditions are derived from studies done in high income countries there is also a small but consistent literature from LAMI countries showing moderation of the impact of children's exposure to nutritional deprivation (DeVries, 1984) or societal violence (Kithakye, Morris, Terranova, & Myers, 2010) by child temperament characteristics.

Research on the role of child characteristics as moderators also illustrates that this process is bidirectional in nature. For example, individual characteristics like positive temperament or high intelligence, which have been shown to buffer children against low-moderate stress, lose their protective power for children faced with multiple cumulative stresses (Jaffee et al., 2007; Sameroff & Rosenblum, 2006; Ungar et al., 2013).

### Individual Biological Characteristics as Moderators

Studies from both high-income (Peek & Stough, 2010) and LAMI countries (Wachs, Chang-Lopez, Walker, & Meeks-Gardner, 2007) have shown that children with preexisting physical vulnerabilities are more sensitive to the negative impact of subsequent risk exposure. Similarly, children

with a history of prior malnutrition are more sensitive to later nutritional deprivation than children who have not been malnourished (Grantham-McGregor, Chang, & Walker, 1998; Pollitt, Cueto, & Jacoby, 1998).

With major advances in gene mapping techniques there also is increasing evidence showing that the impact of a wide variety of microsystem conditions, ranging from parental sensitivity to child abuse, differs as a function of individual gene variations. Of particular importance are those genes involved in *dopamine* (Bakermans-Kranenburg & van IJzendoorn, 2011; Beach, Brody, Philbert, & Lei, 2010) and *serotonin* metabolism (Bakermans-Kranenburg, Dobrova-Krol, & van IJzendoorn, 2011; Petersen et al., 2012). Research on genetic moderation of proximal influences again illustrates the bidirectional nature of moderation processes, with microsystem characteristics acting to influence patterns of genetic influence and expression, both at the behavioral (Asbury, Wachs, & Plomin, 2005) and molecular levels (Meaney, 2010).

### ***Mechanisms Underlying Person Moderation***

Five mechanisms have been suggested as underlying person moderation of ecological influences: (1) differential sensitivity; (2) goodness of fit; (3) differential coping; (4) differential perceptions; and (5) epigenetics. *Differential sensitivity* involves environmental risks interacting with individual biological or behavioral susceptibilities. Biologically, exposure to a given risk factor may or may not result in compromised development depending on the individual's genetic liability (Rutter, Moffitt, & Caspi, 2006). Behaviorally, there is an increasing body of evidence illustrating that children who are high in reactive temperament are either more vulnerable to environmental stressors (*differential reactivity*; Lengua & Wachs, 2012) or are more susceptible to both environmental stressors and environmental supports than children with less reactive temperaments (*differential susceptibility*; van IJzendoorn & Bakermans-Kranenburg, 2012).

Underlying *goodness of fit* is the assumption that children's adjustment varies depending on the degree of congruence between a child's individual characteristics, such as temperament, and ecosystem characteristics such as parental goals, cultural values (Lerner et al., 2005; Wachs, 2005) or the stresses and resources that characterize the historical time period a given birth cohort is living through (Elder & Shanahan, 2006).

Depending on *individual differences in coping strategies* children under stress may either show vulnerability or resilience (Evans & Kim, 2013; Lengua & Long, 2002). Preadolescent children are more likely to successfully cope

with ecological stressors if they have higher usage of active coping strategies such as:

- *Appraisal* (Buckner, Mezzacappa, & Beardslee, 2009; Lengua & Long, 2002)
- *Flexible information-processing strategies* (Qouta et al., 2008)
- *Future orientation* (Seginer, 2008)
- *Ideological commitment* (Lustig et al., 2004)
- *Self-efficacy* beliefs (Qouta et al., 2008)

Illustrating the interplay between the chronosystem and person characteristics a different set of coping mechanisms may be utilized by adolescents. These include goal setting (*selection*), acquisition of goal-relevant strategies (*optimization*) and use of alternate goal relevant strategies (*compensation*) when preferred strategies are not functional (Freund & Baltes, 2002).

Individual differences in *perceiving, interpreting, and evaluating the environment* also can underlie person moderation (Magnusson & Stattin, 2006). Consistent with developmental-ecological theorizing on the intertwined nature of context and person the impact of contextual conditions (actual environment) varies as a function of how the individual perceives their surrounds. For example, the degree of impact of societal violence may depend on the individuals' perceptions of the meaning behind the violence (e.g., whether violence is necessary to achieve an ideological or political goal; Barber, 2001). Similarly, the meaning children attach to parents' discipline strategies can moderate associations between discipline and children's adjustment (Lansford et al., 2010). Biologically, the meaning of family chores for children (perceived as a burden or perceived as meaningful for family functioning) can have physiological consequences in terms of increasing or reducing individual levels of physiological stress markers (Fuligni & Telzer, 2013).

Finally, the classic nature-nurture distinction has been increasingly relegated to the dustbin of history with mounting evidence on experience driven *epigenetic changes in gene expression* (Meaney, 2010). Epigenetics refers to both pre and postnatal ecosystem influences changing patterns of gene expression through fundamental changes in molecular processes such as methylation (van IJzendoorn, Bakermans-Kranenburg, & Ebstein, 2011). Epigenetic changes have the potential to be transmitted across generations (Charney, 2012; Meaney, 2010) and provide a biological mechanism through which individuals with different ecological histories react differently when encountering similar ecosystem conditions (Charney, 2012). While much of the current evidence on epigenetic

processes is based on infrahuman evidence or on human studies with bioecological predictors (e.g., pesticide exposure) there are increasing numbers of studies documenting that epigenetic processes also can occur for human psychosocial influences, (van IJzendoorn et al., 2011). For example, pre- and postnatal maternal stress has been shown to lead to offspring epigenetic changes (Roth & Sweatt, 2011). As a mechanism underlying person moderation epigenetics is totally consistent with those contextual theories emphasizing the unitary nature of individual and context, given that context gets “under the skin” and becomes part of the individual’s biological makeup.

### Summary Conclusions: Person and Proximal Processes

Child behavioral and biological characteristics influence how parents, caregivers and peers react to the child. Children with different characteristics also may select into different ecosystem niches. One important implication of such findings is that children being reared in the same home or attending the same school classroom may be encountering very different microsystems. Depending on person characteristics children may have increased or decreased reactivity when exposed to risk or protective influences. Specific behavioral and biological models have been proposed to explain the mechanisms underlying person moderation of proximal processes. Of the five models presented, epigenetic approaches should have a particular appeal for developmental-ecological theorists as an area for future study.

### THE PPCT MODEL: INTEGRATING TIME INTO THE STUDY OF PROXIMAL PROCESSES

Time (the chronosystem) is most often studied in developmental-ecological research as an age phenomenon, often with regard to the question of the unique salience of early experience for development. Time has also been considered as a cumulative process, in terms of whether the impact of specific experiences will be stronger as these experiences cumulate over time. Cross-generational and historical time influences and chronosystem structuring of ecosystem dimensions also have been investigated (see Elder, Shanahan, & Jennings, Chapter 2, this *Handbook*, this volume, for a review of these areas). In viewing chronosystem influences within a developmental-ecological framework it is essential to recognize that time or age is not viewed as a causal variable, but rather as a proxy term for specific proximal, societal, or biological events that

are characteristic of a given age or time period (Elder & Shanahan, 2006; Wohlwill, 1973b). Exemplifying this viewpoint:

- Adolescence has been characterized as a sensitive period based on significant changes during this time window in the prefrontal and parietal brain regions and the limbic system (Crews, He, & Hodge, 2007).
- The detrimental impact of persistent poverty is not due to the passage of time per se but rather to persistent poverty increasing the probability of increased family stress and disruptions in family proximal processes, as well as reductions in family resources (J. Chen et al., 2010).
- The increasing impact of neighborhood disadvantage as children move into middle-childhood reflects increasing exposure to neighborhood conditions by older children (Ingoldsby et al., 2006).

### Age as a Moderator

Evidence from developmental neuroscience (Lupien, McEwen, Gunnar, & Helm, 2009) illustrates how the sensitivity of the developing brain to biological and psychosocial stimulation varies, depending on the stages and rates of development of different parts of the brain (the concept of “sensitive periods”). At a behavioral level child age has been shown to moderate the impact of multiple ecosystem influences including:

- Microsystem proximal processes (e.g., Aikens & Barbarin, 2008; Burchinal et al., 2002)
- Exposure to biological and psychosocial risks (e.g., Brennan, Hall, Bor, Najman, & Williams, 2003)
- Early educational interventions (e.g., W. Barnett, 2011)
- Neighborhood characteristics (e.g., Hertzman, 2010; Ingoldsby et al., 2006)
- Family economic circumstances (e.g., Huston & Bentley, 2010; Roscigno, 2000)
- Societal violence (Garbarino & Kostelny, 1996) or war (Elder & Shanahan, 2006)

Also exemplifying age moderation is evidence showing that parenting characteristics or rearing patterns that are appropriate for children’s development at one age may not be appropriate at different ages (Dodge & Pettit, 2003; Teti & Huang, 2005). A clinical example of this process is seen in the concept of “parentification,” which occurs when children of substance abusing or severely ill parents take on adult roles and responsibilities at an age when the child is not developmentally ready (Richter & Richter, 2001).

### Comparative Salience of Early Versus Later Influences

For developmental scientists one of the most long-standing issues is the relative importance of early versus later experiences (Bornstein, 1989; Roisman & Fraley, 2013). Are the early years of life a time period when children are uniquely sensitive to biological and psychosocial ecological events or do ecosystem characteristics contribute to development across the life span? Evidence from both the biological and psychosocial domains reviews offers support for both positions:

- There are unique long-term influences upon neural, physical and psychological development resulting from exposure to bioecological and psychosocial events (e.g. adequacy of nutrition, cognitive stimulation, responsive-sensitive parenting, stress) occurring during the first 5 years of life (including the prenatal period; Lupien et al., 2009; Wachs, Georgieff, Cusick, & McEwen, 2014; Yousafzai, Rasheed, & Bhutta, 2013).
- Continued early exposure to proximal risk factors has the potential to influence reactivity to later risk through increasing the child's sensitivity (*sensitization*) to the negative impact of subsequent psychosocial (Catani et al., 2010; Garbarino, 2001) or bioecological risks (Andersen & Teicher, 2009; Grantham-McGregor et al., 1998).
- Complementing sensitization is *blunting*, which refers to children with a history of early risk exposure being less able to benefit from subsequent exposure to protective influences (Wachs, 2000). Evidence for blunting has been shown for both psychosocial (Beckett et al., 2006; Sameroff & Rosenblum, 2006) and bioecological risks (My-Lien, Meyer, & Winick, 1977; Wachs et al., 2007).
- While the early years of life are "privileged" this time span is not the sole period during which ecological influences on development can occur. Later age periods such as adolescence and even adulthood are also a time when individuals are sensitive to extrinsic bioecological and psychosocial influences (Crews et al., 2007; Lupien et al., 2009) or to continuing child-environment transactional processes (Roisman & Fraley, 2013).
- There appears to be a high degree of *specificity* such that sensitive time windows vary, depending not just on rate of development of specific neural and behavioral functions but also on what outcomes are being assessed and the nature of bioecological and psychosocial events (Roisman & Fraley, 2013; Wachs et al., 2014).

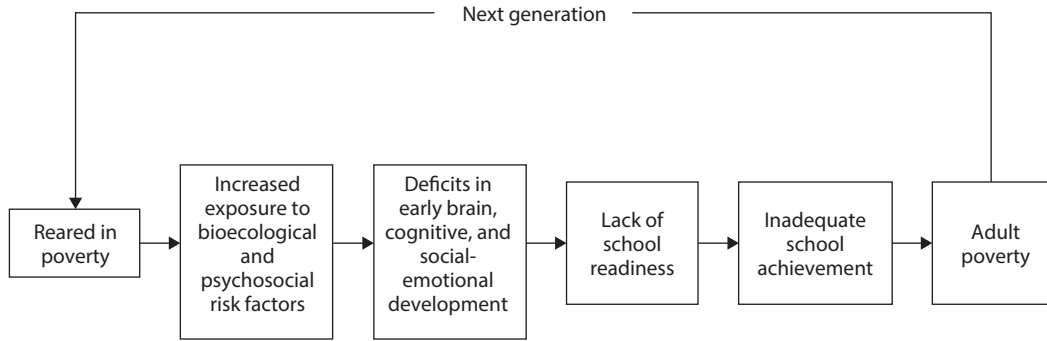

This pattern of findings emphasizes the importance of *both* early interventions for young children with high

levels of exposure to early developmental risks (Heckman, 2000) and the need for follow-up interventions if gains from early intervention programs are to be maintained over time (Love, Chazen-Cohen, Raikes, & Brooks-Gunn, 2013). The need for follow-up of high-risk children is further supported by evidence that the impact of risk factors encountered early in life may not appear until later ("lagged" or "sleeping" effects: Greenberg, Domitrovich, & Bumbarger, 2001).

