# Foreword to the *Handbook of Child Psychology and Developmental Science*, Seventh Edition

WILLIAM DAMON

## THE *HANDBOOK*'S DEVELOPING TRADITION

Development is one of life's optimistic ideas. It implies not just change but improvement, progress, forward movement, and some sense of positive direction. What constitutes improvement in any human capacity is an open, important, and fascinating question requiring astute theoretical analysis and sound empirical study. So, too, are questions of what accounts for improvement; what enhances it; and what prevents it when it fails to occur. One of the landmark achievements of this edition of the *Handbook of Child Psychology and Developmental Science* is that a full selection of top scholars in the field of human development have offered us state-of-the-science answers to these essential questions.

Compounding the interest of this edition, the concept of development applies to scholarly fields as well as to individuals, and the *Handbook*'s distinguished history, from its inception more than 80 years ago to the present edition, richly reveals the development of a field. Within the field of human development, the *Handbook* has had a long and notable tradition as the field's leading beacon, organizer, and encyclopedia of what's known. This latest *Handbook* edition, overflowing with insights and information that go well beyond the scientific knowledge available in previous editions, is proof of the substantial progress made by the field of human development during its still-short (by scholarly standards) history.

Indeed, the history of developmental science has been inextricably intertwined with the history of the *Handbook*. Like many influential encyclopedias, the *Handbook* influences the field it reports on. Scholars—especially younger ones—look to it to guide their own work. It serves as an

indicator and as a generator, a pool of received findings, and a source for generating new insight.

It is impossible to imagine what the field would look like if Carl Murchison had not assembled a ground-breaking collection of essays on the then-almost-unknown topic of child study in his first *Handbook of Child Psychology*. That was 1931, at the dawn of a scholarly history that, like every developmental narrative, has proceeded with a combination of continuity and change. What does this history tell us about where the field of developmental science has been, what it has learned, and where it is going? What does it tell us about what's changed and what has remained the same in the questions that have been asked, in the methods used, and in the theoretical ideas that have been advanced to understand human development?

## The First Two Editions

Carl Murchison was a star scholar/impresario who edited the *Psychological Register*, founded important psychological journals, and wrote books on social psychology, politics, and the criminal mind. He compiled an assortment of handbooks, psychology texts, and autobiographies of renowned psychologists, and even ventured a book on psychic phenomena (Sir Arthur Conan Doyle and Harry Houdini were among the contributors). Murchison's initial *Handbook of Child Psychology* was published by a small university press (Clark University) in 1931, when the field itself was still in its infancy. Murchison wrote:

Experimental psychology has had a much older scientific and academic status [than child psychology], but at the present time it is probable that much less money is being spent for pure

research in the field of experimental psychology than is being spent in the field of child psychology. In spite of this obvious fact, many experimental psychologists continue to look upon the field of child psychology as a proper field of research for women and for men whose experimental masculinity is not of the maximum. This attitude of patronage is based almost entirely upon a blissful ignorance of what is going on in the tremendously virile field of child behavior. (Murchison, 1931, p. ix)

Murchison's masculine allusion is from another era; it might supply good material for a social history of gender stereotyping. That aside, Murchison was prescient in the task that he undertook and the way that he went about it. At the time this passage was written, developmental psychology was known only in Europe and in a few forward-looking U.S. labs and universities. Nevertheless, Murchison predicted the field's impending ascent: "The time is not far distant, if it is not already here, when nearly all competent psychologists will recognize that one-half of the whole field of psychology is involved in the problem of how the infant becomes an adult psychologically" (Murchison, 1931, p. x).

For this first 1931 *Handbook*, Murchison looked to Europe and to a handful of American research centers for child study—most prominently, Iowa, Minnesota, University of California at Berkeley, Columbia, Stanford, Yale, and Clark—many of which were at the time called *field stations*. Murchison's Europeans included a young "genetic epistemologist" named Jean Piaget, who, in an essay on "Children's Philosophies," cited data from his interviews with 60 Genevan children between the ages of 4 and 12 years. Piaget's chapter would provide U.S. readers with an introduction to his soon-to-be seminal research program on children's conceptions of the world. Another European, Charlotte Bühler, wrote a chapter on young children's social behavior. In her chapter, which still is fresh today, Bühler described intricate play and communication patterns among toddlers—patterns that developmental scientists would not rediscover until the late 1970s. Bühler also anticipated critiques of Piaget that were to be again launched during the sociolinguistics heyday of the 1970s:

Piaget, in his studies on children's talk and reasoning, emphasizes that their talk is much more egocentric than social . . . that children from three to seven years accompany all their manipulations with talk which actually is not so much intercourse as monologue . . . [but] the special relationship of the child to each of the different members of the household is distinctly reflected in the respective conversations. (Bühler, 1931, p. 138)

Other Europeans include Anna Freud, who wrote on "The Psychoanalysis of the Child," and Kurt Lewin, who wrote on "Environmental Forces in Child Behavior and Development"—both would gain worldwide renown in coming years.

The Americans that Murchison chose were equally notable. Arnold Gesell wrote a nativistic account of his twin studies—an enterprise that remains familiar to us today—and Stanford's Louis Terman wrote a comprehensive account of everything known about the "gifted child." Harold Jones described the developmental effects of birth order, Mary Cover Jones wrote about children's emotions, Florence Goodenough wrote about children's drawings, and Dorothea McCarthy wrote about language development. Vernon Jones's chapter on "children's morals" focused on the growth of *character*, a notion that was to become mostly lost to the field during the cognitive-developmental revolution, but that has reemerged in the past decade as a primary concern in the study of moral development.

Murchison's vision of child psychology included an examination of cultural differences as well. His *Handbook* presented to the scholarly world a young anthropologist named Margaret Mead, just back from her tours of Samoa and New Guinea. In this early essay, Mead wrote that her motivation in traveling to the South Seas was to discredit the claims that Piaget, Levy-Bruhl, and other "structuralists" had made regarding what they called *animism* in young children's thinking. (Interestingly, about a third of Piaget's chapter in the same volume was dedicated to showing how Genevan children took years to outgrow their animism.) Mead reported data that she called "amazing": "In not one of the 32,000 drawings (by young 'primitive' children) was there a single case of personalization of animals, material phenomena, or inanimate objects" (Mead, 1931, p. 400). Mead parlayed these data into a tough-minded critique of Western psychology's ethnocentrism, making the point that animism and other beliefs are more likely to be culturally induced than intrinsic to early cognitive development. This is hardly an unfamiliar theme in contemporary psychology. Mead offered a research guide for developmental field workers in strange cultures, complete with methodological and practical advice, such as the following: (1) translate questions into native linguistic categories; (2) do not do controlled experiments; (3) do not try to do research that requires knowing the ages of subjects, which are usually unknowable; and (4) live next door to the children whom you are studying.

Despite the imposing roster of authors that Murchison had assembled for this original *Handbook of Child*

*Psychology*, his achievement did not satisfy him for long. Barely 2 years later, Murchison put out a second edition, of which he wrote: “Within a period of slightly more than 2 years, this first revision bears scarcely any resemblance to the original *Handbook of Child Psychology*. This is due chiefly to the great expansion in the field during the past 3 years and partly to the improved insight of the editor” (Murchison, 1933, p. vii). The tradition that Murchison had brought to life was already developing.

Murchison saw fit to provide the following warning in his second edition: “There has been no attempt to simplify, condense, or to appeal to the immature mind. This volume is prepared specifically for the scholar, and its form is for his maximum convenience” (Murchison, 1933, p. vii). It is clear that Murchison, despite his impresario urges, was willing to sacrifice accessibility and textbook-level sales for scientific value in this instance.

Murchison exaggerated when he wrote that his second edition bore little resemblance to the first. Almost half of the chapters were virtually the same, with minor additions and updating. (For the record, though, despite Murchison’s continued use of masculine phraseology, 10 of the 24 authors in the second edition were women.) Some of the authors whose original chapters were dropped were asked to write about new topics. So, for example, Goodenough wrote about mental testing rather than about children’s drawings, and Gesell wrote a general chapter on maturational theory that went well beyond his own twin studies.

But Murchison also made certain abrupt changes. He dropped Anna Freud entirely, prompting the marginalization of psychoanalysis within U.S. academic psychology. Leonard Carmichael, later to play a pivotal role in the *Handbook* tradition, made his appearance as author of a major chapter (by far, the longest in the book) on prenatal and perinatal growth. Three other physiologically oriented chapters were added as well: one on neonatal motor behavior, one on visual–manual functions during the first 2 years of life, and one on physiological “appetites” such as hunger, rest, and sex. Combined with the Goodenough and Gesell shifts in focus, these additions gave the 1933 *Handbook* a more biological thrust, in keeping with Murchison’s long-standing desire to display the hard-science backbone of the emerging field.

### The Early Wiley Editions

Leonard Carmichael was president of Tufts University when he organized Wiley’s first edition of the *Handbook*. The switch from a university press to the long-established

commercial firm of John Wiley & Sons was commensurate with Carmichael’s well-known ambition; and indeed Carmichael’s effort was to become influential beyond anything that Murchison might have anticipated. (The switch to Wiley meant that what was to become known as Wiley’s first edition was actually the *Handbook*’s third edition—and that what we now see as the seventh edition is really the *Handbook*’s ninth.) Carmichael renamed the volume the *Manual of Child Psychology*, in keeping with Carmichael’s intention of producing an “advanced scientific manual to bridge the gap between the excellent and varied elementary textbooks in this field and the scientific periodical literature” (Carmichael, 1946, p. vi).

Despite the small title change, there was significant continuity between the Murchison and Carmichael’s editions. Carmichael acknowledged this in the prefaces to both of his editions, the 1946 and 1954 *Manuals*:

Both as editor of the *Manual* and as the author of a special chapter, the writer is indebted. . . . [for] extensive excerpts and the use of other materials previously published in the *Handbook of Child Psychology, Revised Edition*. (Carmichael, 1946, p. vi)

Both the *Handbook of Child Psychology* and the *Handbook of Child Psychology, Revised Edition*, were edited by Dr. Carl Murchison. I wish to express here my profound appreciation for the pioneer work done by Dr. Murchison in producing these handbooks and other advanced books in psychology. The *Manual* owes much in spirit and content to the foresight and editorial skill of Dr. Murchison. (Carmichael, 1954, p. v)

The first quote comes from Carmichael’s preface to the 1946 edition, the second from his preface to the 1954 edition. We shall never know why Carmichael waited until the 1954 edition to add the personal tribute to Carl Murchison. Perhaps a careless typist dropped the laudatory passage from a handwritten version of the 1946 preface and its omission escaped Carmichael’s notice. Or perhaps 8 years of further development increased Carmichael’s generosity of spirit. It is also possible that Murchison or his family complained. In any case, Carmichael always acknowledged the roots of his *Manual*, if not always their original editor.

Leonard Carmichael took his 1946 *Manual* in the same direction established by Murchison back in 1931 and 1933. First, Carmichael appropriated five Murchison chapters on biological or experimental topics such as physiological growth, scientific methods, and mental testing. Second, he added three new biologically oriented chapters on animal infancy, on physical growth, and on motor and behavioral maturation (a tour de force by Myrtal McGraw that instantly made Gesell’s chapter in the same volume

obsolete). Third, he commissioned Wayne Dennis to write an adolescence chapter that focused exclusively on physiological changes associated with puberty. Fourth, Carmichael dropped Piaget and Bühler, who, like Anna Freud years earlier, were becoming out of step with then-current experimental trends in U.S. psychology.

The five Murchison chapters on social and cultural influences in development were the ones Carmichael retained: two chapters on environmental forces on the child (by Kurt Lewin and by Harold Jones), Dorothea McCarthy's chapter on children's language, Vernon Jones's chapter on children's morality (now entitled "Character Development—An Objective Approach"), and Margaret Mead's chapter on "primitive" children (now enhanced by several spectacular photos of mothers and children from exotic cultures around the world). Carmichael also stuck with three other psychologically oriented Murchison topics (emotional development, gifted children, and sex differences), but he selected new authors to cover them.

Carmichael's second and final *Manual* in 1954 was very close in structure and content to his 1946 *Manual*. Carmichael again retained the heart of Murchison's original vision, many of Murchison's original authors and chapter topics, and some of the same material that dated all the way back to the 1931 *Handbook*. Not surprisingly, the chapters that were closest to Carmichael's own interests received the most significant updating. As Murchison had done, Carmichael leaned toward the biological and physiological whenever possible. He clearly favored experimental treatments of psychological processes. Yet Carmichael still retained the social, cultural, and psychological analyses by Lewin, Mead, McCarthy, Terman, Harold Jones, and Vernon Jones, even going so far as to add a new chapter on social development by Harold and Gladys Anderson and a new chapter on emotional development by Arthur Jersild.

In 1946, when Carmichael had finished his first *Manual*, he had complained that "this book has been a difficult and expensive one to produce, especially under wartime conditions" (Carmichael, 1946, p. vii). But the project had been well worth the effort. The *Manual* quickly became the bible of graduate training and scholarly work in the field, available virtually everywhere that human development was studied. Eight years later, now head of the Smithsonian Institution, Carmichael wrote, in the preface to his 1954 edition: "The favorable reception that the first edition received not only in America but all over the world is indicative of the growing importance of the study of the phenomena of the growth and development of the child" (Carmichael, 1954, p. vii).

The Murchison and Carmichael volumes make fascinating reading, even today. The perennial themes of the field were always there: the nature/nurture debate; the generalizations of universalists opposed by the particularizations of contextualists; the alternating emphases on continuities and discontinuities during ontogenesis; and the standard categories of maturation, learning, locomotor activity, perception, cognition, language, emotion, conduct, morality, and culture—all separated for the sake of analysis, yet, as authors throughout each of the volumes acknowledged, all somehow joined in the dynamic mix of human development.

These things have not changed. Yet much in the early handbooks/manuals is now irrevocably dated. Long lists of children's dietary preferences, sleeping patterns, elimination habits, toys, and somatic types look quaint and pointless through today's lenses. The chapters on children's thought and language were done prior to the great contemporary breakthroughs in neurology and brain/behavior research, and they show it. The chapters on social and emotional development were ignorant of the processes of social influence and self-regulation that soon would be revealed through attribution research and other studies in social psychology. Terms such as *cognitive neuroscience*, *neuronal networks*, *behavior genetics*, *social cognition*, *dynamical systems*, *information processing*, and *developmental psychopathology* were unknown. Margaret Mead's rendition of the primitive child stands as a weak straw in comparison to the wealth of cross-cultural knowledge available in today's "cultural psychology."

Most tellingly, the assortments of odd facts and normative trends were tied together by very little theory throughout the Carmichael chapters. It was as if, in the exhilaration of discovery at the frontiers of a new field, all the facts looked interesting in and of themselves. That is what makes so much of the material seem odd and arbitrary. It is hard to know what to make of the lists of facts, where to place them, which ones were worth keeping track of and which ones are expendable. Not surprisingly, the bulk of the data presented in the Carmichael manuals seems not only outdated by today's standards but, worse, irrelevant.

Carmichael's second and final *Manual* had a long life: Not until 1970 did Wiley bring out a third edition. Carmichael was retired by then, but he still had a keen interest in the book. At his insistence, his own name became part of the title of Wiley's third edition: The edition was called, improbably, *Carmichael's Manual of Child Psychology*, even though it had a new editor and an entirely new cast of authors and advisors.

## Mussen's Transformation

Paul Mussen was editor of the 1970 edition; once again the project flourished. Now a two-volume set, the 1970 third edition swept the social sciences, generating widespread interest in developmental psychology and its related disciplines. Rarely had a scholarly compendium become both so dominant in its own field and so familiar in related disciplines. The volumes became essential sources for graduate students and advanced scholars alike. Publishers referred to Mussen's 1970 *Carmichael's Manual* as the standard against which other scientific handbooks were compared.

By 1970, the importance of theory for understanding human development had become apparent. Looking back on Carmichael's last *Manual*, Mussen wrote: "The 1954 edition of this *Manual* had only one theoretical chapter, and that was concerned with Lewinian theory which, so far as we can see, has not had a significant lasting impact on developmental psychology" (Mussen, 1970, p. x). The intervening years had seen a turning away from the norm of psychological research once fondly referred to as "dust-bowl empiricism."

The 1970 handbook—still called, as noted above, *Carmichael's Manual*—had an entirely new look. The two-volume set carried only one chapter from the earlier books, Carmichael's updated version of his own long chapter on the "Onset and Early Development of Behavior," which had made its appearance under a different title way back in Murchison's 1933 edition. Otherwise, as Mussen wrote in his preface, "It should be clear from the outset . . . that the present volumes are not, in any sense, a *revision* of the earlier editions; this is a completely new *Manual*" (Mussen, 1970, p. x).

And it was. In comparison to Carmichael's last edition 16 years earlier, the scope, variety, and theoretical depth of the Mussen volumes were astonishing. The field had blossomed, and the new *Manual* showcased many of the new bouquets that were being produced. The biological perspective was still strong, grounded by chapters on physical growth (by J. M. Tanner) and physiological development (by Dorothy Eichorn), and by Carmichael's revised chapter (now made more elegant by some excerpts from Greek philosophy and modern poetry). But two other cousins of biology also were represented, in an ethological chapter by Eckhard Hess, and a behavior genetics chapter by Gerald McClearn. These chapters were to define the major directions of biological research in the field for at least the next three decades.

As for theory, Mussen's *Handbook* was thoroughly permeated with it. Much of the theorizing was organized around the approaches that, in 1970, were known as the "three grand systems": (1) Piaget's cognitive-developmentalism, (2) psychoanalysis, and (3) learning theory. Piaget was given the most extensive treatment. He himself reappeared in this *Manual*, authoring a comprehensive (some say definitive) statement of his own theory, which now bore little resemblance to his 1931/1933 catalog of children's intriguing verbal expressions. In addition, chapters by John Flavell, by David Berlyne, by Martin Hoffman, and by William Kessen, Marshall Haith, and Philip Salapatek, all gave major treatments to one or another aspect of Piaget's body of work.

Several other theoretical approaches were represented in the 1970 *Manual* as well. Herbert and Ann Pick explicated Gibsonian theory in a chapter on sensation and perception, Jonas Langer wrote a chapter on Werner's organismic theory, David McNeill wrote a Chomskian account of language development, and Robert LeVine wrote an early version of what was to become "culture theory."

With its increased emphasis on theory, the 1970 *Manual* explored in depth a matter that had been all but neglected in the *Manual's* previous versions: the mechanisms of change that could account for, to use Murchison's old phrase, "the problem of how the infant becomes an adult psychologically." In the process, old questions such as the relative importance of nature versus nurture were revisited, but with far more sophisticated conceptual and methodological tools.

Beyond theory building, the 1970 *Manual* addressed an array of new topics and featured new contributors: peer interaction (Willard Hartup), attachment (Eleanor Maccoby and John Masters), aggression (Seymour Feshback), individual differences (Jerome Kagan and Nathan Kogan), and creativity (Michael Wallach). All of these areas of interest are still very much with us.

Wiley's fourth edition, published in 1983, was redesignated to become once again the *Handbook of Child Psychology*. By then, Carmichael had passed away. The set of books, now expanded to four volumes, became widely referred to in the field as "the Mussen handbook."

If the 1970 *Manual* reflected a blossoming of the field's plantings, the 1983 *Handbook* reflected a field whose ground cover had spread beyond any boundaries that could have been previously anticipated. New growth had sprouted in literally dozens of separate locations. A French garden, with its overarching designs and tidy compartments, had turned into an English garden, unruly but often glorious in

its profusion. Mussen's two-volume *Carmichael's Manual* had now become the four-volume *Mussen Handbook*, with a page-count increase that came close to tripling the 1970 edition.

The grand old theories were breaking down. Piaget was still represented in 1983 by his 1970 piece, but his influence was on the wane throughout other chapters. Learning theory and psychoanalysis were scarcely mentioned. Yet the early theorizing had left its mark, in vestiges that were apparent in new approaches, and in the evident conceptual sophistication with which authors treated their material. There was no return to dust-bowl empiricism. Instead, a variety of classical and innovative ideas were coexisting: ethology, neurobiology, information processing, attribution theory, cultural approaches, communications theory, behavioral genetics, sensory-perception models, psycholinguistics, sociolinguistics, discontinuous stage theories, and continuous memory theories all took their places, with none quite on center stage. Research topics now ranged from children's play to brain lateralization, from children's family life to the influences of school, day care, and disadvantageous risk factors. There also was coverage of the burgeoning attempts to use developmental theory as a basis for clinical and educational interventions. The interventions usually were described at the end of chapters that had discussed the research relevant to the particular intervention efforts, rather than in whole chapters dedicated specifically to issues of practice.

### The Fifth and Sixth Editions

There was a long hiatus between the fourth edition in 1983 and the fifth edition, which was not to appear until 1998. The fifth edition fell to me to organize, and this was not at my own initiative. Two John Wiley editors—Herb Reich, a legendary figure in academic publishing, and Kelly Franklin, an up-and-coming innovative star—approached me about reviving the project, which they correctly believed had a vital tradition behind it, but that they also believed was in danger of falling by the wayside. I had been editing the Jossey-Bass series that I founded, *New Directions for Child and Adolescent Development*, and the two Wiley editors believed that if we could impart a “new directions” tone to a new *Handbook* edition, the project could regain its past appeal. I agreed, and I proposed that this next edition be organized in an intuitively simple four-volume design: a theory volume, a volume on cognitive and linguistic development, a volume on social and personality development, and a volume on child

psychology in practice. When Wiley accepted my proposal, my first action as general editor was to invite an incredibly talented group of volume editors—Nancy Eisenberg, Deanna Kuhn, Richard Lerner, Anne Renninger, Robert Siegler, and Irving Sigel—to collaborate on the selection and editing of chapters. The edition was to become the result of a partnership among all the editors; and the same team collaborated again to produce the sixth edition of the *Handbook* in 2006, with Richard Lerner assuming an added role as my co-editor-in-chief. The 2006 edition closely followed the model of the 1998 edition, with some important additions, such as chapters on the positive youth development approach, on artistic development, and on religiosity and faith in human development.

Our team approached the 1998 and 2006 editions with the same purpose that Murchison, Carmichael, and Mussen before us had shared: “to provide,” as Mussen wrote, “a comprehensive and accurate picture of the current state of knowledge—the major systematic thinking and research—in the most important research areas of the psychology of human development” (Mussen, 1983, p. vii). We assumed that the *Handbook* should be aimed “specifically for the scholar,” as Murchison declared, and that it should have the character of an “advanced text,” as Carmichael defined it. We expected that our readership would be interdisciplinary, given the tendency of scholars in human development to do work across the fields of psychology, cognitive science, neuroscience, history, linguistics, sociology, anthropology, education, and psychiatry. In Volume 4, we hoped that research-oriented practitioners would be among the scholars for whom the *Handbook* had value.

By the time of the 1998 and 2006 editions of the *Handbook*, powerful theoretical models and approaches—not quite unified theories like the “three grand systems” that had marked earlier editions—were again organizing much of the field's research. There was great variety in these models and approaches, and each was drawing together significant clusters of work. Among the powerful models and approaches prominent in the 1998 and 2006 *Handbooks* were the dynamic system theories, life-span and life-course approaches, cognitive science and neural models, the behavior genetics approach, person-context interaction theories, action theories, culture theory, ecological models, and neo-Piagetian and Vygotskian models. Although some of these models and approaches had been in the making for some time, by the end of the 20th century they had fully come into their own: researchers were drawing on them more directly, taking their implied assumptions

and hypotheses seriously, using them with specificity and control, and exploiting all of their implications for practice.

### The Present

The seventh Wiley edition of the *Handbook* continues and strengthens the trends toward specific theoretical analyses of multiple developmental processes, even highlighting this focus by including the term “processes” in three of the four volume’s titles, a designation new to the *Handbook*’s history. The volumes present a rich mix of classic and contemporary theoretical perspectives, but I believe it is fair to say that the dominant views throughout are marked by an emphasis on the dynamic interplay of all relational developmental systems that co-act across the life span, incorporating the range of biological, perceptual, cognitive, linguistic, emotional, social, cultural, and ecological levels of analysis. At the same time, the chapters together consider a vast array of topics and problems, ranging from sexuality and religiosity to law, medicine, war, poverty, and education. The emerging world of digital experience is also given a fuller treatment than in any previous *Handbook* edition, commensurate with our present-day technological revolution. All this gives this seventh edition of the *Handbook* a timely feel.

The present *Handbook*’s combination of theoretical and methodological sophistication and topical timeliness resolves an old tension evident in the *Handbook*’s prior cycling between theoretical-methodological and problem-centered approaches. My impression is that, rather than leaning in one direction or the other, this *Handbook* manages to be *both* more theoretical-methodological *and* more topical than the previous editions. As a developmental phenomenon, this puts the *Handbook* in a class of organisms that develop towards adaptive complexity rather than towards one or another contrasting polar dimension.

I wonder what Carl Murchison would think of the grown-up child that he spawned before the field of human development had become a mainstream endeavor in research and teaching around the world. Murchison’s idiosyncratic assortment of fascinating studies bears little resemblance to the imposing compendium of solidly grounded knowledge that we have in the present *Handbook*. Yet each step along the 83-year way followed directly from what had gone before, with only occasional departures or additions that may have seemed more like gradual revisions at the time. Over the long haul, the change in the *Handbook* has been dramatic, but the change process itself has been marked by substantial continuities. If Murchison were to come back to life today, he may be astonished by the size and reach of his child, but I believe he would recognize it—and proudly so.

## Preface

Across its editions, the title of this handbook has changed, now, five times: *A Handbook of Child Psychology*; *Manual of Child Psychology*; *Carmichael's Manual of Child Psychology*; *Handbook of Child Psychology*; and *Handbook of Child Psychology and Developmental Science*. As well, the field of scholarship represented in the handbook has also been labeled differently: child psychology, child development, developmental psychology, and, today, developmental science. The rationales for the use of these labels involve historically changing ontological and epistemological assumptions.

During the latter years of the 19th century and for much of the past two thirds of the 20th century, and perhaps especially in the United States and Western Europe, the study of human development was a visible subfield of psychology (see Cairns & Cairns, 2006, for a review; see also Damon, in the Foreword to this edition of the *Handbook*). In this literature, and its antecedents in philosophy (see Baltes, 1983; Overton, 2006 for reviews), development was envisioned to be a life-span phenomenon (e.g., Erikson, 1959; Hall, 1904, 1922). However, the majority of the scholarship about human development in the United States and Western Europe was focused on the early years of life (infancy and childhood) (e.g., Binet & Simon, 1905a, 1905b; Gesell, 1929; Piaget, 1923; Preyer, 1882; Terman, 1925).

As a consequence, across this historical period, child psychology emerged as a specific subarea of psychology, spurred on by the research of scientists studying this age period; by the founding of several university centers and institutes devoted to the study of children (e.g., in Iowa, involving scholars such as Boyd R. McCandless; and in Minnesota, involving scholars such as Dale B. Harris); and by the work in the field of home economics, which was focused on children (and families), that was occurring

within land-grant universities in the United States (Cairns & Cairns, 2006; Lerner & Simon, 1998). At the same time, many of the contributors to child psychology also created a purportedly multidisciplinary instantiation of scholarship devoted to the study of children, that is, child *development*. In 1933, the Society for Research in Child Development (SRCD) was founded to promote such a multidisciplinary approach to the study of children (and to the application of child development research) but, in actuality, SRCD was from its outset and remains today dominated by scholars whose training is in psychology. It is not surprising, then, that, whether labeled child psychology or child development, the study of the early portion of the life span was approached in very similar ways by scholars studying children.

At its inception, the child development (or child psychology) field was framed by Cartesian-split conceptions of change across ontogeny and by reductionist accounts of the bases of human development (Overton, 2013a, 2013b; Overton & Müller, 2013). The core conceptual issues of child development were the nature-nurture, the continuity-discontinuity, and the stability-instability controversies (Lerner, 2002), and “solutions” to these debates involved, for instance, reducing development to being a phenomenon explained by either nature variables (genes or maturation; e.g., Hamburger, 1957) or by operant or respondent stimulus-response connections (e.g., Bijou & Baer, 1961). This split, reductionist ontology about development meant that the epistemological route to learning about the basis of development was to identify the essential (nature *or* nurture) explanatory variable(s). Accordingly, the study of development was also marked by variable-centered analyses, as exemplified by the tables of contents of the editions of this *Handbook* published during this period (e.g., Carmichael, 1946, 1954; Murchison,

1931, 1933; Mussen, 1970, 1983; see also Damon, in the Foreword to this edition), as well as by the tables of contents of other major compendiums published during this period (e.g., Reese & Lipsitt, 1970; Stevenson, 1963).

However, as early as 1970, Mussen, the editor of the third edition of the *Handbook* published by Wiley, pointed to the potential meaning of a growing interest among some scientists to move away from a reductionist approach, involving descriptions of the variables purportedly accounting for ontogenetic structure and function, and toward an approach that viewed development as involving interrelations among variables (from multiple levels of organization). Mussen (1970) said that “the major contemporary empirical and theoretical emphases in the field of developmental psychology . . . seem to be on *explanations* of the psychological changes that occur, the mechanisms and processes accounting for growth and development” (p. vii). By pointing to the interest in change processes, Mussen was implying that we needed something more to explain the process of development, unless we believed that nature or nurture variables explained themselves in structure or function.

That “something more” was already emerging within the study of development—for instance, at a series of conferences held at the University of West Virginia in the late 1960s and early 1970s about the nature and implications of a life-span view of human development (e.g., Baltes & Schaie, 1974; Nesselroade & Reese, 1973; Schaie, 1970). These West Virginia University conferences, the edited books that derived from them, and the associated articles published in both theoretically oriented journals (e.g., *Human Development*, *Developmental Review*) and empirically oriented journals (e.g., *Child Development*, *Developmental Psychology*, *International Journal of Behavioral Development*, and *Journal of Research on Adolescence*) discussed the philosophical, theoretical, and methodological problems associated with split/reductionist accounts of development. In addition, they introduced ideas about the potential for plasticity (i.e., the potential for systematic change) in development across life, and pointed to the role of potentially mutually influential relations between individuals and their normative age- and history-graded experiences and, as well, their nonnormative experiences, in instantiating this plasticity. Finally, they underscored the fundamental necessity of studying intraindividual changes (and interindividual differences in intraindividual changes) involved in these individual-context relations in order to describe, explain, and optimize the course of human development. These ideas would act synergistically

with growing scholarship in Europe that provided theory and data fostering a “reversal” of focus for developmental inquiry—from variable-centered to person-centered approaches to human development (e.g., Magnusson, 1999). These ideas were also synergistic with work in sociology that demonstrated that the course of life was shaped by historical events that one encountered at particular times and in particular places (Elder, 1974).

When taken together, the dimensions of human development scholarship that crystallized and coalesced between the 1970s and 1990s pointed to the vacuity of split/reductionist models (and their attendant methodologies). In turn, these ideas underscored the importance of time and place, person–context relations, plasticity, and the need for a focus on longitudinal (change-sensitive) methods to study intraindividual change across life and, as well, the diverse life paths of these intraindividual changes. These ideas, when considered together, presented a major challenge to the then-dominant metatheoretical and theoretical ideas in the field. Indeed, the new ideas about human development that found an impetus at the West Virginia University conferences grew in influence across the field and together, across the last three decades of the 20th century, created a Kuhn-like (Kuhn, 1962) paradigm shift (Overton, 2013a, 2013b; Overton & Lerner, 2012).

The shift in conceptual and empirical foci attendant to this paradigm shift was multifaceted. As I noted, Mussen (1970) observed that the field had been primarily descriptive and normative (Mussen, 1970), with the norms usually generated by studying only a small portion of humanity (i.e., European American middle-class children in the main; Hagen, Paul, Gibb, & Wolters, 1990). In addition, the “paradigm” framing this research was as likely (if not more likely) to use cross-sectional research to study development as it was to employ longitudinal methods. The use of cross-sectional designs (and data analysis methods, e.g., R-technique analyses; e.g., see Cattell, 1966, and for more current versions of these ideas see Molenaar & Nesselroade, 2014; Nesselroade & Molenaar, 2010) was predicated on the assumption of the applicability of the ergodic theorem (e.g., Molenaar, 2007; Molenaar & Nesselroade, 2014). The ergodic theorem holds that data sets are marked by: (a) homogeneity across individuals in a three-dimensional matrix that involves persons, variables, and time; and (b) stationarity of individuals’ scores on variables across time (Molenaar, 2007).

In contrast, the approach to the study of human development that was evidenced by the life-span and life-course perspectives involved research that documented the

presence of systematic variation in trajectories of intraindividual change, both within and across people. As such, the assumptions of homogeneity and stationarity of the ergodic theorem were rejected and developmental scientists placed greater importance on not only person-centered research but, as well, change-sensitive methodologies for both descriptive and explanatory efforts (Molenaar, 2007, 2010). What was distinctive about this research, however, was that it was both derived from and promoted diverse attempts to create theoretical models of human development associated with an emergent, relational paradigm (Overton, 2013a, 2013b; Overton & Müller, 2013), a conception that focused on the individual and on the course of his or her trajectories of reciprocal bidirectional relations with the multiple levels of the ecology of human development (represented as individual  $\longleftrightarrow$  context relations). Examples were the bioecological model of Bronfenbrenner (e.g., 1979), the dialectical model of Riegel (e.g., 1975), the developmental contextual approach of Lerner (1982), the developmental systems concepts of Gottlieb (1997, 1998) and of Ford and Lerner (1992), the model of individual development proposed by Magnusson (1999), and the embodiment model presented by Overton (1994, 1997).

In short, these “strands” of theory merged in the 1970s, 1980s, and 1990s and shifted the predominant developmental “paradigm” away from reductionism, Cartesian-split conceptions, and methods predicated on ergodicity, and created a focus on models emphasizing the mutually influential relations between individuals and their contexts, on person  $\longleftrightarrow$  context relations (Cairns & Cairns, 2006; Lerner, 2006). Such models involved the belief that time and place matter in regard to shaping the course of life (Bronfenbrenner, 2005; Elder, 1998; Elder & Shanahan, 2006), and emphasized that the scientific study of human development needed to study both the individual and the diversity of people in order to understand human development.

In sum, the relational paradigm that framed conceptions of the bases of human development was associated with the generation of several, relational developmental systems models of human development (Lerner, 2006; Lerner & Overton, 2008; Overton, 2013a, 2013b; Overton & Müller, 2013), conceptions that were used to guide the study of individuals, contexts, and their dynamic interrelations across the life span. Table P.1 presents the defining features of such models.

This multilevel and multidisciplinary approach to studying human development was the basis of the view

that the field was best represented by the term developmental science. In turn, given this synergistic history of the links among theory, method, and research, it is not surprising that, at this writing, relational developmental systems theories are at the forefront of the study of human development (e.g., Lerner, 2012; Lerner & Benson, 2013a, 2013b; Overton & Lerner, 2012). Indeed, the fifth edition of the Wiley *Handbook* (Damon, 1998) had pointed to the growing prominence of such approaches to the study of human development and, in turn, the sixth edition (Damon & Lerner, 2006) noted that models derived from relational developmental systems thinking, and from a relational meta-model more generally, had become the predominant conceptual lens for the cutting-edge theory and methodological innovations guiding research in human development across the life span.

In the present seventh edition of the Wiley *Handbook*, this pathway of scholarly progression is continued. Key examples of relational developmental systems models are found across all four volumes of this seventh edition of the *Handbook*. Moreover, accompanying the use of these models are new methodologies to study individuals, to therefore capture the nonergodic character of human development and, as well, to study the developmental system within which individual  $\longleftrightarrow$  context relations are embedded. Examples of these methods are also a prominent contribution of chapters in this edition of the *Handbook*.

Another key feature of the chapters in this edition of the *Handbook* is the applied use of relational developmental systems theoretical models. Based on ideas about the relative plasticity of individual  $\longleftrightarrow$  context relations, this use of theory overcomes yet another traditional split within the study of human development—between theory-predicated explanations of human development and applications aimed at enhancing human development (Baltes, Reese, & Nesselroade, 1977; Lerner, 2002, 2012). For instance, to test explanations of developmental change, scholars need to institute or evaluate actions that are aimed at altering the bidirectional relations theoretically expected to produce changes in behavior and development. These actions must necessarily be embedded in the actual ecology of human development in order to have generalizability to the lived experiences of individuals (Lerner & Callina, 2014) and, as such, they constitute intervention (applied) research; at the same time, such research tests basic explanatory processes of human development. As such, in contemporary developmental science any splits between basic and applied research are regarded as anachronistic representations of the reductionist, Cartesian approaches of earlier eras.

**TABLE P.1 Defining features of the relational developmental systems paradigm****Relational Metatheory**

Predicated on a philosophical perspective that transcends Cartesian dualism and atomism, theories derived from the relational developmental systems paradigm are framed by a relational metatheory for human development. This focus includes an emphasis on process and a rejection of all splits between components of the ecology of human development (e.g., between nature- and nurture-based variables, between continuity and discontinuity, and between stability and instability). Holistic syntheses replace dichotomies, as well as reductionist partitions of the developing relational system, through the integration of three relational moments of analysis: the identity of opposites, the opposites of identity, and the syntheses of wholes. Deriving from the relational metatheory, relational developmental systems posit the organism as an inherently active, self-creating, self-organizing, and self-regulating nonlinear complex adaptive system, which develops through embodied activities and actions, as they co-act with a lived world of physical and sociocultural objects.

**The Integration of Levels of Organization**

Relational thinking, with the rejection of Cartesian splits, is associated with the idea that all levels of organization within the ecology of human development are integrated or fused. These levels range from the biological and physiological through the cultural and historical.

**Developmental Regulation Across Ontogeny Involves Mutually Influential Individual  $\leftrightarrow$  Context Relations**

As a consequence of the integration of levels, the regulation of development occurs through mutually influential connections among all levels of the developing relational system, ranging from genes and cell physiology through individual mental and behavioral functioning to society, culture, the designed and natural ecology, and, ultimately, history. These mutually influential relations may be represented generically as Level 1  $\leftrightarrow$  Level 2 (e.g., Family  $\leftrightarrow$  Community), and in the case of ontogeny may be represented as individual  $\leftrightarrow$  context.

**Integrated Actions, Individual  $\leftrightarrow$  Context Relations, Are the Basic Unit of Analysis Within Human Development**

The character of developmental regulation means that the integration of actions—of the individual on the context and of the multiple levels of the context on the individual (individual  $\leftrightarrow$  context)—constitute the fundamental unit of analysis in the study of the basic process of human development.

**Temporality and Plasticity in Human Development**

As a consequence of the fusion of the historical level of analysis—and therefore temporality—in the levels of organization comprising the ecology of human development, the developing relational system is characterized by the potential for systematic change, by plasticity. Observed trajectories of intraindividual change may vary across time and place as a consequence of such plasticity.

**Relative Plasticity**

Developmental regulation may both facilitate and constrain opportunities for change. Thus, change in individual  $\leftrightarrow$  context relations is not limitless, and the magnitude of plasticity (the probability of change in a developmental trajectory occurring in relation to variation in contextual conditions) may vary across the life span and history. Nevertheless, the potential for plasticity at both individual and contextual levels constitutes a fundamental strength of all human development.

**Intraindividual Change, Interindividual Differences in Intraindividual Change, and the Fundamental Substantive Significance of Diversity**

The combinations of variables across the integrated levels of organization within the developmental system that provide the basis of the developmental process will vary at least in part across individuals and groups. This diversity is systematic and lawfully produced by idiographic, group differential, and generic (nomothetic) phenomena. The range of interindividual differences in intraindividual change observed at any point in time is evidence of the plasticity of the developmental system, and gives the study of diversity fundamental substantive significance for the description, explanation, and optimization of human development.

**Interdisciplinarity and the Need for Change-Sensitive Methodologies**

The integrated levels of organization comprising the developmental system require collaborative analyses by scholars from multiple disciplines. Interdisciplinary knowledge is a central goal. The temporal embeddedness and resulting plasticity of the developing system requires that research designs, methods of observation and measurement, and procedures for data analysis be change- and process-sensitive and able to integrate trajectories of change at multiple levels of analysis.

**Optimism, the Application of Developmental Science, and the Promotion of Positive Human Development**

The potential for and instantiations of plasticity legitimate an optimistic and proactive search for characteristics of individuals and of their ecologies that, together, can be arrayed to promote positive human development across life. Through the application of developmental science in planned attempts (interventions) to enhance (e.g., through social policies or community-based programs) the character of humans' developmental trajectories, the promotion of positive human development may be achieved by aligning the strengths (operationalized as the potentials for positive change) of individuals and contexts.

*Source:* Based on Lerner (2006) and Overton (2013a, 2013b).

In short, the application of developmental science (optimization) is a co-equal partner with description and explanation within developmental science as it now exists. Once again, the chapters in this edition of the *Handbook* provide rich illustrations of the integrated foci of developmental

scholarship on the description, explanation, and optimization of human development across the life span.

Together, the metatheoretical, theoretical, methodological, and applied features of contemporary developmental science that are represented across the four volumes of this

seventh edition of the *Handbook* allow this reference work to continue its history of marking the best scholarship in our field and of specifying the key directions for scientific progress. These contributions of the *Handbook* emerge from the intellectual abilities and wisdom of the volume editors and the authors of the chapters involved in this edition. I am enormously indebted to Willis F. Overton and Peter C. M. Molenaar, editors of Volume 1, Lynn S. Liben and Ulrich Müller, editors of Volume 2, Michael E. Lamb, editor of Volume 3, and Marc H. Bornstein and Tama Leventhal, editors of Volume 4, for their broad and deeply erudite scholarship, vision, and leadership. Their knowledge and skills created and shaped the volumes they edited.

The volume editors and I are also profoundly grateful to the authors of the chapters in this edition. Their singular levels of expertise and mastery of their areas of scholarship are richly and compellingly conveyed in this edition. The work of these colleagues represents the best scholarship in developmental science, and we are deeply grateful for their truly field-defining contributions to this edition.

I wish to express particular gratitude to William Damon, for his thoughtful, illuminating, and generous Foreword to this edition of the *Handbook*. Professor Damon was the editor of the fifth and sixth editions of the *Handbook* and, as well, for five decades he has been a visionary intellectual leader of the field that we now term developmental science. He stands as a model of scholarly excellence, erudition, and wisdom, and I am deeply grateful to have his ideas frame the volumes in this edition.

In addition, as scholars contributing to reference works of the scope of the *Handbook* realize, their work cannot be crystallized, completed, or disseminated without the efforts of the professional editors and publishers who work with them. The editors and authors of the seventh edition have been exceedingly fortunate to have had superb support and, as well, collegial guidance, from our editors in the Institute for Applied Research in Youth Development at Tufts and at John Wiley & Sons.

Jarrett M. Lerner, the managing editor in the Institute at Tufts, was involved with the seventh edition since its inception. He has organized and advanced every facet of the editorial and production process. His professionalism, knowledge, organizational capacities, efficiency, commitment, and indefatigable, positive spirit were vital to the existence, and to any archival contributions, of this edition.

In addition, Patricia A. Rossi, the executive editor for psychology at Wiley, was a masterful and wise guide and catalyst for the seventh edition, again from its inception.

Her deep knowledge of the scholarly qualities that are required to produce a reference work that will set the standard of excellence for its field, and her enthusiasm and unflagging commitment to enabling editors and authors to attain this standard, were essential contributions to the development and completion of this edition. She and her colleagues at Wiley, who enacted a superbly organized, efficient, and invariantly high-quality production process, have enabled the scholarship of the authors and editors to be superbly presented to our readership.

Across the several years that I have worked on this edition of the *Handbook*, I have been blessed by having support, stimulation, and feedback from my colleagues in the Eliot-Pearson Department of Child Study and Human Development, and from my colleagues, staff, and students at the Institute for Applied Research in Youth Development, both at Tufts University. I am grateful for their inspiration and collaboration. I am also extremely fortunate to have had support for my scholarly work provided by the John Templeton Foundation, the Thrive Foundation for Youth, the Poses Family Foundation, the National 4-H Council, the Altria Group, Inc., the Bertelsmann Foundation, the National Science Foundation, the Gary and Joan Bergstrom family, and several individuals who have made private donations to the Institute to support its research. I thank them for their faith in me and for honoring me with their support. My family has been a vital resource of emotional and intellectual support—encouraging me when things seemed overwhelming and grounding me when, on rare occasions, things seemed to be going exceedingly well. My wife, Jacqueline Lerner, merits special recognition—as my life partner, as my chief scholarly collaborator, and my muse. I would have accomplished nothing in my career or my life without her.

Finally, the volume editors and I want to thank the colleagues and students who will read the chapters in this edition of the *Handbook* and who, we hope, will gain from the work presented across its four volumes. Many of these colleagues will find their contributions to developmental science represented in the pages of this edition. We thank them for these contributions. As well, we are grateful to them for another reason. Many of these colleagues will also be training the next generation of developmental scientists, young scholars whom we hope will be inspired by this edition of the *Handbook* to undertake scholarship that will make subsequent editions even better and more useful.

We wish these younger scientists well in this intellectual journey. As such, with the hope that their scientific

aspirations will be realized, we dedicate this seventh edition of the *Handbook of Child Psychology and Developmental Science* to them.

## Volume 4 Preface

*Ecological Settings and Processes*, Volume 4 in this seventh edition of the *Handbook of Child Psychology and Developmental Science*, takes as its starting point the understanding that children are embedded in a complex web of diverse social and physical contexts. In line with the other volumes in this *Handbook*, this volume's chapters are guided by a relational developmental systems perspective (see Overton & Molenaar, Chapter 1, this *Handbook*, Volume 1). The chapters approach the study of ecological settings and processes by adhering to core principles of human development espoused by this perspective: children's environments are complex, multidimensional, and structurally organized; children actively contribute to their development; children and their environments are inextricably linked, and contributions of both child and environment are essential to explain or understand human development; children's development is multidetermined; change over time in the child, the environment, and relations between child and environment is normative; and, on account of the foregoing, development is probabilistic.

The chapters in Volume 4 are organized in a manner that generally conforms to the multiple, hierarchical levels of the bioecological model, beginning with near proximal contexts of children and moving through to distal contexts that influence children. Although not divided into formal sections, the chapters revolve around five spheres of influence on children's development. The first constitutes a broad overview of time and history, laying out the conceptual underpinnings and setting the stage for the rest. The ensuing substantive chapters add contemporary surveys of separate constituents of the relational developmental systems perspective in developmental science. The second group of chapters focuses on the immediate social ecology of children with their significant others, notably parents, families, and peers. The third part sets children

in their most common everyday institutional and group circumstances of childcare and school as well as activities, work, and media. The fourth section complements the third in setting children in their equally prevalent and more encompassing community and physical contexts of home and neighborhoods. The fifth section of this volume casts children and child development in even broader contexts of socioeconomic status, medicine, law, government, war and disaster, culture, and history. The final chapter overviews what precedes in terms of assessment and measurement.

By acknowledging the complexity of the bioecological landscapes of children's development, all of the chapters in Volume 4 share several other commonalities. They draw on knowledge from multiple disciplines and review research employing a large, diverse, and sophisticated set of methods. Doing so enables them to provide a strong foundation that will guide future research in their respective areas and, where relevant, advance evidence-based recommendations for policies and practices to improve children's lives.

We are grateful to the authors of Volume 4 for addressing the challenges inherent in studying the bioecological landscapes of children's development so successfully. Without their dedication, perseverance, and ingenuity, developmental science would not be as evolved as it is today, and the state of knowledge in the specific ecological settings and processes represented in this volume would be much poorer. Volume 4, and the *Handbook* as a whole, would not have cohered around its forward-looking unified conceptual framework without the intellectual leadership of our editor-in-chief, Richard Lerner. He was most ably assisted in this complex endeavor by Jarrett Lerner. We are indebted to both for helping us realize our shared vision for Volume 4 of this seminal and enduring *Handbook* in developmental science.

### BIOECOLOGY AND DEVELOPMENT

Children are embedded in a complex web of diverse social and physical contexts. At the time we organized Volume 4 in this seventh edition of the *Handbook of Child Psychology and Developmental Science*, the relational bioecological developmental systems perspective was the prevailing theoretical framework in our field (Bronfenbrenner & Morris, 2006; Lerner, 2006). Absent a paradigm shift in developmental science, we suspect that it will continue so. In consequence, the chapters in Volume 4 are guided by the relational developmental systems paradigm (see Overton & Molenaar, Chapter 1, this *Handbook*, Volume 1), and we ordered them in a manner that generally conforms to the multiple levels of the bioecological model, beginning with the near proximal contexts in which children find themselves and moving through to distal contexts that influence children in equally compelling, if less immediately manifest, ways. The environmental structure that envelops the child can be viewed as hierarchical, with lower-level more proximal contexts nested within higher-level more distal contexts, all of which shape how children develop.

This volume of the *Handbook* is centrally concerned with the people, conditions, and events outside children that affect children and their development. To understand children's development it is both necessary and desirable to embrace all of these social and physical contexts. Contemporary developmental contextualist theories of human development share core principles that underpin this explanatory stance: The child's environment is complex, multidimensional, and structurally organized

into interlinked contexts; children actively contribute to their development; the child and the environment are inextricably linked, and contributions of both child and environment are essential to explain or understand development; the child's development is multidetermined; change over time in the child, the environment, and relations between child and environment is normative. Because of the foregoing principles, development is probabilistic.

In accord with these principles, bioecological theory defines *development* as a joint function of process, person, context, and time (Bronfenbrenner & Morris, 2006). Characteristics and qualities of the developing person, including, for example, age, gender, temperament, and intellect, interact with characteristics of the environment to influence the nature and structure of developmental outcomes. Developmental settings distinguish process and context. *Processes* refer to dynamic interactions that the developing person experiences. Development proceeds within a hierarchically organized, interlinked set of four nested contexts or systems. Each system has the potential to influence other systems. With respect to context, the microsystem encompasses patterns of activities, roles, and interpersonal relationships that the child experiences in face-to-face settings defined by specific physical and material parameters. At this most proximal and innermost context are patterns of interaction (proximal processes) between children and their immediate social milieus (e.g., parents, siblings, teachers) and physical environments (e.g., objects, places). Distinct microsystems afford children opportunities to experience different types of activities that alone and in combination foster individual

## 2 Children in Bioecological Landscapes of Development

development. Microsystems enable children to take on different roles and identities and establish relationships with various adults. Mesosystems constitute processes and links between two or more microsystems; in a sense mesosystems comprise systems of microsystems. The exosystem encompasses linkages between aspects of the environment the child does not directly encounter, but which influence development through lower-level micro- and mesosystems. At the outermost circle of developmental influences are overarching macrosystem patterns of beliefs, values, customs, and living conditions (e.g., culture, religion, the socioeconomic organization of society). The macrosystem is not separate from children's more immediate environments; rather, it permeates and colors exo-, meso-, and microsystems. Understanding the meaning and impact of proximal influences on the child often requires placing them within the broader macrosystem in which they are found (Bornstein, 1995). Furthermore, the impact of influences from one level can be moderated by factors that compose other linked levels. Finally, crosscutting all of these systems is time, the chronosystem. Effective time frames range from moment-to-moment exposures to developmental processes to periodicities over days or weeks to macro time frames of the life course, generations, or historical eras.

One notable consequence of multiple linkages across different ecosystems that envelop the child is the probabilistic nature they define for development. Another is the requirement that scientists adopt a frankly multidisciplinary approach to understanding child development. As bioecological theory provides a rich and generative framework for understanding the growth of children, it guides the organization of this volume. Multiple systems and numerous disciplines describe the bioecological landscapes of the child.

### A BRIEF TOUR OF VOLUME 4

Although we have not formally divided Volume 4 into sections, this collection of chapters can be seen to arrange itself into five divisions that identify spheres of influence vis-à-vis children and their development. The first constitutes a broad overview of time and history, laying out the conceptual underpinnings and setting the stage for the rest. The ensuing substantive chapters add contemporary surveys of separate constituents of the relational developmental systems perspective in developmental science. The second group of chapters focuses on the immediate

social ecology of children with their significant others, notably parents, families, and peers. The third part sets children in their most common everyday institutional and group circumstances of childcare and school as well as activities, work, and media. The fourth section complements the third in setting children in their equally prevalent and more encompassing community and physical contexts of home and neighborhoods. The fifth section of this volume casts children and child development in even broader contexts of socioeconomic status, medicine, law, government, war and disaster, culture, and history. The final chapter overviews what precedes in terms of assessment and measurement.

In Chapter 2, "Human Development in Time and Place," Glen H. Elder Jr., Michael J. Shanahan, and Julia A. Jennings set the scene of human development in terms of life course theory, bringing contexts and temporality to the full flower of children's lives. They explain life-span concepts and perspectives of human development including, notably, social pathways, cumulative processes, and durations, trajectories, transitions, and turning points. These paradigmatic principles of life course theory turn on human agency and social options, the impact of historical time and place, and societal change in the life course.

The second conceptual section of this volume focuses on children with their significant others, specifically parents, families, and peers. In Chapter 3, "Children's Parents," Marc H. Bornstein first identifies parenting for parents and for children and then considers parenting theory and research in historical and future perspective. He proceeds next to describe biological and social parents and parenting cognitions and practices and then evaluates evidence for parenting effects on children through various designs and experiments. Bornstein afterward explores the multiple determinants of parenting and assesses all-important practical issues related to parenting.

In Chapter 4, "Children in Diverse Families," Lawrence Ganong, Marilyn Coleman, and Luke T. Russell define a panoply of contemporary families and theoretical and conceptual perspectives related to children living with unmarried parents, bereaved children, children in single-parent families after divorce, stepfamilies, gay and lesbian parents, families constructed by assisted reproductive technologies, and children reared by grandparents. The authors conclude with a discussion of the chief challenges and concerns in the study of children and development in these nontraditional, but increasingly frequent, family configurations.

In Chapter 5, "Children in Peer Groups," Kenneth H. Rubin, William M. Bukowski, and Julie C. Bowker discuss

children's peer interactions, relationships, and groups. Using a multilevel model, they describe conceptually how various peer relationships, such as friendship, popularity, and acceptance/rejection, are integrally related, how they are shaped by individual characteristics, culture, and contexts, and how they influence children's development. The authors give careful consideration throughout to issues of measurement and the reciprocal nature of individual attributes and peer relationships.

The third part of Volume 4 sets children in their most common everyday circumstances of institutional childcare and schools and public domains of activities, work, and media. In Chapter 6, "Early Childcare and Education," Margaret Burchinal, Katherine Magnuson, Douglas Powell, and Sandra Soliday Hong review nonparental care today, and use the dimensions of childcare—use, type, quality, and quantity—to describe early childhood experiences. They also address strategies that ensure quality and access to childcare including via public policy.

In Chapter 7, "Children at School," Robert Crosnoe and Aprile D. Benner attend to the role of schools in children's development and the significance of schooling in children's lives. They consider links between education and inequality, schools as educational institutions, and social, emotional, and academic outcomes of schooling. School structure, composition, and curriculum and instruction are all central issues for children, as are children's social relationships in school. Throughout the chapter, Crosnoe and Benner also address desegregation, school transitions, and public health in schools.

In Chapter 8, "Children's Organized Activities," Deborah Lowe Vandell, Reed W. Larson, Joseph L. Mahoney, and Tyler W. Watts delineate children's organized activities in historical and global contexts. Children engage in a breadth of activities, whose prevalence, processes, quality, and selection are all important to their development. Child, family, and program characteristics predict children's participation in organized activities. Vandell and colleagues cover after-school programs, extracurricular activities, unsupervised out-of-school time, self-care, and unsupervised time with peers.

In Chapter 9, "Children at Work," Jeremy Staff, Arnaldo Mont'Alvao, and Jeylan T. Mortimer review demographic precursors of child and adolescent employment and the sectors where children work. They then survey perspectives on children's work, including whether children and adolescents should work, the effects of paid work on adolescent achievement and adjustment, and the injurious as well as beneficial consequences of work for children.

In Chapter 10, "Children and Digital Media," Sandra L. Calvert reviews parasocial relationships and interactions when children go online. She examines the history and evolution of media platforms, the ecology of the digital world, and media access. She then characterizes media exposure and the role of media in various domains of children's lives including imaginative play and creativity, sleep and concentration, violence, stereotyping, and health. Calvert concludes with policy issues related to early media exposure, the V-chip, and the commercialization of childhood.

The fourth section of Volume 4, which complements the third, examines children in their equally prevalent but more encompassing social and physical settings. In Chapter 11, "Children in Diverse Social Contexts," Velma McBride Murry, Nancy E. Hill, Dawn Witherspoon, Cady Berkel, and Deborah Bartz introduce implications of ethnicity for theory and research in child development. They then review demographic shifts in the United States, universal and cultural-specific parenting practices, and parenting multiethnic children in terms of identity, third cultures, adoptions, and developmental outcomes in academics and friendships.

In Chapter 12, "Children's Housing and Physical Environments," Robert H. Bradley shows how affordances of settings and the construction of life niches, in which housing quality, materials, water provision, sanitation, food storage/refrigeration, electricity, ventilation and cooking facilities, indoor and outdoor contaminants, noise, and crowding all contribute to children's development. In addition, he discusses materials at hand for play and equipment for physical activity, home literacy and numeracy environments, and other physical supports to the development of children.

In Chapter 13, "Children in Neighborhoods," Tama Leventhal, Veronique Dupéré, and Elizabeth Shuey provide a survey of how and why neighborhoods matter for children's development in terms of their socioeconomic structure as well as the institutional resources and social processes that exist within them. The authors also attend to how neighborhoods intersect with other contexts, namely families, schools, and peers, and also with key individual characteristics, such as gender, ethnicity, and biological/psychological vulnerabilities. The chapter concludes by addressing neighborhoods as a unit of intervention for improving children's development.

The fifth section of Volume 4 casts children and child development in even broader frameworks of socioeconomic class, medicine, law, government, war and disaster, culture, and history. In Chapter 14, "Children

#### 4 Children in Bioecological Landscapes of Development

and Socioeconomic Status,” Greg J. Duncan, Katherine Magnuson, and Elizabeth Votruba-Drzal define resources based on socioeconomic status (SES) in terms of family and parental income (poverty, wealth), schooling, and occupation. They point to macro trends in family SES and summarize what is known about SES and child development from within-family variation, natural experiments, and empirical research. From these considerations, the authors derive key policy implications.

In Chapter 15, “Children in Medical Settings,” Barry Zuckerman and Robert D. Keder summon an historical perspective on medical care for children, looking at selective impacts of the shifting epidemiology of childhood disease, the hospital environment, and disparities in health care and health. These authors adopt a life-course approach to health development beginning with the prenatal environment and include the material environment and stress, health behaviors, and maternal health as all related to children’s health. Zuckerman and Keder are concerned as well with primary care and prevention, and they discuss children with chronic illnesses and technology-dependent children.

In Chapter 16, “Children and the Law,” Elizabeth Cauffman, Elizabeth Shulman, Jordan Bechtold, and Laurence Steinberg undertake to review the legal treatment of children and the family, including children in custody decisions, adoption, foster care, and the termination of parental rights. They look at the law with respect to children as plaintiffs and emancipated minors; they review zero-tolerance policies and the school-to-prison pipeline, children and adolescents in the justice system, the legal regulation of minors’ medical decision-making capabilities, and exceptions to parental authority in judging children’s maturity in medical and societal contexts.

In Chapter 17, “Children and Government,” Kenneth A. Dodge and Ron Haskins underscore the multiple serious roles of government in children’s lives. They serially address the problems of poverty and inequality, government programs for children, Social Security, the war on poverty, and government spending on children. A broad swath of government policies for children (including economic and budget constraints) falls under their purview, and Dodge and Haskins conclude with a plea for evidence-based policy making.

In Chapter 18, “Children in War and Disaster,” Ann S. Masten, Angela J. Narayan, Wendy K. Silverman, and Joy D. Osofsky underscore the challenges children face from war and natural and technological disasters. They review effects of variation in exposure, determinants of exposure, and diversity of responses. The outcomes for children are

set in terms of risk and resilience models, and the authors also analyze cascading consequences and the intergenerational transmission of trauma. Masten and colleagues review intervention and prevention research strategies to remediate these debilitating circumstances on children.

In Chapter 19, “Children and Cultural Context,” Jacqueline J. Goodnow and Jeanette A. Lawrence outline the meanings of culture and cultural level influences on children. They cover universals as well as situational bases of similarity and difference; common units of analysis in place, activities, and people; continuity and change; and uniformity and diversity. They also consider influences from single and multiple cultural contexts and acculturation for children’s development.

In Chapter 20, “Children in History,” Peter N. Stearns looks at the emergence of the history of childhood and childhood history as a field of study. Topics that dominate this perspective include periodization of the life span, children in agricultural societies, the role of religion, and specific historical periods (such as the early modern centuries and modern industrial childhoods). Contemporary changes in non-Western societies and the globalization of childhood are other pivotal issues Stearns addresses.

The final chapter in Volume 4 provides an overview of the volume by focusing on appraisal and measurement. In Chapter 21, “Assessing Bioecological Influences,” Theodore D. Wachs revisits the bioecosystem structures surrounding the child, stressing methodological implications of the bioecological framework. He addresses children in real-world situations; the use of “social addresses”; integrating higher-order contexts, persons, and time into the study of proximal processes; and integrating across process, person, context, and time. Other topics include measurement precision, the utilization of cost-efficient ecological measures, interpretability, and applications of the process-person-context-time framework to intervention.

All of the chapters in Volume 4 generally adhere to the same overall organization in moving from (or between) theory to research to policy. They commonly adopt a relational developmental systems perspective as embodied in the bioecological approach. Each treatment covers historical ideas, a diversity of theoretical perspectives, research methodologies, developmental trajectories, emerging issues, and directions for future theory and research. Each focuses on research from the United States but includes the rest of the world as well. Where appropriate, each concludes with reflections on policy and calls to action for developmental scientists.

## CONCLUSIONS

The clear lesson imparted by chapters in Volume 4 of the *Handbook of Child Psychology and Developmental Science* is that children's development is dynamic, multifaceted, and complex. Failing to appreciate the many forces affecting development has impeded our understanding of children generally and specifically in the five spheres of influence overviewed by this volume. As these chapters illustrate, it is only by considering how each context contributes to development in relation to other contexts, in relation to person characteristics, and in relation to time that our field will move forward. All of the authors in Volume 4 are mindful of the complexity inherent across the bioecological landscapes of children's development. To realize their stated goals required a deep as well as a broad understanding of the full scope of children's development—moving beyond the comfort of one's own zone of expertise on a particular social ecology to incorporate wisdom from other areas of developmental science and other disciplines. It also required facility with a large, diverse, and sophisticated methodological toolbox. The authors of these chapters do not limit themselves to single measures, methods, or approaches.

These lessons are vital to progress in developmental science. They are also critical for producing research that informs policies and practices to improve children's health and well-being (Huston, 2008). The contexts of children's lives are often viewed as points of intervention. The call for evidence-based policy making echoes across chapters in Volume 4 and contributes to the contemporary dialectic. At least that is our goal.

## INTRODUCTION

The life course and human development has flourished as a field of study during the past quarter century, extending across substantive and theoretical boundaries (Mortimer & Shanahan, 2003), and now appears in many subfields of the social, behavioral, and medical sciences. With this change has come an increasing appreciation for linkages between changing contexts and human development.

---

We thank Ross Parke, Avshalom Caspi, and Richard Lerner for thoughtful reviews of the earliest version of this chapter (Elder, 1998a) and to Lilly Shanahan for her valuable review of the second version (Elder & Shanahan, 2006). Rainer Silbereisen provided a most helpful review of the present version. Our special thanks to the staff of the Carolina Population Center for preparation of the first two versions of the chapter under a grant from *Eunice Kennedy Shriver* National Institute of Child Health and Human Development (NIH/NRSA T32 HD07168) and to Terry Poythress for her preparation of this version.

The term *context* refers to the social embedding of individuals and typically entails study of biographical, historical, and ecological variations. The social concept of life course refers to a temporal pattern of age-graded events and roles that chart the social contours of biography, providing a proximal context for the dynamics of human development from conception and birth to death.

Conceptual and methodological breakthroughs associated with the interdisciplinary life course framework, coupled with the dramatic expansion of long-term longitudinal studies, have generated more research and knowledge than ever before about behavioral adaptations in real-world settings around the globe. We are also increasingly aware of people as agents of their own lives. New avenues of research have opened, and the future offers exciting promise for understanding how dynamic views of context and the person—including biological dimensions—interact to influence achievements, exposure to stressors, physical and psychological well-being, and social involvements.

This contextualization of lives and developmental processes occurs through the patterning of social roles, events, and age distinctions; and in a multilevel context of family/primary group, neighborhood, community, economic region, and country. The meaning of historical time and context stems in large part from the ecological process of place and its multiple levels (Bronfenbrenner, 1979). A distinctive feature of this ecology is its social inequalities of class, ethnicity, and gender. They are expressed across individual lives and the generations in cumulative dynamics of advantage and disadvantage through childhood, adolescence, and the adult years.

We begin this chapter by viewing the evolution of life course thinking as a response to the challenges that stem from following children into young adulthood, middle age, and late life. This chapter is also a product of the remarkable growth of these studies from the 1960s to the end of the century. Life course ideas in developmental science, social roles and relationships, and concepts of the age-graded life course are prominent in this conceptual advance. By the end of the 1990s, a new synthesis, linking theory on social relationships and age, had become a theoretical orientation on the social life course and its influences on human development in historical and ecologically defined contexts. Multiple lives are interdependent in this developmental process.

The elementary concepts and perspectives of life-course theory are surveyed next, with emphasis on the individual life course, its institutionalized pathways, and its social and developmental trajectories and transitions. Early research on social change in lives has generated a set of mechanisms that link lives and developmental dynamics to changing contexts. These mechanisms include the life stage of people when they encounter drastic change to their environment, the social imperatives that structure adaptations to new situations, the control cycle that life change initiates (loss of personal control prompts efforts to regain such control), and the tendency for new situations to accentuate matching dispositions. These mechanisms are embedded in a conceptual framework on the life course and development that is defined by core paradigmatic principles—the life-long process of human development and aging, the timing of events in the life course, human agency, the interdependence of lives, and historical time and place. We discuss these mechanisms and principles by drawing on relevant theory and research.

Traditional thinking about the place or location of individuals is undergoing significant elaboration through ecological studies of human development. We turn to this

work and the theoretical implications of research on social contexts and the flow of families and children between them. Lives are lived by entering and leaving social roles, groups, and places. What factors influence these decisions? How can we understand human agency and contextual effects as parents construct the residential life course of their children? We investigate such questions through studies of place and migration in the lives of families and children. Genetic dispositions are relevant to this process, and we refer readers to our prior edition of this chapter (Elder & Shanahan, 2006) for such coverage.

Ecological influences are expressed in part through the impact of their historical time on lives and developmental processes. Although studies have tended to consider ecological effects apart from historical context, we attempt to inform this section of the chapter with both perspectives. Three topics highlight their interdependence: (1) considerations in studying changing times in lives; (2) societal change in lives, with a focus on contemporary China and its rural–urban divide; and (3) the impact of social discontinuities on the life course of young people during the dissolution of the Soviet Union into multiple sovereign states (late 1980s) and the reunification of Germany (1991). These two events transformed life in Eastern Europe, especially for the young who faced a new world of opportunities and stresses. We conclude this chapter by noting that the contextual frontier on human development is moving toward an integration of ecological and temporal perspectives.

The title of this chapter reflects its intergenerational, life course, and longitudinal perspective. Longitudinal samples enable us to follow children into adolescence and then to young adulthood with its social roles of advanced education, military service, parenthood, and work. According to this developmental life course perspective, children age into adulthood and its family roles, and parents eventually become grandparents. At any point in the life span, all ages are commonly represented in a person's social world. The developmental significance of early life experience becomes most fully understood in the context of the later years.

## THE DEVELOPMENT OF LIFE COURSE THEORY

The magnitude of intellectual development in life course studies is suggested by considering studies of person and society during the 1950s. In his widely read *The Sociological Imagination*, C. Wright Mills (1959) encouraged “the study of biography, of history, and of the problems

of their intersection within social structure” (p. 149). Mills started with the individual and asked what features of society produce such a person. He argued that the seemingly “personal problems” of one’s biography are better understood as repercussions of broad social tensions. He had few empirical examples, however, and was not concerned with dynamic views of person and context. Rather, he focused on types of society and adult behavioral patterns, with little recognition of social change, development and aging, or even human diversity. In this age of the cross-sectional survey, studies that followed children and adults over part of their lives were very rare. This was especially true for longitudinal studies of people in their social and historical contexts. With this in mind, it is not surprising that a dynamic concept of the life course had not yet appeared in the scholarly literature and was not addressed in the seminars of leading graduate programs.

The unfolding story of life course theory up to the present owes much to path-breaking studies that were launched more than 80 years ago at the Institute of Child Welfare (now Human Development) at the University of California in Berkeley: The Oakland Growth Study (birth years 1920 to 1921) and the Berkeley Growth and Guidance Studies (birth years 1928 to 1929). These studies were launched around 1930–1931. When the studies began, no one could have imagined what they eventually would mean for the field of human development. The original investigators did not envision research that extended into the study members’ adult years, let alone into the later years of middle and old age.

There were many reasons for this focus on childhood and adolescence. Except for support from the Laura Spelman Rockefeller Foundation, funds for longitudinal studies were virtually nonexistent. The National Institutes of Health (NIH), major funders of such studies today, were not established until after World War II. With support from NIH, the classic Framingham Longitudinal Heart Study of the adult years was launched in 1946 and has evolved into a multigenerational project. However, the idea of adult development had not yet captured the attention of social, behavioral, and medical science. A mature field of adult development and aging was still decades away from becoming a reality. In the United States, the National Institute of Aging was not established until the mid-1970s.

Nonetheless, these barriers did not restrict the studies from continuing into the adult years and middle age. The Institute of Human Development contacted members of the Oakland Growth Study for interviews in the late

1950s, and another follow-up, scheduled in 1972 to 1973, joined the lives of all study members, some parents, and offspring, in an intergenerational framework. The Berkeley Guidance and Growth Studies became part of this follow-up. By the 1970s, Block (with the assistance of Haan; see Block & Haan, 1971), had completed a pioneering longitudinal study focused on continuity and change in personality from early adolescence to the middle years in the lives of the Oakland and Berkeley study members. Also during the 1970s, Vaillant (1977) followed a panel of Harvard men (recruited as students between 1939 and 1942, known as the W. T. Grant Study) into the middle years of adulthood, assessing mechanisms of defense and coping.

Another study at the Institute of Human Development (Elder, 1974/1999) placed the lives of members of the Oakland Growth Study and Berkeley Guidance Study in the Great Depression and traced the influence of hardship on family life, careers, and health up to midlife. Using data from a retrospective life history survey, this study also investigated the impact of military service in World War II and the Korean War on men’s lives. To cap off this active decade, investigators at the institute conducted a multifaceted study that revealed patterns of continuity and change in social roles, health, and personality, with a distinctive emphasis on life patterns across the middle years (Eichorn, Clausen, Haan, Honzik, & Mussen, 1981). Both historical cohort comparisons and intergenerational connections were part of this project.

At Stanford University, a research team headed by Robert Sears actively followed members of the Lewis Terman sample of talented children into their later years. The Terman Study had become the oldest, active longitudinal study at the time, with birth years extending from 1903 to the 1920s. By the 1990s, the project had assembled 13 waves of data spanning 70 years (Holahan & Sears, 1995), and research was beginning to show the historical imprint of the times on the study members’ lives, from the 1920s to the post–World War II years and into old age (Crosnoe & Elder, 2004; Shanahan & Elder, 2002). Over 40% of the men entered military service during World War II and 25% were involved in war industries on the home front (Elder, Pavalko, & Clipp, 1993). The lives of women in the Terman sample vividly reflect the gender-role constraints of society on their employment.

This extension of the child samples to the adult years provided an initial momentum for the scientific study of adult development and sharpened awareness of the need for a different research paradigm that would pay attention

to human development beyond childhood and to contexts beyond the family. Such work offered great promise for illuminating the intergenerational dynamics of parents and their children. The extension also enabled documentation of the implications of early childhood experience for health in later life, a research domain of major scientific significance in the 21st century (see Herd, Robert, & House, 2011). Child-based models of development had little to offer because they did not address development and aging in the adult life course and were not concerned with changing social contexts. For the most part, the Oakland and Berkeley studies of continuity and change from childhood to the adult years were limited to evidence of correlational patterns between measures at time 1 and time 2 (Jones, Bayley, Macfarlane, & Honzik, 1971). The intervening years and their mechanisms remained a “black box.” Little, if anything, could be learned about linking events and processes from such analysis.

This observation also applies to Kagan and Moss (1962) who studied children in the Fels Longitudinal Study from “birth to maturity” by using correlation coefficients to depict behavioral stability across the years. Their approach ignored the diverse paths children take into adult life. By age 23, some of the study members followed a path to college, full-time employment, and marriage, and others entered military service or mixed employment and education. The timing of such transitions was important in determining their meaning and implications. For example, adolescent marriage and parenting are coupled with more social and economic constraints than the same transitions that follow a normative timetable, whereas late family formation maximizes the disruptive effect of young children. However, these considerations of timing and context—so richly descriptive of lives—were of little interest. In large part, this inattention reflected the view that continuity of behaviors and psychological dispositions required little explanation aside from the label “stability.”

Empirical studies of children into the adult and midlife years revealed major limitations to conventional knowledge of human development, which, in turn, posed major challenges for the future study of behavior:

- To replace child-based, “ontogenetic” accounts of development with models that apply to development and aging over the life course.
- To think about how human lives are organized socially and develop over time, exhibiting patterns of constancy and change.

- To relate lives to an ever-changing society, with emphasis on the developmental effects of social change and transitions.

As a whole, these challenges represent a view of human development advocated by proponents of contextualized development (e.g., Cairns & Cairns, 2006) and by the early Chicago school of sociology (Abbott, 1997), especially William I. Thomas. In the first decades of the twentieth century, a time of transformation in U.S. society, Thomas made a persuasive case for studying social change as “experiments of nature” in the lives of immigrants and children. Inspired by *The Polish Peasant in Europe and America* (Thomas & Znaniecki, 1918), researchers began to use life-record data to investigate the impact of social change. Before most of the innovative longitudinal studies had been launched, Thomas urged in the mid-1920s that priority be given to “the longitudinal approach to life history” (Volkart, 1951, p. 593). He claimed that studies should investigate “many types of individuals with regard to their experiences and various past periods of life in different situations” and follow “groups of individuals in the future, getting a continuous record of experiences as they occur.”

Social transformations of the 20th century raised many questions about historical variations beyond family life and kinship, such as schools, neighborhoods, and communities. In the classic Middletown studies (Lynd & Lynd, 1929, 1937), findings on families during the 1920s seemed to have little relevance to family life in the Great Depression. Life course theory emerged in response to such issues and to the challenge of an aging population as well as the rapid growth of longitudinal studies. In the terminology of this chapter, the life course refers most broadly to a theoretical orientation (or paradigm) that provides a framework for the study of changing lives in changing contexts. To use the distinction of Merton (1968), theoretical orientations establish a common field of inquiry by defining a framework that guides research in terms of problem identification and formulation, variable selection and rationales, and strategies of research design and analysis.

Based in large part on sociocultural theories of age and social relationships (Elder, 1975; Neugarten, 1968; Ryder, 1965), the concept of life course refers to a sequence of age-graded events and roles that defines the sociological contours of biography. A sociocultural perspective gives emphasis to the social meanings of age. Birth, puberty, and death are biological facts, but their meanings in the life course are social facts or constructions. Age distinctions

are expressed in expectations about the timing and order of a transition or change in state, whether relatively early, on time, or late. The life course can be linked historically to specific transitions and to the meanings of cohort membership (Riley, Johnson, & Foner, 1972). Birth year locates people in specific birth cohorts and thus according to particular social changes. The social life course of individuals is embedded within specific birth cohorts and their ecological dynamics. These dynamics may take the form of cumulative processes of life course inequality.

These dynamics may be expressed as cumulative processes of social inequality from early childhood into the adult life course. Disparities in socioeconomic status, ethnicity, and gender can initiate processes of disadvantage or advantage that increasingly differentiate people over the life course. There are numerous scenarios of cumulative disadvantage, such as the early death of a parent, which results in a child's depressed feelings, behavior problems in school, erratic attendance, and the eventual loss of opportunity. Potential turning points along this life course can liberate youth from the grip of this negative dynamic such as through residential change that improves family life and the school environment (Wachs, Chapter 21, this *Handbook*, this volume).

G. H. Elder, this chapter's senior author, encountered such ideas about age and the life course in the 1960s, shortly after arriving at the Institute of Human Development (at UC Berkeley in 1962) to work with sociologist J. A. Clausen on the Oakland Growth Study. The dramatic changes of families and individual lives across the 1930s focused his attention on the patterning of lives and connections to a changing socioeconomic environment. Codes that captured trajectories were needed for people's lives instead of the conventional codes for status at a point in time such as socioeconomic status (SES). The link between age and time provided an important step in this direction. The resulting perspective suggested a way of thinking about the social construction of individual lives, along with ideas from the life-history tradition of the early Chicago School of Sociology. *Children of the Great Depression* (Elder, 1974/1999) represented the published version of this initial effort to fashion a life course framework.

Since its inception, the field of life course studies has expanded its purview beyond historical variations to include dynamic contextual variations within and between cohorts—the ecology of human development (Bronfenbrenner, 1979). Studies revealed dramatic cohort diversity with respect to poverty experiences and economic

fortunes, residential mobility, and neighborhood composition (Shanahan, Sulloway, & Hofer, 2000). Each life is marked by social change in these respects, and the life course framework is useful in studying how these dynamics shape lives and also how the social aggregate of individual life patterns affect social institutions, such as schools and labor markets.

### Bringing Contexts and Temporality to Lives and Development

The socioeconomic context of human development became a compelling social issue in the hard times of the Great Depression (1930s), but the economic crisis did not place this theme on the research agenda of the California longitudinal studies, the Oakland and Berkeley projects (see Duncan, Magnusson, & Votruba-Drzal, Chapter 14, this *Handbook*, this volume). They continued to reflect the research interests of the investigators rather than the economic depression. The Oakland Growth Study focused on physical growth and development, a long-time interest of a codirector, and employed methods of social observation in field settings. The Berkeley Study under Jean Macfarlane's leadership stressed the collection of data on family relationships and parental influences. Data collection for both projects included information on the socioeconomics of family life, but the investigators did not make effective use of the data in empirical research. It would be difficult to know from study publications that the Oakland and Berkeley children were growing up during the Great Depression.

The absence of a socioeconomic-cultural context beyond the immediate family in the Berkeley Study was noted by a faculty member whom Macfarlane had invited to one of the study's seminars. In a letter dated September 25, 1941, this person (identity unknown) expressed dismay concerning the neglect of material culture. In his view, family was overemphasized at the expense of other cultural factors. With reference to the case of a young girl in the study, he observed that "she is described as a person of almost any age in almost any society." Despite an inadequate contextualization of development, the early Berkeley and Oakland studies made sure that measures of the material culture were used in data collection across the 1930s and thus ensured that these data would be available to subsequent generations of investigators. As a result, the senior author was able to carry out a longitudinal study of "children growing up in the Great Depression." The Oakland data archive included socioeconomic information for 1929

(before family income change) and 1933, the very worst year of the economic depression.

This Great Depression project evolved from the senior author's research affiliation with the Oakland study at the Institute of Human Development in the 1960s. Trained in both sociology and psychology, Elder had been hired by the new director of the institute, sociologist Clausen, to work toward a design for coding the Oakland data. The ever-changing families of the Oakland Study sensitized Elder to the need for temporal concepts and measures and focused his attention on "ways of thinking about social change, life pathways, and individual development" (Elder, 1998b, p. 1). But how to conceptualize them? His prior work on adolescence and the transition to adulthood introduced him to the research of Neugarten (1968) on the meanings of age and age-graded expectations and timetables. This anthology includes Neugarten's pioneering papers from the 1950s and early 1960s. Other age concepts on historical time and timing were associated with birth year and age cohorts, as developed by Ryder (1965).

Role theory and the social capital of linked lives provided another way to think of the life course and its relation to other lives. The concept of role transitions by life stage indicates whether the transitions are early or later in a person's life. Roles and their behavior could be viewed in terms of experiences that are brought to them and in terms of the time span of "being in that social role," as well as according to issues of continuity and discontinuity associated with leaving a role. Along with the traditions of life history and career studies, the concept of life cycle was perhaps the most prominent perspective on a person's life at the time, especially regarding family life. In a life cycle of generational succession, the young person is socialized to maturity, gives birth and nurtures members of the next generation, grows old, and dies. Each concept has relevance to a person's life path. Role theory, as well as the life cycle, became part of an effort at the Institute of Human Development to develop a theoretical approach to individual lives and human development that would be useful for a study of the Oakland cohort across the Great Depression. With family income available for 1929 and 1933, the Oakland study could assess the extent of socioeconomic deprivation and its consequences among families and the study members.

This approach to lives in changing times and places has evolved into a prominent theoretical orientation on the life course in the twenty-first century. Notable developments have occurred across the social and behavioral sciences, from sociology (Elder, 1974/1999, 1975, 1985; Riley et al., 1972), demography (Ryder, 1965), history (Hareven,

1978, 1982; Modell, 1989), and anthropology (Kertzer & Keith, 1984), to ecological models (Bronfenbrenner, 1979) and life-span developmental psychology (Baltes & Nesselroade, 1979). Major examples include:

*Recognition of a life course perspective on human development* that extends from the prenatal period to maturity, late life, and death. The rapid growth of longitudinal studies that link childhood to the adaptations of later life has facilitated what might be called a "whole life course" approach to human development and aging (Elder & Giele, 2009). An understanding of the trajectory of human development and aging begins in the prenatal years. This observation is a foundational theme of the Millennium National Longitudinal Study in the United Kingdom. The project was launched during 2000 and 2001 as a study of how the British people age from birth to old age and death.

- *Life-history calendars for the collection of retrospective accounts of life events* have been applied to numerous longitudinal studies (Brückner & Mayer, 1998; Caspi et al., 1996; Freedman, Thornton, Camburn, Alwin, & Young-DeMarco, 1988). Retrospective life history methods enable investigators to collect information on the life history of people and their world, though retrospection always entails some error of recall.
- *Greater appreciation for the necessity of longitudinal and contextually rich data* (Ferri, Bynner, & Wadsworth, 2003; Hauser, 2009; Phelps, Furstenberg, & Colby, 2002). In a special issue of *Science*, Butz and Torrey (2006) refer to the longitudinal study design as one of the greatest innovations of the 20th century in the social sciences—"a living observatory and potential laboratory augmented by case study and ethnography." Bynner (2014) describes the longitudinal survey as "the essential tool for meeting the challenges of a (developmental) science that needs to adapt continually in response to social, economic, technological, and political change."
- *Appropriate statistical techniques have been developed for multilevel, longitudinal studies.* They include hierarchical linear and trajectory models along with structural and dynamic person-variable and person-centered techniques (Bergman, Magnusson, & El-Khoury, 2003; Collins & Sayer, 2001; Little, Schnabel, & Baumert, 2000). Significant advances have also been made in the study of historical and cohort effects through new age-period-cohort methods that provide better estimates and identify explanatory mechanisms (Yang & Land, 2013). The past two decades have also witnessed major

advances in the study of “the ecology” of human development. Sampson (2012) has used the term *ecometrics* to refer to social observational methods in studying urban and rural places (see also Wachs, Chapter 21, this *Handbook*, this volume).