### Time as a Cumulative Phenomenon

Bronfenbrenner and Morris (2006) have emphasized the stability or instability of proximal processes over time as essential for establishing long-term developmental pathways. As exposures to stable developmentally facilitative ecosystem factors cumulate over time the probability of positive developmental trajectories is increased, as seen when early cognitive interventions set off a chain of subsequent facilitative events that result in long-term educational attainment (Ou, 2005). However, the converse also holds. When children are continually exposed to psychosocial and bioecological risk conditions as they are growing up (*cumulative risk*) there is a significantly increased likelihood of cognitive or social-emotional problems (Ackerman, Brown, & Izard, 2003; Brennan et al., 2003; Hertzman, 2010) and increased physiological stress (allostatic load; Blair et al., 2011; Repetti, Robles, & Reynolds, 2011).

Early exposure to multiple risks may be particularly problematic through "built-in" stability which predisposes to cumulative risk exposure over time. Children exposed in their early years to multiple risk factors have an increased probability of encountering other risks later in life (Greenberg et al., 2001; Hertzman & Boyce, 2010; Sameroff & Rosenblum, 2006), which both maintain and accentuate the initial adverse impact of prior multiple risk exposures. Built-in cumulative risk exposure is particularly likely to occur for children growing up in poverty conditions given that poverty is a marker for exposure to multiple developmental risks (see Figure 21.3) and the consequences and risks associated with growing up in poverty may be transmitted *across generations* (S. Walker et al., 2011). The model shown in Figure 21.4 illustrates how the intergenerational transmission of poverty is the result of a cumulative time-linked pathway going from insufficient cognitive stimulation and inadequate nutrition early in life to a lack of school readiness and subsequent school failure. School failure in turn results in an increased likelihood of adult poverty, which means a less adequate

**Figure 21.4** Intergenerational transmission of poverty.

Source: Adapted from “Child Development in Developing Countries 3: Strategies to Avoid the Loss of Developmental Potential in More than 200 Million Children in the Developing World,” by P. Engle, M. Black, J. Behrman, M. Cabral de Mello, P. Gertler, L. Kapiiri, . . . the International Child Development Steering Group, 2007, *The Lancet*, 369, pp. 229–242.

nutritional and rearing environment provided to offspring, thus continuing the cycle.

Consistent with developmental-ecological theories exposure to cumulative risks during development may, over time, “get under the skin” (Hertzman & Boyce, 2010), becoming an integral part of the individual at both a biological and a psychological level. Biologically, there are an increasing number of studies showing how cumulative exposure to early risks can permanently disrupt the functioning of the hypothalamic-pituitary-adrenal axis which governs stress reactivity (Andersen & Teicher, 2009; Hertzman & Boyce, 2010; Repetti et al., 2011) and impair immune system functioning, thus increasing susceptibility to chronic disease later in life (Miller & Chen, 2010).

Psychologically, cumulative risk exposure may influence children’s perceptions of the world they live in and how children evaluate their future (Brandstetter, 2006; Magnusson & Stattin, 2006). For example, Garbarino (2001) has observed that children who experience time-limited trauma can be reassured that things will go back to normal, whereas such reassurance will not necessarily be useful for children experiencing chronic trauma. Similarly, Miller & Chen (2013) have reported that children who are continually confronted with uncontrollable and unpredictable events come to view their world as a threatening place where nothing or no one can be trusted.

### Chronosystem Structuring

Changes in ecosystem characteristics have been associated with changes in *micro-time* (time changes occurring from over the course of a day to over the course of a year), *macro-time* (time across years but within a generation) or *historical time* (across generations).

### Micro-Time

Micro-time changes are associated with changing ecological conditions, as seen in evidence that disruptions in family routines or increased work-family conflict are more likely to occur when adult work hours are irregular (Hsueh & Yoshikawa, 2007; Repetti & Wang, 2010), when parents have little control or sense of control over their work schedules (Kelly, Moen, & Tranby, 2011; Repetti & Wang, 2010), or when there is an overload of time demands (Fiese & Winter, 2010). Studies also illustrate that markers of impaired neighborhood quality, such as drug deals or adolescents hanging around on the streets, are more likely to occur at certain times of the day (Raudenbush & Sampson, 1999). Given that the formation of social ties takes time to develop high residential mobility may weaken neighborhood cohesion (Sampson & Raudenbush, 1997). The bioecological microsystem is also sensitive to micro-time changes, with variability in food availability, disease and child activities being associated with seasonal changes in temperature, rainfall, or exposure to disease agents (Wachs, 2003).

### Macro-Time

Macro-time changes are exemplified by age/time linked variation in economic or national circumstances (e.g., Elder & Shanahan, 2006; also see Elder et al., Chapter 2, this *Handbook*, this volume). One consequence of economic macro-time changes is change in cultural practices. Illustrating this anthropological evidence has shown that over a 20-year period, as the Mayan economy was integrated into the Mexican economy, there were notable changes in traditional cultural practices such as how children were trained

as weavers and the variety of patterns woven (Greenfield, Maynard, & Childs, 2000).

### ***Historical Time***

There is increasing documentation of changes in the nature of microsystem characteristics across different historical time periods (Lichter & Wethington, 2010; also see Stearns, Chapter 20, this *Handbook*, this volume). Historical time influences are also illustrated by evidence showing cross-generational microsystem stability as seen when current adult patterns of child-rearing styles or marital relationships are influenced by the rearing style and marital relationship patterns of prior generations (Bornstein, 2009). Similarly, knowledge of past discrimination towards a given ethnic group may be transmitted across generations and influence patterns of current parental socialization practices and values for that group (Hughes et al., 2006). In some situations cross-generational macrosystem stability can be maintained by current ecosystem circumstances. For example, historically, African Americans who were in slavery may have used harsh physical punishment of their children to promote obedience, so as to avoid even more serious physical consequences if the child was viewed as oppositional by the slave owner (Belsky, 1993). Drawing a parallel between historical and current ecosystem conditions Whaley (2000) has suggested that African American parents living in urban ghettos are likely to also use physical punishment as a disciplinary tool, given that in this context children's acting out behavior could lead to serious legal consequences for child and parent.

There is also intriguing evidence documenting links between historical events and current biological outcomes. Epidemiological research has documented a three generational positive association between African American grandmothers adult height or birth weight with that of their daughters and grandchildren's birth weight (Emanuel, 1997). Although shared genes are one obvious explanation for this cross-generational linkage there is also a compelling case for an historical/chronosystem explanation, based on evidence documenting an association between inadequate maternal diet and lower offspring fetal growth/birth weight for African American women who were slaves (Jasienska, 2009). The metabolic changes required of the fetus to adjust to a nutritionally insufficient prenatal environment could be encoded into their genes through epigenetic mechanisms. These epigenetic changes in gene expression could be carried across generations, resulting in a chronosystem driven cross-generational

association in children's birth weight in African American populations (Kuzawa & Sweet, 2009).

### **Summary Conclusions: Time and Proximal Processes**

The contributions of proximal process characteristics to development can vary as a function of the age of the child. While early bioecological or psychosocial influences have a special salience ecosystem contributions to development are not restricted to just the first 5 years of life but rather continue to be salient across the life span. Time linked cumulative influences may be of particular importance for development and time changes have been associated with changing ecosystem characteristics.

Viewing chronosystem dimensions as a marker for time-linked proximal processes means that understanding the nature of time or age effects can only occur when the proximal events nested under age or time are identified (Schmidt & Teti, 2005). Given this that an important issue for developmental-ecological researchers will be to "unpack time" so as to identify specific underlying mechanisms driving chronosystem associations. Of particular relevance would be research linking neural development to differential sensitivity to proximal conditions at different ages, research investigating processes through which risk exposure becomes stabilized over time, and research on how cumulative risks act to increase children's sensitivity to later risks or limit the child's ability to benefit from later exposure to protective influences.

### **ISSUES IN INTEGRATING ACROSS PERSON, PROCESS, CONTEXT, AND TIME**

A complete specification of the role of the PPCT system in development requires assessment and integration of measures of proximal processes, higher order context, time and individual characteristics. Further complicating matters the distinction between environment and experience made earlier carries with it the implication that researchers may need to measure both the objective environment and the individuals' perceptions of the nature of their environment. All of this is a formidable set of requirements that is, at best, both extremely difficult to implement (G. Gottlieb, 2007; Steinberg, Mounts, Lamborn, & Dornbusch, 1991) and extremely costly in terms of sample sizes, time and effort needed (Card et al., 2008; Sidebotham, 2001; Wachs & Shpancer, 1998). Successfully carrying out a PPCT-based research program requires dealing with three critical issues:

feasibility, interpretability, and utility. Feasibility is primarily a methodological issue while interpretability is primarily an analytic issue. Utility refers to applying PPCT-based research findings to societal problems.

The *feasibility* issue centers on how to realistically limit the time and costs involved in collecting the multidimensional information required for PPCT analyses while still ensuring adequate statistical power and generalizability of findings. Power demands are increased as the number of groups or variables assessed increases (Aiken & West, 1991), as occurs when there is measurement of all four PPCT dimensions. Assuring generalizability of findings requires testing for PPCT interactions to determine if the influence of proximal processes systematically varies as a function of person characteristics, higher-order context or time. However, greater statistical power is needed to detect interactions than to detect main effects (Whisman & McClelland, 2005). Standard approaches to improving statistical power, such as increasing sample size can be quite costly, particularly when using a full PPCT design. Standard approaches to limit time and costs, such as reducing the number of PPCT dimensions assessed, can limit generalizability of findings. Two potential approaches to the feasibility problem are proposed in the next section: *increasing measurement preciseness* and *utilization of cost-effective ecological assessments*. However, it is important to recognize that neither of these approaches totally solves the feasibility issue, particularly when resources are limited (as is usually the case), given the trade-off between power, cost, and generalizability.

### Increasing Measurement Preciseness

Statistical power can be enhanced by increasing sample size (which drives up research costs) or through increasing measurement preciseness (Seifer, 2005; Whisman & McClelland, 2005). Increased measurement preciseness can result from use of subgroup analysis, greater specification of ecological dimensions, use of observational assessments or aggregating across information sources. Descriptions of how each approach enhances measurement preciseness and the problems with each approach are seen in Table 21.2.

#### Subgroup Analysis

Based on person or contextual characteristics a sample can be divided into groups that potentially vary in sensitivity to proximal processes (e.g., Jiang, Pepler, & Yao, 2010; van IJzendoorn & Bakermans-Kranenburg, 2012). Although preciseness can be increased with this procedure power is reduced when analysis is based on subgroups. Hence, this approach appears to be useful primarily when classification data is continuous in nature.

#### Increased Specification

Assessment of the exosystem dimension of social support illustrates how detailed specification of ecological characteristics can reduce measurement error and thus increase preciseness. To understand the role of social support it is necessary to distinguish between social networks and social support. Social networks are structural in nature and

**TABLE 21.2 Approaches to increasing measurement preciseness in developmental-ecological research**

Approach Characteristics	Strengths	Problems
Subgroup analysis	Stronger effect size when sensitive and nonsensitive individuals are not grouped together. Analysis of person $\times$ process or context $\times$ process interactions consistent with PPCT model.	When subgroups are the unit of analysis (e.g., subgroups identified using median splits) sample sizes are reduced with a concurrent loss of power (Whisman & McClelland, 2005).
Greater specification of ecological dimensions that are entered into the analysis	Preciseness can be reduced when different dimensional characteristics, which influence development in different ways, are mixed together (the issue of specificity).	Potentially increased feasibility costs depending on the time and effort required to get the information needed for specification.
Observational assessments: based on either direct coding or coding from videotapes of objective ecological characteristics	Direct observational assessments can accurately describe objective ecological characteristics and thus increase measurement preciseness and statistical power (Seifer, 2005).	High time costs using both direct onsite coding, coding from videotapes rather than as events occur, or when multiple observations are required (Kerig, 2001; Seifer, 2005).
Aggregation across multisource information (mixed methods; Greene, 2005)	Integrating across information sources can improve preciseness given that errors of measurement are reduced when multiple measures are aggregated into a common score (Bates & Novosad, 2005).	If measures other than self-reports are used integration across sources can be more costly (less feasible). There can be a lack of convergence between different sources, as seen in studies reporting significant discrepancies between child and maternal report measures (Gonzales, Cauce, & Mason, 1996; Sessa, Avenevoli, Steinberg, & Morris, 2001; Tein, Roosa, & Michaels, 1994).
	Aggregating information across sources can also increase preciseness by providing a unique perspective on context that is not easily captured by single-source information sources (Sullivan, 1998).	

refer to the extent of linkages between an individual and their friends, neighbors, relatives, or colleagues. Social support is functional in nature and refers to support, help, or information that members of the network provide to an individual (Cochran & Walker, 2005). Assessing the social network using questions designed to assess social support may seriously underestimate the size of the individual's social network. In addition, it also is important to specify sources of support given that results may vary for different sources (e.g., support from spouses, relatives, friends; Coventry et al., 2004). However, as noted in Table 21.2 the time and effort required to get the information needed for increased specification can increase costs. For example, even with a common metric such as family income, the impact of poverty for families in high income countries is not the same as in LAMI countries given cross-country differences in infrastructure characteristics (e.g., sanitation, health services and schooling) and availability of social safety nets (e.g., food assistance programs) (J. Chen et al., 2010; Engle, 2012; Gassman-Pines & Hill, 2013; Sheuya, 2008).