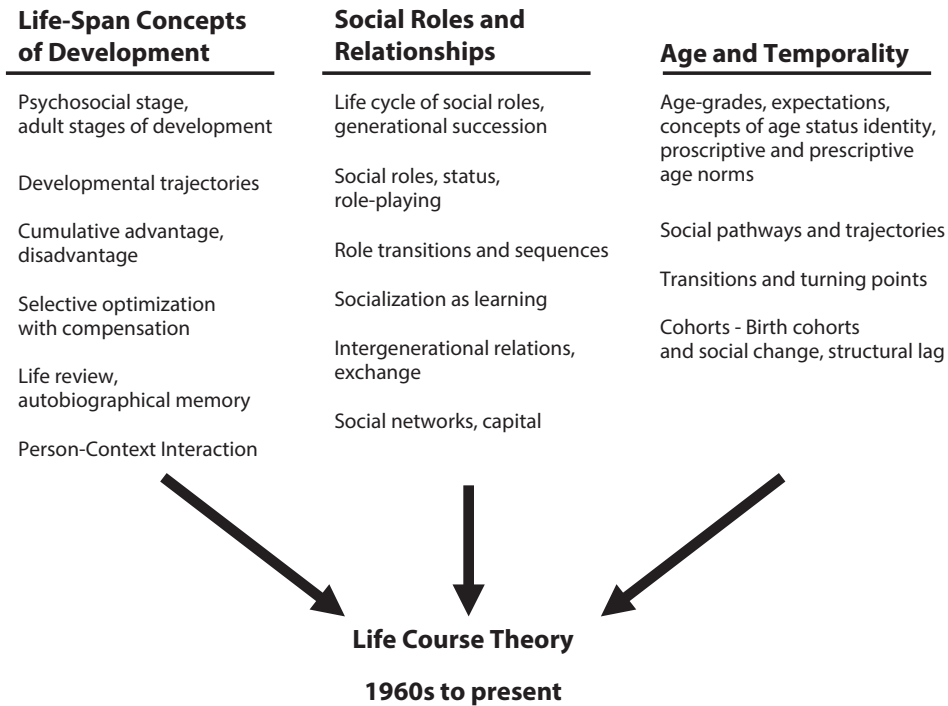

- *Cross-disciplinary models of collaboration*, particularly with psychology and history as well as biology and the medical sciences (Elder, Modell, & Parke, 1993; Levy & the Pave Team, 2005). These models include new and exciting developments in subfields devoted to the study of physical and emotional well-being (Halfon & Hochstein, 2002; Hertzman & Power, 2003; Kuh, Ben-Shlomo, Lynch, Hallqvist, & Power, 2003). New initiatives from the Maternal and Child Health Bureau emphasize the life course perspective, such as the formation of a Maternal and Child Health Life Course Research Network. The objective of the network is to facilitate life course studies that inform Maternal and Child Health programs, policy, and practice and improve “health outcomes for mothers and children.”
- *A growing awareness that*, beyond history and the differing experiences of cohorts, *social change may entail an ecological change within cohorts* through diverse life histories (Shanahan, Mortimer, & Kruger, 2002). Aspects of a social ecology are typically inter-correlated, and their synergistic interactions are critical to an understanding of time and place.

These developments represent significant advances in studies of the life course and human development. Life course theory today has much in common with interactionist thinking at the micro level, with its emphasis on transactions between person and ecology (see Magnusson & Stattin, 2006)—but it also attends to the organizations and reorganization of social structures and pathways through life. As might be expected, life course theory shares many objectives and concepts with Bronfenbrenner’s ecology of human development (1979; with Morris, 2006), especially its multilevel concept of the environment. However, life course models bring a more temporal perspective to the environment and individual. The life course paradigm also shares the ambition of life-span developmental psychology in rethinking the nature of human development and aging (Baltes, Lindenburg, & Staudinger, 2006), but it is more contextual in orientation and application. Indeed, the contextual limitations of the Oakland and Berkeley life-span studies in the early 1960s motivated efforts to place lives and developmental processes in historical time and social pathways.

These connections with life course theory and research add up to a much larger intellectual advance, one framed by relational developmental systems thinking in a multilevel, dynamic perspective known as developmental science. From the 1998 edition of the *Handbook of Child Psychology* and in the sixth edition, Lerner (2006, p. 6) observed that students of human development have witnessed “a sea change that perhaps qualifies as a true paradigm shift in what is thought of as the nature of human nature and in the appreciation of time, place, and individual diversity for understanding the laws of human behavior and development.” Consistent with the central theme of this chapter, Lerner asserted that “one must appreciate how variables associated with person, place, and time coalesce to shape the structure and function of behavior and its systematic and successive change” (2006, p. 7).

The principal traditions that led to an interdisciplinary framework of life course theory are illustrated by Figure 2.1: life-span development, social roles and relationships, and age and temporality. We begin with life-span concepts of development because this line of work prompted efforts to contextualize developmental processes across the life span. Two theoretical traditions in social science, social roles/relationships and age, provide a way to think about the social life course. Social roles and role transitions are basic elements of the life course, but they are timeless. That is, a role transition is not specific in terms of when it occurs. Chronological age brings time and timing to the social life course, and thus makes it more dynamic as a contextualization of development. Age data on birth year also locate individuals in historical time and in relation to ecological processes.

Life-span development refers in some ways to the longitudinal research that was underway at the Institute of Human Development when the senior author joined the staff to work with the Oakland Growth Study (in 1962). Bayley and Honzik were involved in longitudinal studies of intellectual development from childhood into the adult years (Jones et al., 1971). Other longitudinal studies focused on the stability of temperament dimensions from the early years into adulthood. Block had launched a program of research that used the California Q Sort to assess personality in adolescence and the adult years for a longitudinal study of life-span trajectories of personality. This project became *Lives Through Time* (Block & Haan, 1971). In method, most especially, this ambitious study represents a path-breaking example of a person-centered study of life-span trajectories of personality. However, this project, as well as others noted earlier, was seriously

**Figure 2.1** The emergence of life course theory: Research traditions and their concepts.

underdeveloped on the contextual side. None of them provided an understanding of the lived lives of the study members in historical time.

Pioneering work under the theme of life-span concepts features the studies and writings of Erikson (1950) on ego identity and psychosocial stages of development as well as the foundational contributions of Baltes (1997) to the evolution of life-span developmental psychology, from the late 1960s into the 21st century. This contribution includes his conceptualization of the process of selective optimization with compensation, a metatheory of development and aging discussed more fully in the pages to come. In a younger generation, Lerner (1982, 1991) emphasized the relative plasticity and agency of the organism, the multidirectionality of life-span development, and the lifelong interaction of person and social context. The concept of developmental task, perhaps first defined by Havighurst (1949), also represented a way of viewing development across socially defined life stages. The concept alerts the analyst to the possibility that different experiences and skills tend to be highly salient at different points in life. However, empirical evidence for distinct psychosocial stages is not compelling. The perceived or defined life course can change with aging through successive life reviews (Staudinger, 1989) in which the past is assessed in light of the present.

In the theoretical tradition of “social relations,” we come to a long prominent way of thinking about a person’s lived life, with a focus on the sequence of social roles, their socialization, and self or identity. The sequence establishes a life course that links the person to others. Central to this tradition is Merton (1968) on role sets and reference groups, Rosenberg (1979) on self-esteem, and Bronfenbrenner (1970) on socialization, to name a few. Early work in this tradition includes the studies of Thomas (Thomas & Znaniecki, 1918) on social roles and transitions in life histories, Mead (1934) on socialization and the self, Hughes (1971) on work and the self, Lewin (1948) on power-dependence relations, and Vygotsky (1978) on language, the self, and social relationships.

Studies of intergenerational relations have expanded from two to three and now even four generations, with important contributions from Jackson (2000) and his three-generation study of African Americans along with a rural Iowa longitudinal study of three generations (Elder & Conger, 2000). The most impressive multigeneration longitudinal study to date was initiated by Bengtson circa 1970 (Bengtson, Putney, & Harris, 2013) on contemporary issues of the generation gap. Launched in the greater Los Angeles region, this study has continued into the present century with four, and even five, living generations.

Several topics illustrate distinctive contributions to the third strand of life course theory—age and temporality. Every event in life is marked by an age, such as marriage and the birth of children. Birthday celebrations mark each new year for a young child who is surrounded by adults who are getting older. In the first volume of the *Annual Review of Sociology* (Elder, 1975), the senior author's essay focused on two life course perspectives based on age, the role of age and birth year in a cohort historical perspective, and a sociocultural perspective involving age expectations, identities, and norms. Social and cultural anthropologists, such as Mead (1963) and Linton (1942), observed and wrote about the role of age-graded societies and lives. Early contributions to the scholarship of age in the 1920s appear on the cohort level, as in the work of Mannheim (1952). Age as birth year locates people as members of a birth cohort in social history.

During the 1950s and 1960s, Neugarten (1968, 1996) at the University of Chicago's Committee on Human Development developed a social psychology of age across the life span. She explored concepts of age expectations and identities, standards, and norms in pioneering studies during the 1950s. In the 1970s, sociologist Riley (Riley et al., 1972) proposed a framework on age strata and cohorts for a macroscopic perspective on aging, drawing on Ryder's influential perspective (1965) regarding cohorts in the study of social change. A cohort perspective based on people born in a particular year or a specific historical time soon began to appear with some frequency, as in studies of women's work by Uhlenberg (1974), research on role sequences in the transition to adulthood by Hogan (1981), and *Birth and Fortune*, a volume by Easterlin (1987). In the field of social history, accounts of institutional and cultural change brought historical insights to the lives and pathways of young people (Modell, 1989) and adults (Hareven, 1978, 1982). With these brief overviews in mind, we turn to the development of life course theory, beginning with life-span concepts of development.

### Life-Span Concepts of Human Development

A number of efforts in the psychological sciences have been made during the post–World War II era to link developmental trajectories to social structure. However, research questions did not ask about the implications of environmental change for the developing individual.

The theory of psychosocial stages formulated by Erikson (1950) paid attention to cultural variations, but historians report little empirical support of his stages across

time and place (Mitterauer, 1993). In *The Seasons of a Man's Life*, Levinson (1978) outlined a theory of life structure that ignored variations in social structure and culture over historical time. Psychosocial transitions were affixed to age as if immutable to institutional change, such as the midlife transition between ages 40 and 45. For Erikson, Levinson, and other ontogenetic theorists, the starting point is a sequence of stages through which all persons must pass. This perspective views the social context as a “scene or setting” through which the person—loaded with his or her “natural predispositions”—must pass. By contrast, the life course paradigm views the interplay of social context and the organism as the formative process, making people who they are. Individuals do not “develop according to their natures” but, rather, they are continually produced, sustained, and changed by their social context (see Gottlieb, Wahlsten, & Lickliter, 2006).

Proponents of life-span developmental science addressed the challenges of such a view by seeking a perspective on development and aging across the life span that emphasized cultural influences and learned experiences or skills in patterns of aging. In theory, historical and cultural variations emerge as potentially influential sources of human adaptation and development. As Baltes (1979, p. 265) observed, “restricting developmental events to those which have the features of a biological growth concept of development is more of a hindrance than a help.”

Baltes (1993, 1994) played a lead role in the conceptual articulation of life-span development since the 1960s. More than most proponents of this perspective, he interacted with life course ideas and distinctions over the decades (see Baltes et al., 2006). One panel exchange between Baltes and Elder on life-span developmental psychology and life course theory was held at the 2004 Ghent meeting of the International Society of Behavioral Development.

The following propositions on life-span development are not new in themselves but they add up to a distinctive perspective:

- *Life-span development results from lifelong adaptive processes* in which some are cumulative and continuous, and others are discontinuous and innovative, showing little connection to prior events or processes.
- *Ontogenetic development is local, specific, and time bound*, so it is never fully adaptive. There is no pure advance or loss in development.
- *Age-graded influences are most important in the dependency years*, childhood/adolescence and old age, but

history-graded and nonnormative influences are most consequential across the early and middle years of adulthood.

- *Changes occur in relation to positive and negative events, gains, and losses*, with the likelihood of expected losses increasing. Biological resources decline over the life span, but cultural resources may increase through the cultivation of wisdom and problem solving.
- *Life-span development entails selection, optimization, and compensation*. These mechanisms seek to maximize gains and minimize losses or declines. Selective optimization with compensation represents a “life-span model of psychological nature of human aging and the ubiquitous, age-related shift toward a less positive balance of gains and losses” (Baltes, 1993, p. 590).

The way these mechanisms or strategies work in later life is illustrated by an interview with the renowned concert pianist Arthur Rubenstein. When asked how he remained a successful pianist in his later years, Rubenstein referred to three strategies: “(1) he performed fewer pieces, (2) he now practiced each more frequently, and (3) he introduced more *ritardandos* in his playing between fast segments, so that the playing sounded faster than it was” (Baltes, 1993, p. 590). The strategy of selection is illustrated by Rubenstein’s concentration on fewer pieces, the more frequent practice illustrates the use of optimization, and the increasing reliance on contrast in speed exemplifies a strategy of compensation.

This psychological model of successful aging has relevance for development at all ages including childhood and adolescence. Adaptations in adolescence can be viewed through the guidelines of selective optimization in which gains are maximized and risks, losses, or deprivation are minimized (see Heckhausen, Wrosch, & Schulz, 2010). Youth select activities in which they are competent (e.g., athletics, academics, military service, or street life) and optimize benefits through an investment of resources, time, energy, and relationships. Life-span developmentalists such as Baltes have enriched our thinking about development and aging across the life course, and they have given some attention to the role of social, cultural, and historical forces in developmental processes.

However, their perspective on life-span development generally fails to apprehend social structure as a constitutive force in development. The problem stems from the framework’s conceptualization of context—it refers to age-graded, history-graded, or nonnormative influences. Age-graded influences shape individual development in largely normative ways for all people; history-graded

influences shape development in different ways for different cohorts; and nonnormative influences reflect idiosyncrasies (such as physical) (see Stearns, Chapter 20, this *Handbook*, this volume). This conceptualization is unduly restrictive in two senses. First, within-cohort variability largely reflects non-normative influences, which are not easily subject to scientific study (Dannefer, 1984). As a result, the social basis for within-cohort differences becomes a residual category. Second, as Mayer (2004) noted, life-span psychology views historical and nonnormative influences as idiographic (i.e., unique, non-repeating), leaving only age-graded influences, which are thought to be largely based on biology and age norms. Because the larger social forces that lead to age norms are of little interest, within-cohort regularities in behavior are explained solely by personal attributes (biology and institutionalized norms).

In the final analysis, the study of contextual influences in cohorts is hampered because it produces largely invariant patterns through such age-graded influences, or it cannot be studied because of its seemingly random nature. Some of these issues were dampened by the initial enthusiasm of Baltes for cohort studies and the analysis of interindividual differences in intraindividual change. But in retrospect, it appears that Baltes’s volume on cohort studies with Nesselroade in 1979 was followed by a decline in his regard for them. Nevertheless, some life-span investigators (e.g., Heckhausen, 1999) have continued to assess the link between broader social contexts and individual functioning across the life course. In the field of developmental science, there are numerous examples of this line of work, such as Silbereisen’s Jena research program on social change and human development, with its featured research on the impact of German Unification. We provide an overview of this research on pages 44–47.

### Social Relations: Roles and Sequences

The second column of Figure 2.1 refers to how an individual’s life pattern is structured by multiple role sequences, their transitions, and “linked lives.” Transitions into and out of social roles across the life span entail both social and personal changes in status and identity (Glaser & Strauss, 1971). Changes in major social roles, such as from living with parents in a dependent role and then moving to an independent household with a spouse, generally represent a change in life stage to the status of an adult. This process involves human agency in the selection of role options as well as social influences and constraints.

The life cycle represented a dominant model of the social life span from the early 1900s to the 1960s. In its most precise definition, *life cycle* refers to a sequence of roles in parenting, from the birth of children through their maturity and departure from the home to the birth of their own children. In a life cycle of generational succession, newborns are socialized to maturity, give birth to the next generation, grow old, and die. The cycle is repeated from one generation to the next in a human population (O'Rand & Krecker, 1990). As reproductive cycles, the life cycle can vary greatly in tempo through variations in the timing of childbirth, whether very early or late in life between the generations.

Role change in one generation has consequences across the generations, ascending and descending (Burton, 1985). When the eldest daughter has a child before the age of 13, her mother may become a grandmother before the age of 30 and a great-grandmother before the age of 50. A sequence of early childbearing across the generations weakens the generational and age foundation for family authority and social control. Family authority over a newborn child tends to shift upward from the teenage mother to the grandmother. By contrast, late childbearing slows the cycle and minimizes age similarities across adjacent generations. Entry into later-life relationships may provide the social control to stabilize a person's life and minimize involvement in unconventional and dangerous activities. In their Boston sample, Sampson and Laub (1993) reported that bonds to conventional figures provided a route of escape from delinquency for a number of men with a childhood history of delinquency.

During the familistic post-World War II years, the life cycle became well known as the family cycle, through the writings of Glick and Hill, as a set of ordered stages of parenthood defined primarily by variations in family composition and size (Elder, 1978). Major transition points included courtship, engagement, marriage, birth of the first and last child, the children's transitions in school, departure of the eldest and youngest child from the home, and marital dissolution through the death of one spouse. This sequence of life stages is based on a concept of marriage that bears children and remains intact up to old age and death. Deviant patterns are excluded, such as marriages without children, those preceded by children, the widowed and divorced whether with or without children, and serial marriages (see also Ganong, Coleman, & Russell, Chapter 4, this *Handbook*, this volume).

The emerging complexity of contemporary family life did not fit this concept of the life cycle. First, childbearing

has become increasingly uncoupled from marriage. Children are increasingly born prior to marriage or outside of marriage altogether. In the United States, the prevalence of divorce from the 1960s to the present has led to multiple families in a person's life and to the likelihood that most children will experience a single-parent household before they enter adulthood (e.g., Fussell, 2002). Even with these limitations, the life-cycle concept and its family cycle tell us much about the social matrix of one's life—the linked lives. They knit together a full array of family relationships through life stages and the generations, providing insight into family processes such as socialization and social control over the life span. They connect the developing person and his or her career.

Another feature of this complexity emerged as mothers increased their involvement in the labor force over the last quarter of the 20th century. This upward trend posed another limitation for the life-cycle framework and suggested the need for a dual career perspective to study these families and the lives of their members. However, even in the early 1970s, a prime era for life-cycle research, Young and Willmott (1973) found that studies of work and family were typically proceeding along separate paths with no substantial effort to investigate their interdependence and coordination problems. This observation contrasts rather strikingly today with a flourishing study of the interlocking trajectories of work and family life (Drobnic, Blossfield, & Rohwer, 1999; Moen, 2003). Life course models have been constructed to capture this dynamic.

In all of these ways, the life cycle of family roles entailed shortcomings in thinking about the life course of children and their parents. The temporality of age addresses some of these limitations by supplementing its relational approach with a temporal and contextual perspective. Entry into social roles in the life cycle may follow a certain temporal order, but these role transitions are not temporally located in a person's life. For example, a life-cycle model of a person's life might locate marriage before the first birth, but it would not indicate whether the marriage occurred at 20 or 40 years. The evidence suggests that event timing matters because social timetables, age norms, and age-graded sanctions influence behavior.

The concept of generation in the life-cycle perspective occupies a common historical location relative to historical events such as the economic recession that occurred between 1980 and 1983. A parent generation may have birth years that span 30 years, a period that could include eras of economic boom and bust in the 20th century. As such, it is apparent that generational role or position

cannot offer a precise way of connecting people's lives to changes in society, whereas age and/or birth year does offer such a perspective.

A social role-generation perspective and a temporal-contextual perspective based on age are complementary in thinking about the social life course embedded in a social-historical context. One of the best research examples of why this convergence is important comes from *The Polish Peasant in Europe and America* (Thomas & Znaniecki, 1918). This pioneering work was described in the 1960s as "the greatest single study done thus far by an American sociologist" (Nisbet, 1969, p. 316). The lives of immigrants embodied the discontinuities of the age; they were socialized for a world that had become only a memory. The societies they left and entered—the Old World and the New—presented contrasting pathways for individual adaptation and development. Matters of social and historical time are clearly relevant to this project, and yet, Thomas and Znaniecki were largely insensitive to them.

For many years, the social role/life cycle perspective continued to offer a valuable way of thinking about the social patterning and interdependence of lives, although limited in a number of respects that we have noted. In the 1970s, this approach was combined with new understandings of age to form life course models with the analytic virtues of both theoretical traditions: linked lives across the life span and generations, coupled with the temporality of age and context through an age-graded sequence of events and social roles, embedded in birth cohorts. These models were also enriched by life-span concepts of human development that feature the agency of individuals in constructing their lives.

### Age and the Life Course

A greater understanding of the meanings of age in people's lives during the 1950s and 1960s provided a way of thinking about the relation of historical location and its ecology to life patterns with its events and social roles across the life span. The link between age/birth year and historical time occurred in large part through the influential essay of Ryder (1965) on the cohort as a way of studying social change and its effects on people and populations. Riley et al. wrote a comprehensive work on this topic in *Aging and Society* (1972). This important volume relates birth cohorts and age-graded roles. Both Ryder and Riley provided conceptual models for this relatively undeveloped field of study at the time.

Before Ryder's essay on cohorts, the birth years of study members in surveys and longitudinal studies were most unlikely to be considered a way to locate people in history. Even the historical context of empirical studies received minimal attention (Thernstrom, 1964), although Bronfenbrenner (1958) demonstrated the importance of doing so by showing that the findings of two surveys of social class and childrearing made sense when one noted that they were carried out in different eras of the 20th century. Ryder's influential essay increased the sensitivity of social scientists to the historical context of lives and their birth cohorts.

In addition, the surge of newly initiated longitudinal studies provided a dynamic approach to age and its meanings across the life span. This fresh perspective on age reflected the pioneering work of Neugarten (Neugarten, 1968, 1996; Neugarten & Danan, 1973) at the University of Chicago's Committee on Human Development during the late 1950s and 1960s. Her work with colleagues revealed the variability of lives. People do not move across their lives in concert with others of the same age. They vary in the age at which they enter and leave key social roles.

In what follows, we more fully describe contributions to the two research traditions on age and the life course, the link between age cohorts and an age-graded perspective on life patterns. In combination, they bring temporality and context to a social perspective on the life course.

### A Cohort-Historical Perspective

Birth year or date of entry into a system such as school graduation locates the individual according to historical time and related social change. With age peers in the cohort, the individual is exposed to a particular segment of historical experience as he or she moves across age-graded roles. To grasp the meaning and implications of birth year and cohort membership, the investigator specifies the distinctive historical events and processes at the time as well as characteristics of the cohort, such as its size and composition. These characteristics are themselves a consequence of historical changes in birth and death rates, immigration, and migration.

As successive cohorts encounter the same historical event, they do so at different life stages, defined by social roles, maturity, and life experiences. This means that adjacent cohorts bring different life experiences to the change. Ryder (1965, p. 846) stressed this life-stage principle in his account of cohort differences in the life course. As each cohort encounters a historical event, whether depression or prosperity, it "is distinctively marked by the career

stage it occupies.” This mark may take different forms. One type of outcome involves cohort differences, such as the less adverse effects of hardship among the older Oakland boys in the Great Depression study than among the much younger Berkeley boys (Elder, 1974/1999). For another perspective, consider age at entry into World War II. The age range spanned 20 years: Some recruits were launching their adult lives, whereas others were in their mid-30s with families and careers.

In addition to cohort effects, history may take the form of a period effect when the influence of a historical change is relatively uniform across all age groups. Rodgers and Thornton (1985) found that marriage and divorce rates did not vary across the 20th century by age groups. On rates of marital dissolution, they observed that “the big picture is one of overwhelmingly historical effects that influenced all subgroups of the population substantially and surprisingly equally” (p. 29). Concerning divorce, they referred especially to the rising level up to the 1930s, the decline in the Great Depression era, a rapid recovery to the extraordinary peak of divorce in the mid-1940s, and then to the upward trend during the 1960s and 1970s. The precise explanation for such period influences was not determined.

When theory and research focus on the cohort level, the linking mechanisms between lives and changing times have been difficult to pin down. Cohorts can be merely “black boxes” with no information on causal dynamics and linkages. Speculation frequently takes the place of disciplined explication. Another issue concerns environmental variation within cohorts. Thus, some children may be exposed to the economic stress of a plant closing, whereas others are insulated from such stresses by their father’s different place of employment. In response to such heterogeneity, more studies are investigating specific types of differential social change within a single birth cohort (George, 2009).

*The age-graded life course.* During the late 1950s and early 1960s, Neugarten directed a research program that featured the concept of a normative timetable and individual deviations from age expectations. The timetable refers to the social meanings of age, as defined by people’s expectations regarding events and social roles. In theory, age expectations specify appropriate times for major transitions, and violations of them may lead to adverse consequences, from informal sanctions to lost opportunities. There is an appropriate time for entering school, leaving home, getting married, having children, and retiring from the labor force. With colleagues (Neugarten, Moore, & Lowe, 1965), Neugarten observed a high degree of consensus on age norms across some 15 age-related

characteristics in samples of middle-class adults. The data not only show a general agreement among men and women on the appropriate age for a woman to marry but also support the hypothesis that informal sanctions are associated with relatively early and late marriage. Moreover, the women were aware if they were on time, late, or early with respect to marriage and other major role transitions.

This pioneering line of research has been extended in fruitful ways by Settersten. He and Hagestad carried out a study of the perceived deadlines in both family and education/work transitions in the 1990s among men and women in the Chicago area (Settersten, 2003). A large majority of the respondents claimed that there were deadlines for this type of transition, but Settersten noted that the big challenge in this area is to clarify what is meant by the term *age norm*. Research on age norms has been limited by the fact that the identification of an age norm typically requires the observation of a relevant sanction—the two phenomena cannot be studied independently. Settersten also made the point that deviations from age expectations and timetables may entail consequences that have nothing to do with informal sanctions as we know them. A very late marriage, for example, increases the risk of childlessness.

For many decades, age-grades were inferred as possessing common significance for members without evidence of their meaning to these individuals. When do young people assume the perspective of an adult? Neugarten was one of the first developmentalists to pose such questions, and she did this work with a sample of adults during the 1950s. She found (see Neugarten & Peterson, 1957) that men with lower socioeconomic status tended to perceive a more rapid passage through the major age divisions of life than did middle-class men: Maturity, middle age, and old age came earlier in the lower SES strata, owing perhaps to class-linked laboring jobs and stresses. The men who relied on mental skills in a sedentary occupation foresaw a relatively long period of productivity, whereas the manual worker expected a relatively short span of productive activity, followed by retirement.

Contemporary studies of the meanings of age status have focused on the transition to adulthood. Entry into family roles (marital and especially parental) are typically most predictive of an adult definition of *self*, and this is what Shanahan, Mortimer, and Porfeli (2005) observed from a contemporary longitudinal study of the young adult transition in an urban sample of midwestern Americans. It is also the case that entry into these roles has been delayed significantly across the 20th century, owing in part to employment and advanced education opportunities.

Consistent with this interpretation, Americans in their 20s who perceived themselves to be relatively late in the transition to adulthood were found to be most committed to an advanced path of higher education in a national longitudinal study (Benson & Elder, 2011). Young people who defined themselves as adults ranked lowest in socioeconomic origin and educational plans. Similar to Neugarten and Peterson's finding of life course acceleration in later life among adults in the lower SES, these young people were following an accelerated subjective path to adult status.

Research on age and the subjective life course represents an example of how investigations of the meanings of age have opened up a way to think about identity in a context of changing roles across the life course. The sequence of age-graded roles and statuses depicts a social trajectory of the life course, and its transitions from one role to another that influence how young people view themselves and others.

### Converging Research Traditions in Life Course Theory

Contemporary theory on the life course and its social dimensions differs from the perspectives of an earlier era by joining the life-cycle processes of social relationships with the temporal and contextual aspects of age. In *Children of the Great Depression* (Elder, 1974/1999), the social role perspective was combined with the analytic meanings of age for linking family and individual experience to historical change, and for identifying age-graded trajectories across the life course. Both theoretical strands provide essential features of a social life course on matters of time, context, and process. The life course is age-graded through social institutions and structures, and embedded in relationships that constrain and support behavior. In addition, people are located in historical settings through birth cohorts and are linked across the generations by ties of kinship and friendship.

By integrating social relationship concepts and age-based distinctions on social trajectories, along with life-span concepts of the person, the life course framework offered a promising approach to the contextual study of human development in longitudinal samples (Figure 2.1). Both the individual life course and a person's developmental trajectory are connected with the lives and development of others. Life course theory thus took issue with life-span studies that viewed human development as an unfolding process that is not coactive with social and cultural processes in historical time. Moreover, the life course

paradigm is responsive to the call by Lerner (1991, p. 27) for more attention to contextual variability and represents a perspective in the field of developmental science (Cairns, Elder, & Costello, 1996) that extends across system levels and disciplines.

The contextual perspective of the life course framework has much in common with Bronfenbrenner's ecology of human development, now called bioecology theory (Bronfenbrenner & Ceci, 1994). His *Ecology of Human Development* (Bronfenbrenner, 1979) proposed a multi-level view of the sociocultural environment, from macro to micro, but it did not include a temporal perspective on individual development across changing environments. Some years later, Bronfenbrenner (1989, p. 201) noted this major lacuna in his work and proposed the concept of *chronosystem* with its three interacting components over time: (1) the developing person; (2) the changing environment; and (3) their proximal processes. This concept has not been widely adopted, but Bronfenbrenner's ecological perspective has appeared in numerous contextual studies of child development, especially in the field of neighborhood influences (Bronfenbrenner & Morris, 2006; Leventhal, Dupéré, & Shuey, Chapter 13, this *Handbook*, this volume).

Human development in life course theory represents a process of organism-environment transactions over time in which the organism plays an active role in shaping its own development. The developing person is viewed as a dynamic whole, not as separate strands, facets, or domains such as emotion, cognition, and motivation. The course of development is embedded in a dynamic system of social interchanges and interdependencies across and within levels. As noted by Bronfenbrenner (1996), this dynamic in life course theory is illustrated well by the interlocking lives and developmental trajectories of family members who are influenced differently by their changing world. We turn now to perspectives and basic concepts that link the social life course and developmental processes.

## ELEMENTARY LIFE COURSE CONCEPTS AND PERSPECTIVES

For a study that is framed in terms of changing times and places, the objective is to link historical and spatial processes with individual development by examining multiple levels of the social environment (Elder & Russell, 2000). Starting with the macro level, societal change may transform social institutions, communities, and cultures,

and in so doing establish developmental constraints for choices and generate individual agency at the micro level. The multilevel nature of the life course and human development invites different points of entry, each with specific questions, ranging from cultures and social institutions to human biology and the genome (Shanahan & Porfeli, 2002). A single study commonly employs different entry points for aspects of the same project. Thus a project motivated by the impact of rural change on children's social and emotional development should be framed by an initial focus on the transformation of rural communities and the economic well-being and hardships of families within these communities. Such a study would be incomplete without reference to the adaptive patterns of parents and children: their developmental trajectories of behaviors, psychological profiles, and health.

Indeed, empirical studies of the farm crisis (1980 to early 1990s) in the United States, as it played out in central Iowa, tell us that the distinction between families engaged in farming versus families living in the small rural towns was key to linking social change and young people's lives. Parts of this study might also investigate the determinants of specific emotional or social outcomes and relevant protective resources in the family, a point of entry that centers on the developmental status of the child. Still other entry points might begin with the interchange of parents and child or with sibling relationships. Each point could become a framing statement for an independent study, although all entry points provide insight into a central guiding question about context. By studying diverse aspects of the same problem, the processes of social change and individual development give life to variables otherwise considered "social addresses," such as SES, sex, and ethnicity.

Considerable leverage in conducting such studies is provided by concepts and perspectives that bridge social change, place, and individual development, theoretical tools that reflect decades of empirical study. To understand this conceptual bridge, we turn to elementary concepts. First, we begin with multiple levels of the life course, ranging from institutionalized pathways to cumulative patterns of context, which shape the individual life course.

Developmental science is ultimately directed to the study of adaptive and maladaptive patterns of change and constancy at the level of the person. Yet institutionalized pathways provide a broad context for development and set the stage for cumulative patterns of social experiences that shape the individual's life course. Second, other temporally sensitive concepts—most notably, trajectory, transition, and turning point—are taken up with particular emphasis

**TABLE 2.1 Central Concepts of the Life Course: Social and Developmental Dynamics**

Conceptual Description	Examples
<i>Social Pathway:</i> Sequences of positions within and between institutions, organizations, and phases of life	Tracking within schools; occupational career ladders; transitions from school tracks to labor markets
<i>Duration:</i> Time spent in a social status or role, span of exposure	Years in poverty; years married
<i>Cumulative Effects:</i> Increasing effect of earlier experiences with the passage of time (akin to compounding interest)	Effect of education on health becomes stronger as people age
<i>Chains of Interrelated Events:</i> Sequences of risky or salutary experiences across development	Chain of risk: Life events often lead to further life-events; institutionalization in childhood increases likelihood of additional risks
<i>Social Trajectory:</i> Behaviors that likely coincide with pathways	Income stream from an occupational career line
<i>Developmental Trajectory:</i> Behavioral pattern over time, often associated with coinciding social patterns in context	Pattern of change in depressed affect through adolescence is associated with patterns of stressors during the same period
<i>Transitions:</i> Discrete change in social role, set of roles, or membership in social organization	Transition to first grade, to adulthood, to a new school
<i>Turning Point:</i> Change in social circumstances that markedly alters life course, often because of the meaning of the event	Transition to a new school may be associated with substantial improvement
<i>Knifing-Off Experience:</i> Turning point that renders earlier life course much less consequential	Military service can interrupt nascent antisocial career; marriage may have similar effect

on the properties of social transitions (see Table 2.1). Third, we focus on linking mechanisms that have proven highly useful in the study of change and place. Beginning with studies of children who were born before the Great Depression, research has revealed a set of mechanisms that link context and the individual life course and, as will be seen in subsequent sections, these mechanisms have proven highly probative in the study of place. The paradigmatic themes of life course theory draw on these elementary concepts and mechanisms, underscoring the socially dynamic basis for individual development.

### Social Pathways, Cumulative Processes, and Durations

Social pathways, cumulative patterns, and the duration of experiences represent dynamic views of context. Pathways typically refer to sequences of social positions in and between organizations, institutions, and phases of life. Institutionalized pathways generally have specified time

boundaries, what Merton (1984) called “socially expected durations.” Children who are held back in school become aware of their lagging status on the educational ladder (Alexander, Entwisle, & Dauber, 1994), and company managers talk about the relation between age and grade in prospects for promotion to senior rank (Sofer, 1970, p. 239). A growing body of research also considers early entry into adult roles—what Burton (2007) aptly called “adulthood”—as well as pathways into retirement (Kim & Moen, 2002). Whether a new phase of life, emerging adulthood, now characterizes pathways into adulthood is a lively topic of inquiry (Bynner, 2005).

In addition to their age-graded nature, pathways structure the direction that people’s lives can take. Pallas (2003, p. 168–169) observed that pathways have distinct features that govern how strongly people’s trajectories and behaviors are shaped, including, for example, the number of options a pathway leaves open in the future, the extent of mobility that is likely to be experienced, stigma and extrinsic rewards, and the importance of personal choice. Some pathways provide future opportunities and chances for upward mobility based on personal motivation, whereas others effectively block promising avenues irrespective of one’s efforts. Importantly, these pathways reflect social arrangements as found, for example, by McFarland (2006) in how a particular high school chooses to implement a math curriculum.

Pathways are also multilevel phenomena reflecting arrangements in place at levels of culture, the nation-state, social institutions and organizations, and locale. To varying degrees, people work out their life course in established or institutionalized pathways. At the macro end of this multilevel system, governments generally establish pathways (Leisering, 2003). At micro levels, institutional sectors (economy and education) or local communities (school systems, labor markets, and neighborhoods) guide the pathways. Each system level, from macro to micro, socially regulates, in part, the decision and action processes of the life course, producing areas of coordination or discord and contradiction (e.g., marriage, divorce, and adoption laws). At the primary level of the individual actor, some decision pressures and constraints are linked to federal regulation, some to the social regulations of an employer, and some to state and community legislation.

Mayer (1986) had the nation-state in mind when he identified important societal processes, “which impose order and constraints on lives” (pp. 166–167). These include the cumulative effects of delayed transitions, institutional careers, the historical circumstances associated with

particular cohorts, and state intervention. Growth of the state in social regulation counters the modern tendency toward individualism. At the personal level, the state “legalizes, defines and standardizes most points of entry and exit: into and out of employment, into and out of marital status, into and out of sickness and disability, into and out of education. In doing so, the state turns these transitions into strongly demarcated public events and acts as gatekeeper and sorter” (p. 167). To be sure, each nation-state represents a unique configuration of laws, rules, and norms that structure the life course. Viewed from this vantage point, cross-national and historical studies become highly strategic in studying societal forces and individual lives and indeed they have become increasingly common as diverse countries collect data containing the same information. The Panel Study of Income Dynamics in the United States (launched in 1968) has become a model for nationwide longitudinal studies in Europe, as in Great Britain and Germany.

Multilevel accounts of the life course are well illustrated by studies of the transition to adulthood (Settersten, Furstenberg, & Rumbaut, 2005), which highlight how changing institutional arrangements and cultural understandings shape pathways by comparing and contrasting different countries and historical periods. Billari noted that such comparisons are especially powerful among European countries. Each has distinct socioeconomic, political, and cultural features and yet, particularly with the formation of the European Union, they have a growing sense of common identity (Billari & Liefbroer, 2010). His empirical work suggests that the transition to adulthood is becoming increasingly prolonged and diverse (e.g., increasing childbirth outside of marriage), but that this “European pattern” is clearly in evidence in northern Europe and is now diffusing across the rest of the continent. Studies may also examine changing societal arrangements by taking a historical view within a circumscribed geographical area (e.g., Bras, Liefbroer, & Elzinga, 2010).

Within this broader literature on the transition to adulthood, much attention has been paid to transitions from secondary school to work because of its dramatic variability across countries and serious consequences for economic growth and income trajectories for people (Kerckhoff, 2003; Marshall, Heinz, Kruger, & Verma, 2001). For example, considerable structure is provided working-class German youth in a secondary-level system that in theory joins industrial training and education in an apprenticeship system. In principle, placement in a skilled craft is assured for youth who complete their

apprenticeships. American adolescents encounter the least amount of articulation between schooling and workplace. Vocational training in secondary schools is not closely linked to specific industries, their recruitment, and skill needs. In many less-developed countries, youth are forced to leave school early to support their families; in turn, their lowered educational attainment results in low wages, which forces their children to leave school early as well (Shanahan et al. 2002). This intergenerational cycle of disadvantage illustrates how pathways from school to work can reproduce across the generations.

Prior to entry into work, however, young people encounter educational pathways. As with career lines, pathways of education have been institutionalized in historical time, extending through later grades and into college (Shanahan, Miech, & Elder, 1998). Perhaps problematically, vocational training after high school is often not considered desirable for students, unlike the situation found in many European countries. Studies of the educational system in the United States reveal that these pathways begin very early in life and that their effects cumulate to produce marked differences among students and workers. Thus—drawing on data from the Beginning School Study in Baltimore—Entwisle, Alexander, and Olson (2003) documented educational pathways that begin to take form in the first grade. In a school where 88% of the students were on subsidy, every first grade student received a failing mark in reading in the first quarter. In low-SES schools more generally, the average first grade reading score was 1.64 (below a C), in contrast to students in high-SES schools, who averaged 2.15 (above a C). Even controlling for family background and standardized test scores in this Baltimore study, African American children received lower first-grade reading and math scores, and these ethnic differences were subsequently magnified.

Although students of all ethnicities and SES groups benefited from schooling to the same degree, low-SES students' reading ability decreased during the summer vacation, whereas high-SES students' reading improved. Given initial differences in reading and math ability and these invidious summer trends, Entwisle et al. (2003) concluded that "the long-term persistence of early rankings means that inequities visible in the first grade translate into deficits all along the line" (p. 239). Indeed, recent studies drawing on this sample show that first grade attributes—including temperamental factors, grades, and standardized test scores—predict educational attainments at age 22 (Entwisle, Alexander, & Olson, 2005; see also Kerckhoff, 1993).

Research also suggests the importance of organizational characteristics of schools for educational pathways and their implications for human development. As Eccles (2004) observed, schools are multilevel systems reflecting macro-regulatory systems (national, state, and local laws and policies) and "mini-regulatory" systems, including, for example, the school as a formal organization and networks of teachers (see Crosnoe & Benner, Chapter 7, this *Handbook*, this volume). At the level of the high school, sequences of courses define educational career paths. Drawing on this insight, McFarland (2006) found that different high schools generate different patterns of "curricular flows" as students progress through math courses. One school exhibited a differentiated ability model, whereby students progressed according to their ability and had options to continue in math should they encounter failure. Another school showed a different pattern, "upstream and out," whereby students either succeeded and continued in their math courses, or dropped from the sequence altogether.

Ideally, studies of the developmental consequences of life course change take into account the potential constraints and options associated with particular pathways. McFarland (2006) observed that curricular flows rendered students as "constrained agents" who had goals and ambitions but were ultimately enabled and constrained by the organization of their school's curriculum. And as Eccles's Person-Environmental Fit Model details, the developmental status of the student conditions the effects of pathways and their experiences (Eccles et al., 1993). Thus, the study of pathways and development calls for detailed attention to reciprocal patterns between structures of opportunities and constraints, and the capacities of the student.