### **Observations**

Observational procedures have been used to directly measure microsystem characteristics in the home (e.g., Bradley, 1999; Wachs, 1989), school (e.g., Avant, Gazelle, & Faldowski, 2011) and peer group (e.g., Mikami, Gregory, Allen, Pianta, & Lun, 2011), as well as exosystem neighborhood characteristics (e.g., Chirowodza et al., 2009; Raudenbush & Sampson, 1999) and macrosystem cultural parameters (e.g., Gaskins, 2000; Super & Harkness, 1999). As seen in Table 21.2, while observational procedures can increase measurement preciseness there also are high time costs associated with observational measurement, particularly when repeated observations are needed to reduce observer effects and increase representativeness (Kerig, 2001; Pellegrini, 2001; Seifer, 2005).

### **Aggregation Across Measures**

Use of aggregated information can increase preciseness both by reducing error of measurement and by accurately reflect existing ecological complexities. However, as seen in Table 21.2, a critical problem is low convergence between sources, particularly when low source convergence is due to differential accuracy. For example adolescents appear to be more accurate raters of maternal restrictiveness than mothers themselves (Gorman-Smith et al., 2000); in this case, aggregating across maternal and adolescent reports would *reduce* measurement preciseness. Aggregating across low convergence sources also can

reduce preciseness by masking proximal processes, as seen when differences between sibling reports of rearing styles of their parents are the result of siblings being treated differently (Gorman-Smith et al., 2000; Persson, 2011).

### **Utilization of Cost-Efficient Ecological Measures**

Feasibility of PPCT-based research designs also can be increased by greater usage of *cost-efficient approaches*. Increased cost efficiency can be obtained by use of existing data sources, integration of person and context measures into quasi-experimental studies and use of self-report measures.

#### **Use of Existing Data Sources**

As shown in Table 21.3 there are public record databases that describe a variety of exosystem and macrosystem characteristics. Although relatively low-cost to obtain, and thus more feasible, concerns have been raised with regard to how precise is exosystem and macrosystem information derived from existing data sources. Specific concerns include:

- Defining neighborhoods just on the basis of objective information assumes homogeneity of sample or ecological characteristics within a neighborhood, which may not be the case (Sampson et al., 2002).
- Census tract information is often collected at long time intervals and may misrepresent the nature of neighborhoods with high population mobility, or census tracts may not map onto residents perceptions of what are the boundaries defining their neighborhood (Roosa et al., 2003).
- Potentially important information such as neighborhood social networks may not be contained in public databases (Leventhal & Brooks-Gunn, 2000).
- Information contained in existing databases may not be the information needed to answer specific questions. For example, the United Nation's Human Development Index (<http://hdr.undp.org/en/statistics/>) contains little information on psychosocial influences such as quality of parent-child interactions.

#### **Quasi-Experimental Studies**

Quasi-experimental studies typically are designed to look for main effects of natural (e.g., natural disasters) or implemented ecological changes (e.g., intervention programs for at risk families). Person or contextual information can be integrated into quasi-experimental studies through systematic collection of low cost measures of individual characteristics (e.g., gender, age, temperament, mental

TABLE 21.3 Publicly available existing data sources describing exosystem and macrosystem characteristics

Available Information	Source
Neighborhood boundaries	Census tract descriptions available from the U.S. Census Bureau ( <a href="http://www.census.gov">www.census.gov</a> ) (e.g., Sheidow et al., 2001; Shumow et al., 1999)
Neighborhood resource characteristics (e.g., schools, clinics, businesses, libraries)	Obtained through cross-referencing zip codes to address databases (e.g., Peterson, Krivo, & Harris, 2000)
Neighborhood risk factors (e.g., crime rate, physical disorder, or decay)	Police crime statistics for a given area (e.g., Shumow et al., 1999) Neighborhood image databases, such as Google Street View, allow raters to take a “virtual walk” through a neighborhood and code objective physical features (e.g., Odgers, Caspi, Bates, Sampson, & Moffitt, 2012)
Parent work-time demands	Company work-hour records (e.g., Schomann, Giebel, & Nachreiner, 2006)
Economic conditions across multiple countries	Statistical indicators such as per capita gross national income (national income divided by population for a given country) are online at the World Bank ( <a href="http://www.worldbank.org">www.worldbank.org</a> )
National health status or educational outcomes	Country-level information on health (e.g., percentage of children receiving vaccinations) or educational outcomes (e.g., percentage of children in primary school) is available from UNICEF ( <a href="http://www.unicef.org/sowc">www.unicef.org/sowc</a> )
Cultural characteristics	Compilations of anthropological-ethnographic reports on multiple cultures in domains such as cultural values, social organization, family composition, religion, and socialization can be found in the Human Relations Area Files ( <a href="http://ehrafworldcultures.yale.edu">http://ehrafworldcultures.yale.edu</a> ) and the Standard Cross-Cultural Sample database ( <a href="http://www.escholarship.org/uc/item/62c5c02n">http://www.escholarship.org/uc/item/62c5c02n</a> )

health), or overall context (e.g., SES or parental education level). Analysis of person  $\times$  process or context  $\times$  process interactions would enhance preciseness through identification of what characterizes children who do or do not respond to natural or implemented ecological changes. However, as previously discussed, a major downside is the increased power demands when analyzing for such interactions.

### Use of Self-Report Measures

Subjective self-report measures, such as semistructured or unstructured interview procedures and structured questionnaire or survey instruments, are used to assess individuals' perceptions of the nature and reality of their lives across different ecological dimensions (e.g., the family, the neighborhood). As previously discussed adult and child perceptions of family or neighborhood characteristics can mediate the influence of objective measures of these ecosystem dimensions.

A primary strength of *interview-based procedures* (including panel discussions, ethnographic interviews or family narratives) is applicability across a wide range of ages and a wide variety of contexts. For example, interview type procedures have been used with child workers in multiple countries to provide information from the child's perspective on the positive and negative consequences of working (Liborio & Ungar, 2010). Puppet play interview procedures have been successfully used to assess the preschool and young elementary child's perception of their family environment (Sessa et al., 2001; Silk, Sessa, Morris, Steinberg, & Avenevoli, 2004) while telephone interviews

have been used with both parents (Aikens & Barbarin, 2008) and children (Pettit et al., 1999) to reduce time costs through reducing travel time for interviewers.

The downside of interview-based procedures is the potentially high time cost, which can reduce feasibility. Ethnographic interview procedures may require the interviewer to immerse themselves in a culture for sustained periods of time in order to understand the meaning of events for persons in that culture (Cho, Sandel, Miller, & Wang, 2005). In addition, the high time costs involved in recording and organizing the enormous amounts of information generated by interview based assessments can sharply reduce the number of individuals who can be assessed and thus curtail statistical power. (Gorman-Smith et al., 2000).

Reviews of available *structured quantitative questionnaire or survey measures* of parenting practices in high income countries are found in Locke and Prinz (2002) and L. Walker and Kirby (2010); for examples of survey measures of parenting in LAMI countries see Bornstein et al. (2012). A listing of validated self-report questionnaires applicable to children or adults in domains besides parenting is shown in Table 21.4.

With regard to enhancing feasibility quantitative self-report rating scales require far less data collection time than observations or interview/ethnographic assessments. As a consequence larger samples can be assessed which can increase statistical power. Time costs can be reduced even further when self-report questionnaires are sent and returned by postal or by electronic mail (Trevor, 2007). Surveys of neighborhood conditions based on resident

TABLE 21.4 Examples of validated self-report measures used at different ecosystem levels

Reporting Source	Ecosystem Characteristics Assessed
Parents (Western or high-income countries)	<i>Stress exposure</i> (e.g., Gassman-Pines & Yoshikawa, 2006) <i>Marital relationship</i> (e.g., Criss, Pettit, Bates, Dodge & Lapp, 2002) <i>Home chaos</i> (e.g., Matheny, Wachs, Ludwig, & Phillips, 1995) Promotion of <i>child health or nutrition</i> (e.g., L. Walker & Kirby, 2010) <i>Family food insecurity</i> (e.g., Metallinos-Katsaras et al., 2011) Parental <i>social support</i> networks (B. Gottlieb & Bergen, 2010; McConnell et al., 2010)
Parents (non-Western or LAMI countries)	<i>Home chaos</i> (e.g., Shamama-tus-Sabah et al., 2011) <i>Household possessions</i> (e.g., Zevalkink & Riksen-Walraven, 2001) <i>Bioecological resources: availability of medical facilities</i> (e.g., R. Mistry et al., 2009)
Children (Western or high-income countries)	<i>Parental control, warmth, and monitoring</i> (e.g., Barber, 2001; Brody et al., 2001; Persson, 2011) <i>Family chaos</i> (e.g., Hanscombe, Haworth, Davis, Jaffee, & Plomin, 2010) <i>Racial discrimination</i> (e.g., Brody et al., 2006) <i>School characteristics</i> (e.g., Persson, 2011) <i>Social support networks</i> (e.g., Nicotera, 2007) <i>Child friendships or peer relationships</i> (e.g., Yugar & Shapiro, 2001) <i>Working conditions</i> (in countries where child labor is common; e.g., Dawes et al., 2012)
Adults—not necessarily parents (Western or high-income countries)	Use of paper and pencil drawings of an “eco-map,” which describes a families social and institutional mesosystem connections, the strength of the various connections, and connections that are particularly stressful for the family (Hartman, 1995) Neighborhood characteristics such as <i>disorganization, cohesion, social support</i> (e.g., Gorman-Smith et al., 2000; Leventhal & Brooks-Gunn, 2000) <i>Changes in neighborhood characteristics</i> over time (e.g., Axinn & Yabiku, 2001) General <i>work stress</i> (e.g., Stanton, Balzer, Smith, Parra, & Ironson, 2001; Story & Repetti, 2006) or specific work stressors such as overload (e.g., Greenberger, O’Neil, & Nagel, 1994) Cultural characteristics such as individualism (e.g., Oyserman et al., 2002)
Applicable to adults or children (Western or high-income countries)	Measures such as time diaries, event history calendars, or experience sampling (recording time, location, and what activities the individual is engaged in when randomly cued by a wearable preprogrammed signal device) have been used to assess specific events occurring over an extended time period including: <ul style="list-style-type: none"> <li>• Extent of children’s television viewing and videogame playing (e.g., J. C. Wright et al., 2001)</li> <li>• Occurrence of daily stresses (e.g., Stafford, 2009)</li> <li>• Family daily activities (e.g., Schneider, 2009)</li> </ul>
Parallel self-report measures used with both older children and adults	Family violence or parental arguments (e.g., Garbarino & Kostelny, 1996) Level of family cohesion, communication, parental monitoring, acceptance, rejection, discipline, or control (e.g., Sheidow et al., 2001; Tein et al., 1994) Child and teacher measure of school fostering caring and supportive relationships, student autonomy, or student decision making (e.g., Battistich, Solomon, Kim, Watson, & Schaps, 1995)

reports have been criticized for inadequate psychometrics. However, assessments of interrater agreement, item consistency and instrument reliability have validated resident self-report measures (Raudenbush & Sampson, 1999). Cost-effective measures of work stress can be assessed using *ecological momentary analysis procedures* where workers use handheld computers to record their level of job stress at random intervals (Rutledge et al., 2009), or when workers are fitted with ambulatory physiological stress measures (e.g., blood pressure: Zanstra & Johnston, 2011).

Self-report questionnaires can increase both preciseness and feasibility in a variety of ways:

- Self-report measures have built-in aggregation when respondents base their ratings on their experiences

over time within their family, school or neighborhood (Gonzales, Cauce, & Mason, 1996; Seifer, 2005).

- Self-report measures allow assessment of low frequency but highly salient events like encountering overt racial discrimination (Wong, Eccles, & Sameroff, 2003).
- Child self-report measures allow assessment of out-of-home events that parents are not aware of. For example, 32% of inner-city children report having seen a person being stabbed but only 6% of their mothers reported that their child had seen a stabbing (Ceballo, Dahl, Aretakis, & Ramirez, 2001).
- Information gathered from neighborhood residents self-report questionnaires are more likely to be up to date than objective census based measures and are more

likely to indicate locations that residents actually frequent (Roosa et al., 2003).

However, the benefit of enhanced feasibility must be weighed against concerns about the validity of information obtained with self-report questionnaires (Seifer, 2005). One concern is that self-report ratings may only partially reflect objective situations due to respondents' ratings being influenced by systematic biases such as cultural context (Chao, 1994; Pena, 2007), social desirability (Stafford, 2009) or person characteristics (Wachs, 2013). A second previously discussed concern is the meaning of self-reports when there is low convergence between different sources rating the same context. Assessing convergence between adults and children is particularly problematical given that many adult measures are not appropriate or equivalent for children. As noted in Table 21.4, there are a small number of validated parallel self-report questionnaire measures for adults and older children. Unfortunately, there are all too few parallel adult-child measures which can be used with younger children and those that exist are usually based on child interview assessments, which have higher time costs (e.g., Sessa et al., 2001; Silk et al., 2004).