Social pathways often bring with them cumulative processes, which refer to the growing implications of earlier experiences for later outcomes. The defining feature of accumulation is that the effects of earlier differences are magnified when predicting future behaviors, very much like compounding interest leads to an exponential growth in savings (DiPrete & Eirich, 2006). Accordingly, cumulative processes suggest that the effects of small differences earlier in development "grow" according to some exponential function over the life course (Alexander, Entwisle, & Olson, 2014). Some evidence suggests the cumulative effects of early unemployment on future earnings (an effect referred to as *scarring*), and of early disadvantage for obesity and other aspects of health. For example, the effect of education on future self-rated health is time compounding, with poorly educated people

showing increasingly lower self-rated health through adulthood (Willson, Shuey, & Elder, 2007). However, there is surprisingly little evidence for cumulative processes in the sense of compounding interest, and a wide variety of model specifications remain completely untested (DiPrete & Eirich, 2006; Ferraro, Shippee, & Shafer, 2009).

Cumulation depends on duration, the span of time between changes in state. However, not all durations have cumulative effects. Some experiences persist, but their implications are best understood as linear. Furthermore, the full implications of long and short exposures to a situation depend on the nature of the situation itself. The concept of duration has been especially influential in studies of the permanence of marriage and employment, and the effects of stressors, SES, and poverty. For example, is divorce preceded by a lengthy period of family conflict? Little is known about the qualitative nature of experiences of long and short durations, although a lengthy involvement tends to increase behavioral continuity through acquired obligations, investments, and habits (Becker, 1964). The longer the duration of marriage, for example, the greater the chances for marital permanence (Cherlin, 1993); alternatively, marital happiness is likely to decline at all marital durations, with accelerated declines occurring during the earliest and latest years of marriage (Van Laningham, Johnson, & Amato, 2001). Much more needs to be known about the quality of marriages of differing durations (Teachman, 2008) and their development implications.

A particularly telling example of the complexity of durations and their potential meaning is found in Mortimer's 2003 St. Paul longitudinal study of adolescent employment (Staff, Mont'Alvao, & Mortimer, Chapter 9, this *Handbook*, this volume). With monthly educational and employment data, Mortimer and her colleagues developed a typology of work patterns through high school based on duration (whether the student worked more than 18 months through the 48 months of high school) and intensity (during periods of employment, whether the student worked, on average, more than 20 hours per week). Mortimer, Staff, and Oesterle (2003) showed that ninth graders with higher educational promise—as indicated by grades and aspirations—opted for less intensive work. Low intensity workers were also more likely to save their earnings for college. In turn, “steady workers” (high duration, low intensity) are more likely to earn a BA degree within 9 years of high school graduation than high duration-high intensity workers. Indeed, among students with low levels of educational promise, those who chose a steady work

pattern were more likely to receive their BA than their low promise, high-duration/high-intensity counterparts. Such findings suggest that work of differing durations and intensity has distinct meanings and consequences and highlights the misleading nature of cross-sectional studies.

Many processes refer not to the duration of a particular social circumstance but rather to the triggering of chains of interrelated events, which have significant implications for later well-being and attainment (Rutter, 1989). Behavioral continuities across the life course are likely to be found in social interactions that are sustained by their consequences (cumulative) and by the tendency of these styles to evoke maintaining responses from the environment (reciprocal) (Caspi, Bem, & Elder, 1989). In cumulative continuity, both individual dispositions and family values are likely to favor the choice of compatible environments, which reinforces and sustains the match. Thus, antisocial youth tend to affiliate with other problem youth, and their interaction generally accentuates their behavior, producing over time what might be described as cumulative disadvantages (Cairns & Cairns, 1994; Sampson & Laub, 1997; Simmons, Burgeson, Carlton-Ford, & Blyth, 1987). Reciprocal continuity refers to a continuous interchange between person and environment in which reaction forms action and then by another cycle of action and reaction. As with cumulative continuity, the net result of reciprocal continuity is the cumulation of experiences that tend to maintain and promote the same behavioral outcome. Baldwin (1895) referred to such interchanges as “circular functions” in ontogeny. The ill-tempered outburst of an adolescent may provoke a cycle of parental rage and aggression, a widening gulf of irritation, and, finally, parental withdrawal, which reinforces the adolescent's initial aggression (Pepler & Rubin, 1991). Over time, the interactional experiences of aggressive children can establish attitudes that lead them to project interpretations on new social encounters and relationships, thereby ensuring behavior that affirms the expected behavior. Aggressive children generally expect others to be hostile and thus behave in ways that elicit hostility, confirming their initial suspicions and reinforcing their behavior.

A growing body of evidence raises questions about the mechanisms that link early social experiences—particularly forms of inequality—with later health and well-being (Power & Hertzman, 1997). Drawing on the Dunedin sample, for example, Poulton et al. (2002) show that children's SES (based on occupational categories) is an important predictor of physical health at age 26 even with their adult SES controlled. Children growing up in

households marked by low SES conditions have poorer health—defined, for example, by the body-mass index and cardiorespiratory fitness—when compared with children who grow up in high SES households, regardless of the children’s adult SES. The mechanisms that link such early experiences with later physical well-being are not well documented, although plausible mechanisms include health-related behaviors, especially during adolescence (Bauldry, Shanahan, Boardman, Miech, & Macmillan, 2012). The larger point, however, is that there is now abundant evidence that social pathways, cumulative processes, and durations are notably associated with human development, although mechanisms that link these dynamic social experiences and the individual are typically not well-understood.

### Trajectories, Transitions, and Turning Points

Social pathways and cumulative experience present temporally sensitive descriptions of context. Social trajectories provide a dynamic view of behavior and achievements, typically over a substantial part of the life span. Transitions refer to a change in state or states such as when youth leave home. A substantial change in the course of a behavioral trajectory, often during transitions, may represent a turning point.

Trajectories and transitions are elements of established pathways, their individual life courses, and developmental patterns. Among individuals, social roles evolve over an extended span of time, as in trajectories of work or family; and they change over a short time span. The latter may be marked by specific events, such as children entering school for the first time, completing the first grade successfully, and graduating from high school. Each transition, combining a role exit and entry, is embedded in a trajectory that gives it specific form and meaning. Thus, work transitions are core elements of a work-life trajectory, and births are important markers along a parental trajectory.

Trajectories and transitions refer to processes that are familiar in the study of work careers and life events. The language of careers has a distinguished history in the field of occupations and the professions, and it still represents one of the rare languages that depict a temporal dimension or process. Career lines, as pathways, refer to sequences of positions, and careers, as trajectories, refer to coinciding behaviors and achievements. Work careers have been defined as disorderly and orderly, and achievements have been represented as career advancement, whether early or late, rapid or slow (Wilensky, 1960). The term

*career* also has been applied to the trajectories of marriage and parenthood (Hill & Foote, 1970). All of these uses fall in the more inclusive definition of a life course trajectory. The term does not prejudge the direction, degree, or rate of change in its course.

Developmental trajectories are also integral to life course theory, especially when they are studied as interdependent with the changing dynamics of social trajectories (George, 2009). In a four-wave study of early adolescents, based on growth-curve models, Ge, Lorenz, Conger, Elder, and Simons (1994) found that (a) the trajectories of depressive symptoms increased sharply among European American girls, surpassing the symptom level of boys at age 13; (b) the increase for girls was linked to their exposure to an increasing level of negative events; and (c) the initial warmth and supportiveness of a mother minimized the subsequent risk of depressed states and negative events among daughters. Studies such as these have inspired many efforts to interrelate developmental trajectories and context, although frequently neglecting the changing nature of social circumstance. Increasing attention is being devoted to the study of classes of behavioral trajectories based on the supposition that people may be qualitatively distinct in their developmental patterns (Bauer & Curran, 2004).

According to this perspective, the population is heterogeneous with respect to behavioral trajectories; as such, distinct subgroups can be identified, and their covariates examined. Perhaps most famously, Moffitt (1993; see also Moffitt, Caspi, Harrington, & Milne, 2002) hypothesized that aggregate patterns in antisocial behavior conceal two distinct groups: (1) a small percentage of youth engaged in antisocial behavior at every stage of life (“life-course persistent”) and (2) a larger percentage of youth engaged in antisocial behavior during adolescence only (“adolescence-limited”). Indeed, drawing on semi-parametric models, researchers have uncovered evidence for unique trajectories of antisocial behavior (e.g., Nagin & Land, 1993). With greater use of such models there has been increasing appreciation for methodological issues (see Bauer & Curran, 2003 and accompanying exchanges; Eggleston, Laub, & Sampson, 2004; Nagin, 2004) and theoretical nuance that complicate the search for qualitatively distinct types of behavioral trajectories. Nevertheless, this approach raises exciting possibilities for linking behavioral patterns with change and stability in context and experience.

The multiple role trajectories of life patterns describe strategies of coordination or synchronization. Various demands compete for the individual’s or family’s scarce

resources such as time, energy, and money. Goode (1960) argued that an individual's set of relationships is both "unique and over-demanding," requiring strategies that minimize demands by scheduling and rescheduling transitions where possible. To cope with simultaneous, linked trajectories, the scheduling of events and obligations becomes a basic task in managing resources and pressures. The needs of children and financial requirements, for example, play important roles in determining work and leisure options.

The meaning of a transition has much to do with its timing in a trajectory. Consider the case of parenthood: the earlier the event, the greater the risk of social and health disadvantages for mother and child (Furstenberg, Brooks-Gunn, & Morgan, 1987). Early life transitions can have developmental consequences by affecting subsequent transitions, even after many years and decades have passed. They do so through behavioral consequences that set in motion cumulative advantages and disadvantages, with radiating implications for other life domains. A Baltimore study of adolescent mothers who were followed from 1966 to 1984 (Furstenberg et al., 1987) showed that variations in personal resources (e.g., IQ) during adolescence affected their economic success by influencing how they timed and ordered early events from marriage to education or employment. From the vantage point of this study, the quality of transition experiences early in life may foretell the likelihood of successful and unsuccessful adaptation to later transitions across the life course.

Transitions to parenthood during adolescence in the Baltimore panel raise another important general distinction: Life transitions can be thought of as a succession of mini-transitions or choice points. The transition from marriage to divorce is not simply a change in state, but begins with disenchantment and extends across divorce threats, periods of separation, and the filing of divorce papers. Different causal factors may operate at each phase of the process. "Origin" influences that increase the risk of disenchantment are likely to differ from those that sustain the process toward marital dissolution. In like manner, we can think of the transition to motherhood in adolescence as a multiphasic process in which each phase is marked by a choice point with options and social constraints. Developmentalists tend to view transitions as discrete events that occur in a relatively short period. Consequently, very little is known about the sequence of mini-transitions leading to full transitions.

The apparent contrast between institutionalized transitions and personal, idiosyncratic "transition experience"

can misrepresent reality. In many cases, life transitions are an institutionalized status passage in the life course of birth cohorts and a personalized transition for individuals with a distinctive life and social history. The latter may represent an individual working out of the former. These faces of a transition apply to the normative transitions of life, from birth to school entry, marriage, parenthood, and retirement. Transitions of this kind may seem more predictable and structured than non-normative events, but all transitions can be sorted according to their extent of structures or degree of external regulation, duration, timing, predictability, and novelty.

Life transitions into different environments facilitate this process by representing potential turning points in a trajectory for a troubled life course. Such turning points are sometimes referred to as "knifing off" past experiences, which can allow for new opportunities and behavioral patterns. One example of a turning point is the desistance from criminal activity, a knifing-off experience that involves a transition into new situations that provide monitoring, social supports, growth experiences, and the emergence of a new self-identity (Laub & Sampson, 2003). Military service, gainful employment, and marriage are all new role commitments that provide opportunities for a break from the past and social integration (see also Bouffard & Laub, 2004).

A further example of turning points—this time in an educational trajectory—is found in a study of feeder patterns into high school (Crosnoe & Benner, Chapter 7, this *Handbook*, this volume). In the U.S. school system, pathways between middle school and high school are structured in different ways, affecting the proportion of one's middle school classmates who attend the same high school. Schiller's (1999) study of how differing feeder patterns affect subsequent grades is revealing. Among students receiving mostly Cs in middle school, high school math grades decrease as the proportion of one's classmates in the same high school increases. The reverse is true among students receiving mostly As in middle school: High school math grades increase as the proportion of one's classmates in the same high school increases. As Schiller notes, when middle school students disperse into many high schools, opportunities seem to open up for students at the bottom, as peer networks are disrupted. Consistent with a turning point, the old social world is knifed off and new opportunities for growth and identity change present themselves.

The concept of turning point also applies to the particular way people view their life trajectory—a subjective account of lived experience involves some degree of

change in situation, behavior, or meaning. Maruna's (2001) interview study of desistance among ex-convicts is one of a few research efforts to investigate the changing nature of the self during a turning point. Important themes in the life narratives of desistors include acknowledging past crimes, understanding their genesis, and recasting the self as in control and with newfound purpose. Clausen (1995) used detailed analyses of life histories to assess the subjective turning points of people who have been part of a longitudinal study for 60 or more years. Based on this work, he concluded that "one's life does not have to take a different direction for a person to feel that a turning point has occurred. But one must have a feeling that new meanings have been acquired, whether or not life experiences are much changed" (p. 371).

Similarly, Reynolds and Turner (2008) showed that the implications of life-events for mental health depend very much on their meaning to the individual. Life-events that call into question basic understandings of one's life (or assumptive states) have a much bigger effect on depressive symptoms than do life-events not so classified. And as McLeod (2012) observed, stressors of all manner can trigger distress depending on their meaning; in turn, the source of the individual's meaning is found in social and culture structures that characterize a time and place. Across different societies—and within societies, across historical periods—the same events are viewed as more or less stressful depending on changing institutions and cultural meanings.

### Social Change and Life Transitions

The concepts reviewed in the previous section provide ways of thinking about social change and its implications for human development. Accordingly, social change refers to a broad range of transitional phenomena such as residential moves or a change of school. Additional contributions to this perspective come from mechanisms that link transitions and life patterns to historical change and from paradigmatic principles that define the life course as a theoretical orientation. As a whole, these linking mechanisms—life stage, situational imperatives, control cycle, and accentuation principle—represent different understandings of the connections among individual lives, transitions in the life course, and the changing social world. These mechanisms are embedded in a theoretical framework defined by paradigmatic principles of the life course. Consider, for the example, the principle of human development and aging as a lifelong process. The sequence

of role transitions in the life course establishes different life stages, such as leaving home for kindergarten and its peer group experiences. This transition accentuates initial student differences in preparedness and maturity; and the situational imperatives of the classroom call for conformity to classroom standards of behavior. Teacher control in the classroom orients individual student efforts toward greater self-regulation on the part of the child. Each educational transition contributes to a cumulative developmental and social process.

The paradigmatic principles draw on these mechanisms in charting the perspective of life course study—the principles of lifelong development and aging, human agency in making choices, the importance of timing in lives, linked lives, and historical time and place (Elder, 1998b). These principles represent more general theoretical themes that collectively define the analytical scope of life course theory. The mechanisms refer to why the effects of transitions differ in populations, whereas the principles apply beyond the scope of transitions, to properties of the life course as a sequence of age-graded roles.

### Linking Mechanisms

The Depression studies focused on differences between cohorts born at opposite ends of the 1920s; because of their differing birth years, these young people occupied different life stages when the economy collapsed.

#### *Life-Stage Principle*

The life-stage principle holds that young people of different ages are likely to be exposed to the same slice of history but at differing points in development, creating unique patterns of social change and, at the level of the person, opportunities, challenges, strengths, and vulnerabilities. Viewed differently, children in the same family experience social changes in differing ways because of their differing ages. Indeed, the Oakland children passed through adolescence during the worst years of the Great Depression, but the Berkeley children became teenagers in World War II. Consequently, job scarcity, financial pressures, and emotional stress represented defining features of the Oakland cohort's transition from childhood to young adulthood. By contrast, members of the Berkeley cohort were exposed to the "empty households" of World War II when older parents worked from sunrise to sundown in home-front industries.

Consider the Berkeley males who entered the Great Depression when they were highly dependent on family

nurturance and vulnerable to family instability. Economic hardship came early in their lives and represented a prolonged deprivational experience, from the economic valley of the 1930s to the war years and departure from home. By comparison, the Oakland males were older and more independent when hardship hit their families. They assumed important roles in the household economy and entered adulthood with a more crystallized idea of their occupational goals. Despite some handicaps in education, they managed to end up at midlife with a slightly higher occupational rank (Elder, 1999). The vulnerability of the younger Berkeley boys is consistent with the results of other studies that show that family stressors are especially pathogenic for males in early childhood (e.g., Rutter & Madge, 1976).

### *Situational Imperatives*

Another linking mechanism involves situational imperatives, the behavioral demands or requirements of a new situation. The more demanding the situation, the more individual behavior is constrained to meet role expectations. In emergency family situations, helpful responses become an imperative for members, as in hard-pressed families during the worst years of the Great Depression. Rachman (1979) referred to these imperatives as “required helpfulness.” The Oakland children were old enough in the early 1930s to be called on to meet the increased economic and labor needs of their family, and a large number managed to earn money on paid jobs and to help in the household. This money was often used to cover traditional family concerns such as school expenses.

In deprived families, girls generally specialized in household chores and boys were more often involved in paid jobs. This gender difference made girls more dependent on the family and generally fostered greater autonomy among boys. Adolescent jobs in the 1930s typically included what might be regarded as odd jobs in the adult world, from waiting on tables and clerking to delivering newspapers and running errands. Employment of this kind may seem developmentally insignificant, although it had the important implication that people counted on them—they mattered. Indeed, staff observers rated the working boys as more energetic and efficacious than nonworking boys. The flow of influence was no doubt reciprocal. The more industrious were likely to find jobs and success in work that would reinforce their ambition. With additional chores at home, working boys experienced something like the obligations of adult status. To observers who knew them, they appeared to be more adult-oriented

in values, interests, and activities when compared to youth who did not have jobs.

### *Control Cycles*

Situational imperatives are elements of new situations that characterize control cycles, which, as described by Thomas (see Elder & Caspi, 1988), refer to changing relations between expectations and resources that affect a sense of personal control. A loss of control stems from a process in which resources fall below expectations. This change motivates efforts to restore control by adjusting expectations, resources, or both in terms of their relation. During the Great Depression, heavy income loss tended to affect children, sometimes adversely, through family adaptations to such deprivation. These include the reduction of family expenditures, the employment of more family members, and the lowering of living standards (Elder, 1974/1999). Equilibrium in these financially strained families was achieved when expectations matched resources. The psychology of this cyclical process is well described by what Brehm and Brehm called *reactance* (1982). Feelings of reactance occur whenever one or more freedoms or expectations are threatened or eliminated. Such emotions spur efforts to regain or preserve control. “It is the threat to control (which one had) that motivates an attempt to deal with the environment” (p. 375). Once control is achieved, expectations may be raised, thereby setting in motion another round of equilibrating initiatives.

### *Accentuation*

The final mechanism, known as the accentuation dynamic, relates transition experiences to the individual’s life history of past events, acquired dispositions, and meanings. When a transition heightens a prominent attribute that people bring to the new role or situation, the change is said to be an accentuation effect. Entry into new roles or situations is frequently an accentuation dynamic that tends to amplify “preexisting” behaviors. From this perspective, early transitional experiences become prologues for adult transitions that increase heterogeneity over the life course. We see this development in longitudinal studies of divorce and their increasing attention to behavioral changes initiated by it across the life course and the generations (Amato, 2000; Amato & Cheadle, 2005). In children, as well as adults, the divorce transition appears to accentuate dispositions that were present well before the event itself. For example, boys with behavior problems after a divorce were frequently engaged in problem behavior before the divorce.

TABLE 2.2 Mechanisms Linking Transitions to Development

Principle	Examples from <i>Children of the Great Depression</i> (Elder, 1974/1999)
<i>Life Stage</i> : The effects of social change are contingent on the age of the person experiencing it.	Differing effects of the Great Depression were observed among members of the Oakland (older) and Berkeley (younger) cohorts.
<i>Situational Imperatives</i> : Social demands of new situations shape appropriate behavior for the context.	During economic crisis, each member of the household was expected to make role-specific adjustments to scarcity and contributions to household economy.
<i>Accentuation</i> : Behavioral patterns before transition are magnified with social change.	Irritable fathers tended to lose their tempers under the pressures of economic deprivation.
<i>Control Cycles</i> : When confronted with new situations and loss of control, people strive to reassert control over their setting and biography.	During the Great Depression, families developed strategies to adapt the household economy.

As a whole, these linking mechanisms—life stage, situational imperatives, accentuation, and control cycles (Table 2.2)—represent different understandings of the connections among individual lives, transitions in the life course, and the changing social world. These mechanisms are embedded in a theoretical framework defined by paradigmatic principles of the life course.

### Paradigmatic Principles

Like the mechanisms reviewed in the previous section, the paradigmatic principles emerged from studies of *Children of the Great Depression* (Elder, 1974/1999) and subsequent research (Elder, Johnson, & Crosnoe, 2003). Collectively, they define *life course* as a theoretical orientation that provides a framework for studying phenomena at the nexus of social change, social pathways, and developmental trajectories.

#### *The Principle of Life-Span Development*

Human development and aging are life-long processes. Over the years, the life span has been represented as a sequence of life stages, from infancy and early childhood to old age. Each stage became an age-specific domain for specialized study. However, we recognize now that developmental and aging processes are most fully understood from a life-long perspective (Kuh, Power, Blane, & Bartley, 1997). Behavioral patterns at midlife are not only influenced by current circumstances and by the anticipation of the future, but also by prenatal and early

childhood experiences and, in some instances, by intrauterine experiences and the circumstances of prior generations. Long-term studies are documenting the relation between late-life adaptation and the early years of life-span development. Life course epidemiology has experienced explosive growth, as the precursors to adult health are explored among early sensitive periods, chains of risk, cumulating disadvantages, and their temporal complexities extending over many decades of life (Kuh & Ben-Shlomo, 2004; Bauldry et al., 2012). Such research has been propelled by national longitudinal studies of birth cohorts in Great Britain, marked by birthdates of 1946, 1958, 1970, and 2000. These cohorts are all scheduled to be followed into the later years of life (Ferri et al., 2003).

This long-scale temporal frame poses major challenges as well as exciting opportunities. The longer a life is studied, the greater the risk of exposure to social change. The lives of people in their 80s or 90s are thus most likely to reflect the particular contours of a society, with its unique pattern of social changes occurring over many years. In this sense, each birth cohort will result in distinct biographical patterns. Longitudinal data archives generally lack adequate information on social change, however, particularly in the details of social relationships, social organizations, and residential ecologies. Indeed, many longitudinal data collections do not extend beyond the respondent's self-reports, making nuanced understandings of the person's social setting very difficult. With increasing frequency, geographic codes are enabling investigators to assess contextual changes and their effects on lives.

Another challenge posed by the principle of life-long development and aging centers on the reality that each study typically begins “midstream” in the lives of respondents. Studies of adolescent behavioral patterns typically begin at some point during that phase of life, but such studies come with the strong assumption that what happened in the first decade of life is of negligible consequence. Given the strong tendencies toward behavioral continuity—often reflecting continuity of social settings—the researcher may be attempting to explain small amounts of behavioral change. This challenge may be especially acute for studies of the later life course, when decades of experiences—largely unmeasured—are not available for study. The point is well illustrated by a study of mastery among the elderly (Pearlin, Nguyen, Schieman, & Milkie, 2007). Mastery in old age reflects intractable hardships in early life, status attainment processes through adulthood, and stressors in old age. However, all of these factors are mediated by a sense of life course mastery,

the belief that one has directed and managed her or his life across the decades. Ideally, such complexities would be studied with data extending from childhood to old age.

Transitional experiences across the life course involve individual initiatives, situational constraints and opportunities, the dispositions and prior experiences that people bring to new situations, and the influence of others. Although many factors influence lives, young people play an important role in constructing their own lives though the choices they make.

### *The Principle of Human Agency*

Individuals construct their own life course through choices and actions they take within the opportunities and constraints of history and social circumstance. Elements of human agency have been prominent in studies of lives (see Haidt & Rodin, 1999; Thomas & Znaniecki, 1918) and are central to studies that relate lives to broader social contexts. People make choices in constrained situations that enable them to exert a measure of control over their life course. These choices ensure a degree of loose coupling between social transitions and life stages. Even during the economic turmoil and distress of the 1930s, families engaged in many strategies in the face of severe constraints: Mothers found jobs amid scarce options, and many of their children carried responsibilities in the home and community.

In *American Lives*, Clausen (1993) focused on the question of agency in lives, with emphasis on the formative adolescent years of Californians who were members of the Oakland and Berkeley Guidance studies. He hypothesized that competent adolescents who think about the future with a sense of personal efficacy are more effective in making sound choices and in implementing them during the transition to adulthood. These more “planful decisions” lead to greater success in work and family through adulthood. Indeed, the highly competent males in adolescence were most likely to achieve a successful start through education, occupational careers, and family, apart from the influence of IQ and SES background. Moreover, this beginning anticipated achievements across the life course, even into the 60s. The young men with a planful competence were more likely to have stable marriages and careers and tended to find satisfaction and fulfillment during their final decades.

Do these findings reflect the special circumstances of the study members’ early adult years—the beginning of World War II and an unparalleled era of prosperity? Postwar benefits for veterans encouraged them to obtain a college education, but what if we stepped back a decade

of two so that both a Great Depression and global war loomed ahead? To do this, we turned to the Lewis Terman data archive (Holahan & Sears, 1995), a longitudinal study of the brightest Californians. This study of talented children was launched in the 1920s, a time when California’s economy seemed to offer unlimited opportunity. Half of the children were born before 1911, the other half by the early 1920s. By selecting only the most able of California’s children for the study, Terman could direct his attention to great promise and the expected rise of talent to positions of accomplishment and leadership.

But history changed this trajectory (Shanahan & Elder, 2002; Shanahan, Elder, & Miech, 1997). The older cohort had completed most of its post-high school education by the time of the stock market crash and looked ahead to a stagnant and declining labor market, whereas the younger men faced the prospects of going to college in the later years of the Depression decade. Lacking good job prospects, a substantial number of the older men stayed in graduate school, extending their list of degrees. By contrast, World War II reduced significantly the educational opportunities of the younger men, but having no impact on the education of the older men who were well past the college years.

With these different historical paths in mind, it is not surprising that planful competence in adolescence had much greater relevance for the future of the younger men, when compared to the older cohort. The planfulness of the older men in adolescence had no effect on their chances for advanced education and career achievement. In large part, this outcome reflects the process of “warehousing” in which the young prolong their stay in school during economically troubled times. School persistence had less to do with personal motivation than with a way of getting out of hardship situations. Parallels between the Terman studies and early 21st-century cohorts of young people completing their educations are striking. Unprecedented numbers of young people around the world are completing university degrees, only to find little opportunity in the labor market. The Terman studies suggest a disabling, to some degree, of their sense of agency, as their adult lives reflect a lack of meaningful opportunities in the workplace. Yet many people will retain a high sense of agency even in the face of such challenges, a form of resilience that has not been adequately studied to date.

The constraints of social structures on agency extend beyond societal change, and powerfully reflect dynamics within the family and among peers. Bozick, Alexander, Entwisle, Dauber, and Kerr (2010) examined educational expectations from the fourth grade onward. Although

many studies of college planning begin with high school students, the authors found that by the fourth grade, most students were planning and expecting to attend college. Between the fourth grade and high school, many students remained steadfast in their plans, reflecting the socioeconomic advantages of their parents. Yet many students drifted away from college plans, and most of these students came from low-SES households. By high school—when most studies of college expectations begin—these processes were by and large complete, and thus the major developmental story could not be captured.

Once in high school, many students are tracked (either *de jure* or *de facto*). Efforts to “detrack” students by creating freedom of choice with respect to coursework, however, are often unsuccessful (Yonezawa, Wells, & Serna, 2002). That students opted not to leave their tracks—often despite their ability to perform at “higher tracks”—reflected several social and cultural features. Students in lower tracks often were not as informed about courses as their higher track counterparts; administrators were often resistant to moving Latino/a American and African American students into higher tracks; and, most importantly, tracks fostered a sense of identity that few students were willing to abandon to “move up” to higher tracks. Thus, even when faced with new options, many students prefer continuity because of how they come to view themselves and “how the world works.”

### *The Principle of Timing*

The developmental antecedents and consequences of life transitions, events, and behavior patterns vary according to timing in a life course.

Life-long processes of human development and human agency underscore ways of thinking about the timing of lives and their social contexts. As Neugarten (1968) showed in her pioneering work, people do not march through life in concert. They tend to vary by the age at which they pass through life transitions—when they begin and complete their schooling, enter a first job, establish an independent domicile, share a household with a friend, marry, have children, see children leave home, and lose their first parent. They also vary in when they perceive themselves as young, middle age, and old. In *Children of the Great Depression* (Elder, 1974/1999), some members of their cohort entered marriage before their 20th birthday, whereas others were still unmarried a decade later. Early marriage tended to produce life disadvantages, from socioeconomic hardship to the loss of education. Early childbearing had similar consequences.

All of these age variations can make a difference (Hogan, 1981) by setting in motion a dynamic of cumulative events and processes. The timing principle may suggest that different points in life represent sensitive periods during which life events and transitions affect age-specific vulnerabilities. Such a perspective is evident in many studies of the timing of poverty and cognitive development, which often are based on the assumption that deprivations have differing effects at different ages because of the course of neurological development. Another perspective, however, and one that is not mutually exclusive, is illustrated by these examples from the Depression studies: Different ages represent different constellations of opportunities, constraints, roles, and social connections, all of which condition the effects of transitions and stressors. To illustrate this point, we turn to the ages at which children experience the breakup of their family. The timing principle has been productively applied to a range of phenomena, however, including retirement, widowhood, first birth, age of onset of many physical and mental health challenges, degree completion, and unemployment spells.

No time is good for a child’s loss of a parent through separation or divorce, but the child’s age when such change occurs can make an important difference in its consequences. To address the impact of a single-parent household, Krein and Beller (1988) matched mother-daughter and mother-son samples from the National Longitudinal Surveys to investigate three relevant hypotheses: (1) the transition to single-parent status is most damaging during the early preschool years, owing to heavy time demands; (2) duration of residence lessens the educational achievement of offspring by diminishing social resources; and (3) boys are likely to be more impaired by the change than girls, owing to modeling processes (see also McLanahan & Sandefur, 1994). Although Krein and Beller designed precise measures of the age and length of time a child lived in a single-parent household, the reports of family structure are retrospective because the mothers were interviewed between the ages of 30 and 44. The offspring were interviewed when they were 14 to 24 years. However, such retrospective reports are reasonably accurate.

The study found that timing mattered, along with duration and gender: (a) the adverse effect on education was much greater for the preschool versus the later years, (b) the adverse effect increased with the number of years a child spent in a single-parent household, and (c) the adverse effect was more negative for males than for females. The strongest and most consistent timing and duration effects were obtained among European American

males, with family income controlled. African American females and males were next in line on effects, followed at some distance by European American females. Whether family income was controlled, the timing and duration of living in a single-parent household mattered least for European American females. The meaning of this result was not pursued in the study, although these young daughters of single-parent mothers may be protected by maternal support and the model of a self-sufficient woman.

### *The Principle of Linked Lives*

Lives are lived interdependently and social-historical influences are expressed through this network of shared relationships. The principles of timing and linked lives address in complementary ways the temporality, process, and context of lives and human development. Interdependent lives highlight the role of significant others in regulating and shaping the timing of life trajectories through a network of informal control. This network can be thought of as a “developmental context” (Hartup & Laursen, 1991) and as a “convoy” of significant others through life (Antonucci & Akiyama, 1995). Whatever the plans of an individual, these “significant others” initiate or experience life transitions that produce transitions in his or her own life. As Becker (1964) once observed, the expectations and informal sanctions of these “others” channel behavior and the life course in certain directions.

Linked lives are expressed in *Children of the Great Depression* (Elder, 1974/1999) across the generations, in the parental marriage, and in the relationship of parents and siblings. Older and younger siblings influence each other directly through their encounters, whether nurturant, competitive, or conflictual (Brody, 1996). In an African American sample, Brody et al. (2003) found a significant link between the antisocial behavior of older and younger siblings, but it was strongest in disadvantaged neighborhoods that provided abundant opportunities for the younger sibling to express this behavior, when compared to siblings in affluent residential areas. Examples of an indirect path include the experience of parents with the eldest child that undermines or strengthens their sense of competence in parenting. A third potential sibling link involves the differential treatment of siblings by parents, relatives, or teachers. Little is known about continuity and change in sibling relationships from childhood into the adult years.

Family changes are especially relevant to the principle of linked lives and its implications. Hernandez (1993) referred to a number of revolutionary family changes in

the lives of children and adults, including the decline in family size, migration from the land, growth in women’s employment, divorce, and single parenting. Marriage and the mutual regulatory influence of each partner illustrate both the process of timing through the synchronization of lives and the embeddedness of each family member’s life. For example, Caspi and Herbener (1990) investigated the influence of marital relationships on the developmental trajectories of husbands and wives. In “choosing situations that are compatible with their dispositions and by affiliating with similar others, individuals may set in motion processes of social interchange that sustain their dispositions across time and circumstance” (p. 250). Among marriages with strong ties, they observed trajectories of parallel development over 20 years. Husbands and wives did not change toward greater resemblance in developmental trajectory, but they did show a parallel course of development. When marriages dissolved, the former partners tended to follow less parallel trajectories.

Linked lives also refer to mechanisms of transmission across generations, including the reproduction of education, occupation, income, values and beliefs, poor health behaviors, health, and even place of residence from parent to offspring. For example, drawing on the Youth Development Study, Ryu and Mortimer (1996) found parental work experiences and values to be correlated with the children’s work values. Mothers’ extrinsic work values (such as on money and security) fostered similar values in the lives of their teenage and young adult daughters, and mothers with strong intrinsic values (including work autonomy and interest in job) were least likely to have daughters who valued extrinsic rewards such as high income and status. For sons, the supportiveness of parents mattered more than parents’ actual work values and occupational experience. The more supportive the father and mother, the stronger the son’s intrinsic values. Intergenerational relations are an important medium for the transmission of work values.

Although *transmission* implies influence from parent to child, the opposite pattern is also possible, as was recognized long ago by the concept of reciprocal effects, evocative patterns, and child effects. For example, a young girl’s pregnancy can have consequences that fundamentally change the lives of her mother and grandmother, among others. When a 13-year-old has a child, her 28-year-old mother becomes a grandmother, and her grandmother becomes a great-grandmother. Using data on 41 female lineages from urban multigenerational African American families in Los Angeles, Burton (1985; Burton

& Bengtson, 1985) creatively explored the ripple effects of teenage pregnancy across the generations. The age ranges of respondents in the early lineages were 11 to 18 for the young mothers, 25 to 38 for the grandmothers, and 46 to 57 for the great-grandmothers. The other lineage units were judged on time in transitions. The age ranges for mothers, grandmothers, and great-grandmothers were 21 to 26, 42 to 57, and 60 to 73, respectively.

Interdependent lives also extend beyond the family to friends, teachers, and neighbors. Theories of resilience commonly assume that positive influences can offset negative influences originating in the family (Luthar, 2003; Werner & Smith, 2001). A positive school environment of classmates and teachers might compensate for a child's punitive family environment or a drug-infested neighborhood. Relevant to these issues is a short-term longitudinal study of adolescents in Prince George's County in the area of Washington, DC (Cook, Herman, Phillips, & Settersten, 2002). The influence of nuclear families, friendship groups, schools, and neighborhoods was assessed in the lives of mainly African American and European American students in the seventh and eighth grades during the early 1990s. The quality of all four contexts had independent and additive influences on adult success, defined by a composite of school performance, social behavior, and mental health indicators. The effect of any one context was not large, but the total contextual effect proved to be substantial.

### *The Principle of Historical Time and Place*

Individual life course is embedded in and shaped by historical times and places over a lifetime. One of the best examples of both historical and spatial variations in the life course and human development comes from studies of lives during military times. The immediate years after World War II, for example, were hard times in many parts of Europe and Asia, unlike the prosperity experienced in the United States. Children who grew up in financially strained families in California during the Great Depression frequently saw military service as a "bridge to greater opportunity." Without getting into the details of selected studies, we note some basic features of the transition to military service, in eras of World War II, the Korean conflict, and the Vietnam War (Elder & Caspi, 1990). More generally, the effect of military service varies according to its historical time and place (MacLean & Elder, 2007).

First, military service tended to pull young people from their past, however privileged or unsavory, and in doing so it created new beginnings for developmental life changes.

Basic training defined a recruit's past as irrelevant. This definition encouraged independence and responsibility, separated recruits from the influence of their home community and family, and allowed a degree of social autonomy in establishing new ties. Basic training also promoted equality and comradeship among unit members, made prior identities irrelevant, required uniform dress and appearance, minimized privacy, and rewarded performance based on group achievement.

A second distinctive feature involves "a clear-cut break from the age-graded career," a time-out in which to sort out matters and make a new beginning. Military duty legitimized a time-out from education, work, and family, and liberated the recruit from all conventional expectations for an age-graded career, such as expectations regarding progress and life decisions. Just being in the armed forces released the recruit from probing life-decision questions from parents (e.g., Have you decided on a job or career? When will you be promoted or get married?). This time-out would be far less timely for men and women who were mobilized in the midst of family and career responsibilities.

A third feature of mobilization offered a broadened range of developmental experiences and knowledge, including exposure to in-service skill training and educational programs, as well as exposure to new interactional and cultural experiences through service itineraries that extended across the country and overseas. Out of such experiences came a greater range of interpersonal contacts, social models, and vocational skills. Horizons were broadened and aspirations elevated.

The principle of historical time and place acknowledges the essential complementarity of two perspectives—historical and ecological. The impact of historical time is expressed through its ecology. Thus the Great Depression's impact varied in manifestation by region and size of place in the United States. Many of the basic life course concepts just noted and the linking mechanisms and principles emerged from an historical study of children who were influenced by the Great Depression, though the project paid little attention to ecological variations. However, remarkable progress in recent decades has been made in applying such analytic tools in spatially oriented research on changing neighborhoods, communities, and societies. This work investigates migration, a form of social change that begins with the geographic movement of people from one context to another. Progress to date reflects increasing sophistication with respect to sampling, research design, and measurement. We turn now to a consideration of these advances.

## LIVES AND CONTEXT: HUMAN AGENCY AND SOCIAL OPTIONS

Contexts of human development generally bring to mind social environments at a point in time, but the life course framework views environment as highly interactive and temporal. A child's social network is not a fixed social structure but rather a dynamic system of social relationships. A key feature of this process involves the continual entry of new participants and the departure of members through mortality and exit transitions such as residential change. Although communities vary greatly on residential stability, most gain and lose a significant number of residents over several years. Ever since the 1960s, the increasing application of longitudinal designs to the study of lives has encouraged a corresponding study of their temporal social environments as well, and of the interplay between the lives of individuals and their changing world.

Context, in this chapter, refers to a range of settings, from clusters of houses to neighborhoods, villages, communities, and regions. The residential unit is common to all of these settings, but contexts may also include schools, daycare, and other social and physical environments that children are exposed to and interact with over the life course. Consider, for example, school mobility, or changes between schools (Crosnoe & Benner, Chapter 7, this *Handbook*, this volume), a source of change in children's exposure to social and institutional environments that can be a positive or disruptive force in school performance and social and emotional well-being. The effects of these transitions, especially moves between grade school and middle school and middle school and high school, are dependent on timing, the interplay among transitions and other life events, and what resources the individual child brings to the transition. Earlier transitions from elementary to middle school are associated with negative student outcomes, as younger children may be less able to adapt to their changing contexts (Simmons & Blyth, 1987). A mismatch between children's needs and their new, less intimate and more impersonal environments in middle school contributes to some of these negative effects (Eccles et al., 1993). However, if a change improves the person-situation fit for students, such as moves to schools that offer special programs and services that better suit a child's needs, outcomes are more likely to be positive despite the potential disruptive effects of attending a new school. In addition, school moves and life transitions may have cumulative effects that persist and grow, like compound interest, through time.

As the number of school moves increases, or if school moves are coupled with one or more residential moves, family disruptions, and other major life events, the chances of negative outcomes for children increase (Simmons & Blyth, 1987). Children from disadvantaged socioeconomic and family backgrounds appear not only to have more disruptions associated with school transitions, but also fewer resources to draw on to cope with their changing lives and contexts (Beatty & the National Research Council, 2010). In the process of school mobility, social and institutional contexts, individual development and resources, and the cause of, or motivation for, moving interact in both time and place to influence a range of child outcomes, from test scores to measures of self-esteem.

An additional, well-studied source of change in place in the lives of children is migration. The scientific study of human migration has always involved a focus on the interplay between individual lives and changing environments, in theory if not in life record data, and it has told us much in recent years about how to think about the contextualization of human development. During the first decades of the 20th century, the early Chicago School of Sociology featured studies of neighborhoods (Leventhal, Dupéré & Shuey, Chapter 13, this *Handbook*, this volume) in cities and research on migration and immigration. Fifty years later, Wilson (1987) reinvigorated the contextual study of urban social disadvantage with his penetrating analysis of the causes of concentrated poverty. Similarly, Massey and Denton (1993) gave renewed visibility to the pervasiveness and consequences of segregation in *American Apartheid*. All of these developments in theory, methods, and research have contributed to a new ecology of human development, which we sketch in the following sections.

### Context and the Life Course

Three life course themes are important in thinking about the contexts of children and young people. First, the contextual history of the individual is inextricably linked to his or her movement, both into and out of geographic places, most especially residential locations that are so much a part of one's life course and a source of social ties and role models. For the young who are still dependent on their family, parents select a community or neighborhood of destination within various constraints. This choice making shifts to offspring as they leave home for other places, whether within or outside their community. The qualities of human agency (initiative, resourcefulness, optimism, determination) play an important role in this process.

Selection of a place in which to live or to attend school is not merely a unidirectional process, according to the new ecology of human development; it is a reciprocal process. People select schools and neighborhoods, and the latter select students and families through incentives and standards, among other processes.

Second, the sequence of single and multiple social roles across one's life can be coupled with movement within and across places. Although frequently ignored, entry into a new social role may involve more than exposure to new responsibilities—it may also include exposure to a new geographic location, such as a new neighborhood, school, or workplace. This linked change in roles and contexts is common for young people as they leave home to make their way in education, work, and family. Geographic, social role and age-graded trajectories are interwoven across the life course as an evolving context of human development.

A third consideration is important in thinking about the contextual influences and constraints on human development—that all geographic places include individuals who did not actively select them. These individuals play a role in shaping contextual influences. In addition, these places are located in a surrounding environment (sometimes called an *externality*). The new interdisciplinary ecology of human development, which emerged during the last two decades of the 20th century (Sampson, 2012), has shown that a school or neighborhood's location within this surround (e.g., encompassing area) makes a significant difference in the context's developmental impact on its families and young people.

### Conceptualization and Measurement

The increasingly nuanced understanding of the relation between lives and contexts that form this ecological perspective relies, in part, on improvements in how contextual units are conceptualized and measured (Wachs, Chapter 21, this *Handbook*, this volume). These advances are closely linked, as it is necessary to develop concepts about the nature of the effects of space and place before they can be measured. In assessing the influence of contexts on children's lives, some important considerations include specifying the spatial extent of contexts, identifying and measuring contextual traits, and integrating the spatial aspects of context with the inherently temporal nature of lives.

In pioneering studies of ecological psychology, Barker and colleagues examined behavior settings, which consist

of small, contained units such as classrooms, churches, and banks (Barker, 1968; Barker & Gump, 1964). Bronfenbrenner expanded the concept of context to include a nested hierarchy of ecologies, not unlike a Russian Matryoshka doll (Bronfenbrenner, 1979). These nested systems might include the family, but also the school, community, and nation. Following the works of Wilson (1987) and Massey and Denton (1993), neighborhood and community studies sought to investigate the effects of local areas on a range of outcomes. Multilevel trajectory statistical models were joined with new data collection methods regarding social ecologies (Sampson, 2012). Studies of neighborhood effects have demonstrated that the poverty rate, ethnic composition, and educational level of the census tracts, counties, and zip codes that children live in are important factors in their development.

Typically in neighborhood studies, administrative units associated with an individual's place of residence, such as census tracts, are used as proxies for neighborhood or community. Indeed, demographers have long used geographic territories and the aggregate characteristics of residents to describe places, sometimes called “compositional effects” (Voss, 2007). However, recent work has advanced the measurement of context beyond administrative or census geography to include spatial territories that are more meaningful representations of the places in which people reside. For example, Matthews, Detweiler, and Burton (2005) developed an approach called “geo-ethnography,” which combines ethnographic information on families and neighborhoods with geographic information system (GIS) technology. With this approach, they are able to situate families and children in both space and time as they go about their daily activities. This work demonstrates that the lived experiences of families extend beyond the fixed spatial contexts of census tract and neighborhood.

Understanding the spatial extent of contexts and contextual processes has been expanded through the consideration of extralocal processes, or spatial externalities (Sampson, 2012). Rather than simply focusing on the effects of neighborhood of residence on individuals, one may also consider the effects of adjacent neighborhoods on individual or aggregate outcomes. This allows higher-order processes, such as the social structure of the city, to be considered in tandem with local effects. For example, Sampson and colleagues (Sampson, Morenoff, & Earls, 1999) showed that a neighborhood's spatial proximity to areas with high levels of social control for children and adult-child exchange confers advantages beyond the characteristics of that particular neighborhood.

Neighborhood advantage and disadvantage are the result of more than local conditions. Social and political dynamics that extend beyond the borders of any particular neighborhood shape local contexts. Consider how extralocal decision processes can undermine the quantity and quality of resources that are available in a community. Decisions regarding the incorporation or annexation of territory can exclude minority-inhabited areas from rural municipalities. Such exclusion creates disadvantaged residential areas lacking infrastructure (such as sewers), services (including policing), and local political representation (Marsh, Parnell, & Joyner, 2010). Under such conditions, residents are exposed to greater health risks and lower property values. In this manner, selective annexation contributes to ethnic segregation and unequal access to resources (Lichter, Parisi, Grice, & Taquino, 2007).

However the geographic boundaries of places are defined, places have some qualities that can be summarized by the traits of their inhabitants, such as median income or ethnic composition. Yet other aspects of places must be approached in a different way. As the understanding of contextual effects has become more nuanced, it has been recognized that places have traits that are more than simply the aggregate of the local population. With increasing interest in neighborhood effects, it has become clear that community-level properties are worthy of systematic measurement in their own right. The term *ecometrics* was coined to describe the growing set of methods and techniques used to produce and evaluate measurements of ecological settings (Raudenbush & Sampson, 1999).

An important addition to the study of context is the application of techniques of systematic social observation, or SSO (Reiss, 1971), to the measurement of the qualities of neighborhoods. This measurement system provides metrics of places that are independent of the perceptions of survey respondents. For example, in a study of responses to crime in Baltimore neighborhoods, interviews were conducted with residents that included questions about the perception of the neighborhood (Taylor, Shumaker, & Gottfredson, 1985). Then, trained raters walked the streets surrounding the respondents' homes and collected information on a range of physical and social traits, including housing layout, traffic volume, and persons loitering (Taylor, 1997). This early work demonstrated that reliable and consistent measurements of observed neighborhood environments could be carried out.

The Project on Human Development in Chicago Neighborhoods (PHDCN) enlarged the ways in which

contexts are conceived of and measured (Sampson, 2012). The project followed the example set by earlier work in that it combined family surveys with SSO while incorporating a breadth of additional material about community contexts. These studies aimed to capture aspects of community context that cannot be gleaned from methods that focus on individuals and families. A community survey addressed the structural and cultural organization of neighborhoods and interviews with community leaders who were included in a key informant study. Other aspects of community context were measured using a variety of sources, including census returns, police and court records, and health statistics. Follow-ups were conducted for the SSO, community survey, and informant interviews, allowing for the study of neighborhood stability and change.

Subsequent studies, such as the Los Angeles Family and Neighborhood Survey (L.A. FANS), have drawn on the materials developed for the PHDCN (Peterson, Sastry, & Pebley, 2007). The National Children's Study (NCS) developed protocols for SSO that are applicable to rural contexts, such as Duplin County, North Carolina (Walter, Dole, Siega-Riz, & Entwisle, 2011). Rural contexts had previously proved challenging to measure with SSO methods designed for cities. Census tracts, often used as a definition of neighborhood or community, are less applicable to rural settings, and a commonly used observation unit, the block or block face, does not occur on rural roads. In addition, the NCS includes local measures of the environment, such as air quality, in its data collection effort.

Some social processes occur at the neighborhood or community levels that are not well captured by aggregate data. For example, collective efficacy is a social process that is measured and evaluated at the community level. Broadly defined, it indicates the social cohesion among neighbors and their willingness to intervene for the common good (Sampson, Raudenbush, & Earls, 1997). Just as individuals vary in self-efficacy, communities also vary in the extent to which they achieve collective action. Neighborhoods ranked high on collective efficacy are associated with lower levels of violence, as well as a variety of other outcomes including increased supervision and monitoring of children (Sampson, Morenoff, & Gannon-Rowley, 2002). One of the mechanisms through which collective efficacy operates is the activation of social ties to bring about community action.

The measurement and conceptualization of contexts and contextual processes is an essential first step in understanding how individuals and contexts interact, yet it is

also important to connect contexts with the temporal flow of lives. Local networks of social ties represent another dimension of contexts that have consequences for children. In Coleman's study of high school completion (1988), frequent residential mobility decreased the chances of high school graduation. Residential moves may entail the loss of social capital, as local social ties are severed, adversely affecting educational outcomes. A study of residential mobility in Toronto demonstrated that life course concepts, specifically the concept of linked lives, offers a more nuanced understanding of the connections between local social ties and high school completion (Hagan, MacMillan, & Wheaton, 1996). Children from families with low levels of parental support are more susceptible to the negative effects of moving than children from families with high levels of support, suggesting that parents can partially compensate for the loss of social capital.

Children's social networks also change over time. Friendships are moving sets and systems of relationships that change frequently during childhood (Rubin, Bukowski, & Bowker, Chapter 5, this *Handbook*, this volume). In a longitudinal study of almost 700 youth, Cairns and Cairns (1994) tracked, among other things, the stability and change in peer groups. Moving by changing schools or classrooms and taking up new activities provide new opportunities for forming friendships, and, as a result, the peer groups of children and adolescents can be rather fluid. Indeed, spatial propinquity is one of the most important factors in forming and maintaining childhood friendships. Despite the changeable nature of peer groups, they have a lasting impact, as members of the same social groups in childhood tend to have similar outcomes later in life, including the experience of dropping out of school and bearing children in the teenage years. Early peer affiliations may place constraints on subsequent pathways for children, or new friendships may repeat the features of earlier ones.

Children are exposed to a sequence of different contexts over varying durations and periods in their development. There are certain times when they are more susceptible to the influence of their ecological settings. For example, it has been demonstrated that early exposures have important and enduring effects. In a longitudinal study of children in British Columbia, exposure to concentrated disadvantage in kindergarten (i.e., a composite measure of several dimensions of social and economic inequality), had a lasting effect on reading comprehension scores at Grade 7 (Lloyd, Li, & Hertzman, 2010). The effect of neighborhood concentrated disadvantage during Grade 7 had no

independent effect on reading scores, implying that early exposure had significant and enduring effects.

Duration of exposure to contexts is another important consideration in assessing the interaction of ecological effects and the life course. Wheaton and Clarke (2003) found a lagged and cumulative effect of childhood socioeconomic disadvantage on mental health in young adulthood. Young adults' current exposure to socioeconomic disadvantage had no effect on mental health net of the effects of childhood exposure. Using the PHDCN data, Sampson, Sharkey, and Raudenbush (2008) found that early exposure to neighborhood disadvantage has lagged effects on verbal scores several years later. The effects of exposure to concentrated disadvantage on verbal ability were long lasting rather than instantaneous. Contextual influences vary by "dosage," and the frequency, intensity, timing, and cumulative exposure to a particular context are determinants of the strength of neighborhood effects (Galster, 2011).

A complete understanding of context and the life course includes an integration of the spatial aspect of places with the temporal dynamics that characterize the life course. Places are not static entities, they change as their inhabitants enter and exit, the physical environment alters, and local social dynamics shift. Consider the Nang Rong study in rural Northeast Thailand, an example of a longitudinal study of both changing individuals and their changing environments, with emphasis on the transition to adulthood. Because this study illustrates many of the concepts of context and lives, we provide a full account of it. This multidisciplinary project began as a community-based rural development intervention in 1984 (Walsh, Rindfuss, Prasartkul, Entwisle, & Chamratirinthrong, 2005). Nang Rong is a rural, formerly frontier area, dominated by small-holder agriculture, with rice and cassava as principal crops. Once the frontier closed, in-migration to the region ceased and a period characterized by out-migration to urban areas, labor migration, and development efforts began. Several waves of social surveys and migrant follow-up studies were supplemented by a wealth of contextual information, including aerial and satellite image time series, and other detailed geographic information. With this information, analysts were able to track individual, community, and environmental change over time. Modeling efforts also link individual and household behavior with land use change (Entwisle, Malanson, Rindfuss, & Walsh, 2008).

Studies using data from the Nang Rong project illustrate concepts that tie contexts to the life course, particularly exposure to new contexts and opportunities associated

with young adult migration and the effects of the duration and cumulative exposure to contexts. With a longitudinal design, and a series of migrant follow-ups, these data are well suited to study the transition to adulthood, which in Thai society involves the completion of education, entry into the labor force, marriage, and the initiation of childbearing. In Nang Rong, migration is an important component of the transition to adulthood because both short- and long-term labor migrations are common for men and women. As young people leave the parental home and natal village, they are exposed to new contexts that influence and are influenced by the changes in roles and statuses that occur during the transition to adulthood.

In Thai society, there are strong norms about the ordering of employment and marriage, especially for young men, who are expected to be financially equipped for marriage. Though migration tends to delay marriage in Western contexts (Rindfuss, 1991), in Nang Rong, both young men and women who participate in labor migration marry sooner than their counterparts who remain in their village of origin (Jampaklay, 2006). For women, the positive effect of migration on marriage remains even after controlling for schooling and employment, whereas for men, the effect of migration on marriage is entirely explained by employment. There are differences between migrants and nonmigrants not only in the timing of marriage, but also in the village of origin of their spouses. Migration exposes young people to new social groups, and as a result, they are more likely to marry individuals from outside of their village. Young people who seek work in nonagricultural settings, such as factories, are even more likely to have a village exogamous marriage.

Migration experiences also influence entry into childbearing. However, the effect of migration on childbearing varies by family formation stage, suggesting that the new settings migrants are exposed to operate differently at different points in the life course. For instance, migrant status is associated with higher fertility, but only among low-parity (0 or 1) women, who are in the early stages of family formation (Edmeades, 2006). Migration influences fertility by encouraging early entry into marriage, and thereby earlier childbearing. Despite the earlier initiation of childbearing by migrants, cumulative urban experience over the life course has a dampening effect on total fertility, as urban migrants adopt the lower childbearing norms of city dwellers. Thus, the effect of migration experiences and urban contexts play out over an extended period, and one must consider an entire childbearing career to gain a complete understanding of its relation to migration.

As we have noted, contexts are not static entities in the lives of children. They move through different contexts as a result of residential mobility, changing schools, and changing roles in the course of their lives and development. It follows that the context of human development is a system of complex and reciprocal interactions between individuals and their ecologies. Places can shape and influence the trajectories of children, often in complicated ways, as in the case of lagged and cumulative effects. Young people also shape their contexts, as they choose certain actions, such as labor migration, or build networks of friends. However, no understanding of the relation between individuals and their contexts is complete without considering the ways in which individuals select or are sorted into particular contexts.

### **Selection and the Life Course: A Social Process**

Some young people leave their community to seek work, whereas others stay behind. Individual qualities tied to agency, such as initiative and resourcefulness, are certainly factors in determining who migrates. However, the selection of places to live, work, and attend school are not solely determined by individuals. Through mechanisms such as structures of opportunities, limitations, and incentives, places also select people. The process of selection into and out of contexts illustrates how individual agency and broader structural factors combine to influence the contextual history of the individual.

In a study of Iowa adolescents conducted in the wake of the farm crisis of the 1980s, Elder, King, and Conger (1996) examined the pathways by which adolescents decide to remain near home or move to new communities. Residential choices are contingent on educational and work plans, but are also shaped by preferences to live near family. These preferences, sometimes established by 8th grade, before adolescents formulate concrete notions about future work or college, can set geographic boundaries on other choices, such as whether to attend an in-state college or search for work in the local area. Yet, adolescents' preferences are influenced by changing conditions, such as the perception of limited job opportunities and family conflict, which weaken the inclination to remain near home. School performance and college prospects also change over time and can draw students away from family and community. Thus, residential decisions are formed in part by individual preferences, but are also molded by sets of social contexts, ties, and options, such as employment and educational prospects and the quality of family relationships.

Self-selection into situations and contexts represents a fundamental conceptual dynamic in the life course. With every transition, individuals are faced with choices and decision making within the bounds of their knowledge, resources, opportunities, and constraints. Selection has also been treated as a methodological concern because failure to account for preexisting differences that contribute to selection can skew estimates of the outcome of interest. Selection in this sense presents challenges in understanding cause and effect. For example, there are competing hypotheses about the relation between low SES and health (George, 2003a). Hypotheses of social causation assume that low SES contributes to poor health outcomes among young people. Social factors affect health either directly, through access to health resources, or indirectly, as in the case of exposure to stress and toxic environments. Alternately, a social selection hypothesis states that poor health has social consequences that contribute to declining SES, such as impaired capacity to work. However, both hypotheses can be valid, because the relation between SES and health is reciprocal. Social factors may contribute to health at the same time that health may cause changes in social status.

Research concerned with the methodological dimensions of selection has prevailed for many years. Experimental designs were proposed to address selection effects through random assignment to treatment groups. The Moving to Opportunity (MTO) program represents an ambitious attempt to apply an experimental design to the implementation of housing assistance programs (Sanbonmatsu et al., 2011). The experiment was designed to assess whether moving from a high-poverty neighborhood to a lower-poverty neighborhood improves the social and economic prospects of low-income families. Selection bias makes this question difficult to answer because certain types of families, such as those possessing more resources, are more likely to move. To address this methodological concern, MTO provided a randomized design capable of parsing the differences between movers and nonmovers (for more detail on MTO and selection, see Elder & Shanahan, 2006).

Randomized designs, such as MTO, are rare and often impractical to implement. Despite some of the traction gained on the methodological challenges associated with selection, they offer an imperfect solution. For example, these designs cannot uncover the specific mechanisms through which neighborhoods influence well-being (Sampson et al., 2002). Selection is not solely the domain of methodology, because the process of selection into

particular contexts can be viewed through life course theory, especially the concepts of agency and pathways (George, 2003b). From a life course perspective, selection represents a substantive research issue. In this light, contexts reflect prior experiences, or the pathways through which individuals become exposed to a particular environment.

As Sampson (2012) made clear, selection is a social process worthy of study in its own right. Sorting into and out of particular places can be seen as a series of linked processes that operate through individual actions and broader community and social structures. Individuals choose where to live, but make their choices within sets of preferences and constraints. Particular contexts may be characterized as recruiting and sorting individuals through incentives or obstacles to membership. Developing conceptual models of how selection occurs aids in understanding these processes. This is not the case when selection effects are merely statistically controlled (Caspi, 2004).

When selection is considered a social phenomenon, it is possible to investigate the reciprocal processes by which contexts choose people and people choose contexts. Although not concerned directly with changes in place, several lines of research have elucidated the dynamics of selection processes. This reciprocal perspective is illustrated by the choices young people make as they decide to enter the voluntary armed forces, the work force, or college. Using data from the National Longitudinal Study of Adolescent Health (Add Health), Elder, Wang, Spence, Adkins, and Brown (2010) examined the role of disadvantaged background, lack of social connectedness, and behavioral problems in drawing young men into the military instead of college or the labor market. The volunteer military offers socioeconomic, educational, and developmental incentives and presents a set of risks including injury and death. Other options, such as enrollment in college, also have associated incentives, as well as prerequisites such as resources to meet tuition expenses and adequate academic performance. The results of Elder and his colleagues suggest that young people weigh the advantages and disadvantages of joining the military against alternative paths.

Access to resources is a factor in the decision, as the most advantaged are more likely to attend college, whereas the most disadvantaged may not meet the minimum requirements for enlistment. Prior experiences are also important, as students with less stable families, low levels of social support, and involvement in problem behaviors such as fighting are more likely to enlist than their respective counterparts. Social ties may also lead students to

select into different tracks, as those with friends in the military or a family history of military service are more likely to enter the military rather than college or work. When students exit school, a variety of individual and social factors interact with a set of institutional incentives and obstacles to channel young adults toward college, the work force, or the military. The benefits and costs incurred by joining the military vary with the particular background of the individual, but the goal of maximizing opportunities drives decisions that are made within the constraints and opportunities afforded by an individual's own set of traits (Wang, Elder, & Spence, 2012).

Students are faced with selection into certain pathways before they leave school and make choices about entering work, the military, or college. School tracking, or the selection of students into different curricula based on previous performance, can allocate students to different pathways, such as college preparation or vocational training. Yet, there is great variation among tracking systems in selection criteria and the possibility to move between different tracks (Gamoran, 1992). In some schools, tracking may be a strong signal of student's future achievement, especially when it permits advantages to accrue to students who already have them (Lucas, 1999), but there is a significant amount of contextual variation. In some cases, students elect their curricular track, but in other instances a track is chosen for them. Regardless of whether the track is elective or not, it places a student on a path that has consequences for their future educational and occupational trajectories.

Young adults also exercise agency when they leave the parental home and select the community in which they will reside. However, these acts of agency are not disconnected from the reciprocal selection processes that occur between individuals and contexts. For example, although a young person may choose the community in which to reside after leaving the parental home, subsequent residential changes may occur that are out of his or her control, such as shifts in neighborhood composition. These changes illustrate how the reciprocal relation extends beyond individuals and their contexts to include the people around them.

In a study of geographic change during young adulthood using PHDCN and the Panel Study of Income Dynamics (PSID), Sharkey (2012) observed patterns of continuity and change in residential conditions between childhood and adulthood in segregated urban areas. Among young adults who exit segregated cities, he observed a trend toward ethnic equality, as young adults move into more integrated neighborhoods. Yet, as these individuals move further into

adulthood, there is a reproduction of initial neighborhood inequality. Sharkey described this process in terms of "selected" and "unselected" change. Young adults who "select out" of extremely segregated areas end up returning to segregated areas later in life. One explanation for this trend is the process of "unselected change," or change in the neighborhood environment that occurs around individuals. Such change, in this case increasing segregation, runs counter to the preference of the individual for an integrated neighborhood. Put another way, "selected change" leads young adults into relatively integrated environments, but "unselected change" contributes to increasing segregation around them over time.

The agency of young adults is a factor in selection into residential areas, but it is only one part of a reciprocal process, as residential environments change around individuals. In Sharkey's words, "to understand change, one must move beyond an exclusive focus on individual choices and instead consider systems of interrelated decisions made by individuals responding to the change occurring around them" (2012, p. 21). So, neighborhood inequality is transmitted from childhood to adulthood not only because of individual choices, and the choices made by other people in their community. Neighborhood contexts change as their inhabitants change, but some qualities of neighborhoods, such as segregation, are also reproduced over time. Thus, a complete understanding of selection into a context requires the consideration of individual choices as well as overarching structures (in this case ethnic and class segregation) and the decisions of others.

Much of the work that stems from a renewed focus on contextual influences owes a debt to the ecological models of Barker, Bronfenbrenner, Lewin, and their students. When principles of life course theory are connected with increasingly nuanced understandings of place and context in the new ecology of human development, we gain a fuller appreciation of the ways in which lives shape places and places shape lives. This bidirectional interaction of contexts and the life course sheds light on the processes through which individuals self-select or are channeled into contexts. The inherently temporal nature of the life course, which is concerned with change, trajectories, and human agency, reminds us that people are not entities on which static contexts exert influence. Contexts are constantly changing as well, and the interplay between people and contexts often depends on the timing, duration, and intensity of exposures and interactions. We turn now to a consideration of the developmental impact of social change in historical time and place.

## THE IMPACT OF HISTORICAL TIME AND PLACE

Major historical events and the proliferation of longitudinal studies have drawn attention to the potential developmental influence of historical change and its ecologies. As we noted earlier, the Great Depression of the 1930s persuaded psychologists at the Berkeley Institute to collect information on the changing SES of the Oakland and Berkeley study children. These data were not used at the time, but their presence in the data archive some 30 years later enabled research on the life-long impact of this economic crisis.

This incident is not an isolated case, and it was not so even in the 1930s to 1940s, a time when few longitudinal studies were in operation. For example, Terman decided to collect information on military experience in World War II when an increasing number of young men in his study of “gifted children” (Holahan & Sears, 1995) were mobilized into the armed forces. The W. T. Grant Study of college men at Harvard University (1938–1942) also focused much of the data collection during the 1940s on military service (Monks, 1957). War-related data from these two studies have been used to assess the life course influence of military experience (Elder, Shanahan, & Clipp, 1997; Lee, Vaillant, Torrey, & Elder, 1995). In addition, data collection of longitudinal studies has been influenced by the Great Recession that took place between 2008 and 2011 (Vuolo, Staff, & Mortimer, 2012), resulting in the collection of more detailed information on socioeconomic adaptation.

### Studying Lives in Context: Some Considerations

In designing a longitudinal study to investigate the influence of social change and its social ecologies, researchers are advised to add a comparative cohort to obtain insights regarding historical change. Lacking such a cohort, the analyst would not be able to determine the generality of a study’s findings. Consider *Children of the Great Depression* (Elder, 1974/1999), which is based on children who were born and reared in a specific historical time and place, defined by culture, social institutions, and diversity of people—the 1920s, the San Francisco East Bay, California. The book also describes a very different Depression experience in Great Britain, Germany, and Japan. Even in the United States, conditions during the Great Depression varied among cities, East and West, and between rural and urban places. In view of this variation, the study’s generalizations are uncertain. Also uncertain

are generalizations across historical time such as periods of economic depression and prosperity.

However, it is still possible to focus on historical variations “within a specific birth cohort” because not all members are uniformly exposed to the same change. Consider the Oakland cohort with birthdates of 1920–1921 (Elder, 1974/1999). Some of the young people were exposed to severe economic loss in the 1930s, while others were largely spared hardship and family disruption. Variations of this kind were observed among families in the middle and working class as of 1929, enabling a delineation of nondeprived and deprived groups for systematic comparison. This design revealed enduring differential consequences for children’s life chances that extended into their middle years.

This study of children of the Great Depression eventually added a comparative cohort for the Oakland sample, the Berkeley study members who were born at the other end of the 1920s just prior to the economic collapse. With this extension, the project was able to show that the younger Berkeley boys were at greater risk of impaired development in hard-pressed families during the Great Depression than were the older Oakland boys. In the younger Berkeley cohort, boys in hard-pressed families tended to lose contact with their self-absorbed fathers, even when physically present. Cohort differences were generally reversed among the girls. The younger Berkeley cohort fared better, owing to the nurturance of the mother-daughter relationship and the social disadvantage of the Oakland girls who were going through physical and social maturation during hard times.

The Great Depression transformed the social world of the Oakland and Berkeley children, but this event proved to be merely part of their changing life story since they were exposed to the mobilization of World War II during the early 1940s and then the Korean War in the early 1950s. The Oakland cohort completed high school just prior to the onset of World War II and soon nearly all of the young men had entered the armed forces. Most of the Oakland girls were eventually drawn into the home-front labor force in the San Francisco region, especially the booming shipyards. The Berkeley children were too young for military service at the beginning, but three-fourths of the males served in the military between 1945 and the end of the Korean War in the early 1950s. Although *Children of the Great Depression* did not explore this wartime experience, the adult lives of both cohorts suggested that an understanding of them would be incomplete without investigating the lifelong impact of both economic

depression and war. To obtain essential life history data on the wartime experience and its effects, a research team in the mid-1980s obtained a completed military service questionnaire from men in both cohorts.

The men who grew up in financially strained families during the Great Depression frequently saw military service as a “bridge to greater opportunity.” However, just as *Children of the Great Depression* noted, the impact of this life transition depended on when it occurred in men’s lives—their life stage. According to the balance of costs and benefits, military service in both cohorts favored the recruit who entered shortly after completing secondary school. This time of recruitment came well before commitments to higher education, a marriage partner, children, and a line of work. By contrast, later recruitment tended to disrupt all of these activities (Elder & Caspi, 1990). The later the time of entry, the greater the disruption and life consequences among men in both birth cohorts.

Especially in the Berkeley cohort that was more adversely affected by hard times (Elder, 1986), young men with multiple disadvantages (such as a deprived family, poor grades, and feelings of inadequacy) were most likely to join up and to do so as soon as possible. In combination, these factors predicted early entry into military service and its pathway to personal growth and greater opportunity. Early entrants experienced greater life benefits from the service up to the middle years than did later entrants and their occupational achievements by age 40 showed no adverse effect of hard times. These benefits occurred through situational changes in the service that made recruits more ambitious, assertive, and self-directed as well as through government benefits to veterans in access to higher education and in loans for the purchase of housing.

The influence of military service remains largely a “black box” of unknown processes in the Berkeley and Oakland cohorts. However, insights regarding some of these processes have come from a compelling test of the early entry hypothesis. Two sociologists, Sampson and Laub (1996) made use of life record data on men who grew up in poverty areas of Boston (birth years, 1925–1930). More than 70% entered World War II. The sample came from a study of 500 delinquent European American boys (aged 10–17) who were committed to correctional schools in the state (Glueck & Glueck, 1968). They were matched with European American nondelinquents from the Boston schools. A rich body of life-history data collected on these study members between 1940 and 1965 provides unusual detail on the men’s service experiences (they entered at

18 or 19 and served over 2 years) including in-service training, special schools, exposure to military justice, and arrests. The delinquent boys ended up with a much longer string of antisocial events, and were less apt to obtain in-service training and veteran benefits from the GI Bill. But they were more likely to benefit from the service over their life course, when compared to the controls, and this pattern was especially true for men who entered the service at an early age. In-service training, overseas duty, and veteran benefits for education and housing significantly enhanced the job stability of men with a delinquent past, especially when they entered the service at a young age.

Life stage at exposure to Depression hardship and military duty in World War II tells contrasting stories of risk. “Young boys” were most adversely influenced by hard times, whereas older male recruits to the armed forces were at greatest disadvantage when they entered the service. Because these males were drawn to military service at an early age, they experienced its greatest benefits (as a benefit/cost ratio), thereby tending to counter the negative effects of their adversities in the Great Depression. For this cohort, the military clearly represented a pathway to greater opportunity through postwar prosperity, offsetting much of the damage of growing up in hard times. In this manner, they avoided becoming members of the “lost generation from the Depression years” that was forecast at the time. In the aftermath of military defeat in World War II, the war and postwar eras proved to be much harder and perilous for those who served in the armed forces of Germany and Imperial Japan.

The Oakland and Berkeley studies of the effects of social change used data from small longitudinal samples that were designed to address different questions. The initiation of these and other studies prior to the Great Depression and World War II provided a rare opportunity to investigate the impact of these historical events on study members’ lives. In the following section we look at more contemporary projects with much larger cohorts and samples. Their ecological units are also much larger in size, such as rural versus urban and entire provinces.

We begin with a comparative cohort study of the life course and health in regions of contemporary China that is based on methods that are particularly useful in the first stage of a social change project. The rural-urban divide provides the major ecological contrast, although significant advances have been made toward more detailed studies of ecological variations within the country. This section is followed by longitudinal studies of transforming change in

Eastern Europe, with a focus on the life course and human development of young people as they make their transition to new political worlds. Contemporary ecological models of human development will enrich future extensions of these studies.

### **Social Change in Life Course Health: The Case of China**

Research on societal change often requires a general analytic approach that maps the conceptual territory and identifies the primary influences for more intensive study like that provided by the Oakland and Berkeley studies. One such study design focuses on the age/period/cohort distinction. *Age* refers to aging, the life course and the study member's life stage at any time; *period* indicates the historical time of survey measurement and context; and *cohort* refers to a group defined by year of birth or entry into the system, such as a child's transition to primary school. Traditionally, an age/period/cohort analysis represents the initial step toward identifying significant effects that can then be investigated in a more focused and in-depth manner. The troubling statistical issue here is that each parameter is completely defined in terms of the other two, producing an unsolvable identification problem.

Recent advances in statistical evidence address this challenge. A book by Yang and Land (2013) presents applications of this advance within the history of age/period/cohort studies. A possible solution to the identification problem is to exclude one of the three components on the basis of substantive and/or methodological issues. The simplicity of this approach is an advantage as is its substantive relevance when the issue concerns study of an historical effect because this effect is expressed in terms of both period and cohort influences.

A good example includes only age and cohort in the model, with a focus on their interaction. Consider a pronounced downturn in the economy. A period effect tends to widen the gap between cohort trajectories over time and thus indicates a cohort effect. A longitudinal design also favors this interpretation because repeated observations over time for an individual generate a person/year data set that is distinguished by only a single indicator of time—it can be either age or period but not both. The best way to grasp these distinctions is to see them at work in a research project on a changing society, such as China.

Social change and rural–urban inequality are central themes of contemporary China, and, as Whyte observed

(2010), socioeconomic prosperity is heavily concentrated in the urban sector which is still largely “walled off” for people who live in rural China, owing to the migration constraints of rural household registration. Over 60% of the Chinese population resides in rural provinces. A study by Chen, Yang, and Liu (2010) addressed the health consequences of social inequality and the rural–urban divide in China. They used survey data from the longitudinal China Health and Nutrition Survey, a collaborative project with institutions in the United States and China. The survey includes a five-wave data set that spans 13 years, from 1991 to 2004. The age span begins at 21 years and extends well into late life.

Multiple waves in the project enabled a cohort analysis of age change in health and its relation to historical, rural–urban, and life-stage contexts. Respondents aged as members of each 10-year cohort across the follow-ups, producing age-graded cohort trajectories of self-reported health. The cohort members were asked about their health on a standard 4-point scale in each follow-up. Numerous studies have shown that this global measure is predictive of subsequent health and mortality (Chen et al., 2010). SES was measured by education and per capita family income. The investigators used a theory of cumulative disadvantage to account for the enduring effects of socioeconomic inequality.

The analysis addressed the effect of social inequality on self-reported health across the life course (within cohort) and the question of whether this life pattern varied across cohorts (an intercohort or social change effect). As noted earlier, the study focused on the effects of age as well as cohort and their interaction, and excluded the period parameter from the analysis. Because cohorts vary by age across historical moments, any historical effects would likely generate cohort differences in age-related outcomes. The results clearly document a strong intracohort link between patterns of social inequality and health differentials across the life span. With adjustments for cohort, the data reveal a process of cumulative disadvantage involving both limited education and income—the socioeconomic differential in access to health care, health self-care, and social support is greater at older than at younger ages and is influenced by income and education. These findings are consistent with those obtained in the United States.

However, variations across birth cohorts differ sharply from those observed in the United States. The impact of educational attainment on mean level of health decreased across successive cohorts, from the older to the younger, a

trend that is most pronounced in rural China. In addition, rural health care has declined more than urban health care in the recent reform era. More advantaged populations in developing societies tend to adopt a life style with unhealthy diets, less frequent exercise, and excessive drinking and smoking (Chen et al., 2010; Harris, 2010). Longitudinal research indicates that this problematic life style is established in childhood and adolescence, and follows an upward trend of accentuation into the middle years (Harris, 2010). Problems of obesity and chronic disease are associated with this life style.

The two major findings based on “within and between” cohort analyses are suggestive of promising next steps in this line of research. The study clearly shows a strong cumulative effect of social inequality on self-reported health, and identifies some explanatory processes, such as inadequate access to health care. We know that educational level makes a significant difference in the selection of available health care, but what other factors account for this process? What about the declining influence of educational level on self-reported health between older and younger cohorts? Can we learn something from the study members who are most and least likely to show a relation between education and the use of available health care? These are the kinds of questions that might emerge from an age/period/cohort analysis.

The census-like design of this China longitudinal survey clearly leaves much to the imagination on explanatory processes. A large-scale study of this kind can only provide a skeletal picture of the relation between social change and health across the life course. More focused research is needed on each sequential life transition across the life course, but this China project helps to frame more explanatory studies. One possibility is to extend the age range downward to the middle years of adolescence. These early years of development are vulnerable to the risks of a rapidly changing society, and set in motion the direction of developmental and health trajectories, with major consequences for the transition to adulthood and the young adult years.

The China longitudinal study addressed a long-term process of social change and thus differs significantly in adaptational requirements from the drastic economic decline and recovery cycle of the Great Depression. Observation of such change requires a shorter time span, one that may provide a sharp contrast of before and after the event. We turn now to studies that capture the life course effect of drastic change in the Soviet empire and in East Germany many decades after the end of World War II.

### **Societal Dissolution and Unification: Their Impact on Young Lives**

Very little is known about the lives of Europeans who grew up in the hard years of social displacement, institutional change, and extreme poverty after World War II (Judt, 2005), but studies of social transformation in Eastern Europe and the Central Asian sector of the continent provide vivid evidence of the human consequences of this era of personal change—from the break-up of the Soviet Union in 1990–1991 following “an era of liberalization” to the unification of Germany after 40 years of separation between West Germany and the German Democratic Republic.

These two examples of social change in young peoples’ lives represent contrasting processes. The dissolution of the Soviet Union led to 15 republics that became sovereign states. In a unique nationwide longitudinal study (Titma & Tuma, 2005), young people who began their schooling in the USSR suddenly found themselves in different countries defined by different cultures, socioeconomic systems, and life opportunities.

By contrast, the postwar history of Germany was shaped by its division into two countries, the Federal Republic of Germany in the west and the German Democratic Republic in the east within the orbit of the Union of Soviet Socialist Republics. Greater liberalization in the USSR during the late 1980s set in motion a process of change that led to the “fall of the wall,” separating West and East Germany, and the political process of unification. East Germans were incorporated into the Federal Republic of Germany as the latter’s social institutions and financial resources were transferred to the former East Germany. We begin this section with the Soviet Union’s dissolution and its life course effects because this process defined the larger context for German unification.

#### ***When the Soviet Union Dissolved***

Imagine the beginning of a national longitudinal study of young people’s lives just prior to a political transformation that turned all of the society’s states into sovereign countries with different governments, socioeconomic structures, and cultures. This scenario actually occurred during the research project of sociologist Mikk Titma, which began in the 1980s in the Soviet Union and continued into the 1990s. The good fortune of such unexpected change is that he managed to continue collecting data on the lives of the study members in their diverse post-Soviet worlds. They were all secondary school

graduates across the Soviet Union when first surveyed in 1983–1984.

The Paths of a Generation project (see Titma & Tuma, 2005) focused initially on the developmental trajectories of early life careers, but in the post-Soviet era it became a study of social change in socioeconomic attainment and loss. With his research team, Titma succeeded in following up most of the study members who were living in six successor states—Estonia and Latvia along the Baltic rim, Russia, Belarus, the Ukraine, and the Central Asian country of Tajikistan. The first follow-up occurred in 1988 to 1989, the second in 1993 to 1994, and the third in 1997 to 1999 when the study members were in their 30s. The analysis is based on approximately 12,000 young men and women.

As a birth cohort from the late 1960s, the study members were following a timely trajectory because they had completed their basic education before the dissolution of the Soviet Union and thus were able to move into the post-Communist era and take advantage of available opportunities for entrepreneurship, employment in a firm, and higher education. The basic level of education became less available in the post-Soviet era. Moving from the known world of Soviet control to an emerging, unfinished society entailed great uncertainty for many and no assured framework for expectations. Opportunities varied significantly from the Baltic States to Tajikistan. Estonia and Latvia were incorporated into the Soviet Union before World War II but they had greater commerce with the West than the other post-USSR countries. Indeed both achieved substantial growth in their market economy during the 1990s and established parliamentary democracies. Russia and the Ukraine along with Belarus (under strong Russian influence) lagged in the post-Communist decade, followed at the end by Tajikistan with its resemblance to Afghanistan in culture, economic development, and topography.

When a young person makes a transition into a new world of opportunities, risks, and constraints, as during the break-up of the Soviet Union, does he or she become a different kind of person? In life course terms, the answer would be, *It depends*. What life history of experiences, resources, and dispositions is brought to the new situation? Is the transition made with the support of other like-minded people? What kind of new environment is the person entering? Are there strong situational constraints to channel behavior? Caspi and Moffitt (1993, p. 315) proposed that “people become agentic when they encounter an unpredictable situation; whether they are impulsive or reflective, predatory or altruistic, lazy or conscientious, they are actively trying to reinstate predictability.” As Caspi and

Moffitt suggested, this situation is the type of circumstance in which individual differences of personality are most likely to play an organizing role in channeling behavior.

Caspi and Moffitt’s account meshes well with the Titma study’s empirical findings on an “agentic theme,” expressed through education, abilities, goals, and self-efficacy. These agentic influences on young people before the Soviet Union’s demise predicted their adult success, as indexed by social class, occupational status, and total earnings in the post-Communist era. But this outcome of human initiative depended on whether the new society favored such initiative and offered relevant life opportunities for self-fulfillment. Social and economic success was consistently greater in the two Baltic societies, whereas Tajikistan ranked at the bottom. It is noteworthy that economic initiatives outside the main job during secondary school proved to be predictive of entrepreneurial activities in the adult years. Again this relation turned out to be strongest in the Baltic countries, owing partly to their opportunity structure for starting new businesses. Gender inequality was least evident in these Baltic societies.

Pervasive movement in social status, up but especially down, represents a distinctive feature of life in eras of disruptive change (see Titma & Tuma, 2005). Poverty and unemployment rates increased significantly as did rates of divorce and mortality. In the western part of the old Soviet Union, the size of birth cohorts in the 1990s declined by nearly half. Despite the social flux of the times, human capital (grades, educational level, etc.) consistently predicted young adult attainment during the 6 years that followed the end of the Soviet Union, with the most pronounced effects in the Baltic States.

### *The Unification of Germany*

As liberalization pressures in the Soviet Union were pulling it apart in the late 1980s, demands for unification were building in West Germany and the German Democratic Republic, leading to the reunification of Germany in 1990. At the time, West Germany was 3 times the size of the GDR in population, and its economy, wealth, and educational-cultural institutions were appreciably greater as well. Despite such differences, the shared history of West and East Germany as well as the reach of Western media could well have blurred the expected differences.

Two major research programs in Germany have focused on the personal impact of unification—Mayer’s German Life History Study (Diewald, Goedicke, & Mayer, 2006) and Silbereisen’s (2005) research over some 20 years on social change and human development. We begin

with Mayer's sociological perspective on life course changes following the collapse of the German Democratic Republic, and then turn to Silbereisen's Jena project with its interdisciplinary perspective. The Life History project is focused on the adult years, whereas the Jena project draws on surveys as well as longitudinal data spanning the years from childhood into young adulthood. These two projects are among our most impressive long-term studies of drastic social change in human lives.

The German Life History Study was launched in 1979 by using retrospective life history interviews on a succession of birth cohorts of West German adults (1919–1921, 1929–1931, 1939–1941, 1949–1951, 1954–1956, 1959–1961, 1964, and 1971). This method of data collection enables study of past years of the life course in the absence of relevant data archives. The ability to recollect prior life history accurately is an important issue, although all longitudinal data collection relies on the accuracy of memory. Nevertheless, the dependence on long-term recall is obviously greatest in retrospective life history projects. In such studies data collection instruments are designed to maximize accurate recall.