### Interpretability

The complex multidimensional nature of the PPCT model stands in stark contrast to the fondness of many developmental scientists for main effects analysis, as exemplified by the widespread use of experimental designs or statistical control techniques (e.g., analysis of covariance). Experimental designs or statistical controls are appropriate if the research goal is to isolate unique effects of a specific predictor such as neighborhood or iron status, or if the child's world consists of unrelated sets of independent influences. Both theoretically and empirically the former goal is antithetical to a developmental-ecological framework whereas the latter situation rarely applies in the "real world" ecosystem (Bronfenbrenner & Morris, 2006; Huston & Bentley, 2010; Magnusson & Stattin, 2006; Wachs, 2000). However main effect analysis, while all too often yielding oversimplified conclusions, is more easily summarized and understood (more interpretable). PPCT-based research encompassing multiple linked mediating and moderating influences is not as easily summarized or understood (less interpretable).

Interpretability could be enhanced by limiting the number of PPCT dimensions tested so as to reduce the number of relations that need to be interpreted. However, with

reduced predictor models generalizability of findings will be limited to those PPCT dimensions that are in the analysis. A more appropriate strategy would involve applying analytic techniques that capture multiple PPCT dimensions without sacrificing interpretability (Magnusson & Stattin, 2006). Four such techniques are described next.

### *Principal Component Analysis*

(See Burchinal, Roberts, Hooper, & Zeisel, 2000.) Interpretability is enhanced given that either exploratory or confirmatory principle component analysis allows identification of a reduced number of dimensions defining ecological characteristics, which can then be used as the unit of analysis.

### *Hierarchical Linear Modeling (HLM)*

(See McCartney, Burchinal, & Bub, 2006.) By capturing the multilevel structure of the child's ecosystem in an analytical meaningful way HLM in its various forms has the potential to enhance interpretability. HLM procedures also can enhance interpretability by modeling of individual (person) reactivity to proximal or contextual characteristics. Finally, interpretability is enhanced when HLM latent variables defining a specific construct are constructed out of multiple conceptually related ecological characteristics.

### *Cluster Analysis*

(See von Eye & Bergman, 2003.) Rather than interpreting multiple predictors individually cluster analysis is based on comparisons between a limited number of multidimensional clusters differing on sets of person, process and/or contextual characteristics. Because membership in a multidimensional cluster is the unit of analysis this procedure is highly consistent with developmental-ecological theory.

### *Latent Class Growth Analysis (LCGA)*

(See von Eye & Bergman, 2003.) LCGA is of special relevance to chronosystem assessments. Similar to cluster analysis LCGA enhances interpretability through grouping individuals into smaller sets of distinct clusters. However, in LCGA clusters are based on the similarity of individual developmental trajectories rather than person or ecological characteristics. Cluster differences in trajectories can be related to a variety of individual or ecological characteristics.

### *Analytic Drawbacks*

While the four analytic approaches described above have the potential to increase interpretability of findings from

PPCT based research there are also potential problems when these methods are utilized (Bauer & Curran, 2003; Magnusson & Stattin, 2006; von Eye & Bergman, 2003). Because clusters are multidimensional this can obviate the chances of identifying specific unidimensional predictors. This should not necessarily be seen as a weakness, given that multidimensional clusters have greater ecological validity because they capture more of a child's overall experience and the interplay between person and context (McGroder, 2000). However, these methods do often require large sample sizes, which can be problematical for exosystem or macrosystem analyses. For example, when neighborhood or cultural influences are part of the overall model it may be difficult to obtain sufficient numbers of neighborhoods or cultures for HLM analyses to be successfully applied (Brody et al., 2001; McCartney et al., 2006). Finally, there is concern that cluster analysis and LCGA techniques can yield misleading group classifications when an overall sample is actually homogeneous. When spurious groupings are derived this will likely result in lower power when attempting to identify influences leading to cluster membership (Bauer & Curran, 2003).

### Utility

Neither the complex multidimensional nature of the child's world or the probabilistic nature of findings from PPCT based ecological studies easily lend themselves to "universal laws," parsimonious undetermined explanations or the assumption that findings will be applicable across context, person or time (Huston & Bentley, 2010; Lerner et al., 2005; Sidebotham, 2001; Sullivan, 1998). Unfortunately, results couched in probability statements, confidence intervals or limited generalizability of findings are not likely to appeal to public policymakers. Policymakers tend to prefer specific yes/no answers to broad questions (has this intervention been proven to reduce behavior problems) rather than answers that are more realistic but also more complex (yes, the intervention works for children with certain characteristics living in certain types of neighborhoods; Gormley, 2011). If PPCT findings are to be applied to real world problems a critical goal is to summarize conclusions in a way that will appeal to policy makers without sacrificing complexity.

A possible solution to the utility issue may lie in greater use of cumulative risk indices (CRI; Sameroff & Rosenblum, 2006). CRI are based on evidence showing that children's exposure to a single isolated biological or psychosocial risk is often less detrimental to development than

children's repeated exposures to multiple biological and/or psychosocial risks (Appleyard, Egeland, van Dulmen, & Sroufe, 2005; Bradley, 2004; Sameroff, Gutman, & Peck, 2003). CRI's summarize the individual's (or populations) level of exposure to a variety of known *biological* (e.g., low birth weight, exposure to toxins), *psychosocial* (e.g., harsh parenting, home chaos, classroom crowding), *individual* (e.g., difficult temperament), *exosystem* (e.g., neighborhood disorganization), or *macrosystem risk factors* (e.g., minority status). Each specific risk the individual is exposed to is given a score of 1. All the risk items scored as 1 are summed into a total cumulative risk score for that person (e.g., Appleyard et al., 2005). With regard to enhancing utility the CRI has four important advantages:

1. CRI's accurately represent the overall nature of the child's world in terms of assessing the simultaneous contribution of multiple risk factors.
2. By using a common metric CRI's facilitate comparison of the risk for compromised development for children from a variety of different macrosystem contexts, as seen in studies from both high-income (Moore, Vandivere, & Zakia, 2006) and LAMI countries (Barnes, Noble, Wright, & Dawes, 2009) successfully using CRI's generated from existing data sources.
3. By reducing the impact of multiple predictors to a single number the CRI allows for easier interpretation than if the contribution of multiple risk factors had to be considered individually. Children at greater risk for compromised development will have a higher CRI score and thus a greater need for intervention.
4. Reducing multiple risk predictors to a single number can improve feasibility by promoting a better variable-sample size ratio, which can lead to greater statistical power (Burchinal et al., 2000).

An expanded version of this approach involves combining a set of empirically validated known protective influences into an overall cumulative protective index (CPI; Sameroff et al., 2003) and assessing the CRI/CPI balance. An illustration of the developmental consequences associated with the balance between risk and protective influences is shown in Figure 21.5.

One drawback is that the cumulative risk/protection approach does not allow for identification of specific risk or protective influences that may be particularly salient for a given developmental outcome (Burchinal et al., 2000). However, when samples of children with high CRIs (or low CPIs) are identified interventions should focus on

**Figure 21.5** Balance between risk and protective factors.

Source: From “Inequality Begins by Early Childhood: Risk and Protective Factors for Early Child Development,” by S. Walker, T. D. Wachs, S. Grantham-McGregor, M. Black, C. Nelson, S. Huffman, . . . L. Richter, 2011, *The Lancet*, 378, pp. 1325–1338. Reprinted under STM permission guidelines.

reducing the number of risks a child is exposed to (or on increasing exposure to protective influences). Given that risk factors often covary, Wachs and Rahman (2013) have proposed that targeting of risks with the strongest covariance network with other risks would be a cost-effective means of reducing children’s exposure to multiple risks (e.g., targeting maternal depression, which covaries with multiple bioecological and psychosocial risks).

### Summary and Conclusions: Issues in PPCT Research

Research based on a PPCT model requires dealing with issues of feasibility interpretability and utility. Comparisons across multidimensional clusters or use of HLM procedures offer a promising direction for dealing with issues involved in ease of interpretability of PPCT-based findings. Generating multidimensional CRI’s can promote utility of PPCT-based findings to solving real-world issues. However feasibility, defined in terms of assessing PPCT ecological characteristics in a cost-effective yet valid way, remains a persistent and critical problem. Each of the feasibility solutions reviewed has both strengths and drawbacks. Given the trade-off between research costs, statistical power, and generalizability of findings there appears to be no single “gold standard” approach that will solve the feasibility issue. As a result, the choice of which approach to use when dealing with feasibility issues should

be individualized for each study, based on balancing the cost of the different approaches with the levels of power and preciseness needed to answer the questions that are being asked and the resources that are available to the investigator (e.g., Seifer, 2005).

### APPLICATIONS OF A PPCT FRAMEWORK TO INTERVENTION STRATEGIES

PPCT approaches have been applied to a variety of societal issues including peer bullying (Card et al., 2008), child abuse (Sidebotham, 2001), the design of child mental health programs (Dishion & Stormshak, 2007) and promoting children’s resilience in both high (Urban et al., 2009), and LAMI countries (Wachs & Rahman, 2013). The applicability of the PPCT framework to real-world issues should not be surprising given that this framework is rooted in the study of the child in his/her real world context. In this final section applications of the PPCT model to the design and implementation of intervention programs are presented.

#### Applications of the Person Dimension

There is an extensive body of evidence documenting how individual (person) characteristics can moderate individual reactivity to naturally occurring proximal risk

and protective influences and to developmental interventions. Much of the evidence illustrating differential reactivity is based on individual differences in temperament, preexisting biological or behavioral characteristics or specific gene variants.

### ***Implications for Application of the Person Dimension***

- Information on individual characteristics associated with differential reactivity should be built in and routinely collected as part of the intervention strategy.
- Identification of children at risk for later developmental or behavioral problems should encompass not just children's exposure to ecological risk conditions but also differentiation of children who are most likely to be adversely affected by risk exposure. For example, children who are high in impulsiveness or low in attention and are living in low quality housing or disorganized neighborhoods are a group that is likely to be at elevated risk for accidental injuries (Hampson & Vollrath, 2012).
- Design of interventions should not be based on a "one size fits all" model. Rather a range of interventions varying in both intensity and type should be designed and offered.
- Assignment to a given intervention should be based on goodness of fit, with specific types of interventions targeted to those who are most likely to benefit from that form of intervention. In the short run targeted interventions may be more costly than the same intervention provided to all. However, targeted interventions are likely to be more cost-effective in the long-run, given that providing interventions to those who are unlikely to benefit is a waste of resources (Kraemer et al., 2001).
- Traditional approaches to measuring intervention success by comparing mean outcome differences between an intervention group and an untreated control group can lead to misleading conclusions if intervention benefits are restricted to a subsample of children with specific characteristics (Jiang et al., 2010). To fully evaluate outcomes information should be provided on intra-intervention group outcome heterogeneity, either by reporting both the outcome mean and standard deviation for the intervention group, by comparing outcomes for clusters of children with different person characteristics, or by using meta-analysis to assess outcome heterogeneity across multiple intervention studies.

### **Applications of the Process Dimension**

Both the multidimensional nature of the microsystem and the covariance among proximal risk factors means that children are more likely to be exposed to multiple

#### **No Intervention**

#### **Unidimensional Intervention**

#### **Multidimensional Intervention**

**Developmental Trajectory**

**Figure 21.6** Why multidimensional interventions are necessary.

bioecological and psychosocial risks than to single isolated risks. For example, children exposed to societal violence are also more likely to experience reduced levels of social (e.g. family support networks) and physical resources (e.g., health services, nutrition) (Barber, 2013). When children are exposed to multiple proximal risks unidimensional interventions are less likely to be sufficient as an intervention strategy (Greenberg et al., 2001; Kraemer et al., 2001; Nation et al., 2003). Figure 21.6, derived from prevention science research (Brennan et al., 2003; Dodge & Pettit, 2003; Greenberg et al., 2001), illustrates that unidimensional intervention programs are less likely to be sufficient because interventions directed to reducing just one developmental risk may not reduce other developmental risks that continue to inhibit development.

### ***Implications for Application of the Process Dimension***

- For children exposed to multiple risk factors multidimensional-multilevel interventions are necessary. Existing examples include programs linking health and nutrition interventions to parent education, parent support and early child stimulation (Engle & Black, 2008) or integrating cash transfer programs for low income families with improvements in health and educational services (Lomeli, 2008).
- Level of risk exposure should be reduced for children exposed to high levels of cumulative risk *before* attempting interventions which provide exposure to promotive influences that facilitate development (Jaffee et al., 2007; Sameroff & Rosenblum, 2006).

- Choice of which risk or protective factors to target in an intervention program should be based on evidence identifying risk or protective factors linked to given outcomes (specificity), what risk or protective factors can be changed by intervention, and the degree of covariance among risk or protective influences (Wachs & Rahman, 2013).
- Supportive relations between positive microsystem elements should be enhanced to maximize the facilitative influence of the mesosystem (Ungar et al., 2013).
- Particularly in LAMI countries it is essential to promote coordination across health, nutrition, social service, and education ministries so as to facilitate the provision of multidimensional microsystem interventions (Engle & Black, 2008).
- In addition to evaluating developmental outcomes degree of reduction in cumulative risk exposure also can be used as an outcome measure (Gassman-Pines & Yoshikawa, 2006).

### Applications Based on Contextual Characteristics

Higher order distal characteristics can both structure the nature of lower order proximal processes or mesosystem links and can moderate the influence of lower order proximal processes upon development. Exemplifying higher-order moderation intervention programs which do not fit culturally based values or practices are less likely to be accepted by targeted communities and thus less likely to succeed (Harkness, Super, Mavridis, Barry, & Zeitlin, 2013; Nation et al., 2003).