When the Berlin Wall fell, the research team took advantage of the opportunity to extend the project to East Germany because it represented “an exemplary case for studying the life course under the conditions of extreme societal discontinuities” (Brückner & Mayer, 1998, p.154). Retrospective life history data were collected through interviews with members of four East German birth cohorts (1929–1931, 1939–1941, 1951–1953, and 1959–1961). The respondents were surveyed again in 1993 and interviewed from 1996 to 1997 to cover the entire social transformation process and its impact on the lives of men and women. The remarkable span of birth cohorts in this research reflects the teams' recognition that historical time and its correlated life experiences are important dimensions of the 20th-century life course in Central Europe.

Institutional differences between West and East Germany were observed to be very large on the eve of political and economic unification, especially in the realm of families, women, and children. State policies in East Germany provided families with access to housing, advocated equal employment opportunities for women, and offered abundant childcare, especially for working mothers. Young women in East Germany tended to marry earlier and had more children than women in West Germany, and yet they were also more likely to be employed. Introduction of a free-market system in East Germany removed support

for these family services and nearly half of all East German workplaces were lost during the first years after the fall of the Berlin Wall (Pinquart, Silbereisen, & Juang, 2004). Rates of unemployment and poverty increased sharply. Marriage and childbearing rates declined significantly at this time in East Germany, along with a substantial delay in having a second child.

Consistent with life course studies (Elder, 1998a) the German Life History Study discovered that success in the new economy of East Germany had much to do with both life stage and gender (Diewald et al., 2006). Unemployment was highest among the youngest and oldest men. In the middle-age category, men were favored over women by employers. The middle-age category included men with work qualifications who also had enough work years ahead to be retrained if necessary. As an index of a particular life stage, age combined the influence of prior experiences and acquired skills as well as the constraints of aging in the second half of the life span. Thus, prior experience with work transitions enhanced the adaptive ability of middle-aged East Germans, even in a period of socioeconomic transformation. Reentering work after a phase of joblessness depended on age status to a greater extent for women than it did for men.

Despite the social disruptions and economic hardships associated with unification in East Germany, the Life History Study found that emotionally close relationships before 1989 tended to become stronger among young people and their families in the East. The evidence shows a high level of stability in marital relationships and family networks, suggestive of a compensatory adaptation to the hard times that was observed here as well as among American families during the Great Depression in the United States (Liker & Elder, 1983), especially when marital ties were relatively strong before the crisis. However, social ties associated with work in East Germany seldom survived the unification process. Many workplaces were closed down. Observations from the German Life History Study (Diewald et al., 2006) suggest that the rapid transfer of West German social institutions to the former East German region constrained the agentic influence of individuals, unlike the liberating shift toward self-direction among young men and women who were in their 20s following the dissolution of the Soviet Union and its control structure. The demise of Soviet control placed more emphasis on individual initiative.

This portrait from the Life History Study comes from adults in social roles and their constraining influence. East German organizational and institutional models were

quickly replaced after unification by a West German model in the Eastern region. Young people in East Germany were not constrained by adult roles and enjoyed opportunities for self-direction, especially in the transition from leaving home to establishing their social and economic independence. This age group was the target of Silbereisen's Jena project on German unification, a research program focused on the years from childhood into the 20s. It collected a rich array of survey and longitudinal data on psychosocial functioning, including the qualities of human agency in adapting to social change.

Some 14 years after German unification, Silbereisen (2005) shared his reflections about the challenge of studying the developmental impact of this social transformation in his 2004 presidential address to the International Society for Behavioral Development at Ghent, Belgium. He noted that a great many errors had been made in poorly designed research to assess the resulting population change, including the comparison of birth cohorts from each region. In designing a framework for the Jena program of research, Silbereisen drew on the Oakland and Berkeley cohort studies of children who grew up in the Great Depression and were followed into the middle years of life (Elder, 1974/1999). Of particular relevance to studies of the effects of German unification, as he saw it, was the multilevel model of economic decline and recovery, the family and its adaptations to socioeconomic change, and the developing individual. He also borrowed concepts of mechanisms from this project that specified processes by which social change could make a difference in children's lives. These included the control cycle process of losing control in a social transition, which then initiates efforts to regain it. Silbereisen expressed the hope that developmental scientists in the future would be "better prepared with adequate heuristics and theories on the nature of social and political transformations and their consequences" (2005, p. 4).

The Jena project was launched with two primary research foci: (1) the influence of German unification on the timing of life events in the transition to young adulthood, such as the age at leaving school and home, and (2) on adaptations to social change—the personal as well as social resources that favor successful adaptations, including qualities of human agency, commitments, and social support. The complexity of German unification as a social change contributed to mixed findings concerning the timing of life transitions and underscored the importance of a more adequate model of the unification process. It also revealed the need for more microtheories on variables that

link social change to life course outcomes. This recognition led to the development of new models (Silbereisen & Chen, 2010) featuring perceived demands, stress, and personal control.

More attention to the mediational process highlighted qualities of human agency that were relevant to coping with social change, such as beliefs regarding one's ability to make a difference in school or work. Studies of adaptation to social change have consistently shown that qualities of human agency are instrumental in successful coping (Titma & Tuma, 2005), and a series of studies by the Jena research group provides substantial evidence of this link. In a Leipzig sample of East German adolescents, Piquart et al. (2004) observed that youth who were highly committed to the old political system were likely to experience greater emotional distress after unification, but only if they lacked a sense of their own self-efficacy. Adolescents who identified with the old system and possessed stronger beliefs in their self-efficacy prior to unification did not experience such distress. In addition, the study found that higher self-efficacy predicted a decline in psychological distress over time.

The investigators also asked whether stronger feelings of self-efficacy among young adolescents would enhance their chances for a successful transition to work in adulthood. The longitudinal study began in 1985, well before German unification and it continued from ages 12 to 21. Only the noncollege study members were included in this research on the transition to employment (Piquart, Juang, & Silbereisen, 2003). The investigators tested a model in which efficacious beliefs about academic achievement and academic success promote young adult employment and job satisfaction through career-related motivation and work aspirations. The empirical findings provided support for the causal sequence linking academic success, self-efficacy and career-related motivation to positive work life outcomes, and it is noteworthy that this sequence corresponds in many respects with those obtained in an American longitudinal study during the 2008 to 2011 economic recession (Vuolo et al., 2012). In both studies, efficacious beliefs are associated with career-related motivational striving, and stable employment during the young adult years.

Unification occurred at different times in the young lives of East Germans and had different consequences for adults, as noted in our review of findings from the German Life History Study. We might expect differing effects by age of students in the East German school system, which was radically transformed after unification. Silbereisen and his collaborators (Vondracek, Reitzle, & Silbereisen,

1999) observed a significant differential effect by age on vocational preferences. Older youth who had a number of years in the old system experienced large changes in preferences (away from state-sponsored options), whereas those at a younger age with virtually all of their education in a Western-styled system displayed no differences in preferences. Another unstudied source of differential impact would likely involve very young children and their dependence on families that experienced socioeconomic hardships and marital stress, as suggested by the life stage findings from *Children of the Great Depression* (Elder, 1974/1999).

Empirical studies of the effects of German unification in this review are based on observations over a relatively short period of the life span. What will the long-term consequences be? The early years are not necessarily predictive of the later years. As in Titma's post-Soviet cohort, the German young people and adults who fared well in the radically changed world that emerged from unification of East and West Germany tended to view themselves as agents of their own lives. And they were significantly better educated than other East Germans. In *Children of the Great Depression*, the post-Depression era of World War II and growing prosperity played a major role in the resilient accomplishments of this American Depression generation across the adult years. Hopefully, the next stage of the Jena project will follow up the lives of East Germans who experienced the social transformation of unification.

## HUMAN DEVELOPMENT IN CONTEXT

The past half-century has witnessed an increasing tendency to view human development in context by linking complementary perspectives, temporal (historical/biographical) and ecological. The temporal perspective locates individual lives by birth year and cohorts according to *historical time*, and depicts their evolving biography across age-graded events, or *social time*. The ecology of a specific historical time is defined by distinctive institutional arrangements and cultural meanings. For individuals, the ecology of human development varies from such macrolevel attributes to the microlevel of social interaction across life stages in successive birth cohorts. The integration of these complementary perspectives represents a defining feature of the multilevel life course framework proposed in this chapter.

The two perspectives emerged at different times in studies of human development during the 20th century and only recently have converged in life course models.

The temporal cohort perspective on life patterns and human development first appeared in the mid-1960s through research based on birth cohorts, especially in the seminal work of Ryder. An early cohort-historical study, *Children of the Great Depression* (Elder, 1974/1999), used longitudinal samples to investigate the lifelong impact of Depression hard times on Californians born in the 1920s. However, it paid little attention to the children's ecology, other than to note regional variations in crisis. The study highlighted the developmental importance of taking historical time into account in longitudinal studies of children. But its nature remained largely unspecified beyond the economic hardship of families and children.

During this lengthy study of Depression children and their adult lives, Bronfenbrenner carried out an ecological study of socialization in societies with contrasting political systems, the United States and the USSR. In his book *Two Worlds of Childhood*, Bronfenbrenner (1970) observed that peer groups of students in the Soviet Union tended to reinforce adult approved patterns of conduct, whereas in the United States they more often exerted a contrary influence. This work was not informed by a perspective that locates children in historical context and follows them into adulthood. Consequently, it would not have been sensitive to the subsequent years of transforming change in the Soviet Union. In his now classic book *The Ecology of Human Development*, Bronfenbrenner (1979) drew on longitudinal studies of child development in historical times, although his ecological framework did not include a temporal perspective on the environment and individual.

To date, the most compelling research integration of these perspectives has been made by Sampson's program of Chicago research that evolved from the Project on Human Development in Chicago Neighborhoods during the early 1990s. He invested heavily in the conceptualization, measurement, and analysis of neighborhoods and their outcomes. Data sources include longitudinal samples of young people, community surveys, systematic observations of neighborhoods, and network assessments, among others. Sampson's contributions to the contextualization of human development reflect long-standing interests in community and criminology, as well as his longitudinal study of crime and the life course with Laub (Laub & Sampson, 2003; Sampson & Laub, 1993). Contemporary advances in studying the context of human development led Sampson (2012, p. 24) to propose that the 21st century may become "the era of context."

Sampson (2012) vividly documents the payoff for understanding "lives in context" in *The Greatest City*,

a study of Chicago neighborhoods and their residents over a decade. Virtually all Chicago neighborhoods in his study, he found, were connected across the years through the movement of people, families and children, the old and the young. This movement typically linked neighborhoods of advantage as well as those of disadvantage, thereby perpetuating their inequality across historical time and the generations. Sharkey extended the Chicago research with Elwert (Sharkey & Elwert, 2011) by using nationwide longitudinal data to investigate the effects of neighborhood and family on cognitive ability across the generations. The study shows neighborhood and family to be “closely intertwined” environments that jointly influence the “developmental trajectories of individuals in ways that extend across the generations.”

The interplay of multilevel contexts and human development has come a long way toward recognition of the centrality of this perspective in the field of developmental science. The flourishing study of the life course and human development is one example of such progress, and Bronfenbrenner’s (Bronfenbrenner & Morris, 2006) ecology of human development is another in studies of neighborhood influences. Both fields emerged from awareness of the neglected social world of children in developmental studies. The historical context and ecology of development still remain largely unintegrated in research, although we see encouraging movement toward their integration in this chapter and volume.

## CHAPTER 3

# Children's Parents

MARC H. BORNSTEIN

States Parties agree that the education of the child shall be directed to:

- (a) The development of the child's personality, talents and mental and physical abilities to their fullest potential . . .
- (b) The development of respect for the child's parents.

—Article 29, Convention on the Rights of the Child United Nations Children's Fund (United Nations General Assembly, 1989)

## INTRODUCTION

Childhood is the time when we forge our first social bonds, first learn how to express and read basic human emotions, and first make sense of the physical world. In childhood, individual personalities and social styles also first develop. Children's parents normally lead them through all of these dramatic firsts (Bornstein, 2002a). Evolutionary theory distinguishes between bringing a new individual into the world and caring for an existing one, childbearing versus

childcaring (Bjorklund, Yunger, & Pellegrini, 2002). Whereas species lower in the phylogenetic hierarchy are principally childbearers, mammals such as *Homo sapiens* also are devoted childcarers perhaps because the investment in a small number of offspring is great or young human children are totally dependent on their parents. Parents are fundamentally invested in their children: their survival, their socialization, and their education.

Each day approximately three-quarters of a million adults around the world experience the joys and rewards as well as the challenges and heartaches of becoming a new parent (<http://www.worldometers.info/world-population/>). Each reader of this page has had the experience of being

---

I thank R. M. Lerner, T. Leventhal, and D. L. Putnick for comments and K. Woo for invaluable assistance.

parented, and many of us relive the experience when we parent our own children. Parenthood is culturally normative, and most adults become parents (86% of women and 84% of men among adults ages 45 and older; Child Trends, 2002) only 3 years into their relationship (Claxton & Perry-Jenkins, 2008). Yet, parenting remains a somewhat mystifying subject about which few people agree, but about which almost everyone has opinions. That said, parenting science is enjoying popularity today as never before, and in consequence a surprising amount of solid science is accumulating about children's parents. As a testament to increasing demands for evidence-based parenting and to bring order to existing information, the first formal chapter on parenting per se appeared in the 2006 sixth edition of the *Handbook of Child Psychology*. The present chapter on children's parents updates and refocuses that treatment.

Historically, theorists of many stripes looked to parents as those actors believed to influence children the most, although childrearing is acknowledged to involve a wider cast of personalities. Children's parents are tasked with preparing them for the physical, economic, and psychosocial situations that are characteristic of the environment and culture in which they must survive and, it is hoped, thrive. In doing so, parents multitask; parenting is more than feeding and protecting and teaching and being emotionally available. Parenting requires planning, organizing, and executing (arranging birthday parties, identifying summer camps, finding doctors), all of which consume mental and physical energy and time. Parenting is disambiguating moment-to-moment novel, complex, rapidly changing, uncertain information associated with children. Parenting is expecting of oneself and being expected by others to caregive consistently, appropriately, and effectively. Parenting is being highly motivated to succeed at these many assignments.

Parenting blends tuition and intuition. Adults already know (or think they know) something about parenting by the time they first become parents (Civitas Initiative, Zero to Three, & Brio Corporation, 2000). Indeed, human beings appear to possess some intuitive knowledge about parenting (Papoušek & Papoušek, 2002), and certain characteristics of parenting may be wired into our biological makeup (Barrett & Fleming, 2011; Bornstein, 2013a). For example, people almost everywhere speak to infants even though they know that babies cannot understand language, and people even speak to babies spontaneously in a speech register especially reserved for them. However, human beings also acquire important knowledge of what it means

to parent children through generational, social, and media images of parenting, children, and family life, knowledge that plays a significant role in helping people formulate their parenting cognitions and guide their parenting practices. For these reasons, parents from different cultures differ in their opinions about all manner of parenting- and child-related issues, such as the relevance of competencies specific to their children's successful adjustment, the ages they expect children to reach different developmental milestones, and so forth (Bornstein & Lansford, 2010; Goodnow, 2010). Direct experiences with children and self-constructed ideas also help formulate parenting attitudes and actions. This chapter on children's parents applies the prevailing relational developmental systems perspective to parent-child relationships (Bronfenbrenner & Morris, 2006; Lerner, 2006; Lewontin, 2005; Overton & Molenaar, Chapter 1, this *Handbook*, Volume 1).

For their part, children seem primed to profit from parental care. Early childhood has long been thought to be a period in the life cycle when humans are especially malleable, a time when they are open to influences they will carry forward—even long after they have left their family of origin. Childhood characteristics thought to be especially plastic to parent-provided experiences range from the language children speak and the foods they prefer to the academics they achieve and the social customs they retain to the politics they follow and the religious beliefs they profess.

What forces affect when and how children develop? It has been observed that only two kinds of information are transmitted across generations—genes and culture (Dawkins, 1976). Children's parents are the “final common pathway” of both. So, this question goes to the heart of much of parenting science. Of course, children's genetic makeup affects their characteristics as it does how children are treated by their parents. However, there is unassailable evidence that parenting can and does guide child development, and the burgeoning scientific approach to parenting sheds bright light on how and why parental practices shape child outcomes (Belsky & de Haan, 2011; Collins, Maccoby, Steinberg, Hetherington, & Bornstein, 2000). Children's inherited dispositions and their parents' childrearing are reciprocally interwoven and function jointly.

In surveying central issues concerning children's parents, this chapter pursues the following course. First, the chapter addresses the two faces of parenting; that is, parenting as a phase of adult development, and parenting as an instrumental activity vis-à-vis children. Parents are concerned about themselves as parents, and parents are

concerned about their children's everyday well-being and long-term development. Next, the chapter provides a brief overview of thinking and research about parenting. Here, three topics are touched on: the origins of parenting studies, theories of parenting, and future directions in parenting research. The next two sections of the chapter address, *in seriatim*, parents, the principal actors in human caregiving, and, then, cognitions and practices that principally make parenting public. With the actors, attitudes, and actions associated with children's parents in mind, arguments for the meaningfulness of parenting effects are then evaluated. Here, correlational designs, and various kinds of experiments that demonstrate the value of parenting are discussed as are challenges to parenting effects from behavior genetics and group socialization theory. Parents and parenting vary impressively, and determinants of parenting are a major issue in the field; the multicausal origins of parenting in characteristics of parents, characteristics of children, and contextual characteristics are explored next. The chapter closes with some practical issues, for example neglect, abuse, and parenting interventions, before reaching more general conclusions.

### Parenting for Parents and for Children

Parenting is Janus-like: It is a formative status in the life course with consequences for parents themselves, and it is also a responsibility whose primary object of attention and action is the child. Human children cannot and do not grow up as solitary individuals, so parents want to know how best to take advantage of the opportunities parenting affords as well as cope with parenting's unrelenting demands. Some consider this instrumental construal of parenting a lifelong 24/7/365 job.

Parenting is most certainly a functional activity, but parenting is pleasures, privileges, and profits as much as frustrations, fears, and failures. Sociobiological theories of evolution assert that all species are compelled to see their childbearing (and childrearing) succeed on the argument that in that way genes ensure their immortality (Dawkins, 1976). However, there is much more to human parenting than biological continuity. Parenting has its intrinsic rewards. According to a nationwide survey conducted by the National Center for Children, Toddlers, and Families, more than 90% of parents say that, when they had their first child, they not only felt "in love" with their baby, but were personally happier than ever before in their lives (Civitas Initiative et al., 2000). Using a strategy of converging evidence, Nelson, Kushlev, English, Dunn, and Lyubomirsky

(2013) assessed whether parents evaluate their lives more positively than do nonparents, feel relatively better than do nonparents on a day-to-day basis, and derive more positive feelings from caring for their children than from other daily activities. Parents (conspicuously fathers) reported relatively higher levels of happiness, positive emotion, and meaning in life than did nonparents. Parents find interest and derive considerable and continuing personal reward in their relationships and activities with their children. Parents report that spending time with their children, especially in recreation or educational childcare, ranks among their most enjoyable activities (Krueger, Kahneman, Schkade, Schwarz, & Stone, 2009). Notably, mesocorticolimbic dopamine is involved in both reward-related learning and mammalian maternal caregiving (Insel, 2003).

For many, parenthood enhances psychological development, self-confidence, and a sense of well-being. Parenting translates into a constellation of new trusts, provides opportunities for enrichment and wisdom, and unlocks a panorama on the "larger picture" of life. Parenthood also gives adults ample occasion to confront new challenges and to test and display their competencies (Crittenden, 2004). Markus, Cross, and Wurf (1990) learned that feelings of competence as a parent constitute a highly common aspect of the self as desired by adults. Parenthood is known to alter the adult brain (Bornstein, 2013a; P. Kim, Leckman, Mayes, Feldman, et al., 2010; Leuner, Glasper, & Gould, 2010). Furthermore, from early infancy children recognize their parents, prefer their sights, sounds, and scents, and over the course of just the first year of life develop deep and lifelong attachments to sensitive and responsive parents (Bornstein, Arterberry, & Lamb, 2014). Filial piety prescribes how children should behave toward their parents: Children who perceive their parents as warm and rational develop a reciprocal filial piety that entails natural intimate affection and gratitude toward their parents, are emotionally and spiritually attentive to them, offer physical and financial care as their parents age, and so forth (Huang & Yeh, 2013). In essence, then, children's parents receive a great deal "in kind" for their hard work and commitment: They are often recipients of unconditional love, and through their children they access immortality.

That said, although marriage per se is associated with reduced morbidity and mortality (Kiecolt-Glaser & Newton, 2001), meta-analysis reveals that parents report diminished satisfaction compared with nonparents (most pronounced among mothers of infants) and a negative association between marital satisfaction and number of children, perhaps ascribable to role conflicts and restrictions

of freedom (Twenge, Campbell, & Foster, 2003). Furthermore, parenting is an expensive proposition (estimates from the U.S. Department of Agriculture reveal that middle-income husband-wife families can expect to spend roughly \$300,000 to rear a child to age 18; Lino, 2013); becoming a parent generates depression in many new mothers and fathers (Miller, 2002; Paulson & Bazemore, 2010) and erodes some domains of cognition (Brett & Baxendale, 2001; Ellison, 2006); and parents often judge their own parenting more positively than do their children (Bögels & van Melick, 2004; Gaylord, Kitzmann, & Coleman, 2003). The status of parenthood for parents and its implications for adult development, marriage, and family life constitute subjects of continuing debate (see Bhargava, Kassam, & Loewenstein, 2013; Nelson, Kushlev, Dunn, & Lyubomirsky, 2013). Two dismaying truths about parenting are that children really know not what their parents have done for them unless and until they become parents themselves and, poignantly and paradoxically, only profoundly despondent parents will know how the drama of their child's life course ultimately unfolds.

Surveying three approaches to measuring parents' well-being—comparing parents to nonparents, assessing parents' well-being across the transition to parenthood, and comparing parents' well-being when they are with their children versus when they are not—Nelson, Kushlev, and Lyubomirsky (2014) concluded that the relation between parenthood and well-being is complicated. Parents may experience happiness and joy when children are seen to improve the meaning of life, satisfy their basic needs, enhance their positive emotions, and diversify their social roles; however, parents may be unhappy if and when they experience negative emotions, financial difficulties, sleep disorders, and unsettled marriages.

More commonly, parenting is defined by its instrumental character, as acts of providing for and supporting the biological, physical, intellectual, emotional, and social development of progeny. Parenting presents the unique prospect of contributing to the development of a new life, and if there are universal human values, it is probable that nurturing (and not abusing) children falls among them. The conception of parenting as a set of functions expands the discussion beyond biological parents to embrace other related and nonrelated child caregivers (grandparents, adoptive parents, or other "carers") who may also centrally engage in parenting (Leon, 2002). This chapter focuses on children's parents and their parenting, but does not eschew significant others in the lives of children (or children's own contributions to parenting and so their development;

Lerner, Lewin-Bizan, & Warren, 2011). Animal research offers a rather barebones description of parenting behaviors as encompassing expenditures of time and energy, for example, in carrying, thermoregulating, and nourishing offspring. A functionalist approach to human parenting broadens the scope of caregiving considerably in that it is desirable to promote traits in human children that will lead to their becoming adults who manage well within the requirements of the social groups among whom they live.

Becoming a parent is a transforming experience (L. Bornstein & Bornstein, 2008; Nazarinia Roy, Schumm, & Britt, 2014). New parents change in many aspects of their life (e.g., self-efficacy expectations, gender roles, personal control, anxiety, and depression). Freud reputedly counted bringing up children as one of the three "impossible professions" (the other two being governing nations and psychoanalysis). Some parents more fully commit to the status and responsibilities of parenting than others (Baumrind & Thompson, 2002). In the end, children's parents have the "means, motive, and opportunity" to care for them, and commitment may rival in importance the ways parenting is expressed. Parenting children is enjoyable and educational, it is constructive and productive, and it is answerable and daunting.

### Parenting Theory and Research in Brief Overview

How did studies of children's parents begin, and how did they arrive at the state we find them today? What principles guide contemporary theory and research in parenting? A glance backward and a short excursion into currents of thinking about parenting provide answers to both questions. Furthermore, informed perspective on future directions in the field of parenting studies may help to guide the reader in how best to understand the ensuing accounts of parents, their cognitions and practices, and their effects, as well as their origins.

#### *A Glance Backward at How Parenting Study Got to Be the Way It Is*

Child rearing has traditionally been viewed as fundamental to societal well-being, and so cultures throughout history have paid considerable attention to parenting (French, 2002). Written appraisals of parenting date back at least to ancient Egypt, the Code of Hammurabi, and the pre-Socratics. In the *Laws*, Plato (ca. 355 BC) theorized about the significance of parenting. Over succeeding centuries, the musings of philosophers and the sermonizing of clerics—as well as folk wisdom—have been replete with propositions, convictions, and aphorisms concerning

what kinds of child training best ensure social order. Historians, anthropologists, and sociologists of family life have documented evolving patterns of childcare (see Stearns, Chapter 20, this *Handbook*, this volume). However, a formal understanding of parenting seems to have its beginnings in attempts by philosopher, educator, and scientist parents to do systematically what parents around the world may do naturally every day: Observe their children. Such reflections on child rearing entered the literature in the form of diary descriptions of children in their natural settings written by their own parents, referred to as “baby biographies” (Darwin, 1877; Hall, 1891; Jaeger, 1985; Preyer, 1882; Rousseau, 1762; Wallace, Franklin, & Keegan, 1994), and they still appear from time to time (Lamott, 2013; Mendelson, 1993; Stern, 1990). These rich observations had many salutary effects for parenting, heightening awareness in parents and inciting systematic studies of children and how to channel child development. It was not until the 20th century, however, that parenting became a focus of scientific study.

On account of extraordinary high rates of child mortality, parents in early times may have cared for but resisted emotional investment in the very young (Dye & Smith, 1986; Stearns, Chapter 20, this *Handbook*, this volume), an orientation that sometimes persists where especially dire circumstances reign (Scheper-Hughes, 1989). One historian theorized that parents have generally improved in their sentiments toward and treatment of children because parents have, through successive generations, changed in their capacities to identify and empathize with the special qualities of childhood (deMause, 1975). Today, advice on parenting abounds. It begins well before the birth of a child in “preconception care,” where the goal is to reduce risks to women, fetuses, and neonates by optimizing maternal health and knowledge before planning and conceiving (American College of Obstetricians and Gynecologists, 2005; Centers for Disease Control and Prevention, 2013b). There’s even an iPad app for that: *Pregnancy Week to Week* features images that track the development of a new baby, a timeline and organizer for physician visits and to-dos, and even a kick counter. Parent guidance overflows in professional compendia that provide comprehensive medical treatises of prenatal, perinatal, and postnatal development, such as *A Guide to Effective Care in Pregnancy and Childbirth* (Enkin, Keirse, Chalmers, & Enkin, 2000) and *The A to Z of Children’s Health: A Parent’s Guide from Birth to 10 Years* (Friedman, Saunders, & Saunders, 2013); in classic how-to books, such as *Dr. Spock’s Baby and Child Care* (Spock & Needlman, 2013), *Your Baby and Child*

(Leach, 2012), and *What to Expect When You’re Expecting* (Murkoff & Mazel, 2008); in practical guides, such as *The 10 Basic Principles of Good Parenting* (Steinberg, 2005) and *Teach Your Children Well* (Levine, 2013); in evidence-based academic compilations, such as the *Handbook of Parenting* (Bornstein, 2002b) and *Parenting: A Dynamic Perspective* (Holden, 2009); as well as innumerable popular periodicals that overflow magazine racks in supermarkets, airports, and bookstores.

### *Parenting Theory and Research in Perspective*

Various theories in philosophy and psychology have focused on parenting or appeal to parenting. The ensuing recapitulation follows Maccoby (1992) who observed that, at first, two overarching theories presumed to encompass most of what was significant about the socialization of children, psychoanalysis and behavior theory, but these twin sweeping perspectives yielded over time to narrower views specific to developmental domains or child ages. Early work sought direct connections between parental practices and child outcomes, whereas current work focuses on processes that may mediate the ways parental cognitions and practices operate to affect children and to identify key moderators of those process pathways. Parents were once seen primarily as trainers or transmitters of culture and children as empty vessels who were gradually filled up with necessary and appropriate social repertoires; today, complex models of socialization involve relational and transactional dynamics in developmental systems (Bornstein, 2009; Lerner et al., 2011).

Sigmund Freud (1949), the father of psychoanalytic theory, asserted the principal role of children’s parents in their development. Freud hypothesized that the parent’s personality determined the nature of parenting, the parent-child relationship, and the child’s development as children “internalize” models of their parents and “introject” their values. Another consistent theme among psychoanalytic theorists was that, if parents’ emotional needs had not been met during the course of their own development, then their neuroses would be reflected in their parenting (Holden & Buck, 2002). Anna Freud (1955/1970) described mothers who rejected their children, sometimes due to psychosis but more often because of their own neurotic conflicts. Likewise, Winnicott (1948/1975) and Spitz (1965/1970) detected the roots of aggressive, impulsive, immature, self-centered, and self-critical caregiving in parents’ own experiences. Psychoanalysis confined itself largely to theorizing, however, and failed to foster much systematic basic research (Cohler & Paul, 2002).

Early empirical studies of parenting were advanced from a behaviorist perspective and consisted of straightforward demonstrations that specific child behaviors (e.g., in babies smiles or vocalizations) could be conditioned or extinguished (Rheingold, Gewirtz, & Ross, 1959). From John Watson (1924/1970) to B. F. Skinner (1976), attempts were made to redefine socialization in learning theory terms. Children's aggression, dependency, gender typing, and identification with parents were common foci of behavioral study. Miller and Dollard (1941) reformulated hypotheses derived from psychoanalytic theory into simple testable behavior-theoretical propositions. These efforts to predict complex outcomes in children from parental socialization proved less than successful, however. Sears, Maccoby, and Levin (1957), for example, found few connections between parental child-rearing practices (as reported by parents in interviews) and independent assessments of children's personality.

Many later-emerging theories of child psychology also placed strong emphasis on parents. According to scaffolding theory, for example, cognitive and social development occur mainly in interactive contexts with trusted, more competent partners who do not reward, punish, or correct children so much as provide structures for learning that increase the likelihood of children's succeeding in their own attempts to learn. Parents who foster their children's development arrange circumstances so that the demands of a situation fall beyond the child's "zone of actual development" into the child's "zone of proximal development." According to this Vygotskian formulation (Vygotsky, 1978), the parent, being more advanced than the child, raises the child's level of competence through their reciprocal interactions.

Other prominent theories emphasize the active role of the child in parent-child interaction. In one view, children acquire new behaviors without needing to perform them overtly with reward, but merely by observing them being performed by nurturant and powerful parents (Bandura, 1989). A central tenet of this social learning theory posits that observing the actions of their caregivers is the primary means by which children learn about the world. In this way, children absorb the beliefs and behaviors of these key figures in their lives (Maccoby, 1959). What children imitate in others, what they remember, and how they process what they remember also depend on characteristics of the child, for example their level of development. Along these same lines, Piaget's (1936/1952) interactionism theorized that children use parental input in learning rather than parental input *per se* determining what children learn.

Bowlby (1969) infused an ethological perspective into socialization, contending that through their reciprocity parent and child develop a mutual attachment. Attachment theory postulates the formation of internal working models or representations of the attachment relationship, schema that tint future interpersonal relationships (Allen, Porter, McFarland, McElhaney, & Marsh, 2007; Sroufe, Egeland, Carlson, & Collins, 2005). What is gained from a child's attachment experience is the quality of the relationship with a parent (Ainsworth, Blehar, Waters, & Wall, 1978). Sensitive and responsive parenting provides a secure base from which children develop cooperation, self-regulation, and social initiative as well as internalize values, explore the world, and engage socially with others (Bugental & Grusec, 2006; Sled & Fonagy, 2012).

Finally, in the view of family systems theory, what transpires between parent and child is governed, not only by the characteristics of each individual, but also by patterns of transaction between them and others (Bornstein & Sawyer, 2005; Minuchin, 1985). Parent and child develop in a system that functions as an organized whole, composed of interdependent elements or subsystems that include individuals as well as relationships among individuals. Each element within the family both affects and is affected by other elements; a change in any one can lead to changes in others. Thus, the structure and organization of relationships across the family affect the quality of the relationship between any two family members. For example, each parent's relationships with his or her own parents affect their ability to coparent their child. Similarly, a major life transition for one family member is likely to affect other family members. How responsive a mother or father may be at any given moment is determined, not only by that parent's characteristic warmth and the child's characteristic responsiveness, but also by the patterns they have created jointly between them and with others.

A full family systems approach embeds parenting in the context of all relationships within the family as well as relationships between the family and its many larger social contexts so that theory and empiricism circumscribed to dyads is *perforce* partial and insufficient to explicate family interaction patterns. Parents behave one way when the whole family is together but another when each parent interacts one-on-one with their young child (Cox & Paley, 2003). In family systems theory, interconnected subsystems are also organized hierarchically; an asymmetrical nature in the parent-child relationship is necessary, especially early in child development (Kochanska & Aksan, 2004; Maccoby, 1992), but as children grow older, they

rely more on themselves and less on parents (Eisenberg & Morris, 2003); and family members are always in the process of developing, so concomitantly the family system is always in the process changing. Yet, like other living systems, families continually strive to attain a dynamic balance amid experiences of growth and maturation on the one hand and needs for consistency on the other.

Many theoretical accounts for how and why children's parents caregive have been proposed (Bornstein, Mortimer, Lutfey, & Bradley, 2011; Bugental & Grusec, 2006). For most theories, it is primarily through parental example, control, teaching, and so forth that children are shaped and the adult culture is passed down to the next generation. Parents are the primary agents who set the agenda for what children learn and who administer the rewards and retributions that strengthen desired characteristics and weaken undesired ones in children. Additional theoretical formulations acknowledge multiple roles of the child in continuing interaction with the parent. All theories centrally assume that, even though socialization and resocialization can occur at any point in the life cycle, childhood represents a particularly susceptible period when enduring personality attributes, social skills, and cultural values are inculcated, and children's parents robustly influence them even if children's development remains pliable to other circumstances at later times.

### ***Looking Ahead to Where Parenting Theory and Research Are Going***

As this chapter proceeds to show, researchers know a lot, but still not nearly enough, about parenting. Some key questions that must be addressed in parenting theory concern the further specification of processes by which parents' cognitions and practices promote or inhibit development in children and the multiple moderators that condition their effects (Bornstein, 2013b; Bornstein, Bradley, Lutfey, Mortimer, & Pennar, 2011; Patterson & Fisher, 2002). By the other side of the same token, theorists are charged to explain how children and their perceptions of parenting impact parents (Lansford et al., 2010). Successful parenting theories will likely have two other key characteristics: They will be based on constructs that are readily operationalized, and they will specify effective means of assessment.

Measurement is an importunate challenge in parenting science. Parenting is complex, nuanced, and difficult to evaluate, and the parenting literature is replete with mixed findings. Empirically there is widespread lack of agreement regarding which features of parenting are most

important; which assessment methodologies may be most suitable and valid (observations, tests, and interviews and questionnaires have differing strengths and limitations; Bögels & van Melick, 2004; Collett, Gimpel, Greenson, & Gunderson, 2001; Dadds, Maujean, & Fraser, 2003; Gaylord et al., 2003; O'Connor, 2002; Reitman, Rhode, Hupp, & Altobello, 2002; Rhoades & O'Leary, 2007); and whose reports are best representative of parenting (Achenbach, 2012; Barry, Frick, & Grafeman, 2008; McLeod, Weisz, & Wood, 2007). As lamented by Dix and Gershoff (2001, p. 138), a lack of validity and reliability information gives rise to "inconsistent findings, wasted effort, and slow progress" in parenting research. Related empirical concerns increasingly acknowledge the need to assess invariance across parent gender, socioeconomic status, ethnicity, and culture (Adamsons & Buehler, 2007; Furman & Lanthier, 2002; Huang et al., 2011; Locke & Prinz, 2002; Senese, Bornstein, Haynes, Rossi, & Venuti, 2012; Stolz, Barber & Olson, 2005).

Additional challenges for the future are to recognize and rectify that, up to now, the rapidly developing discipline of parenting research has focused too narrowly on mother-child relationships rather than multiple family relationships; on selected topics such as attachment to the near exclusion of others such as religion; on normative nuclear families when the present-day world is populated with a bewildering panoply of family compositions (shot-gun cohabitations; unwanted pregnancies; out-of-wedlock births) and circumstances (families affected by military deployment, state enforcement of fertility policies, and yo-yoing in and out of poverty); and on parenting in the minority Western, educated, industrialized, rich, and democratic developed world rather than the majority developing world (Bornstein, 2010; Henrich, Heine, & Norenzayan, 2010; Ganong, Coleman, & Russell, Chapter 4, this *Handbook*, this volume; Tomlinson, Bornstein, Marlow, & Swartz, 2014). Quizzed, parents think a broad swath of basic developmental research is interesting and important but would support more funding for practical issues such as speech and language, developmental disorders, and adaptation to childcare (Johnson & Lloyd-Fox, 2008).

Future cutting-edge designs in parenting science will account for assortative mating, control one parent in analyzing effects of the other parent, covary confounding third variables, move beyond cross-sectional approaches that leave the direction of parenting effects ambiguous, identify parenting influences separate from putative genetic confounds, and so forth (see, e.g., Kenny & Ledermann, 2010). Likewise, increasing rigor and sophistication are

expected of intervention research in parenting (Powell, 2013). Parenting is a multilevel phenomenon and will be better understood eventually by converging evolutionary, genetic, biological, comparative, behavioral, and cultural perspectives. Another pervading critique of contemporary parenting science is that research in the field has not yet adequately confronted the subtle practical complexities of everyday parenting. Using nonparticipant unobtrusive naturalistic observational methods, Radesky et al. (2014) captured frequency, duration, and modality of mobile device use versus caregiving of caregivers of young children eating in fast food restaurants. Caregivers who were highly absorbed with their devices responded harshly to child misbehavior.

The imperfect situation of contemporary parenting research is ripe for revolution and evolution. In the meanwhile, the account of children's parents that follows must be understood in light of the extant literature, and in weighing the ensuing survey the reader is best informed by a clear understanding of these many constraints and shortcomings. Still others are exposed as successive topics are tackled.

Parenting is not an activity people normally think of as being especially "scientific." Folks just seem to parent, without giving it all that much thought. Like most things in life, however, better parenting benefits from greater knowledge and understanding which in turn depend on theory and research. Happily, there is a science of parenting with developing theory and growing systematic research behind it. The contemporary parenting literature, however inadequate and incomplete, is bursting with thousands of studies. This chapter reflects that consolidating science of parenting.

## PARENTS

The majority of children throughout the world grow up in family systems with more than one significant parenting figure guiding more than one child's development at a time; yet the research literature usually focuses on first-borns and first-time mothers. Biological and adoptive mothers and fathers are children's acknowledged principal caregivers. However, parents are not the only agents who normally contribute to the upbringing of children. Big brothers and sisters (Zukow-Goldring, 2002) and other members of the extended family (P. K. Smith & Drew, 2002) also play important parts in caregiving. Outside the family, peers (J. R. Harris, 1995, 1998; Rubin, Bukowski, & Bowker, Chapter 5, this *Handbook*, this volume) influence children's development, and now, as historically, children

have been regularly tended by nonparental, nonfamilial care providers—slaves and nurses, daycare workers and metaplot—whether in family daycare at home, daycare facilities, or fields (Burchinal, Magnuson, Powell, & Hong, Chapter 6, this *Handbook*, this volume; Clarke-Stewart & Allhusen, 2002; Powell, 2008). In short, many individuals "socially" parent children (Leon, 2002). This chapter is largely circumscribed to children's parents, although for completeness sake nonparental caregiving is briefly described.

## Mothers

Mammals tend to be devoted child carers (Bjorklund et al., 2002), and almost all mammalian species are matrilocal, the norm in mammalian care falling to mothers (Clutton-Brock, 1991; E. O. Wilson, 1975). Trivers (1972, 1974) acknowledged the biological reality that in land-dwelling mammals after copulation, the female is left in physical possession of the embryo. Even if females lay fertilized eggs almost immediately, males still have time to abscond; females have the decision of whether to leave the young to certain death or stay, care for, and rear/raise them. On this account, maternal care is much more common than paternal care (in mammals, males provide care in fewer than 5% of species; Moller, 2003). Even among species where males show considerable parental altruism, they commonly do less work than females and vanish more quickly (E. O. Wilson, 1975). Among human beings, fathers may withdraw from their children when they are unhappily married; mothers typically do not (Kerig, Cowan, & Cowan, 1993), and one finds many more non-resident dads than moms (Sorensen, 1997). Mothers and fathers do not necessarily share the same "investments" in parenting (Geary, 2000). Women are primarily responsible for home and family, tend to be more interested in infants and caregiving activities, and are conceded to carry a heavier burden in routine parenting (Barnard & Solchany, 2002; Calzada, Eyberg, Rich, & Querido, 2004; P. Kim et al., 2013; Maestripieri & Pelka, 2002; Metsäpelto & Pulkkinen, 2003; Verhoeven, Junger, Van Aken, Deković, & Van Aken, 2007). According to life history theory, maternal versus paternal parental investment becomes manifest in the trade-off between mating and parenting (Draper & Harpending, 1982; Mascaro, Hackett, & Rilling, 2013). Given that organisms have finite amounts of time, effort, and energy to maximize fitness (the ability to both survive and reproduce), evolution optimizes allocation of these resources in males and females toward one or the other.