### Implications for Application of the Context Dimension

- It is important to identify existing macrosystem barriers to microsystem intervention efforts *prior* to implementing interventions (Wachs & Rahman, 2013; Yousafzai et al., 2013). Known macrosystem barriers can include *cultural values or beliefs that have a poor fit* with current school or intervention practices (Dishion & Stormshak, 2007; G. Wright & Smith, 1998), culturally driven *status differences* based on person characteristics such as gender, which can influence who makes decisions in families or controls family resources (Rahman, 2007), and *social exclusion or social stigma* based on gender, caste, ethnicity, or having a child with disabilities (Cueto et al., 2012; Engle, 2012; S. Walker et al., 2011).
- To maximize the probability of success intervention programs should be designed with community values and beliefs as an essential element of the intervention

process (see Rahman, 2007, as an example of how this was accomplished in a program treating maternal depression in rural Pakistan). Alternatively, interventions could be designed to circumvent macrosystem barriers. For example, given that mothers are more likely than fathers to use economic resources in ways that benefit children's health and nutrition, some cash transfer programs in LAMI countries are now ensuring that funds are allocated directly to mothers (Lomeli, 2008).

- Interventions to strengthen facilitative mesosystem linkages also should include strategies to remove exosystem barriers to promoting such linkages *prior* to carrying out the intervention. For example, schools could implement more flexible scheduling of parent-teacher meetings and school events or provide transportation to school events for parents living in resource poor or dangerous neighborhoods (Heymann, 2000).

### Applications Involving the Chronosystem

Children are particularly sensitive to ecosystem influences during the early years of life because of rapid neural and behavioral growth during this time period. Ecosystem events occurring during the early years of life can increase or reduce the child's exposure and/or reactivity to later risk or protective influences. However, within a PPCT framework development is a continuous process that is not limited to just one age period. Interventions or experiences occurring in middle childhood, adolescence, and adulthood also can influence subsequent development and stabilizing the long-term impact of positive early influences may require exposure to later supportive experiences. Cumulative risk is a particularly salient influence on development and excessive time demands or time disruptions can adversely impact on family functioning.

### Implications for Applications of the Chronosystem Dimension

- Timing of interventions should be guided by when the behavioral and biological systems mediating behavioral development in specific domains are developing most rapidly rather than just by the age of the child (Wachs et al., 2014).
- Given that important biological and behavioral systems develop rapidly over the first 5 years particular emphasis should be placed on early biological or psychosocial interventions, which are likely to be stronger and more cost-effective than interventions occurring later in childhood (Heckman, 2000; Yousafzai et al., 2013).

- We cannot assume that exposure to early protective influences will “immunize” children against later risk exposures. To promote stability of benefits from exposure to early promotive influences, there needs to be continued monitoring of children’s developmental trajectories and the availability of follow-up intervention programs for children whose developmental trajectories begin to fall off.
- The need for continued monitoring and follow-up is essential for children living in stable high-risk settings where the likelihood of cumulative risk exposure is higher, or for children with developmental deficits who are reexposed to proximal processes that led to their initial problems (Ungar et al., 2013).
- Given that development is continuous it is not surprising to find evidence that time limited intervention programs are less likely to be developmentally effective than interventions continuing over time (Greenberg et al., 2001; Love et al., 2013; Reynolds & Temple, 1998).
- There is a need to develop strategies to reduce exosystem time pressures upon proximal processes. One such validated strategy would be re-defining the workplace culture to allow workers greater flexibility in scheduling their job responsibilities as a means of reducing work-family conflict (Kelly et al., 2011).

### Summary Conclusions: Application of the PPCT Bioecological Framework

Particularly for those working in the front lines of intervention efforts with disadvantaged families or with poverty populations in LAMI countries, the need for intervening in multiple domains, targeting interventions to specific groups of children and continuing intervention efforts for prolonged time periods may seem to reflect the academic ivory tower and not the nature of the real world, given the cost of implementing multidimensional, targeted, longitudinal interventions (Card et al., 2008) and the difficulties in taking research based intervention programs to scale (Aber, Brown, & Jones, 2003). However, promoting oversimplified solutions to complex real-world problems is not likely to produce meaningful change and, in the long run, may be less cost-effective than solutions that reflect the reality of the ecological conditions encountered by children from around the world. A fundamental thesis of this chapter is that a PPCT based bioecological approach, centered on the core principles initially presented, offers the most accurate picture of the child’s world and in so doing maximizes our

ability to both understand development and to promote optimal development for all children.

## 890 Subject Index

### Context (*cont'd.*)

- cultural (*see* Cultural context; Diverse social contexts)
- definition of, 6
- educational (*see* Early childcare and education; Education; Schools)
- historical (*see* Historical perspectives)
- life course theory/perspective on, 6–7, 10–14, 15, 19, 20–24, 33–39, 40–42, 47–48, 270–271
- organized activities in, 306–312
- parenting influenced by, 98–103
- peer groups as social context, 209–210, 288–289
- physical (*see* Geography; Housing and physical environments; Neighborhoods)
- PPCT framework on, 819–823, 838 (*see also* PPCT (process-person-context-time) framework)

### Contracts, 645–646

### Creativity:

- creative expression interventions using, 724
- digital media impacts on, 386–388

### Crime and delinquency. *See also* Antisocial and aggressive behavior;

- Law and legal issues
- culpability and competence issues related to, 634–639
- death penalty for, 632, 637–638, 644, 662, 669, 804
- deviancy training leading to, 196, 197, 198, 661
- diverse family issues with, 143, 145, 146, 150
- government policies and programs as protection against, 660–663
- juvenile and criminal justice system on, 630–639, 644, 648, 660–663, 666, 801, 802, 804
- juveniles tried as adults for, 631, 633–634, 661
- life course perspective on, 25, 26, 35, 41
- neighborhood issues of, 35, 494–495, 499, 502, 508, 509–510, 515, 516–517, 518, 520, 522
- organized activity participation influence on, 320–321, 331, 335, 337
- parenting links to, 81, 104
- peer relations/dynamics impacting, 195, 196, 197, 198, 334, 354, 515, 661
- school-to-prison pipeline, 629
- socioeconomic status relationship to, 494–495, 508, 509–510, 522, 535, 556–557
- unsupervised out-of-school time links to, 334, 354, 515
- working youth issues of, 351, 354, 359

### Critical incident stress debriefing, 731

### Cultivation hypothesis, 378–379

### Cultural context. *See also* Diverse families; Diverse social contexts

- acculturation to, 422–426, 437, 444–445, 751, 765–771
- activities as common unit of analysis in, 754, 756–757, 775
- biculturalism and bicultural identity in, 769–770, 777
- children's development in relation to, 4, 746–781
- common units of analysis in, 754–760
- conceptual frames for, 748–752
- context and development interactions in, 773–774
- continuity and uniformity vs. change and diversity in, 760–765, 773–774
- cultural homelessness in, 769, 777
- cultural identity development, 429–430, 769–770, 776–778
- culturally valued knowledge/cultural competence in, 434, 774–776
- culture and cultural, meaning of, 748–750
- directionality in, 752
- early childcare and education in, 224, 234, 239–240, 245–247
- ecological approach to, 755–760
- education in, 224, 234, 239–240, 245–247, 272–275, 280–282, 289–290, 434–438, 761–762, 771
- enculturation in, 421, 422–423, 444, 766, 768
- ethnic and racial (*see* Ethnicity and race)
- gender-specific (*see* Gender differences)
- immigrant-specific (*see* Immigrants)
- implications of and future research on, 773–779
- influence of, 751–752, 774

- intergenerational differences of, 767–768
  - intergenerational transmission of, 762
  - language as element of (*see* Language and communication)
  - lines of analysis on, 747–748, 752–773
  - methodology and interpretations considering cultural meanings, 778–779
  - multiple, 765–771
  - negotiations in, 764, 775–776
  - organized activities in, 309–310, 757, 775
  - overview of, 746–748, 779–781
  - parenting in, 56, 63, 67–68, 69, 70–71, 73, 78, 91, 101–103, 421–428, 444–445, 767–768, 822
  - peer/friend groups in, 182–183, 184, 188, 193–194, 206, 211–212
  - people as common unit of analysis in, 754–755, 757–759
  - persistence of practices in, 762
  - place as common unit of analysis in, 754, 755–756
  - play behavior in, 474, 754

- Family systems theory, 60–61
- Federal Communications Commission v. Pacifica Foundation* (1978), 623
- Fels Longitudinal Study, 9
- Female circumcision, 762
- The Fifth Dimension, 310
- Financial status. *See* Socioeconomic status
- First Amendment (free speech and expression) rights, 622–624
- Food. *See* Nutrition and diet
- Food allergies, 604
- Food stamps, 565. *See also* Supplemental Nutrition Assistance Program
- Formaldehyde contamination, 467
- 4-H, 306, 308, 311
- Fourteenth Amendment (due process/privacy) rights, 625, 632, 640, 643
- Fourth Amendment (search and seizure) rights, 625–628
- Friends. *See* Peer/friend groups
- Fukushima Daiichi nuclear accident, 707, 726–727

*Gault, In re* (1967), 632–633, 660–661

Gautreaux Program, 501–502, 505, 522

### Gay/lesbian families. *See also* Sexual minorities

- child outcomes in, 155–156
- as diverse family structure, 153–159
- diversity among, 153–155
- epistemic and nonepistemic values applied to, 158–159
- legal unions/marriage in, 157–158
- parent-child relationships in, 155–156
- political and legal issues for, 157–158
- prevalence of, 153
- research methodology on, 156–158
- sexual identity of children in, 155
- single-parent, 154
- stepfamilies as, 154–155
- theories applied to, 158

Gear Up program, 283

### Gender differences:

- childhood history study of, 791–792, 794, 795, 796, 797, 800, 801
- in color preferences, 464
- digital media portrayal of, 377, 378, 397–400
- in digital media use/exposure/response, 385, 395, 397, 398–400, 475
- in divorce effects, 147
- in early childcare and education, 245
- in education, 245, 274–275, 282, 286, 290
- gender bending and, 399
- gender schema theory on, 398
- life course perspective on, 8, 24, 27, 30–31, 37, 45
- in neighborhood effects, 516–517
- in organized activities, 320, 332
- parental influences on/by, 75, 76–77, 79, 97
- in parenting responsibilities, 62–65

- in peer/friend groups, 182, 195, 197, 204, 289, 395, 440, 516–517
- in play behavior, 475
- PPCT (process-person-context-time) framework on, 824
- in stepchild outcomes, 150
- stereotypes based on, 275, 398–399, 400
- in war and disaster experiences/responses, 712, 716, 718, 721, 724–725, 728
- in working youth, 348–349, 350, 362

General systems models, 225, 457

### Genetics:

- behavior genetics research on, 83–85, 87–88, 501
- diverse family research on, 165
- divorce effect risk and resilience related to, 148
- early childcare and education interaction with, 227, 243
- ecological moderating factor of, 825–826
- health-related issues to, 581
- parenting in relation to, 56, 57, 80, 82, 83–85, 87–88, 98
- war and disaster gene-expression impacts, 712–713

### Geography:

- childhood history research disparities by, 792, 806
- cultural context in relation to, 754, 755–756, 759, 776
- diverse social contexts based on, 420–421, 443
- geographic information systems, 34, 496, 498, 523, 525
- housing and physical environment mobility or migration by, 33, 36–37, 38, 39, 481–482
- neighborhoods based on (*see* Neighborhoods)
- rural vs. urban settings, 42–43, 420–421, 443, 460, 461, 463, 465–466, 494–495, 503

German Life History study, 44–46

German unification studies, 43, 44–47

Gini index, 658, 659

*Ginsberg v. New York* (1968), 623, 646

Globalization, 803–805

*Godinez v. Moran* (1993), 634

*Goss v. Lopez* (1975), 625

### Government policies and programs:

- on adoption, 433–434
- on assisted reproductive technologies, 160
- bioecological perspective on, 655, 657
- budget and economic constraints on, 694–696
- on child abuse, 666–669, 689–690
- Child Care and Development Block Grant as, 689
- childhood history in terms of, 789, 802–803
- on child labor/work, 310, 365, 666, 799, 804
- Child Protective Services as, 668–669
- children's development in relation to, 4, 654–697
- conditional cash transfer (CCT) programs as, 554, 559, 676, 681–682
- on crime and delinquency, 660–663
- on cultural context, 771–773
- current major programs for children, 677–690
- data sources on, 692–693
- on digital media, 390, 404–407
- on diverse families, 142, 157–158, 160, 166, 433–434, 663–666
- on early childcare and education, 224, 231, 236, 249, 252–256, 507, 657, 679, 686–688, 689, 691, 693–694
- on education, 224, 231, 236, 249, 252–256, 276, 281, 283, 295, 507, 565, 656–657, 674–675, 679–680, 683–688, 689, 690, 691, 693–694 (*see also* Education; Schools)
- evidence-based policy making for, 696–697
- executive branch role in, 655
- on families, 142, 157–158, 160, 166, 433–434, 663–666
- goals of, 656–669
- Head Start as, 249, 252–254, 657, 686–687, 691, 693–694
- on health and medical care, 579, 600, 604–605, 657–658, 675, 678, 679–680, 680–681, 799–800, 802–803
- historical perspective on, 674–677
- on housing, 679, 688–689

- on inheritance laws, 771
- insurance programs as, 676, 677, 678, 680, 682, 695–696 (*see also* Social Security program)
- international, 669
- interventions as, 142
- Jobs Corps as, 690
- judicial branch role in, 654–655
- on legal policy, 616–651, 660–663 (*see also* Law and legal issues; Laws, specific; Legal cases)
- legislative branch role in, 655
- on marriage, 142, 157–158, 166, 664–665
- means-tested programs as, 676, 677–678, 680–681
- Medicaid as, 677, 678, 679, 680, 681
- Medicare as, 676, 677, 680, 695–696
- National School Lunch Program as, 682–683
- on neighborhoods, 494–495, 501–502, 506, 509, 521–522, 688–689
- on nutrition, 537, 538, 539, 554, 559, 565, 658, 677, 678, 679, 682–683
- optimizing outcomes for children via, 655–660
- organized activities/afterschool programs as, 306, 311–312, 337
- overview of, 654–655, 697
- on parents/parenting, 656, 663, 696–697
- peer/friend groups impacted by, 178
- population level impacts of, 656–660
- protection of society, families, and children via, 660–669
- research on, 656–697
- role of, in children's lives, 655–669
- scholarly study of, 691–694
- social dissolution and unification based on, 43–47
- social pathways influenced by, 21
- Social Security as, 668, 670, 675–676, 677, 678, 680, 681–682, 695–696
- on social services, 689–690, 803
- Social Services Block Grant as, 689
- on socioeconomic status, 537, 538, 539, 552, 554, 559, 564–565, 658–660, 669–690
- spending for, 677–680, 694–696
- Supplemental Nutrition Assistance Program as, 537, 538, 539, 677, 678, 682 (*see also* Food stamps)
- Supplemental Security Income as, 677, 681–682
- taxes and tax credits as, 537, 538, 552, 554, 564, 657, 670–672, 673, 678, 679–680, 681, 682
- Temporary Assistance for Needy Families Program as, 675–676, 681, 689, 690
- War on Poverty programs as, 252, 657, 674, 676–677, 690, 691
- Women, Infants, and Children Special Supplemental Nutrition program as, 683
- on work and employment, 310, 365, 565, 666, 678, 679, 690, 799, 804
- Youth Service Activities program as, 690
- Graham v. Florida* (2010), 638–639, 644, 662
- Grandparents:
  - child outcomes of custody by, 162
  - diverse families lead by, 161–163
  - early childcare by, 228
  - parenting support through, 66, 100
  - socioeconomic status of, 161–162

- Head Start, 249, 252–254, 657, 686–687, 691, 693–694
- Health. *See also* Medical settings
  - ADHD impacting, 467, 468, 590–592, 605, 805
  - adolescent health care transitions, 599–600
  - anxiety impacting (*see* Anxiety and anxiety disorders; Stress)
  - autism spectrum disorder impacting, 99, 296, 580, 587, 602–603
  - chronic illness impacting, 576, 585–586, 590–601
  - concussion and head injury impacting, 213, 603–604
  - cystic fibrosis impacting, 592
  - depression impacting (*see* Depression and depressive disorders)
  - developmental and identity formation impacts of, 592–593
  - developmental surveillance/screening related to, 586–587
  - disparities in, 579–580
  - education on, 585
  - education relationship to, 22–23, 42–43, 271–272, 294–295, 562–563, 593–594, 805
  - emergency/urgent care as, 589–590
  - emotional functioning impacted by, 594
  - ethnic and racial disparities in, 579–580
  - factors influencing children's, 577–580
  - food allergies impacting, 604
  - future of health care for, 601–606
  - government policies and programs on, 579, 600, 604–605, 657–658, 675, 678, 679–680, 680–681, 799–800, 802–803
  - health behaviors impacting, 583
  - historical perspective on, 575–577, 579, 587–588
  - home care for, 600
  - hospice care related to, 601
  - hospital environment impacting, 578
  - housing and physical environments impacting, 458, 460–472, 581
  - injury and traumatic stress impacting, 589–590 (*see also* Posttraumatic stress disorder)
  - life course perspective on, 22–23, 23–24, 38, 42–43, 577, 580–583
  - maternal, 583, 605–606
  - minors' medical decision-making rights related to, 637, 639–644
  - neighborhood relationship to, 494, 509, 510–511
  - neonatal, 587–589
  - new morbidity trends in, 578–579, 589–590
  - obesity impacting (*see* Obesity and overweight)
  - pain and pain management related to, 596–598
  - palliative care related to, 600–601
  - parenting influenced by, 97, 595–596, 599
  - pasteurization impacting, 575
  - peer dynamics relationship to, 212–213, 294–295, 593, 594–596
  - polio impacting, 576
  - posttraumatic stress disorder impacting (*see* Posttraumatic stress disorder)
  - prenatal impacts on, 580–581, 712–713
  - prevention and wellness initiatives impacting, 577, 579, 584–587, 604–606
  - public, in schools, 294–295
  - rural-urban divide in, 42–43
  - screening for health issues, 586–587, 602
  - sibling response to child's chronic illness, 598–599
  - smallpox impacting, 575–576
  - socioeconomic status relationship to, 23–24, 38, 42–43, 535, 545–546, 550–551, 556–560, 562–563, 577, 579–580, 581–582, 604–605, 659
  - substance use impacting (*see* Substance use/abuse)
  - two-generation approach to health care for, 605–606
  - vaccines impacting, 575–576, 580, 585, 663
  - vulnerable child syndrome and, 595–596
  - water and sanitation impacting, 460–461, 575
  - working youth's, 355, 364
- Healthy Marriage Initiative, U. S., 142, 166

   diverse family research issues of, 142, 144–145, 156–158, 160–161, 164–166  
   experience-sampling as, 314  
   experimental/quasi-experimental, 81–83, 501–502, 505–506, 525, 831–832  
   government program data analysis, 693–694  
   measurement issues for, 157  
   mixed methods approach to, 525–526  
   neighborhood research issues of, 499–502, 503–506, 524–526  
   nonexperimental, 500–501, 503–504, 525  
   observational assessments as, 185–186, 316, 383, 499, 831  
   organized activity research issues of, 312–316  
   parenting research issues of, 103  
   qualitative interviews and ethnographies as, 312–313  
   quantitative studies as, 312  
   questionnaires as, 315–316  
   sampling and samples in, 156, 164–165  
   selection as issue in, 38  
   surveys as, 314  
   time diaries as, 313–314, 383  
*Meyer v. Nebraska* (1923), 640  
*Michael M. v. Superior Court of Sonoma County* (1981), 647, 648  
 Michigan Study of Adolescent Life Transitions, 327  
 Military service. *See also* War and disaster

 Neighborhoods:  
   assessment of, 499, 524–525, 818, 820, 821, 822–823, 831–832  
   bioecological perspective on, 496  
   boundaries of, 496–497, 523  
   “broken windows” theory on, 495  
   children’s development in relation to, 3, 493–526  
   collective efficacy of, 35, 508–509  
   crime, delinquency, and legal issues relationship to, 35, 494–495, 499, 502, 508, 509–510, 515, 516–517, 518, 520, 522  
   cross-context interactions in, 510–516  
   definition of neighborhood context, 495–499  
   educational interactions with, 505–506, 515–516  
   ethnic and racial composition of, 34, 35, 39, 494, 497, 503, 504, 506, 517–520  
   experimental/quasi-experimental approaches to studying, 501–502, 525  
   families and parenting in, 496, 501, 510–512, 823  
   framework for improved research on, 522–526  
   gender differences in effects of, 516–517  
   gentrification of, 505  
   government policies and programs on, 494–495, 501–502, 506, 509, 521–522, 688–689  
   health relationship to, 494, 509, 510–511  
   immigrants in, 517–520  
   individual biological/psychological vulnerability to effects of, 520–521  
   influences of, on child development, 502–521  
   institutional resources in, 498, 506–508  
   interventions through, 521–522  
   life course perspective on, 32, 33–36, 38, 39, 47–48  
   linked lives principle on, 32  
   nonexperimental approaches to studying, 500–501, 525  
   organized activity relationship to safety/assets of, 323, 333  
   overview of, 493–494, 526  
   peer/friend group interaction with, 512–517  
   person-context interactions in, 516–521  
   PPCT (process-person-context-time) framework on, 818, 820, 821, 822–823, 831–832  
   processes in, 498–499, 506–510  
   Progressive Era changes to, 494–495  
   public or affordable housing in, 495, 501–502, 506, 509, 521–522, 688–689  
   research on, 493–526  
   residential stability vs. mobility in, 497, 505–506, 521–522  
   social address based on, 818  
   social organization/processes of, 498–499, 508–510  
   “social push” perspective on, 520  
   socioeconomic status of, 38, 273, 360, 494–495, 497, 503–512, 521–522, 523, 545  
   “strong situation hypothesis” on, 520

## 900 Subject Index

### Neighborhoods (*cont'd.*)

- structure of, 497, 503–510
- urban vs. rural, 494–495, 503
- violence and social disorder in, 509–510, 518
- working youth in specific, 360

### Neonatal Intensive Care Unit (NICU), 587–589

### Neuroscience:

- Behavioral Activation and Inhibition Systems in, 180
- cognitive function in (*see* Cognition and cognitive development)
- concussion and head injury issues in, 213, 603–604
- early childcare and education in relation to, 686
- health and medical issues related to, 213, 581–583, 588, 590–592, 593–594, 603–604
- housing and environmental neurocognitive impacts, 468–470, 472
- legal issue consideration of, 637–639, 643–644
- life course perspective on health and, 581–583
- parenting relationship to, 89, 91, 96–97
- peer/friend dynamics interaction with, 180, 213
- traumatic brain injury research in, 213, 603–604
- war and disaster neurodevelopmental impacts, 712, 721

### Newborn Individualized Developmental Care and Assessment Program (NIDCAP), 589

### New Hope program, 657

### New Jersey Negative Income Tax Experiment, 657

### *New Jersey v. T.L.O.* (1985), 625–626

### New York Society for the Prevention of Cruelty to Children, 666

### *New York v. Ferber* (1982), 649

### Nixon administration policies and programs, 686

### No Child Left Behind (NCLB) Act, 276, 295, 684

### Noise, environmental levels of, 470

### Nuclear accidents, 706–707, 726–727

### Nurse Family Partnership (NFP), 696–697

### Nutrition and diet:

- digital media impacts on, 402–403
- early childcare and, 240, 255, 683
- ecological moderating factors of, 824–825, 827–828
- food allergies related to, 604
- government policies and programs on, 537, 538, 539, 554, 559, 565, 658, 677, 678, 679, 682–683
- health issues related to, 575, 580, 603, 604, 805 (*see also* Obesity and overweight)
- housing and physical environments relationship to, 461, 462, 463–464
- parenting issues related to, 85, 101
- school health education on, 295
- war and disaster impacting, 714

### Oakland Growth Study, 8–9, 10–11, 12, 26–27, 29, 40–41

### Obama, Barack/Obama administration:

- multiracial-ethnic background of, 427
- policies and programs under, 142, 495, 657, 665, 669, 684, 686, 687, 688, 690, 696–697

### Obesity and overweight:

- childhood history in terms of, 805
- digital media relationship to, 377, 401–404, 406, 476–477, 479
- energy balance (intake vs. expenditure) impacting, 402–403
- health and medical impacts of/responses to, 603, 605
- health behaviors impacting, 583
- neighborhood safety impacting physical activity and, 509
- peer dynamics in relation to, 212–213
- prevalence of, 603
- school-based public health efforts on, 295

### Occupation. *See* Work and employment

### Oil spills, 726, 727–728, 729–730

### Oklahoma City bombing, 707, 717

### Online influences. *See* Digital media

### Oportunidades, 554

### Organized activities:

- activity types in, 317, 327–328, 331, 336
- afterschool programs as, 306, 317, 318, 323, 324–326, 335–336
- age-appropriate, 320, 337
- bioecological approach to, 307–309
- breadth or number of, 317–318, 328, 336
- child outcomes from, 323–333, 335–336
- child/person characteristics impacting, 308, 320–321, 330–331, 332
- children's development in relation to, 3, 305–339
- combining research parameters on, 331, 337–338
- competencies related to, 320–321, 330
- consistency of participation in, 329–330
- context of, 306–312
- cultural context for, 309–310, 757, 775
- definitions and descriptions of, 306–307, 338
- developmental changes considered in, 337
- ethnicity and race in relation to, 309–310, 320, 332, 338
- extracurricular activities as, 306–307, 317, 326–331, 336, 354, 356, 368
- family involvement/impact in, 313, 321–322, 332–333
- future directions in research on, 337–339
- gender differences in, 320, 332
- global context for, 311–312
- historical context for, 310–311
- immigrant youth in, 310, 312
- key parameters and processes in, 316–319
- moderators of, 308, 331–333, 336–337, 338
- nonlinear effects of, 338
- overscheduling hypothesis on, 328–329
- overview of, 305–306, 335–339
- participation in, 316–317, 324, 327, 329–330, 333, 337, 757, 775  
(*see also* selection of *subentry*)
- peer/friend impacts/involvement in, 322–323, 330–331
- program characteristics impacting, 323, 324–326, 336
- proximal processes in, 308, 318–319, 330–331
- quality of experiences in, 315, 316, 318–319, 323, 325–326, 330–331, 336
- research on, 312–339
- school and community factors impacting, 323, 333
- selection of, 308, 317, 319–323, 324, 327, 3337
- self-care vs. participation in, 334
- socialization via, 313
- social relationships in/impacting, 307, 313, 322–323, 330–331
- sociocultural perspectives on, 309–310
- socioeconomic status in relation to, 309–310, 321–322, 332–333, 337, 338
- staff effectiveness and education for, 325–326, 338
- time/dosage-related context of (duration, frequency), 308, 318, 326, 328–329, 331, 336
- unsupervised out-of-school time vs., 333–335, 354
- working youth's participation in, 354, 356, 368
- youth with special needs in, 338