Human cultures distribute the tasks of childcare in different ways. Even if fathers' social and legal claims on and responsibilities for children were preeminent historically (French, 2002), most people agree that mothers (and female relatives) normally play the central role in child rearing (Barnard & Solchany, 2002; Civitas Initiative et al., 2000; de Rosnay & Murray, 2012). As in most mammalian species (Briga, Pen, & Wright, 2012), cross-cultural surveys and meta-analyses of the human research literature consistently attest to the primacy of (biological or adoptive) females in child rearing. Analyzing data from 186 societies worldwide, Weisner and Gallimore (1977) found that in the vast majority mothers (and female adult relatives and female children) served as the primary caregivers of infants and young children. In the United States, where fathers are moving to provide more care to their infants and young children, fathers still do considerably less baby tending than mothers (Lareau & Weininger, 2008; Pleck, 2012). Observations of parental care in preindustrial traditional societies where social customs center on equality among group members reveal the same pattern found in modern and Western nations. In a hunter–gatherer society, the Aka (Central African Republic), fathers provide more direct care to their children than do fathers in any other society that has been studied (Hewlett, 1988, 1992). Nevertheless, during the course of the day, “the father would on average hold his infant for a total of 57 minutes while the mother would hold the infant 490 minutes” (Hewlett, 1988, p. 268). The maternal role is better articulated and defined than is the paternal role. The online site Insure.com uses household duties to calculate “salary figures” for mothers and fathers by referencing occupational wage data from the U.S. Bureau of Labor Statistics. The 2013 Mother’s Day Index estimated the dollar value of mothers’ responsibilities at \$59,862 and the Father’s Day Index that for fathers at \$23,344. In their own life course, women are generally afforded more opportunities to acquire and practice skills that are child centered. Often, indeed, mothering helps to interpret and condition fathering, and mothers frequently serve as “gatekeepers” to children’s fathers and other caregivers encouraging or discouraging their involvement in child rearing (Allen & Hawkins, 1999; Cannon, Schoppe-Sullivan, Mangelsdorf, Brown, & Sokolowski, 2008). Seven language families are hypothesized to have formed an ancient Eurasiatic superfamily that is supposed to have arisen from a common ancestor over 15,000 years ago; the term *mother* is one of only 23 words that have remained associated with their particular meanings since the end of the last ice age (Pagel, Atkinson, Calude, & Meade, 2013).

For all these reasons, theorists, researchers, and clinicians have historically concerned themselves preponderantly with mothering, rather than parenting generically. Mothers and mothering are investigated much more often and comprehensively than fathers and fathering. In consequence, a more extensive body of information has developed about children’s mothers than about their fathers or children’s other caregivers. Western industrialized nations have witnessed increases in the amount of time fathers spend with children (Gauthier, Smeeding, & Furstenberg, 2004; Pleck, 2012); in reality, however, fathers still typically assume little responsibility for (especially early) childcare and rearing, and fathers are still primarily helpers to mothers (Cabrera, Tamis-LeMonda, Bradley, Hofferth, & Lamb, 2000). According to regular reports from the American Time Youth Survey, conducted by the U.S. Bureau of Labor Statistics, mothers (even those who work fulltime) spend about twice as much time as do fathers in child caregiving of all sorts (Guryan, Hurst, & Kearney, 2008), and similar ratios are common in many different lands (see Bornstein, 2006). In both traditional U.S. American families (Belsky, Garduque, & Hrcir, 1984) and nontraditional father primary-caregiver Swedish families (Lamb, Frodi, Frodi, & Hwang, 1982), parental gender exerts a greater influence on childrearing than do parental role in the family or employment status.

### Fathers

Some contemporary observers point to continuing and widespread abrogation of responsibility by fathers (Blankenhorn, 1996, 2009; Popenoe, 2009), whereas others note fathers’ increasing involvement with their children (Gray & Anderson, 2010; Pleck, 2012). However, fathers’ involvement remains much lower than mothers’ (Craig, 2006), as noted especially when children are very young (Rhoads & Rhoads, 2012). In nonhuman animal species, paternal behavior is common among birds (90%), but very rare among mammals, if somewhat higher in primates (Moller, 2003). There are, of course, many examples of devoted fathers in the animal kingdom, including sea horses (which gestate their young), Antarctic emperor penguins (which incubate eggs through dark and bitter winters), and rodent prairie voles (which are notoriously paternal). Generally speaking, fathering goes along with social monogamy (Fernandez-Duque, Valeggia, & Mendoza, 2009; H. J. Smith, 2005). Our closest living relatives, chimpanzees and bonobos, provide no meaningful paternal care; given their respective mating

systems and troop life, males may not even be aware which are their offspring, much less devote time and attention to them (Bales & Jarcho, 2012). Fathering among *Homo sapiens* is therefore unique in the primate genus, and the paternal role appears more volitional and discretionary and less scripted than the maternal role (Cabrera et al., 2000; McBride, Schoppe, & Rane, 2002). Human paternal care exhibits considerable cultural and longitudinal variation, an indication of how flexible that parenting behavior is.

Father “involvement,” including engagement, accessibility, and responsibility, is a contemporary watchword in human parenting science (Cabrera & Tamis-LeMonda, 2013; Pleck, 2010), and as a burgeoning research literature is beginning to reveal fathers contribute in multiple, often unique ways to their children’s development. Mothers may serve as children’s primary caregivers and principal socializers (Greenfield, Suzuki, & Rothstein-Fisch, 2006), but fathers support autonomy development in children and, compared to mothers, encourage competitiveness, independence, and risk taking (Cabrera et al., 2000). Where researchers once contrasted absent with present fathers, or quantified father involvement in terms of financial contributions or sheer time spent with children, investigators today have moved beyond binary and unidimensional measures to better articulate the many parts children’s fathers play as well as their effects. For example, diets of fathers-to-be may affect the health of their future children (Lambrot et al., 2013); father involvement is associated with more optimal socioemotional and academic functioning and decreased behavior problems in childhood (Aldous & Mulligan, 2002; Flouri, 2010; Howard, Burke Lefever, Borkowski, & Whitman, 2006) and better mental health, occupational success, and educational attainment in adulthood (Brown, McBride, Shin, & Bost, 2007); and fathers’ positive engagements in low socioeconomic status (SES) families buffer developmental delay in children (Shannon, Tamis-LeMonda, London, & Cabrera, 2002).

Thus, fathers are neither inept nor uninterested in their offspring. Therefore, mother-father differences in parental roles and responsibilities cannot be attributed to a general inability of males to care for children. Fathers hold the same diversity of parenting cognitions that mothers do and engage children in the same wide range of parenting practices (Parke, 2002; Pleck, 2012). When feeding children, fathers, like mothers, respond to children’s cues, either with social bids or by adjusting the pace of the feeding (Parke, 2002). Both father and mother touch and look more closely at a child after the child has vocalized, and both equally increase their rates of speech following a child’s

vocalizing. Nor can gendered differences in parenting be attributed to father absence (because fathers tend to be away hunting or working outside of the home): When both parents are present, for example, U.S. American mothers spontaneously engage their children and provide routine care more frequently than do fathers (Belsky, Gilstrap, & Rovine, 1984). Moreover, fathers’ contributions to child development are independent from those of mothers. Fathers’ and mothers’ supportive parenting separately predict children’s language and cognitive status (Tamis-LeMonda, Shannon, Cabrera, & Lamb, 2004), for example. In addition, in accounting for contrasting mother-father emphases, some have pointed out that fathers are occupied with key external family concerns, such as planning, monitoring, and garnering finances that constitute essential but indirect caregiving (Palkovitz, 2002). In the end, father presence is critical, as father absence has broad deleterious effects on children’s well-being (King & Sobolewski, 2006; Manning, Stewart, & Smock, 2003). Even children in joint physical or legal custody fare better than those in sole parent custody (Bauserman, 2002). Thus, research now consistently points to benefits for children of father involvement (Gray & Anderson, 2010; Raeburn, 2014; Sarkadi, Kristiansson, Oberklaid, & Bremberg, 2008).

With science catching up to life and shedding light on fathers, it is dismaying in the extreme to note that, according to the U.S. Census Bureau, 24 million children in America—one out of three—live in biological father-absent homes (U.S. Census Bureau, 2011). Being reared by a single mother increases the risk of many adverse life circumstances, such as teen pregnancy and marrying with less than a high school degree (Teachman, 2004). Even after controlling for income, youth in father-absent households have higher odds of incarceration than those in dual mother-father families (Harper & McLanahan, 2004).

### Coparenting and the Division of Parenting Labor

In point of fact, children’s mothers and fathers appear to interact with and care for them in many complementary ways; that is, parents tend to divide the full labor of caregiving and engage children by emphasizing different responsibilities and interactions. For example, mothers spend proportionally more time in routine care of children; fathers spend proportionally more time in teaching and play (Craig, 2006; Guryan et al., 2008; Ho, Chen, Tran, & Ko, 2010; Pleck, 2012). Mothers’ and fathers’ perceptions of their parental efficacy vary in complementary ways

as well: Mothers of young children are more confident than fathers in their ability to use strategies that involve reasoning or talking to the child; in contrast, fathers are more confident than mothers in their use of directives or the threat of force (Perozynski & Kramer, 1999).

Reflecting a family systems perspective, marital relationships affect the quality of child-mother and child-father affiliations and child outcomes (Grych, 2002), just as how parents work together as a coparenting team can have multiple far-reaching consequences for children's development (Teubert & Pinquart, 2010). Coparenting refers to ways that parents (or parental figures) relate to each other in the role of parent (McHale et al., 2002; McHale & Lindahl, 2011; Van Egeren & Hawkins, 2004). Coparenting comprises multiple interrelated components: agreement on child-rearing issues; support of the parental role; and joint management of family interactions (Feinberg, 2003). Mutual emotional support and validation, modeling and sharing parenting skills, and buffering marital conflict or dissatisfaction from spilling over into relationships with children constitute some of the ways coparenting functions to nurture children's development. Direct effects of coparenting postulate that exposure to interparental conflict, for example, undermines children's physiology, cognitions, and emotional security (Crockenberg & Langrock, 2001; Cummings & Davies, 2011; El-Sheikh & Hinnant, 2011), colors their peer relationships (Crockenberg & Langrock, 2001), and even reverberates in children's romantic relationships as young adults (Bornstein, Jager, & Steinberg, 2012; Cui & Fincham, 2010; Ladd & Pettit, 2002) and does so similarly in different ethnic groups (Stutzman et al., 2011). Perhaps this is why parents hide the vast majority of marital conflict from their children (Papp, Cummings, & Goeke-Morey, 2002). Indirect effects suppose that the impact of a parent on a child is mediated by the nature and structure of the parent-parent relationship per se (Grych & Fincham, 2001); infants just one year of age are less likely to look to their maritally dissatisfied father for information or clarification in the face of stress or ambiguity than are infants of maritally satisfied fathers (Parke, 2002). A prime example of indirect effects is gatekeeping—how each parent regulates the other's interactions with the child (Cummings, Merrilees, & George, 2010; Fagan & Barnett, 2003; Rane & McBride, 2000). In certain circumstances, fathers may be more involved with their children, as when mothers are more satisfied with paternal caregiving and assess fathers to be more competent at caring; many (but not all) paternal influences on children are indirectly mediated through the father's impact on

the mother (Walker & McGraw, 2000). Thus, maternal encouragement is linked to enhancing father involvement in child rearing ("gate opening"; Schoppe-Sullivan, Brown, Cannon, Mangelsdorf, & Sokolowski, 2008), and maternal discouragement with diminished father involvement in child rearing ("gate closing"; Meteyer & Perry-Jenkins, 2010; Trinder, 2008).

If children's parents divide the labor of caregiving, the question arises of how the content, meaning, and effects of father-child interactions resemble or differ from mother-child interactions. Some researchers have argued that one or the other parent's acceptance, for example, is more predictive of child functioning (E. Chen, Matthews, & Boyce, 2002; Khaleque & Rohner, 2012; Khan, Haynes, Armstrong, & Rohner, 2010; Veneziano, 2003). Others have reckoned that mothers and fathers make independent contributions to children's development. Ryan, Martin, and Brooks-Gunn (2006) and A. Martin, Ryan, and Brooks-Gunn (2007) video-recorded mothers and fathers during separate free-play interactions with their 2-year-olds and used cluster analysis to describe each parent's pattern of supportive parenting based on six scales. After parents were distributed into four primary support pairings, children were compared on the Bayley MDI and later Age-5 math and language. Not unexpectedly, children with two supportive parents scored highest, and those with two unsupportive parents scored lowest. However, having at least one supportive mother or father benefited children's cognitive development over having none, and among children with one supportive parent the gender of that parent was inconsequential. Thus, no significant interactions emerged between maternal and paternal supportiveness on children's math or language, and the combined effects of maternal and paternal supportiveness appear to be additive. Notably, mothers and fathers exhibited similar within-family supportive patterns. These kinds of findings evidence why future studies of parenting and child development should consider mothers, fathers, and the two in concert (see also Tamis-LeMonda et al., 2004).

### Children's Other Caregivers

Cooperatively breeding vertebrates (like human beings) often enlist helpers to take care of immature offspring within the social group that are not their own—activity termed "alloparental care" (Hrdy, 2009). In nonhuman mammals, such care typically encompasses pup feeding, babysitting, and carrying; 88% of 63 species that live in family groups employ alloparental care (Emlen, 1995). Most children

in the United States grow up with siblings (Kreider & Ellis, 2011), and siblings sometimes care for one another (Zukow-Goldring, 2002); grandparents often assume central roles in child caregiving (Ganong et al., Chapter 4, this *Handbook*, this volume; Smith & Drew, 2002); and increasing numbers of young children normatively participate in nonparental care (Clarke-Stewart & Allhusen, 2002). Consider the second two scenarios, caregiving grandparents and young children in nonparental care.

The position of grandparents in the British class system has a direct effect on which class their grandchildren belong, even after the parents' education, income, and wealth are taken into account (Chan & Boliver, 2013). In recent times, increased life expectancy, decreased family size, more maternal employment, the rise of single-parent families, and high rates of divorce have conspired to raise the demand for grandparents to play more central parts in the lives of their grandchildren (Arber & Timonen, 2012; de Toledo & Brown, 2013; Dunifon, 2012; Kornhaber, 2002; Witkin, 2012). In 2011, 1 in 10 children in the United States were living with a grandparent, and approximately one-half of those 7.7 million children were being cared for primarily by that grandparent (Livingston, 2013; Murphey, Cooper, & Moore, 2012). In some societies, grandparenting has become the norm: According to the Municipal Population and Family Planning Commission (2008), 90% of young children in Shanghai, China, are being looked after by a grandparent. Grandparental help may be indirect or direct: Grandparents can provide emotional and financial support, wisdom and love, and positive influences of stability and a sense of community that benefit children. Grandparents are pressed into (even sole) custodial service as the result of family/cultural preference, but grandparent-child relationships can be stressed if they require major family adjustments or result from crises of parental incarceration, substance abuse, migration, death, disability, abuse, or neglect (Lou & Chi, 2012; Poehlmann et al., 2008; Stelle, Fruhauf, Orel, & Landry-Meyer, 2010).

Many tasks associated with childcare can be traded or purchased in the marketplace. Today, children enter nonparental care early, stay for longer periods of time, and change types of care often (Burchinal et al., Chapter 6, this *Handbook*, this volume). Beginning in the child's first year, about 50% of the children in the United States, for example, experience regular nonparental child care, and by the preschool years more than 75% of children have lived through some type of childcare. As a consequence of contemporary social and cultural forces (mentioned above), reliance on child care services has burgeoned, parents are forced to resort to all manner of circumstances and

individuals for assistance, and nonparental caregivers are entrusted with increasing responsibility for meeting children's developmental needs and preparing children for their future in society (Gottfried, Gottfried, & Bathurst, 2002; Powell, 2008). Looming issues for all parties (children, parents, child care educators, researchers, and policymakers) are how parents reconcile contrasting patterns of child care cognitions and practices with these significant others and the long-term cumulative impact of grandparental and nonparental child care on children and parents alike (Dodge & Haskins, Chapter 17, this *Handbook*, this volume).

### Summary

Children's mothers and fathers share central parenting responsibilities, although siblings, grandparents, and various nonparental figures also fill salient childcare roles. Often, child caregivers behave in a complementary fashion to one another, dividing the labor of childrearing by emphasizing mutually reinforcing responsibilities and activities. Still unclear, however, are the long-term cumulative implications of diverse compositions of parenting. To fathom the complex associations that exist between parenting and child outcomes, it will be essential to study each child caregiver in the context of the full network of relationships that have both direct and indirect influences on children.

### PARENTING COGNITIONS AND PRACTICES

Now that the principal actors in parenting have been identified, it is fitting to consider how parenting is expressed. What defines parenting operationally? What about parenting might affect children? Parenting is instantiated in cognitions and practices. In their bioecological theory, Bronfenbrenner and Morris (2006) hypothesized that human development is the joint product of process, person, context, and time. In this formulation, *process* refers to dynamic interactions that the developing person experiences, and "proximal processes"—the person's social interactions with others and engagement in particular activities with particular materials—are hypothesized as particularly significant to children's development. Parenting instantiates proximal processes for children, and parenting is multidimensional, modular, and specific (Bornstein, 2002a, 2006), underscoring identification and empirical focus on individual cognitions and practices. Foreshadowing the discussion of these twin realms of parenting and their effects, it is important to recognize that the two are linked and that they separately and jointly affect children's development.

## Parenting Cognitions

Parenting cognitions have long held a popular place in the study of parenting and child development, and they span a wide array of mentations about parenthood, about one's own parenting, about childhood, and about one's own child(ren). Consider examples in each of these four domains. First, researchers have adopted innumerable measures designed to assess adults' thinking about parenthood generally. For example, Winstanley and Gattis (2013) developed a Baby Care Questionnaire to measure parents' endorsement of structure (reliance on regularity and routines in daily life) and attunement (reliance on infant cues and close physical contact in daily parenting practices). Likewise, Budd et al. (2012) investigated cognitions about acceptable versus unacceptable parenting practices. Second, how parents see their parenting is consequential as it can lead to their expressing one or another kind of affect, thinking, or behavior in childrearing. According to the Civitas Initiative et al. (2000) survey, 90% of new parents in the United States have confidence in their abilities and think of themselves generally as good parents. Mothers who consider themselves efficacious and competent in their parental role tend to be more responsive and empathic and less punitive and hold more appropriate developmental expectations (Meunier, Roskam, & Browne, 2011; De Haan, Prinzie, & Deković, 2009). Third, how parents generally construe childhood influences their parenting: Parents who believe that they can or cannot affect characteristics in children likely act accordingly. One-quarter of parents in the United States think that a baby is born with a certain level of intelligence that cannot be increased or decreased by how parents interact with the baby (Civitas Initiative et al., 2000). Such a statistic incites some wonder about investment in children's parenting in that 25% of the population. Last, how parents see their own children has specific consequences. Mothers who regard their child as being difficult, for example, are less likely to pay attention or respond to their child's overtures; their inattentiveness and nonresponsiveness can then foster temperamental difficulties and undermine cognitive advances in a child (Putnam, Sanson, & Rothbart, 2002). Parental "reflective functioning" represents the capacity to think about parent's own and a child's mental states and how mental states may influence behavior. Mothers with greater interest and curiosity in their child's mental states persist longer in soothing a crying life-like baby simulator (Rutherford, Goldberg, Luyten, Bridgett, & Mayes, 2013). In all these ways, parents' cognitions shape their transactions with children. Indeed, mothers and fathers develop some

stable parenting cognitions during pregnancy or before (Gloger-Tippelt, 1983; Zeanah, Keener, Stewart, & Anders, 1985) that reverberate going forward. In this connection, it is therefore well to recall the words of a prominent social psychologist that, "beliefs are like possessions" (Abelson, 1986, p. 223), and children's parents cling to their parenting cognitions and their children equally dearly.

Parenting cognitions prominently include goals, attitudes, expectations, perceptions, attributions, and actual knowledge of child rearing and child development (Goodnow, 2002; Holden & Buck, 2002; Sigel & McGillicuddy-De Lisi, 2002). Furthermore, cognitions are generally believed to serve many functions. They affect parents' sense of self, help to organize parenting, and mediate the effectiveness of parenting. Cognitions contribute to how to parent and how much time, effort, and energy to expend in parenting, and they form a framework in which parents perceive and interpret their children's behaviors. A brief exploratory taxonomy of these prominent parenting cognitions follows.

Some of parents' *goals* for their own parenting and for their children may be universal; after all parents everywhere presumably want physical health, academic achievement, social adjustment, and economic security for their children (however those goals are instantiated in a culture). In one study, African American, Dominican immigrant, and Mexican immigrant mothers in the United States reported the qualities they deemed desirable or undesirable in children aged 1, 14, and 24 months. Mothers spontaneously referred to a common set of qualities, including achievement, self-maximization, proper demeanor, and connectedness; most mothers approved of desirable qualities like achievement and disapproved of undesirable qualities like improper demeanor (Ng, Tamis-LeMonda, Godfrey, Hunter, & Yoshikawa, 2012). Other goals arise, in part, out of societies' unique expectations of their adult members. For example, some (often Western) societies are thought to stress independence, self-reliance, and individual achievement in children, whereas other (often Asian and Latin) societies emphasize interdependence, cooperation, and collaboration (Oyserman, Coon, & Kemmelmeier, 2002), and these societal values are associated with parents' socialization goals and practices. In accord with these expressed goals, in real-time interactions U.S. mothers encourage their children to feed themselves as early as 8 months of age, whereas Latina mothers hold their children close on their lap and control feeding from start to finish (Harwood, Leyendecker, Carlson, Asencio, & Miller, 2002). On this construal, parents' socialization

goals are additionally important to the transmission of culture across generations.

*Attitudes* refer to an individual's predispositions, reactions to, or affective evaluations of the supposed facts about an object or situation. Some children are relatively relaxed when confronted with a novel environment and show little distress. Other children react to new situations with anxiety, try to remain close to a caregiver, and do not easily interact with unfamiliar people. This pattern indicates behavioral inhibition. Inhibited children can be found in China as well as Canada, but parents' attitudes toward this behavioral constellation differ in the two societies with consequences for children's further development. Traditional Chinese mothers view behavioral inhibition as a positive trait and express warm and accepting attitudes toward it, whereas Canadian mothers of European origin hold opposite attitudes, in which children's behavioral inhibition is negatively associated with maternal acceptance and encouragement of children's achievement. Traditional Chinese mothers of inhibited children are less likely to believe that physical punishment is the best way to discipline and are less likely to feel angry toward their child. However, maternal punishment orientation is positively correlated with behavioral inhibition in Canadian families; Canadian mothers of inhibited children are more likely to believe that physical punishment is a correct discipline strategy. In school, shy Chinese children fare better academically and are rated more positively by their teachers and peers in contrast to shy Canadian children who fare worse (X. Chen & French, 2008). In short, the same demonstration of behavioral inhibition in children is associated with positive attitudes in one context and negative attitudes in another, and situation dictates different consequences.

*Expectations* about a child as well as developmental norms and milestones—when a child should achieve a particular skill—affect parents' appraisals of their child, their parenting, and their child's development. Expectations also generally bias observations so that information consistent with the expectancy is more likely to be attended to, processed, and acted on. Expectations have formed a notable (and provocative) subject of pregnancy studies. Siddiqui & Hägglöf (2000) found that mothers' antenatal attachment expectations of their unborn child predicted their sensitivity and infant attentive behavior at 3 months postpartum (see also Thun-Hohenstein, Wienerroither, Schreuer, Seim, & Wienerroither, 2008). Using an equivalent longitudinal design, Dayton, Levendosky, Davidson, and Bogat (2010) learned that mothers who professed affectively disengaged prenatal representations of their

children were at 1 year more behaviorally controlling; mothers whose representations were affectively distorted were hostile; and mothers with balanced representations demonstrated more positive parenting. Similarly, Haltigan et al. (2014) determined that mothers' attachment representations assessed prenatally predicted observed maternal sensitivity at 6 months postnatally. More typical are studies of parents' expectations of their children after parturition. For example, mothers with more education generally expect children to attain developmental milestones earlier than those with less education (Williams, Williams, Lopez, & Tayko, 2000).

Especially salient *self-perceptions* of children's parents have to do with parents' feelings of competence in the role of caregiver, satisfaction gained from caregiving, investment in caregiving, and balance of caregiving with other social roles. Most is known about parenting competence (Bornstein, Hendricks, et al., 2003). Self-efficacy theory posits that adults who evaluate themselves as competent, who know what they can do, and who understand the likely effects of their actions will, as parents, more likely act as constructive partners in their children's development (Bandura, 1989). Parents' confidence in their ability to influence their children's academic performance and school achievement is associated with parents' school involvement and predicts parents' helping with children's academic interests (Epstein & Sanders, 2002). Parenting satisfaction affords a sense of well-being in the parenting role that translates to positive emotionally available parent-child interactions (Bornstein, Putnick, & Suwalsky, 2012). Investment in, involvement with, and commitment to children is foundational to positive childrearing; indeed, Baumrind and Thompson (2002, p. 3) defined ethical parenting "above all [as] requiring of parents enduring investment and commitment throughout their children's long period of dependency." High-investment parents are more responsive and view their children more positively (Greenberger & Goldberg, 1989). In turn, parental investment in children's lives and parental responsibility for children's care help to ensure that children receive the proper nutrition, physical activity, and medical care they require for wholesome development (Cox & Harter, 2003). How individuals balance their multiple roles in life—parent, spouse, and employee—reflects on their effectiveness in those diverse roles (Perry-Jenkins, Repetti, & Crouter, 2000). People who maintain greater balance score higher on measures of self-esteem and other indicators of well-being and lower on measures of role strain and depression (Marks & MacDermid, 1996). Mothers' role balance has more

impact on child development than mothers' work status per se, and mothers who are happy with their roles are more accepting of their children (Repetti & Wang, 2014).

*Attributions* are interpretations of causations of events and behaviors; parenting attributions refer to assigned meanings and definitions of a child's behavior and so can shape parents' caregiving practices, and in turn affect children's lives (Bugental & Happaney, 2002). Parental attributions typically distinguish between internal or intentional and external or situational. An internal attribution might refer to parental interpretations of a child's behavior as dispositional and deliberate, whereas an external attribution might refer to parental interpretations of a child's behavior as contextual, transitory, and even accidental (Coplan, Hastings, Lagacé-Séguin, & Moulton, 2002). In certain circumstances, parents might believe their children are behaving purposefully in one or another way when their children's behavior may be, in fact, developmentally typical. For example, higher levels of internal attributions of child misbehaviors are more prevalent among neglectful and abusive mothers and among authoritarian mothers (Wang, Deater-Deckard, & Bell, 2013). Parenting attributions vary with culture (see the introduction to the special issue of *Parenting* by Lansford & Bornstein, 2011), and research has documented that parents' differential attributions about the relative contributions of effort and ability are key ingredients to parents' successful parenting as well as to children's development (Bornstein et al., 1992). For example, mothers from Argentina, Belgium, Italy, Israel, Japan, and the United States were asked if being able to successfully comfort their child when the child cried was due to their parenting ability (e.g., "I am good at this"), effort (e.g., "I have tried hard"), mood (e.g., "I am in a good mood"), task difficulty (e.g., "This is easy to do"), or a child characteristic (e.g., "My child makes this easy to do"). Many culturally differentiated patterns of findings emerged; for instance, Japanese mothers were less likely than mothers from all other nations to attribute parenting success to their own ability and more likely to indicate that, when they were successful, it was because of the child's behavior.

Whereas goals, attitudes, and other like cognitions may or may not be factual, parenting *knowledge* draws on the science base as well as social construction and is thought to be valid and reliable by members of the clinical and research communities. Parenting knowledge of child rearing and child development encompasses many domains: parents' opinions about various approaches appropriate to fulfilling the biological and physical as well as socioemotional and cognitive needs of children as they develop;

parents' understanding of normative child development, including both developmental processes and the abilities and accomplishments of children as they grow; and parents' awareness of health care, identification and treatment of illnesses, and accident prevention. Parenting knowledge equips parents with information needed to interpret children's abilities and accomplishments and to tailor their interactions accordingly. In turn, parenting knowledge is associated with enhanced parental self-perceptions of competence, satisfaction, and investment in parenting (Bornstein, Hendricks, et al., 2003). The relation between parental self-efficacy and parenting competence is also moderated by parenting knowledge: Parental self-efficacy and parenting competence are positively associated when parenting knowledge is high; by contrast, self-efficacy and competence are inversely associated when knowledge is low (Hess, Teti, & Hussey-Gardner, 2004). The general state of knowledge that parents possess about children's development therefore affects parents' everyday decisions about their children's care and upbringing. For example, sudden infant death syndrome (SIDS) is the leading cause of reported neonatal mortality in the United States (Centers for Disease Control and Prevention, 2014b), and sleeping prone or on too-soft bedding that may cover an infant's mouth and nose increases the likelihood of asphyxiation (Scheers, Rutherford, & Kemp, 2003). Still, approximately 20% of infants, ages 1 to 3 months, are placed to sleep on their stomachs (Gibson, Dembofsky, Rubin, & Greenspan, 2000). Proper parenting practices follow knowledge of principles related to early experience, bidirectionality of social influences, individual differences, and the responsibilities of being a parent. In a famous dictum, the pediatrician Benjamin Spock wrote: "Trust yourself. . . . You know more than you think you do" (Spock, 1946, p. 3). On the whole, however, European American mothers demonstrate a fair, but less than complete, basic knowledge of parenting, and mothers' age, education, and written materials each uniquely contributes to their knowledge (Bornstein, Cote, Haynes, Hahn, & Park, 2010).

### Parenting Practices

Parents' practices give expression to parenting cognitions and constitute a large measure of children's worldly experience. They also span a range as expansive and varied as life has to offer: Parenting is an emotional endeavor that entails a mix of pride, patience, sacrifice, and humility (Pomerantz, Wang, & Ng, 2005), and parenting is responsibility and accountability (for example, parents in the United

States have set aside more than \$190 billion just toward their children's future college education; College Savings Plans Network, 2013). Parenting behaviors and children's development are linked (Belsky, Fearon, & Bell, 2007; Bernier, Carlson, & Whipple, 2010; Chang, Schwartz, Dodge, & McBride-Chang, 2003; Gaertner, Spinrad, & Eisenberg, 2008).

Despite the wide range of activities parents naturally engage in with children, classical authorities, including psychoanalysts, personality theorists, ethologists, and attachment theorists, historically tended to conceptualize maternal behavior as trait-like and unidimensional, often denoted as "good," "good enough," "sensitive," "warm," or "adequate" (Ainsworth et al., 1978; Brody, 1956; Brody & Axelrad, 1978; Mahler, Pine, & Bergman, 1975; Rothbaum, 1986; Schaefer, 1959; Symonds, 1939; Winnicott, 1973). One leading system that adapted this dimensional perspective cast parenting in terms of combinations of two prominent independent dimensions, warmth and control. Warmth connotes parents' acceptance, displays of affection, sensitivity, expressiveness, support, and involvement (Pomerantz & Thompson, 2008; Rohner, Khaleque, & Cournoyer, 2005); control ranges from supervision, monitoring, and maturity demands to demandingness, power assertion, and harsh discipline (Berger, 2011; Kochanska, Aksan, Prisco, & Adams, 2008; Racz & McMahon, 2011; Stormshak, Bierman, McMahon, & Lengua, 2000).

Parental warmth and control, especially in their extremes, have both positive and negative expressions and consequences. There is positive parental control or limit setting, which is associated with higher levels of child competence and lower levels of child disruptive behavior (Gardner, Shaw, Dishion, Burton, & Supplee, 2007; Jackson, Brooks-Gunn, Huang, & Glassman, 2000; Koblinsky, Kuvalanka, & Randolph, 2006; Pettit, Keiley, Laird, Bates, & Dodge, 2007), but also negative control or rejection, which is identified with children's internalizing and externalizing (Chang et al., 2003; Deater-Deckard, Ivy, & Petrill, 2006; Ispa et al., 2004; Rodriguez, 2003; Stormshak et al., 2000; Veneziano, 2003); there is warmth and involvement, which are associated with social competence, prosocial behavior, and academic achievement (Chung, Zappulla, & Kaspar, 2008; Fingerman et al., 2012; Gülay, 2011; Ip, Cheung, & McBride-Cheng, 2008; Kim, Han, & McCubbin, 2007; Segrin, Woszidlo, Givertz, Bauer, & Murphy, 2012; Yagmurlu & Sanson, 2009), but also "helicopter parenting" (oversolicitousness) and "parenting perfectionism" (excessively high standards),

which appear to instill feeling unsatisfied with family life and diminished psychological well-being (Lee, Schoppe-Sullivan, & Kamp Dush, 2012; LeMoyne & Buchanan, 2011; Pomerantz, Moorman, & Litwack, 2007; Schiffrin et al., 2013; Snell, Overbey, & Brewer, 2005). Hypo-responsiveness and -stimulation in parenting predict insecure attachment, aggressive and disruptive behavior, and acting out in children; likewise, hyper-responsiveness and -stimulation can impede development and are associated with decreased attentiveness and increased negative affect. When all is said and done, it may be the case that a middle course ("less is more") is optimal in parenting (Bornstein & Manian, 2013), a deduction gaining support in neurobiology (LeDoux, 2002; Mascaro, Hackett, Gouzoules, Lori, & Rilling, 2013).

Baumrind's (1967, 1978, 1991) well-known styles of parenting—authoritative, authoritarian, permissive, and disengaged—combine the two dimensions of warmth and control in different weights (Kuppens, Grietens, Onghena, & Michiels, 2009; Maccoby & Martin, 1983). These parenting styles are hypothesized to contribute differentially to children's identity formation and cognitive and sociomoral development. The authoritative style joins high levels of warmth with moderate to high levels of control and the use of negotiations (Larzelere, Morris, & Harriet, 2013), and in middle-class European American families authoritative parenting is associated with children's achievement of social competence and overall better adaptation (DeVore & Ginsburg, 2005; Jaffe, Gullone, & Hughes, 2010). Authoritarian parenting, by contrast, is characterized by low levels of warmth, high levels of control, and avoiding negotiations, and it is generally associated with internalizing, externalizing, and social problems in middle-class European American children (Barber & Harmon, 2002; Cunningham & Boyle, 2002; Gülay, 2011; Zhou et al., 2002). However, other research has revealed that different outcome patterns obtain in different social classes and ethnic groups. For example, adolescents from European American and Latin American authoritative homes perform well academically, and better than those coming from nonauthoritative households; however, school performance is similar for authoritatively and for nonauthoritatively reared Asian Americans and African Americans (Dornbusch, Ritter, Leiderman, Roberts, & Fraleigh, 1987).

One aspect of authoritative parenting is parental warmth. So-called PARTheory asserts that all children need warmth, affection, love, and regard from their primary caregivers and describes a continuum of parenting acceptance-rejection (Rohner, 2004; Rohner et al., 2005;

Prinz, Stams, Deković, Reijntjes, & Belsky, 2009). Although PARTheory was developed in a Western (U.S.) setting, meta-analyses and reviews of cross-cultural and intracultural studies generally (but not universally) support the broader applicability of its basic propositions (Rohner & Britner, 2002). In each of nine countries Bradford et al. (2003) unearthed relations between parental acceptance and lower levels of depression in adolescents. Gülay (2011) found that mother and father reports of acceptance-rejection are related to teacher-rated child prosocial behaviors in Turkey, as Carlo, Mestre, Samper, Tur, and Armenta (2010) discovered in Spain, and Yagmurlu and Sanson (2009) in Australia. On the basis of meta-analysis, 26% of the variance in child adjustment (a composite measure of 14 aspects of child functioning) can be explained by parental acceptance-rejection (Khaleque & Rohner, 2002). Children who perceive rejection from their parents tend to become hostile, emotionally unstable, and develop negative self-esteem and a pessimistic worldview (Hughes, Blom, Rohner, & Britner, 2005).

Since their initial formulation, warmth and control have undergone considerable scrutiny, articulation, and question with respect to construct operationalization as well as parent, child, and culture moderation. Take protectiveness as an expression of warmth. The developmental literature historically treated protectiveness as a unidimensional construct (Parker, 1983; Sargent, 1983). Besides trying to protect their children from physical harm, however, parents engage in diverse behaviors to protect their children from psychological and social harm (Power, 2004). Parent protectiveness has proved to be better conceptualized as multidimensional, and the effectiveness of parent protectiveness better explored with respect to its different dimensions and effects. Not unexpectedly, different kinds of protectiveness show different relations with different domains of child adjustment (Power & Hill, 2008). Which parent is involved is another moderating factor. Some studies report relations between maternal or combined maternal and paternal acceptance and child social competence (Ip et al., 2008; Kim et al. 2007), but others report no direct relations (S. M. Chan, 2011; Swanson, Valiente, Lemery-Chalfant, & O'Brien, 2011). Chung et al. (2008) found that greater perceived warmth from mothers and fathers is associated with higher teacher-rated academic achievement in children in Brazil, Canada, China, and Italy, and Kim and Rohner (2002) reported similar results for Korean American children. This finding is not a universal either, however (Bodovski & Youn, 2010; Boon, 2007; Swanson et al., 2011; Tulviste

& Rohner, 2010). A meta-analysis that distinguished maternal and paternal acceptance-rejection found that maternal acceptance-rejection explained 24%, and paternal acceptance-rejection explained 38%, of the variance in child adjustment (Khaleque & Rohner, 2012). It might be that paternal, but not maternal, warmth/acceptance is tied to child academic performance (Chen, Liu, & Li, 2000) or that one parent's acceptance is related to school performance in girls or in boys (Khan et al., 2010).

For its part, understanding the composition and dynamics of control is challenging contemporary researchers. For example, two types of control, behavioral and psychological, have been distinguished (Barber, Stoltz, & Olsen, 2005). Psychological control, characterized by high power assertion, intrusiveness, and hostility, is associated with love withdrawal, manipulation, invalidation of feelings, and ineffective behavioral management, and appears to provoke internalizing, externalizing, and social problems (negative self-concept and low self-esteem) in children (Aunola & Nurmi, 2005; Barber & Xia, 2013; Bean, Bush, McKenry, & Wilson, 2003; Cunningham & Boyle, 2002; El-Sheikh, Hinnant, Kelly, & Erath, 2010; Kunz & Grych, 2013; Silk, Morris, Kanaya, & Steinberg, 2003; Wijsbroek, Hale, Raaijmakers, & Meeus, 2011). Meta-analysis of the literature has revealed relations among parenting psychological control, negative support (rejection, hostility, and neglect), and inconsistent discipline with adolescent delinquency (Hoeve et al., 2009). It contrasts in association and effects with control characterized by reasoning, reminding of rules, and explaining (Paulussen-Hoogbeem, Stams, Hermanns, & Peetsma, 2007). The pathway(s) by which control exerts effects demand attention and clarification from research. It could be that parents who resort to psychological control fail to regulate their behavioral choices and therefore model problem behavior for their children; it could be that they do not command more optimal socialization strategies; it could be that they establish an emotional climate of invalidation and pressure within the family that permeates development (Barber & Xia, 2013; Snyder et al., 2013).

Behavioral control is usually intended to discourage antisocial behavior and promote prosocial behavior (Bjorknes, Kjøbli, Manger, & Jakobsen, 2012). Apparently, the vast majority of parents (in China 98% and the United States 84%, for example) outright lie to their children to get them to behave (Heyman, Hsu, Fu, & Lee, 2013). In disciplining children, parents too often escalate to corporal punishment. For example, 77% of U.S. American men and 65% of women endorse the statement that sometimes a

child needs a “good, hard spanking” (Child Trends, 2009), and almost 50% indicate that they had spanked their 2- to 5-year-old child in the past month (MacKenzie, Nicklas, Brooks-Gunn, & Waldfogel, 2011). Sanction of corporal punishment is widespread worldwide: A study of 30,470 families with 2- to 4-year-olds in 24 developing countries revealed that 29% of parents endorsed the belief that using corporal punishment is necessary to rear a child properly and that 63% reported that their child had been corporally punished in the last month (Lansford & Deater-Deckard, 2012). However, meta-analysis of the extant literature indicates that the only desirable outcome associated with corporal punishment is immediate compliance with a parent’s request and that many other short- and long-term negative outcomes (low child moral internalization, aggression, and delinquent behavior; adult aggression, antisocial, and criminal behavior) attend parental resort to corporal punishment (Gershoff, 2002). Punishment in conjunction with reasoning is linked with lower levels of disruptive behavior, but is unrelated to prosocial behavior and may promote moral reasoning based on fear. By contrast, parental inductive reasoning is linked with a variety of positive outcomes in children including prosocial behavior, empathy, and sympathy (Eisenberg & Fabes, 1998). Whichever, the effectiveness of parental discipline that emphasizes communication and reasoning appears to depend on children accurately perceiving and construing their parents (Grusec & Goodnow, 1994).

Dimensional, trait, and person approaches (like those just recounted) are popular ways of conceptualizing parenting, but entail a debatable set of assumptions and implications about the nature of parenting. In the 1970s, Thomas and Chess (1977) observed that such formulations assume an all-or-nothing character and they argued that it is insufficient and inaccurate to characterize a parent in an overall diffuse way as adhering to one or another general style. This view supposes that parents package a great variety of beliefs and behaviors together into a monolithic set and display the self-same beliefs or behaviors across domains of interaction, time, and context. Operationally, that is, a parent who engages the child in more emotional and interpersonal exchanges is also the parent who engages the child in more teaching and learning experiences and does so in all situations. Trait conceptualizations project parenting as more or less fixed in recurrent patterns, so that the particular pattern embodied by a parent represents the essence of that parent’s childrearing. Moreover, the trait approach to parenting does not invite more differentiated developmental questions or allow for bidirectionality,

the fact that different child characteristics may affect or evoke particular factors of parenting. Yet, child effects acknowledge the many and diverse behavioral adjustments parents make to children’s age and gender, appearance and behavior, temperament and intelligence (see later in this chapter on determinants). Alternatively, childrearing reflects multiple interactions of parent, child, and context, and parents naturally engage their children in a range of diverse activities and do not only or necessarily behave in uniform ways. Rather than employing a broad style, parents flexibly change in parenting as children age, vary their approach with children of different temperaments, and differ in response to situational constraints such as whether they are in public or in private. Like personality, parenting may be a social construction that judiciously combines personological consistency with situational specificity (Fleeson, 2004). Instead of broad styles, it may be helpful to explore more fine-grained parenting practices.