### Palestinian-Israeli conflict, 716, 719, 721, 722, 724, 725

### Panel Study of Income Dynamics, 315, 328, 332, 383, 385, 471, 500, 504, 505, 555, 559, 564, 691, 692

### ParentCorps program, 656

### Parents and parenting. *See also* Families

- action processes influenced by, 75–79
- adoption by (*see* Adoption and adopted children)
- as adult development phase, 56
- age and life stage influences on, 89–91, 97–98, 826
- alloparental/nonparental caregiving in, 62, 65–66 (*see also* Early childcare and education)
- assessment of, 57–58, 61, 67, 817–818, 819–820, 821, 822–823, 826, 829, 832–834
- attitudes of/toward, 68

- attributions of/toward, 69
- attunement of children and parents in, 79
- authoritarian parenting style, 70, 151, 424, 512
- authoritative parenting style, 70–71, 77, 140, 235, 512
- behavior genetics research related to, 83–85, 87–88
- bioecological perspective on, 2, 86, 107
- biological influences on, 87–89 (*see also genetics in relation to subentry*)
- caregiving division of labor among, 64–65
- characteristics of children in, 96–98
- characteristics of parents in, 87–96
- child abuse related to, 94, 95, 99, 104, 151
- children's active influences on, 60, 74, 78–79, 96–98, 752
- children's development in relation to, 2, 55–108
- cognitive influences on, 91–92
- concerted cultivation of children by, 549–550
- contextual characteristics affecting, 98–103
- coparenting, 65
- correlational studies of, 80–81
- cultural context for, 56, 63, 67–68, 69, 70–71, 73, 78, 91, 101–103, 421–428, 444–445, 767–768, 822
- custody decisions impacting, 162, 619–620
- didactic strategies of, 73, 76
- discipline and punishment by, 68, 71–72, 77, 78, 91, 102, 103, 104, 618, 667–668, 669, 793, 795, 797, 800, 829
- diverse family issues of, 64, 99, 139–140, 151–152, 155–156, 421–434, 444–445
- diverse social contexts for, 421–434, 441, 444–445
- domestic violence among (*see Domestic violence*)
- drawbacks of, 57–58
- education of, 101, 288, 321, 349, 440, 540, 542–543, 560–563, 565, 672, 673
- education role/influence of, 73, 76, 273–274, 287–288, 292, 507
- effects of, 79–87
- ethnic and racial issues in, 101–103, 421–428, 431–434, 441
- expectations of/toward, 68
- experimental studies of, 81–83
- family structure influencing, 99
- fathers, specifically, 63–64, 140–141, 146, 166
- filial piety of children toward, 57
- gender roles/differences influenced by, 75, 76–77, 79, 97
- genetics in relation to, 56, 57, 80, 82, 83–85, 87–88, 98
- government policies and programs for, 656, 663, 696–697
- grandparent role in, 66, 100
- health of/health impacts on, 93, 94, 97, 100, 140, 510, 583, 595–596, 599, 605–606, 817
- historical perspectives on, 788–789, 790, 793, 794–796, 797–798, 800, 804–805, 829
- housing and physical environments in relation to, 73, 471, 481
- imitation of, by children, 76, 759
- as instrumental activity, 56, 58, 79
- intergenerational transmission of, 95–96
- interventions for, 83, 105–106, 656
- intuitive, 89
- knowledge of/about, 69, 425
- language use by/in, 73, 77, 89, 97, 101
- legal treatment of children in relation to, 618–621, 639–644, 663
- life cycle including, 16
- linked lives principle on, 31–32
- material provisions by/in, 73
- meaning of actions associated with, 78
- moderating effects on, 77–78
- mothers, specifically, 62–63
- multicausal origins of, 87–104
- of multiracial-ethnic children, 426–428
- neighborhoods in relation to, 496, 510–512, 823
- nurturing of/in, 72–73
- occupation of, 540–541, 563–564, 565, 673–674 (*see also Work and employment*)
- organized activities role/involvement of, 313, 321–322
- overview of, 55–62, 107–108
- parental roles in, 62–66
- parenting cognitions for, 66–69, 74–79, 91–92, 425
- parenting practices for, 66, 69–79, 139–140
- parenting theory and research on, 58–62, 75–76, 80–83, 103
- PARTheory on, 70–71
- peer influences vs., 85–86
- personality of/in, 92–94
- physical/motor development promotion by/in, 72, 73
- PPCT (process-person-context-time) framework on, 817–818, 819–820, 821, 822–823, 826, 829, 832–834
- practical parenting, 104–106
- protection/protectiveness of, 71, 72, 421–426
- psychometric characteristics of, 74–75
- resources for, 59
- rewards and enjoyment of, 57, 58
- self-perceptions of/toward, 68–69
- sibling relations and, 66, 84–85, 87, 99
- socialization/social domain influences of, 59, 60, 67–68, 73, 75–79, 83–86, 421, 433–434, 444, 549, 564
- socioeconomic status affecting, 100–101, 273–274, 287, 288, 321–322, 544–550, 564, 817–818
- specificity principle on, 77
- substance use/abuse issues related to, 80, 85–86, 94, 104, 481, 585
- support networks for, 99–100
- termination of parental rights, 620
- of third culture kids, 428–431
- transaction principle on, 78–79
- transitions to parenthood, 25
- two-generation approach to health care involving, 605–606
- war and disaster moderation via, 705, 714, 718–719, 720, 722–723, 727–728, 729
- warmth and control of, 70–72, 78, 421, 424
- Parents' Evaluation of Developmental Status (PEDS), 586
- Parham v. J.R.* (1979), 640
- Partnerships for Inclusion (PFI), 251
- Paths of a Generation project, 44
- Patient-centered medical home (PCMH), 604–605
- Peer/friend groups:
  - acceptance in, 184–185, 189–190, 192, 197–198, 291
  - assessment of peer dynamics in, 185–192, 202
  - childhood history in terms of, 790, 801
  - children's development in relation to, 2–3, 175–214
  - clarity and specificity in study of, 213–214
  - cliques in, 176, 209, 210
  - cognitions about, 189, 206–208
  - complexity of, 179–185
  - cross-ethnic/interracial, 438–442, 445
  - crowd affiliation in, 209–210, 289
  - cultural context for, 182–183, 184, 188, 193–194, 206, 211–212
  - deviancy training in, 196, 197, 198, 661
  - digital media impacts on, 178, 200, 377, 389–394, 395, 442, 480
  - dissolution/termination of, 195
  - diverse social contexts involving, 435, 436–437, 438–442, 445–446
  - dominance hierarchy in, 176, 182, 184, 209
  - early childcare and education issues with, 178, 244
  - educational issues with/impacts of, 178, 199, 200, 244, 286–287, 288–289, 291, 294–295, 435, 436–437, 442–443, 445–446
  - effects of relationships in, 195–197
  - emotional reactivity and regulation in, 180
  - ethnicity and race in, 181, 435, 436–437, 438–442, 445–446
  - exclusion in, 176, 180, 201–203
  - friendships in, 176, 183, 187–189, 192–197, 207–208

### Peer/friend groups (*cont'd.*)

- group formation, characteristics, and dynamics in, 182, 190–192, 209–210
  - group socialization theory on influence of, 85–86
  - health issues in relation to, 199, 200, 207, 208, 212–213, 294–295, 593, 594–596
  - history of research on, 177–178
  - the individual in, 179–180, 206–208
  - interactions in, 181–182, 183, 185–187
  - interdependencies between levels in, 183–185
  - interventions addressing issues in, 200–201
  - intrapersonal cognitions and emotions about, 206–208
  - life course perspective on, 32, 36
  - linked lives principle on, 32
  - neighborhood interactions with, 512–517
  - neuroscientific approach to, 180, 213
  - organized activity involvement/impacts of, 322–323, 330–331
  - other-sex relationships in, 197
  - overview of, 175–177, 210–214
  - parenting support networks through, 99–100
  - peer relations, defined, 177
  - perceived popularity in, 176, 189–190, 203–206, 289, 291
  - quality of relationships in, 188–189, 196
  - rejection in, 176, 180, 183, 189–190, 192, 197–199, 200, 201, 208, 289
  - rejection sensitivity models on, 208
  - relationship building in, 181–182
  - research on, 177–179, 185–206, 210–214
  - self-perception impacted by, 208
  - sexual minority issues in, 442–443
  - social context of, 209–210, 288–289
  - social information-processing (SIP) models on, 206–208
  - socialization through, 85–86, 177
  - social withdrawal from, 183–185, 196–197, 198, 199, 200, 202–203, 206–207, 208
  - socioeconomic status of, 439–440
  - status in, 182, 186, 189, 203, 204–205, 288–289, 291
  - substance use influenced by, 198, 204, 291, 334, 335, 439
  - theoretical perspectives on, 32, 36, 85–86, 179
  - third culture kids' challenges of, 430
  - unsupervised time with, 334–335, 354, 515
  - victimization in, 176–177, 184, 199–201, 207, 212, 395, 436–437, 442–443, 480, 595
  - working youth's, 354–355
- ### Personality:
- agreeableness in, 92–93
  - Big Five factors of, 92–93
  - conscientiousness in, 92, 93
  - extraversion in, 92, 93
  - neuroticism in, 92, 93
  - openness to experience in, 92, 93
  - parenting relationship to, 92–94
  - PPCT (process-person-context-time) framework on, 823–824
  - war and disaster effects moderated by, 712, 721

  - childhood history in terms of, 791, 798
  - children's development in relation to, 3–4, 534–566
  - correlation and causation in studies of, 550–553
  - cultural perspective on, 548–550, 760–761, 763
  - definitions of SES-based resources, 535–541
  - diverse families', 138, 139, 151, 161–162, 542, 544, 664, 672–674, 675–676
  - diverse social contexts based on, 420–421, 439–440, 446–447
  - early childcare and education in relation to, 224, 235, 236, 238, 245, 252–253, 256, 507–508
  - educational links to, 101, 224, 235, 236, 238, 245, 252–253, 256, 271, 273–274, 281–282, 287, 288, 292–293, 349, 507–508, 534–535, 540, 542–543, 545, 547, 553–556, 560–563, 565, 659, 672, 673, 674–675, 827–828
  - empirical research on effects of, 553–564

- ethnicity and race in relation to, 274, 420–421, 439–440, 446–447, 504, 538, 659, 672
- familial trends in, 541–544, 669–672
- family and environmental stress perspective on, 544–546
- government policies and programs on, 537, 538, 539, 552, 554, 559, 564–565, 658–660, 669–690
- health relationship to, 23–24, 38, 42–43, 535, 545–546, 550–551, 556–560, 562–563, 577, 579–580, 581–582, 604–605, 659
- housing and physical environments in relation to, 470, 545
- human capital attainment in relation to, 555–556
- income as element of, 536–537, 553–560, 669–674
- inequality of, in U.S., 541–544, 658–660, 669–674
- intergenerational transmission of, 544, 548, 550, 827
- life course perspective considerations of, 10–11, 18–19, 23–24, 26–27, 36, 38, 40–41, 42–43
- marital status relationship to, 138, 139, 151
- measurements of, 537–539, 658
- neighborhood issues in relation to, 38, 273, 360, 494–495, 497, 503–512, 521–522, 523, 545
- organized activities in relation to, 309–310, 321–322, 332–333, 337, 338
- overview of, 534–535, 565–566
- parental education as element of, 540, 560–563, 565, 672
- parental occupation as element of, 540–541, 563–564, 565, 673–674
- parenting influenced by, 100–101, 273–274, 287, 288, 321–322, 544–550, 564, 817–818
- peer/friend relativity of, 439–440
- play behavior perception differences by, 474
- poverty as element of, 537–539, 553–560, 581–582, 658–660, 669–678, 820–821
- PPCT (process-person-context-time) framework on, 816–818, 820, 821, 827–828
- research on, 534–566
- resource and investment perspective on, 546–548
- rural-urban divide in, 42–43, 420–421
- social address assessments based on, 816–818
- taxes and tax credits based on, 537, 538, 552, 554, 564, 657, 670–672, 673, 678, 679–680, 681, 682
- theoretical perspectives on, 544–550
- wealth as element of, 539–540, 556, 558, 672–674
- working youth background of, 349, 350, 353, 360–361, 362–363, 364–365
- Somalia, armed conflict in, 714
- Soviet Union dissolution study, 43–44
- Special needs, people with:
- education for, 684
  - government policies and programs for, 676, 677, 681, 682
  - medical care and health of, 576, 590–601
  - organized activities for, 338
- Sri Lanka, tsunami in, 711, 728, 729, 732
- Stanford v. Kentucky* (1989), 637
- Stepfamilies:
- change and instability in, 150–151
  - child abuse in, 99, 151
  - child outcomes in, 149–150
  - demographics of, 148
  - as diverse family structure, 99, 134, 135, 148–153, 154–155
  - family processes in, 151–152
  - gay/lesbian, 154–155
  - marital and coparental relationships in, 152
  - parent-child relationship quality in, 152
  - parenting issues in, 99, 151–152
  - research on, 135
  - siblings in, 149, 152
  - socioeconomic status of, 151
  - stress effects in, 150
  - structural complexity of, 148–149
  - theoretical perspectives on, 150–152
  - transitions in, 149
- Stigmatization:
- diverse families facing, 137, 143, 153, 156, 157, 159, 164, 166
  - peer, 210
- Stimulation hypothesis, 386–387
- Stress:
- critical incident stress debriefing, 731
  - divorce creating, 146
  - early childcare and education issues of, 227, 243–244
  - ERASE-Stress program addressing, 725, 732
  - family and environmental stress perspective on, 544–546
  - family stress theory on, 712
  - health and medical care-related, 578, 590, 594, 599
  - health impacts of, 581–582 (*see also* Posttraumatic stress disorder)
  - housing and physical environments creating, 470, 471, 481–482
  - neighborhood-related, 510–511
  - organized activity-related, 312
  - parenting impacted by, 93–94, 101, 140, 510–511, 817–818
  - posttraumatic or acute stress disorder from (*see* Posttraumatic stress disorder)
  - socioeconomic, 544–546, 581–582, 817–818 (*see also* Socioeconomic status)
  - stepfamilies creating, 150
  - stress inoculation training for, 725
  - toxic levels of, 712–713
  - war and disaster creating, 4, 704–737
  - working youth experiencing, 355
  - work-related, 541, 545, 564, 565
- Study of Early Child Care and Youth Development (SECCYD), 229, 230, 234, 235, 237, 238, 239, 240, 243, 283, 315, 329, 332, 692
- Substance use/abuse:
- advertising of tobacco and alcohol, 406
  - cultural influences on, 766, 767
  - digital media portrayal of, 377, 404, 406, 480
  - housing and physical environments impacted by, 468
  - legal issues related to, 624, 625–628, 629
  - life course perspective on, 583
  - minors' medical decision-making rights related to, 641
  - neighborhood influences on, 522
  - organized activity participation deterring, 327, 328, 329
  - parenting issues related to, 80, 85–86, 94, 104, 481, 585
  - peer dynamics impacting, 198, 204, 291, 334, 335, 439
  - prenatal impacts of, 580–581, 584–585
  - school zero-tolerance policies toward, 629, 661
  - socioeconomic status relationship to, 557
  - unsupervised out-of-school time links to, 334, 335
  - working youth access to, 353, 354, 355, 356, 357, 359, 361
- Sudan, armed conflict in, 715
- Suicide, 143, 583, 602
- Supplemental Educational Services, 323, 337
- Supplemental Nutrition Assistance Program (SNAP), 537, 538, 539, 677, 678, 682. *See also* Food stamps
- Supplemental Security Income, 677, 681–682
- Supporting Healthy Marriage (SHM) program, 665
- Survey of After-School Programs in Elementary Schools, 323
- Survey of Income and Program Participation (SIPP), 315, 334, 672, 691, 692
- Systems:
- family systems theory, 60–61
  - general systems models, 225, 457
  - Relational-Developmental-Systems (*see* Relational-Developmental-Systems)
- Talfourd's Law, 619
- Teen Pregnancy Prevention Program, 665
- Televised media. *See* Digital media

## 906 Subject Index

- Temporary Assistance for Needy Families Program (TANF), 675–676, 681, 689, 690
- Terman Study, 8, 29, 40
- Terrorism, 704–705, 707, 714, 717, 720, 721, 722, 725. *See also* War and disaster
- The After-School Corporation (TASC), 326
- Third culture kids, 428–431, 769
- Thompson v. Oklahoma* (1988), 637
- Time:
- age changes through (*see* Age and aging)
  - chronosystems in bioecological landscapes of development reflecting, 2, 19, 815, 826, 828–829, 838–839
  - as cumulative phenomenon, 827–828, 835–836
  - digital media use/exposure measurements of, 383–386, 388
  - duration of experiences in life course, 20–21, 23, 30–31, 36–37
  - early childcare and education duration over, 228, 230, 235, 242–243
  - global time estimates of, 383
  - historical, 829 (*see also* Historical perspectives)
  - intergenerational transmission over, 31–32, 95–96, 272, 544, 548, 550, 714, 762, 827, 829
  - life course theory/perspective over, 2, 6–48, 270–271, 346, 577, 580–583
  - macro-time, 828–829
  - micro-time, 828
  - organized activity dosage in, 308, 318, 326, 328–329, 331, 336
  - parenting moderated by timing, 77–78
  - PPCT framework on, 826–829, 838–839 (*see also* PPCT (process-person-context-time) framework)
  - reciprocal continuity over, 23, 34
  - resource and investment perspective on parental time, 546–548
  - schools, amount of time in, 268
  - socioeconomic challenges, timing of, 557–558
  - temporality, in life course perspective, 10–14, 16–17, 20, 24–26, 30–31, 36–37
  - time diaries on use of, 313–314, 383, 388
  - timing principle, in life course theory, 30–31
  - trajectories, transitions, and turning points in, 20, 24–26, 30, 33–34, 272, 293–294, 761–762
  - war and disaster-related developmental timing, 712, 713, 718, 720–722, 728
  - working youth time use/management, 356, 361
- Tinker v. Des Moines Independent Community School District* (1969), 622
- Tobacco use. *See* Substance use/abuse
- Transracial adoption, 431–434
- Tsunamis, 711, 726–727, 728, 729, 732, 761
- 21st Century Community Learning Centers, 306, 308, 323, 337
- Twitter, 393
- Uganda, armed conflict in, 715, 724–725
- Uniform Marriage and Divorce Act, 619
- United Nations Convention on the Rights of the Child, 104, 618, 642, 669, 804
- Unmarried-parent families:
- characteristics of, 138
  - child outcomes in, 138–142
  - cohabitating-parent, 137–142
  - as diverse family structure, 137–142, 663–664, 672–674
  - economic resources in, 139, 664, 672–674
  - father's involvement in, 140–141
  - interventions with, 142
  - parental skills and effectiveness in, 139–140
  - prevalence of, 663–664
  - single-parent, 137–139, 663–664, 672–674
  - stability and change in, 141
- Uses and gratification theory, 379
- Vaccines, 575–576, 580, 585, 663
- Vernonia School District 47J v. Acton* (1995), 626
- Violence. *See also* Antisocial and aggressive behavior
- in digital media, 376–377, 378–379, 382, 394–397, 405, 475, 480, 646–647, 719, 735
  - domestic, 94, 95, 99, 104, 151, 582, 583, 606, 620–621, 666–669, 689–690
  - in neighborhoods, 509–510, 518
  - peer victimization and, 176–177, 184, 199–201, 207, 212, 395, 436–437, 442–443, 480, 595
  - school zero-tolerance policies toward, 629, 661
  - violent crime, juveniles tried as adults for, 633–634, 661
  - war and disaster creating, 4, 704–737, 803
- Virtual School technique, 202
- Vulnerable child syndrome, 595–596
- War and disaster. *See also* Military service
- age influences on effects of, 711–712, 718, 720–722, 728
  - bioecological perspective on, 705, 710, 719
  - challenges of research on, 708
  - childhood history in terms of, 803
  - children's development in relation to, 4, 704–737, 803
  - child soldiers in, 705, 714, 715–716, 720–721, 723, 803
  - community, cultural, and geopolitical context of, 717, 719, 721, 732, 736, 761
  - determinants of exposure to, 717–719
  - developmental timing in relation to, 712, 713, 718, 720–722, 728
  - differential susceptibility and sensitivity to, 713–714
  - disaster preparedness, 733
  - dose-response gradients with, 710–711, 719–720, 727–728, 734
  - familial/parental role in exposure/response to, 705, 714, 718–719, 720, 722–723, 727–728, 729
  - family stress theory on, 712
  - future directions in research on, 735–737
  - gender differences in experiences/responses to, 712, 716, 718, 721, 724–725, 728
  - historical perspectives on, 705–708
  - hurricanes as, 707, 726–727, 728, 729–730, 732, 733
  - individual differences in experience of, 712, 713–714, 718, 720–722, 728–730
  - intergenerational transmission of trauma from, 714
  - interventions addressing effects of, 707, 715, 724–726, 730–733, 735–737
  - media coverage of, 719, 735
  - mediating processes of exposure to, 712–713, 719–723
  - natural and technological disasters, specifically, 706–707, 711, 726–733, 761
  - overview of, 704–705, 733–735
  - pathways of response to, 709–710, 729–730
  - personality as moderating factor after, 712, 721
  - posttraumatic growth following, 709
  - prenatal and postnatal impacts of, 712–713, 720, 728
  - prevalence of, 705
  - prevention of war and peace promotion, 725–726
  - recovery context from, 723, 729–730
  - refugees and resettlement from, 705, 723–724, 730, 803
  - research on, 704–737
  - resilience following, 709–710, 710–714, 713, 721, 736
  - risk and resilience models on, 710–714
  - theoretical perspectives on, 708–714
  - variations in exposure to, 714–717, 727–728
  - variations in response to, 713, 719–723, 727–728
  - war, terrorism, and violent political conflict, specifically, 704–705, 707, 714–726
- War on Poverty programs, 252, 657, 674, 676–677, 690, 691
- Washington, Booker T., 683
- Welfare Reform Law, 664, 676, 689

- Wilson, Wilson by v. Wilson* (1984), 621
- Winship, In re* (1970), 632
- Women, Infants, and Children Special Supplemental Nutrition program (WIC), 683
- Work and employment:
- apprenticeship programs for, 324, 361, 369
  - child labor laws on, 310, 365, 666, 799, 804
  - children's development in relation to, 3, 310, 345–370, 666, 793, 794–795, 798, 799–800, 803–804 (*see also* Working youth for details)
  - complexity of, 549, 564
  - early childcare and education ties to parental, 223, 228, 235, 236
  - education transition to, 21–22, 368–370
  - familial impacts of, 16
  - government policies and programs on, 310, 365, 565, 666, 678, 679, 690, 799, 804
  - international perspectives on, 363–365
  - life course perspective on, 16, 21–22, 23, 24, 27, 29, 31, 37, 45, 346
  - nonstandard work schedule for, 541, 563–564
  - PPCT (process-person-context-time) framework on, 821
  - sexual harassment in, 355
  - situational imperatives necessitating, 27
  - social pathways related to, 21–22, 23
  - socioeconomic status relationship to, 540–541, 542, 563–564, 565, 673–674
  - stress from, 541, 545, 564, 565
  - trajectories, transitions, and turning points in, 21–22, 24, 368–370
  - workers' compensation for injuries in, 675
- Workforce Investment Act, 690
- Working youth:
- age segregation of, 351–352
  - antisocial or problem behaviors among, 354, 358–359
  - childhood history in terms of, 793, 794–795, 798, 799–800, 803–804
  - child labor laws on, 310, 365, 666, 799, 804
  - decline in, 347–348, 362, 365–367
  - demographics of, 348–349, 350, 359–361
  - earnings of, 353, 357, 363, 364–365
  - economic recession impacts on, 347, 366, 367–368
  - educational context/issues for, 351–353, 356–358, 360–361, 362–366, 368–370
  - entering labor force by, 347–348, 362–363
  - ethnicity and race of, 349, 350, 360
  - future research on, 365–370
  - gender differences in, 348–349, 350, 362
  - hazardous work for, 345, 362, 363, 364
  - health of, 355, 364
  - hours worked by, 347–348, 349, 357, 360
  - life course perspective on, 346
  - “minor effects of work” perspective on, 357–359
  - “moderate amount of work beneficial” perspective on, 355–357
  - “not working is best” perspective on, 350–355
  - organized activity participation by, 354, 356, 368
  - overview of, 345–347, 370
  - peer/friend groups of, 354–355
  - perspectives on, 346, 350–361, 363–365
  - places/types of employment for, 349–350, 363, 368
  - prevalence of, 347–348, 362, 365–368
  - research on, 346–370
  - sexual behavior of, 354–355, 359
  - sexual harassment of, 355
  - skill development of, 352, 355–356, 357, 360, 364
  - social context for, 354–355
  - socioeconomic status of, 349, 350, 353, 360–361, 362–363, 364–365
  - substance use/abuse by, 353, 354, 355, 356, 357, 359, 361
  - time use/management among, 356, 361
  - in United States, 347–350, 365–367, 369
  - outside of United States, 361–365, 367–368, 369–370
  - volunteering youth vs., 356, 366–367, 368
  - “worker-specific effects” perspective on, 359–361
  - worldwide scope of, 361–362
- World Trade Center terrorist attacks, 704, 717, 720, 722, 725
- World War II, 704, 705–706, 720
- Yarborough v. Alvarado* (2004), 636
- YMCA, 308
- Yonkers Project, 506, 511, 514, 521
- Youth Development Study (YDS), 353, 356, 359, 360, 361, 365–366
- Youth Service Activities program, 690
- Zero-tolerance policies, 629, 661