In *inhuman* primates the majority of maternal behaviors appears to consist of biologically requisite or obligatory feeding, grooming, and protection (Bard, 2002). Some related primate actions focus on assessing and monitoring brood behavioral state. Primate mothers also engage offspring in physical exercise and play and thereby encourage motor development. By contrast, the contents of human parent-child interactions are more dynamic and varied and include multiple obligatory as well as discretionary activities. Parents nurture and protect children, but they also guide children in understanding and expressing proper feelings and emotions, educate children in behaviors that are acceptable for the stage of childhood they occupy, and prepare children for adaptation to a wider range of life roles and contexts they will encounter as they grow (Bornstein, 2002a). Like cognitions, parenting practices are multidimensional, modular, and specific, and a number of domains of parenting practices has been identified as a common core of parental care (Bornstein, 2002a, 2006; for other componential taxonomies, see Bradley & Caldwell, 1995; E. Skinner, Johnson, & Snyder, 2005). They are nurturant, physical, social, didactic, verbal, and material forms of caregiving.

When parents *nurture*, they meet the biological, physical, and health requirements of their offspring. In an evolutionary perspective, survival to reproduction constitutes an ultimate criterion of adaptation. After reproduction, survival is achieved through provision of nourishment and protection of the child. Child mortality is a perennial parenting concern, and parents are centrally responsible for promoting children’s wellness and preventing their

illness. To do so, parents provide sustenance, protection, supervision, grooming (and the like) and shield offspring from risks and stressors. Adjusting for possible confounds, breastfeeding is associated with greater activations in select brain regions to a woman's own baby cry (P. Kim et al., 2011) and sensitive responsiveness and greater attachment security (Tharner et al., 2012) in mothers as well as higher language scores in children (Belfort et al., 2013).

Parents promote children's *physical* development, that is their gross and fine motor skills, and do so in many direct and indirect ways. Parents physically move and manipulate babies to reach or step, and they set goals and reward achievements. For example, Jamaican mothers expect their children to sit and to walk early, whereas Indian mothers living in the same city expect their children to crawl later. In each case, children's actual attainment of developmental milestones accords with their mothers' expectations (Hopkins & Westra, 1989, 1990). Super (1976) found advanced sitting, standing, and walking among Kenyan Kipsigis babies, but retarded head lifting, crawling, and turning over; more than 80% of Kipsigis mothers deliberately taught their infants to sit, stand, and walk. Indeed, the mothers who report "teaching" their babies to crawl have babies who crawl earlier in six African societies.

Parenting in the *social* domain includes a variety of visual, verbal, affective, and physical behaviors parents deploy in engaging children in warm interpersonal exchanges. Through positive feedback, openness and negotiation, listening, and emotional closeness, parents make their children feel valued, accepted, and approved of. Social caregiving also includes all the ways parents help and direct children to regulate their own affect and emotions and influence the communicative styles and interpersonal repertoires that children use to form meaningful and sustained relationships with others. Mothers' affectionately touching, rocking, holding, and smiling at their infants predict children's cognitive competencies (Olson, Bates, & Bayles, 1984).

Parenting includes a variety of *didactic* strategies used to stimulate children to engage and understand the wider natural and designed environments. Didactics organize the child's attention to properties, objects, or events in the surroundings; introduce, mediate, and interpret the external world; describe and demonstrate; as well as provoke or provide children with opportunities to observe, to imitate, and to learn. Education is a vital human parenting function and is foundational to children's proper embedding in their culture. Mothers who prompt more and respond more during their child's first year have preschoolers who score higher in

standardized evaluations of language and cognition (Bornstein, 1985; Nicely, Tamis-LeMonda, & Bornstein, 1999).

*Language* use in parenting is fundamental to child development and to the parent-child bond itself. The motivation to acquire language is social and born in interaction, usually with parents (Trevvarthen & Aitken, 2001). Rowe (2012) examined the quantity and quality of parent verbal input longitudinally to determine which aspects contribute most to children's vocabulary skill; controlling for social class, input quantity, and children's prior vocabulary skill, parents' using diverse and sophisticated vocabularies and narrative explained variation in child vocabulary (see also Song, Spier, & Tamis-LeMonda, 2013). Language also crosscuts the foregoing domains, as speech to children supports and enriches all domains of child development (Hoff, 2003): Labeling children's behavior is a common way to call attention to it and promote later recall. For example, Meins et al. (2002) described parents who treat their children as persons with thoughts and feelings as being "mind-minded;" the more mothers' language refers to and comments on their infants' minds, the more advanced children's theory of mind becomes.

Finally, caregiving includes those ways in which parents materially provision and organize the child's world, especially the home and local environments (Bradley, Chapter 12, this *Handbook*, this volume). Parents influence their children not only by what they do and the roles they play, but by the stimulation and opportunities they provide. Adults are responsible for the number, variety, and composition of inanimate objects (toys, books, tools) available to the child, the level of ambient stimulation, the situations and locales children find themselves in, the limits on their physical freedom, and the overall physical dimensions of children's experiences. Features of the parent-oufitted physical environment affect child development (Wachs & Chan, 1986): New toys and changing room decorations promote child language acquisition in and of themselves and independent of other parenting actions.

Certain characteristics of this parenting taxonomy merit brief comment: (a) nurturant and physical parenting seem obligatory; by contrast, social, didactic, language, and material parenting appear more discretionary; (b) nurturant, physical, social, didactic, and verbal parenting are active forms of interaction; physical and material parenting may be active or passive; (c) no one category of parenting is the most prominent all the time, although any one may dominate parent-child interaction at a given time; and (d) there is initially asymmetry in parent and child contributions to parenting practices in that responsibility

for nurturing, promoting physical growth, sociability, teaching, language, and material provisions in early child development appear to lie unambiguously with parents, but as time passes children play more active and anticipatory roles in their own development.

Together, the foregoing domains encompass virtually all of parents' important activities with their children and are perhaps culturally universal, even if their qualitative instantiations or quantitative emphases (in terms of sheer frequency or duration) vary. Although these modes of caregiving are conceptually and operationally distinct, in practice parent-child interaction is dynamic, intricate, and meshed, and parents regularly engage in combinations of them. When a parent gathers a child on his or her lap to read a picture book together, a lot is going on physically, intellectually, verbally, emotionally, and socially. These modes also have been studied for their variation, stability, continuity, and covariation as well as for their influences on child development. Taken as a totality, this constellation of parenting practices constitutes a varied and demanding task set, and (as with cognitions) adults differ considerably in terms of how they esteem components of the caregiving repertoire as well as in how successful they are in executing different components. For their part, human children are reared in, influenced by, and adapt to a social and physical ecology commonly characterized by this parenting taxonomy and its elements. Contra a person orientation, the componential construction is more faithful to a variable orientation to parenting.

### Some Principles of Parenting Cognitions and Practices

For parent cognitions and practices to be meaningful in child development they best meet several psychometric criteria. To be better understood, relations between cognitions and practices also need to be explicated, processes of their action explained, and myriad other considerations that apply to them addressed. Each of these principles is considered in turn.

*Psychometric characteristics.* Four significant psychometric characteristics help to define and distinguish parenting cognitions and practices. The first has to do with variation. Adults vary among themselves, within as well as across social groups, in terms of how tenaciously they cling to their parenting cognitions, how often and long they engage in parenting practices, and how they interpret and invest meaning in both. For example, the amounts of language which parents address to children vary enormously: Some mothers talk to their infants during as little

as 3% and some during as much as 97% of a naturalistic home observation, even when mothers are sampled from a relatively homogeneous population in terms of education and social class (Bornstein & Ruddy, 1984). This variation does not preclude startling systematic group differences in parenting, for example, by social class or ethnicity or culture. In a year, the child in a "professional" family hears 11 million words, whereas the child in a "welfare" family hears 3 million and by middle childhood spoken vocabularies of children of "professional" families exceed spoken vocabularies of parents of "welfare" families (Hart & Risley, 1995, 1999).

A second psychometric feature of parenting has to do with developmental stability and a third with continuity. The term *stability* means consistency in the relative ranks of individuals in a group over time, and *continuity* means consistency in the mean level of a group over time; the two are conceptually and statistically independent developmental constructs (M. Bornstein & Bornstein, 2008). Holden and Miller (1999) meta-analyzed consistency of attitude questionnaires and behavioral observations of parents (mostly mothers) and arrived at a relatively high median correlation of .59 (see also Dallaire & Weinraub, 2005; Haltigan, Roisman, & Fraley, 2013). Within-family parenting of first- and secondborns shows similar moderate consistency (Hallers-Haaloom et al., 2014) even if parental investment in daily interactions with children varies inversely with family size, regardless of family SES (Lawson & Mace, 2009). The fact that individual differences in parenting are stable (to some degree) implies that cognitions and practices assessed at one point can be assumed to reflect past as well as future parenting. It also means that indices of parenting might be related meaningfully to concurrent or future child behavior or performance.

Individual parents appear to maintain their standing relative to one another from day to day: Parents who talk to their children more on Monday likely talk to their children more on other days of the week. Over longer periods, of course, group mean levels in parenting change, and they certainly do so in response to children's development. Thus, stability does not negate age-appropriate continuity or discontinuity in parenting. For example, the ratio of adult-directed speech to child-directed speech increases across just the first postpartum year (Bornstein & Tamis-LeMonda, 1990). In infancy, dyadic attunement serves as a foundation for sensitive and warm communication and interpersonal interaction (Bornstein, 2013a); in childhood and adolescence, parents mediate and monitor their children's social relationships with others, such as peers (Bornstein, Jager, &

Steinberg, 2012; Ladd & Pettit, 2002; Racz & McMahon, 2011; Stattin, Kerr, & Tilton-Weaver, 2010). Keeping an eye on a toddler in the park when the child is beginning to walk and giving a cell phone to a teen who is beginning to drive a car appear superficially different but may be conceptually similar in the sense of reflecting continuity in parental monitoring. More generally, some domains of parenting wax while others wane as children develop, but parents adjust relative to both child age and child competence or performance.

A fourth characteristic of parenting concerns the covariation among parenting domains. Positions alternative to the person conceptualization of parenting are that caregiving cognitions and practices are not necessarily or rigidly linked psychologically, but that individual parents vary in patterning their beliefs and behaviors in ways that call into question any monistic or trait organization of parenting. In shorter words, parenting is multidimensional, modular, and specific, and individual parents may profess particular cognitions and emphasize particular practices with their children at different times, in different places, and so forth (Bornstein, 2002a, 2006).

*Cognition-practice relations.* Do parents' cognitions always animate their practices? Parents' cognitions are often hypothesized to prompt or direct parents' practices and, ultimately, children's development (Darling & Steinberg, 1993; Sigel & McGillicuddy-De Lisi, 2002). Importantly, relations between beliefs and behaviors are historically an unsettled area in social psychology (Festinger, 1964; LaPiere, 1934), and relations between parental beliefs and behaviors specifically have proved equally elusive (Coleman & Karraker, 2003; Cote & Bornstein, 2000; Okagaki & Bingham, 2005).

Those parenting beliefs and behaviors whose causal relation has been evaluated have been very general, giving little reason to expect covariation. When more circumscribed and conceptually corresponding domains are studied, some maternal childrearing beliefs have been found to relate to some self-reported or observed childrearing behaviors, supporting expected links in the putative causal chain, as for example between authoritarian attitudes and discipline strategies, intuitions about parenting effectiveness and caregiving competence, and the like (Coplan et al., 2002; Huang, O'Brien Caughy, Genevro, & Miller, 2005; Kinlaw, Kurtz-Costes, & Goldman-Fraser, 2001). Thus, the association between parents' cognitions and practices appears to depend, at least in part, on alignment of the contents of the beliefs and the behaviors in question. For example, Benasich and Brooks-Gunn (1996), using the

prospective longitudinal study data set of a low-birthweight preterm cohort from the multisite U.S. Infant Health and Development Program, found that maternal knowledge of child development and child rearing conditioned the quality and structure of the home environment mothers provided, which in turn affected child cognitive and behavioral outcomes. Fathers' perceptions of their investment in parenting relate to their actual levels of involvement (McBride et al., 2005).

Beliefs do not always map onto behaviors directly, but the two coexist in complex ways, and meaning assigned to each is critical (Bornstein, 1995). What may be called the "standard model" of cognition → practice → development relations is widely assumed but seldom confirmed *in toto*. Many associations between parents' cognitions and practices reflect shared source and method variance (much research in these associations has utilized parents' self-reports to measure the two or has measured the two at the same time), inflating their relations. All of these considerations have unsurprising practical implications as targets of parenting interventions (discussed later in this chapter; see Pinquart & Teubert, 2010). All also represent areas ripe for further research.

*Action processes.* Parenting is readily identified with socialization, but formal socialization is only one process by which children's parents influence their development. Other general psychodynamic, learning, cognitive, and opportunity processes have been identified (as hinted at in the earlier discussion of theory). These processes are thought to apply broadly as they are applicable to diverse contents and contexts across the life span.

Psychodynamic socialization, internalization, and attachment constitute one interrelated group of correlational mechanisms. Sigmund Freud (1949) speculated about the special importance of early experiences in socialization, suggesting that the ways parents treat their young progeny establish lifelong personality traits (Cohler & Paul, 2002). Freud and his followers posited *psychodynamic* mechanisms like introjection and internalization to account for developmental phenomena, such as gender socialization. Girls usually identify with mother and adopt female behaviors, boys with fathers and male behaviors. Children who work alongside their same-gender parents internalize roles and rules for appropriate gendered behavior and identities as members of their communities (Lancy & Grove, 2010). Bowlby (1969) and successive attachment theorists subsequently proposed that, arising out of their early interpersonal experiences with caregivers, young children develop "internal working models" of their

caregivers that incorporate both sides of the caregiver-child relationship. Attachment research assumes that, on the basis of repeated patterns of interaction, children develop enduring representations of socioemotional relationships (Fraley & Shaver, 2000; Mikulincer, Shaver, & Pereg, 2003). Moreover, predictive links have emerged between mothers' own attachment classification and her child's attachment (Miljkovitch, Pierrehumbert, Bretherton, & Halfon, 2004) and between impaired maternal-infant attachment and internalizing behavior in early childhood (Madigan, Atkinson, Lauren, & Benoit, 2013). Malberg and Mayes (2013) provide a contemporary treatment and amalgam of these two perspectives.

Classical, operant, and observational *learning* all refer to contingencies that govern the formation and encoding of information and are thought to constitute species-general rules. From the very beginning of life, human beings make associations and subsequently use what they have learned. Moreover, early simple behavior patterns are asserted to underlie later more complex behavior patterns. Although learning processes apply to many aspects of development, one example of a direct avenue of socialization is posited to flow through parents' differential treatment, which may assume various forms. One type operates through parenting cognitions; for example, parents possess different beliefs about (their) girls and boys across a wide array of domains. Mothers of toddlers underestimate their girls' motor skills and overestimate their boys' motor skills even when objective tests show no gender differences in children's motor performance (Mondschein, Adolph, & Tamis-LeMonda, 2000). Parents tend to expect boys to do better than girls in science and math (Eccles, Freedman-Doan, Frome, Jacobs, & Yoon, 2000; Tenenbaum & Leaper, 2003), again despite a lack of actual gender differences in performance (Hyde, Lindberg, Linn, Ellis, & Williams, 2008; Tenenbaum & Leaper, 2003). These messages are hypothesized to influence children's self-concepts, motivation, and choices. A second type of differential treatment occurs through parenting practices, parents' direct active or passive interactions with children. Mischel's (1970) social learning perspective called attention to parents' (and others') direct reinforcement of children's conformity to expected or desired norms, as with respect to gender when adults compliment a girl when she nurses a toy doll and a boy when he builds a model airplane. Girls are more likely to be involved in housework than boys (Huebler, 2008). Children's execution of different behaviors often depends on rewards or injunctions associated with their outcomes. Praise is a good example of reinforcement. Parents' praising of their

children's efforts at 18 to 38 months predicts children's attributing success to hard work and enjoying challenges at 7 to 8 years (Gunderson et al., 2013). Indeed, praise is known to operate as early as 4 to 9 months and in different cultures (Japanese) inflecting the trajectory of children's later social confidence (Shinohara et al., 2010).

Parents, too, offer children different models for *imitation*. In one view, children acquire new behaviors without ever performing them overtly and without ever being rewarded, but merely by observing behaviors being performed by parents (Bandura, 1989). To the extent that mothers, fathers, or other caregivers are important and influential figures in children's lives, often to be emulated or feared, they shape children's impressions of what it means to be a woman or a man, for example, simply by acting like a woman or a man (Bussey & Bandura, 1999). Imitation is a particularly efficient process for acquiring information just by watching or listening. Observation is also motivated by the expectation that, at a future time, the observer will be responsible for the action in question (Rogoff, 2003; Rogoff, Pardies, Arauz, Correa-Chavez, & Angelillo, 2003). Imitation may be hardwired and virtually automatic (Chartrand & Bargh, 1999; Molenberghs, Cunningham, & Mattingley, 2012; Rizzolatti & Fogassi, 2007).

As briefly mentioned earlier, in an *instruction* and *scaffolding* view, socialization is more an interactive, bidirectional process. Vygotsky (1978) saw the individual as actively engaged with his or her surroundings and emphasized the crucial importance of social interaction in socialization, contending that the more advanced partner (the socializer) influences (raises the level of performance) of the less advanced partner (the socializee) through their social-cognitive interactions. Wood, Bruner, and Ross (1976) identified the teaching roles adults adopt in interactions with children under the rubric of "scaffolds." As engineers would in constructing a building, caregivers sometimes employ temporary aids to support and guide a child's development. Scaffolding strategies vary depending on the nature and age of the child and the actual activity, and caregivers can vary in the scaffolds they favor. Mothers and fathers tend to scaffold children's learning differently, and they encourage girls' and boys' participation in different learning activities and household chores in anticipation of their expected later gender roles in adulthood (Coltrane, 2000; Leaper, 2002; Raley & Bianchi, 2006), just as children possess and reference stereotypic expectations about family activities (Schuette & Killen, 2009).

Another important route by which socialization proceeds is through the types of opportunities parents provide

or promote. Access to certain settings affords children chances to develop certain self-conceptions and to engage in particular activities as well as to receive encouragement for repeating those activities. For example, the availability of feminine-stereotyped toys prompts caregiving behaviors (e.g., feeding a doll), whereas the availability of masculine-stereotyped toys prompts instrumental behaviors (e.g., constructing a model). Stereotyped girls' toys (dolls) provide girls with practice in learning rules, imitating behaviors, and using adults as sources of help for certain outcomes, whereas stereotyped boys' toys (models) refine visual/spatial skills, problem solving, independent learning, self-confidence, and creativity (Martin & Dinella, 2002). The creation and affordance of children's opportunities mean that parents do not need to model, reinforce, or scaffold gendered beliefs or behaviors because contexts or implements per se may ordain or elicit desired gendered beliefs or behaviors.

*Desiderata: Specificity, moderation, transaction, thematicity, and direct and indirect effects.* A common historical assumption in parenting (stemming in part from the trait view) was that the overall level of parental involvement or stimulation affects the child's overall level of development. An example of this simple model suggests that language acquisition in children is determined (at least to some degree) by the sheer amount of language children hear (Hart & Risley, 1995). Increasing evidence suggests, however, that more sophisticated and differentiated pathways govern parenting effects. First, specific (rather than general) parental cognitions and practices appear to relate concurrently and predictively to specific (rather than general) aspects of child competence or performance. It is not the case that the overall level of parenting directly affects children's overall level of functioning and can compensate for selective deficiencies: Simply providing an adequate financial base—a big house, or the like—does not guarantee, or even speak to, children's development of healthy eating habits, an empathic personality, verbal competence, or other valued capacities. The *specificity principle* states that specific cognitions and practices on the part of specific parents at specific times exert specific effects over specific children in specific ways (Bornstein, 2002a, 2013b). The specificity principle helps to explain numerous observations and discrepancies in the parenting literature. With respect to time, for example, it has been observed: "Parents who are highly effective at one stage in the child's life [are] not necessarily as effective at another.... Similar practices do not necessarily produce the same effects at successive stages in [a] child's life" (Baumrind, 1989,

p. 189). Similarly, maternal responsiveness to infants' vocalizations predicts child vocabulary size, but not symbolic play, whereas maternal responsiveness to the same infants' symbolic play predicts child symbolic play, but not vocabulary (Tamis-LeMonda, Bornstein, Baumwell, & Damast, 1996; see also Paavola, Kunnari, & Moilanen, 2005). Parental responsiveness to child distress, but not warmth, predicts children's regulation of negative affect and greater empathy and prosocial sensitivity; parental warmth, but not responsiveness to distress, predicts children's regulation of positive affect (Davidov & Grusec, 2006). The specificity principle is apparently counterintuitive because, according to the Civitas Initiative et al. (2000) national survey, a majority of parents simplistically thinks that the more stimulation a baby receives, the better off the baby is. In fact, parents need to carefully match the specific amounts and kinds of stimulation they offer to a specific child's specific level of development and specific interests, temperament, mood at the moment, and so forth. The specificity principle accords with a relational developmental systems view of parenting and with the multidimensional and modular character of parenting.

One implication of specificity is that parenting effects are likely *moderated* by multiple conditions. To detect regular relations between antecedents in parenting experience and environment on the one hand and outcomes in child characteristics on the other, researchers need to seek and to find more precise combinations of independent and dependent variables. For example, the same parenting practice might differ in its effectiveness when employed by parents with different parenting styles: Parents' use of punitive discipline is linked with problematic adjustment among children from nonauthoritative families but not authoritative families (Fletcher, Walls, Cook, Madison, & Bridges, 2008). Gender-differentiated parenting is more probable in structured settings like problem-solving tasks than in relatively unstructured ones like free play (Leaper, Anderson, & Sanders, 1998). The supermarket checkout line is a more challenging context to parental authority than the playground (Lecuyer-Maus, 2000).

Consider again the role of timing as a moderator of parenting effects. Psychoanalytic, learning, ethological, and attachment theories of parenting posit that early parenting influences the child at a particular time point and the consequences for the child endure, independent of later parenting. Mother-infant attachment status has a direct effect on young adolescents' emotional maturity and scholastic skills net concurrent representations of relationships, self-esteem, and changes in caregiving arrangements

(Aviezer, Sagi, Resnick, & Gini, 2002). Alternatively, early effects may not persist or they may be altered or supplanted by subsequent conditions that are more consequential. On this argument, some theorists challenged the importance of early experience (Kagan, 1998; Lewis, 1997). Empirical support for contemporary experience models of parenting effects typically consists of recovery of function from early enrichment or deprivation and failures of early interventions to show sustained effects (Clarke & Clarke, 2000; Peisner-Feinberg et al., 2001). Specific language input is unrelated to certain verbal skills early in development, but is related later in development (Huttenlocher, Vasilyeva, Cymerman, & Levine, 2002). At 5½ years, concurrent television exposure, but not sustained television exposure to that point, is associated with diminished social skills (Mistry, Minkovitz, Strobino, & Borzekowski, 2007). A cumulative (or additive and stable) experience model combines these views and contends that repeated experiences are requisite to shape child development. That is, a parent-provided experience at any one time (antecedent or contemporary) does not necessarily affect the child, but meaningful longitudinal relations are structured by parenting interactions repeating continually, and aggregating, through time (Belsky & Fearon, 2002). Children of mothers who are consistently responsive show higher levels of certain cognitive skills, and greater increases in them over time, than children whose mothers show only early or only late responsiveness (Landry, Smith, Swank, Assel, & Vellet, 2001). Although longitudinal data provide evidence for early, contemporary, and cumulative experiential effects between parents and children, for the most part children are reared in stable environments (Holden & Miller, 1999), so that cumulative experiences are likely.

A concomitant of moderation is *meaning*. Depending on several factors, the same parenting cognition or practice can have the same or different meaning, just as different parenting cognitions or practices can have the same or different meanings (Bornstein, 1995, 2013b). For example, parental control is equated with loving concern and is associated with adolescent perceptions of warmth among Asian and Latino/a, but not European, Americans (Chao & Tseng, 2002; Harwood et al., 2002), and physical discipline administered by some parents might communicate concern for children's welfare and, therefore, carry a different meaning than does physical discipline administered by other parents (McLoyd & Smith, 2002). Reciprocally, parental warmth is a protective factor against children developing externalizing problems in European American families, but it is a

risk factor for children in African American families (Lau et al., 2006).

Human beings do not develop in isolation. Throughout development, people and their experiences jointly create and regulate their socialization. Traditionally, the socialization processes asserted to convey intergenerational transmission of beliefs and behaviors include identification, conditioning, reinforcement, and modeling, teaching and scaffolding, and the provision of opportunity. It has been easy to assume that parents and other adult socializers are responsible for, say, gender-differentiated conduct in children. However, it is also the case that daughters elicit more feminine stereotypes (affection) and sons more masculine ones (building). Child effects on parent are in play and coexist with parent effects on children (Lerner, 1982), and these mutual influences interact to consolidate socialization in children (Bornstein, 2013a). The principle of *transaction* in child development acknowledges that characteristics of an individual shape his or her experiences, while, reciprocally, experiences shape the characteristics of the individual through time (Bornstein, 2009). Bell (1968; Bell & Harper, 1977) was among the first to emphasize the key role that bidirectional effects play in child socialization. By virtue of their unique characteristics and propensities—state of arousal, perceptual awareness, cognitive status, emotional expressiveness, and individuality of temperament and personality—children actively contribute, through their interactions with their parents, to producing their own development. Children influence which experiences they will be exposed to, and they also interpret and appraise those experiences and so (in some degree) determine how their experiences affect them. Child and parent bring distinctive characteristics to, and each is believed to change as a result of, their interactions with one another; parent and child alike then enter later interactions as changed individuals. So, child temperament and maternal sensitivity operate in tandem to shape one another and eventually the attachment status of the child (Rothbart, 2011); parental psychological control and adolescent depressive symptoms exert reciprocal effects (Soenens, Luyckx, Vansteenkiste, Duriez, & Goossens, 2008); parents' use of corporal punishment predicts subsequent child behavior problems, while children with more behavior problems elicit more corporal punishment from their parents (Lansford et al., 2011), and mothers' and fathers' harsh verbal discipline provokes increases in adolescent conduct problems and depressive symptoms as adolescent misconduct elicits increases in mothers' and fathers' harsh verbal discipline (Wang & Kenny, 2013). In

the end, effects in socialization run in both directions—parent-to-child and child-to-parent—and this consistency is mutually reinforcing.

An important in-the-moment instantiation of transaction is *attunement*, the dyadic, dynamic, and wholistic intricate patterns of sensitive mutual understandings and unfolding synchronous interactions between children and their parents (Bornstein, 2013a; Deater-Deckard & O'Connor, 2000; Harrist & Waugh, 2002). Attunement expresses the active adaptation of partners, of sensing and reading one another's state and adjusting biology and behavior accordingly. Parents and children share many characteristics, and attunement is a multilevel phenomenon with correspondences in the hormonal, autonomic, and central nervous system as well as in affective, cognitive, and behavioral domains. When interactions with caregivers fall out of attunement by becoming mistimed or mismatched, children and parents both experience distress.

Socialization messages are often delivered consistently in different social contexts via different social channels. Through *themacity*, diverse processes of socialization work in concert with one another. Studies of children's household work indicate patterns that are pertinent to a thematic consideration of gender socialization, for example. First, mothers and fathers typically model a traditional gender-stereotyped division of labor in their own household work (Coltrane, 2000). Second, parents tend to allocate gender-typed chores to children, typically assigning childcare and housework to daughters and allotting maintenance work to sons (Pinzas, 2008; Raley & Bianchi, 2006). Third, mothers teach daughters how to change a baby's diaper, and fathers teach sons how to build a model. On outings to museums parents focus on explanations of scientific content with their boys more than with their girls and so may foster boys' greater interest in and knowledge about science (Crowley, Callanan, Tenenbaum, & Allen, 2001). Fourth, parents instill gender development in their children by placing girls and boys in gender-distinctive contexts (e.g., rooms with certain furnishings; Pomerleau, Bolduc, Malcuit, & Cossette, 1990). Last, children actively participate in gender-organized activities, and children prefer gender-stereotyped clothes and being delegated gender-stereotyped chores (Schuette & Killen, 2009).

Finally, effects of parenting cognitions and practices on children may be *direct* or *indirect*. Much empirical research attests to short- and long-term direct influences of cognitions and practices of parents on children's development, and diverse processes (socialization, teaching and scaffolding, conditioning, reinforcement, and modeling)

likely convey direct effects. Indirect effects are more subtle and perhaps less noticeable than direct effects, but no less meaningful. One type of indirect effect includes the opportunity structures parents provide. Another concerns interparental relationships. Effective coparenting in marital support and communication bodes well for child development (McHale et al., 2002): For example, fathers' education predicts the quality of mother-child engagements (Tamis-LeMonda et al., 2004). An additional type of indirect effect concerns the effect pathway. Here two approaches have been distinguished. Mediation of parenting practices (Y) in a relation between parenting cognitions (X) and child outcomes (Z) normally requires establishing a relation between X and Z and then assessing whether that direct X–Z relation attenuates when Y is added to the model as an intermediary (Cole & Maxwell, 2003). By contrast, a cascade is a developmental relation where X uniquely affects Y, which in turn uniquely affects Z, separate from any X–Z relation or other intrapersonal and extrapersonal factors (Masten & Cicchetti, 2010). A cascade explains a key temporal process in the model regardless of any direct relation from X→Z.

### Summary

Parenting expresses itself in both the beliefs parents hold and the behaviors they exhibit. Parenting cognitions include, for example, perceptions about, attitudes toward, and knowledge of all aspects of parenting and childhood. Out of the dynamic range and complexity of individual activities that constitute parenting, major domains of parent practices have been discerned. These domains are conceptually separable, but each is developmentally significant. Whether direct or indirect, parental influences on children appear to operate on several noteworthy principles, such as specificity, moderation, transaction, and thematicity.

### PARENTING EFFECTS

As indicated at the outset of this chapter, parenting has two-fold significance: One is as a phase of adult life, and the other is as an instrumental activity. To be meaningful in child development, parenting must have some demonstrated predictive validity, or to reiterate a contemporary challenge: *Does parenting matter?*

"The apple does not fall far from the tree." "As the twig is bent, so grows the tree." These sayings reflect the belief (some would say *assumption*) that the attitudes and actions of children's parents, and the environments they create,

shape children and the course of their intellectual, psychological, behavioral, and social development (Collins et al., 2000; Domitrovich & Bierman, 2001; Roksa & Potter, 2011). (The agrarian metaphor for parenting is omnipresent, stretching as it does from “kindergarten” to “culture.”) The early literature on “parenting effects” built up as a natural consequence of this unidirectional way of thinking about socialization, and much of it relied on parent-child correlations as its evidentiary base. In such study, parents who did more of something had children who did more of a related something. However true it may be that parents influence children, we recognize that correlation does not prove causation, that the arrows of influence in an association may run in either or both directions (*viz.*, that parents influence children and children influence parents), and that associations between parent-rearing and child characteristics could arise from shared third familial or extrafamilial factors (parents and their children share genes, come from the same socioeconomic stratum, etc.). There follows a brief comment on parenting effects derived from correlational designs and thereafter a more extended discussion of more robust supports of parenting effects. This section of the chapter then speaks to complementary information and challenges to parenting effects from behavior genetics and group socialization theory.

### Correlational Designs

Most studies of parent-child relations have employed correlational designs, the resultant associations have usually been modest, and early advocates of “socialization” often assumed the truth value of  $r$ , only interpreted directional effects, and sometimes overstated its implications. By consensual reckoning, parenting is reported to share 20% to 50% of common variance with child outcomes (Conger & Elder, 1994; Reiss, Neiderhiser, Hetherington, & Plomin, 1999). Some correlational studies address the more obvious shortcomings of the design. For example, Patterson and Forgatch (1995) reported substantial correlations between parents’ disciplinary and monitoring practices and children’s negative and coercive behavior both at home and in out-of-home contexts, and Chilcoat and Anthony (1996) reported a significant increase in risk of adolescents’ drug sampling for every unit of decrease in parental monitoring after partialling age, gender, and ethnicity. The foregoing illustrations provide stronger inferences than simple associations because, in the case of the first, associations between parenting and child development at least transcend a common context, and, in the case of the second,

associations obtain after common-cause third-variable controls are instituted. In actuality, the sizes of zero-order correlations between parent cognitions or practices and child characteristics vary considerably depending on what parent and child variables are considered, the way they are measured, the length of time between parent predictive and child criterion measurements, what kind of analyses are conducted, which children or families living in which circumstances are studied, and whether background variables are statistically controlled (Bornstein, 2013b). For example, depending on the topic and informant behavioral observations and parent or child reports yield different effect sizes (see Collins et al., 2000).

Furthermore, it is not reasonable to expect generalizations about the nature and effects of specific parent-child associations to span all ages/stages and all domains of child development. On specificity, parents might foster the development of specific talents (e.g., by providing sports practices or music lessons) and might influence some characteristics (e.g., religious affiliation or political persuasion), but may have less influence on others (e.g., alcohol consumption with peers). Longitudinal associations, adoptive parent-adopted child associations, and other methodological strategies that supplant simpler zero-order correlations constitute further design improvements on cross-sectional and genetically related parent-child approaches. To overcome the critique of parenting effects as mere epiphenomena of shared genetics, for example, some designs have included biological-adoptive comparisons. Adoption studies separate the effects of environmental and genetic factors (although the standard design can be compromised by gene-environment interactions). For example, Bjoerklund, Lindahl, and Plug (2006) reported strong associations between adoptive mother and father educational achievement and adopted children’s schooling. Utilizing a design that included adoption triads of birth mothers, adopted child, and adoptive parents, Marceau et al. (2013) discovered distinct patterns of associations among genetic (birth mother psychopathology), prenatal (obstetric and pregnancy complications, toxin exposure), and postnatal influences (adoptive parent 18-month internalizing symptoms to toddler behavior problems at 27 months).

Contemporary parenting research has also moved beyond a fixed focus on main effects of parenting toward concerns with process and understanding more complex parent-child interactions. For example, a given parent-provided experience may have different effects on a child depending on the child’s traits. Tienari, Wynne, Moring, Lahti, and Naarala (1994) contrasted children with a

schizophrenic biological parent and adopted children who did not carry this risk factor to illustrate how a predisposition can either manifest itself or not, depending on whether certain triggering environmental conditions are present. Adoptees who had a schizophrenic biological parent were more likely to develop a range of psychiatric disorders (including schizophrenia) than adoptees not at risk, but only if they were adopted into dysfunctional families. Bohman (1996) studied adopted children whose biological parents did or did not have a history of criminality. Among adoptees who carried a risk factor from their biological parents, those who had been adopted into dysfunctional homes were more likely to engage in criminal behavior than those whose adoptive parents provided stable and supportive environments.

### Experimental Designs

Experimental manipulations advance beyond parent-child correlations in attempts to uncover causal relations between children's parents and their development. Perhaps the strongest statement that could be made about parenting effects would be based on experimental treatments in which parents are assigned randomly to an experimental versus a control group with resulting changes in the beliefs or behaviors of both the parents and their otherwise untreated children in the experimental group relative to the controls. Such experiments show (a) that the treatment alters parenting in the experimental group, (b) that there are no changes in the comparison control group, and (c) that change in the parent effects a change in the child. The extant literature appeals to animal experiments and three kinds of experiments with human beings: natural experiments, designed experiments, and experimental interventions.

*Animal experiments.* Experiments with animal populations provide invaluable and unique data about parenting effects because many informative manipulations (from sacrificing animals to drug administration to deprivation to cross-fostering) are unethical with human beings. Classic work directly germane to this point dates from Harlow's (1958) studies on sustenance versus contact comfort given to infant monkeys. Harlow raised infant monkeys with only two simple mother-surrogate models available to them: One was made from wire mesh and had an attached milk bottle from which the infant monkeys could feed, and the other had a soft cloth surface but did not deliver any food. Despite the wire mother being a source of nourishment, infant monkeys preferred to cling to the cloth mother and,

when frightened, almost always held her tightly. When put into an unfamiliar environment, the presence of the cloth mother reduced infant panic reactions, and infant monkeys used it as a safe haven from which to explore. These differential rearing effects also endured in monkeys' later peer interactions and mating. Contemporary cross-fostering experiments in nonhuman animals support causal links from parenting (Champagne & Meaney, 2001).

Males in the biparental marmoset species *Callithrix jacchus* engage in high levels of parenting and express enhanced circulating reproductive hormones, such as Arginine vasopressin (AVP). The brains of first-time and experienced marmoset fathers have a greater abundance of AVP V1a receptors and greater density of V1a receptor-labeled dendritic spines on pyramidal neurons in prefrontal cortex than nonfathers (Kozorovitskiy, Hughes, Lee, & Gould, 2006). Woller et al. (2012) examined the release of several reproductive neurocrines, including oxytocin (OT) and prolactin (PRL), in cultured explants of the hypothalamus of paternally experienced male marmosets compared to naïve, paternally inexperienced males. OT and PRL levels were higher than levels found in inexperienced males, suggesting that paternal experience prompts secretion of neurocrines in a male biparental primate. Kenkel et al. (2012) exposed reproductively naïve male prairie voles to infants or control manipulations and measured plasma concentrations of OT and AVP in the paraventricular nucleus of the hypothalamus; pup exposure increased activation of neurons that stained for OT and AVP.

Animal experiments in epigenetics further support parenting effects. Approximately 1 in every 33 children in the United States is born with a birth defect, most with unknown nongenetic causes (Centers for Disease Control and Prevention, 2013a). Diet folate deficiency is, however, associated with birth defects. Male mice that were fed a diet containing less than 15% of the recommended amount of folate for their lifetime (from the time they were fetuses through to reproductive maturity) showed deficiencies in fertility as well as litter offspring with approximately 30% more birth defects than controls (Lambrot et al., 2013). In another study, male mice were taught to fear the smell of cherry blossoms (through associative conditioning with foot shocks); they were then mated with females. Their offspring, raised to maturity without ever have been exposed to the scent of cherry blossoms, demonstrated fearfulness the first time they were exposed to the scent, had a lower threshold for cherry blossom detection, and their brains had more neurons specialized for the odor. The pups of females artificially inseminated with sperm of fear

conditioned father mice showed similar effects (Dias & Ressler, 2013). Some characteristics outside DNA appear to be inherited from parents (see also Vassoler, White, Schmidt, Sadri-Vakili, & Pierce, 2012).

*Natural experiments.* Studies of children with genetic endowments that differ from those of their nurturing parents provide one naturally occurring means of simultaneously evaluating the impacts of parenting *qua* experience vis-à-vis hereditary endowment on child development. In (ideal) natural quasi-experiments, say of adoption, one child shares genes and environment with biological parents, one child shares genes but not environment with biological parents, and one child shares environment but not genes with adoptive parents. In France, a cohort of children was identified who had been given up in infancy by their working-class parents and adopted by middle-class parents. These children all had biological siblings or half-siblings who remained with their biological families and were reared in impoverished circumstances. No selective factors differentiated the two groups. When tested in middle childhood, the adopted children's IQs averaged significantly higher than those of their natural siblings, and children who remained with their biological mothers were more likely to exhibit failures in school performance (Duyme, Dumaret, & Stanislaw, 1999). Adoptive mothers' sensitivity and support are associated with better social and cognitive development in adopted children at the age of 7 (Stams, Juffer, & van IJzendoorn, 2002) as well as with stronger attachment relationships at the age of 14 (Beijersbergen, Juffer, Bakermans-Kranenburg, & van IJzendoorn, 2012).

Contemporary technology has afforded even more penetrating natural experiments. Where previously it was not possible to assess human offspring whose prenatal environment was provided by a biologically unrelated mother, this is now feasible because of the increased use of in vitro fertilization (IVF) and surrogacy as a means of conception. For example, maternal stress during pregnancy is associated with increased emotional and antisocial problems in children even when controlling for important confounds (Rice et al., 2007; Swanson & Wadhwa, 2008; Talge, Neal, Glover, & Early Stress Translational Research Prevention Science Network, 2007). Prenatal stress could arise through early environmentally mediated programming effects on the fetus, or through factors that influence mothers during pregnancy and which are inherited. Rice et al. (2010) employed a prenatal cross-fostering design, including pregnant mothers who were related or unrelated to their child as a result of IVF and surrogacy, to disentangle

inherited and environmental influences. Their logic was as follows: If links between prenatal stress and offspring outcome are environmental, the association should be observed in unrelated as well as related mother-child pairs. Associations between prenatal stress and offspring birth weight, gestational age, and antisocial behavior were seen in both related and unrelated mother-offspring pairs, consistent with environmental links being determinative. The association between prenatal stress and offspring anxiety in related and unrelated groups appeared to be due to current maternal anxiety/depression rather than prenatal stress. By contrast, the link between prenatal stress and offspring attention deficit hyperactivity disorder was only present in related mother-offspring pairs and therefore likely attributable to genetic factors.

*Designed experiments.* Studies that randomly assign human families to treatment versus control groups and that intervene with the parents but do not simultaneously treat the children are rare (for obvious reasons), but several have shown that treatment can change parental thinking and action toward children in specified ways and, in consequence, child development. For example, Stein et al. (2012) randomized mothers to either a worry/rumination prime (WRP) or a neutral prime (NP) and assessed mother-infant interactions before and after priming. Type of priming predicted maternal cognitions. WRP resulted in more negative thoughts, higher thought recurrence, and more self-focus relative to NP. Moreover, compared with NP, WRP inhibited maternal responsiveness and decreased maternal vocal interactions. Experiments modify parenting practices as well. Belsky, Goode, and Most (1980) reinforced mothers' didactic interactions with their young children during play in an experimental group and found increases in mothers' didactic interactions and higher exploratory play in children compared to a control group. When Anderson, Lytton, and Romney (1986) paired conduct-disordered boys with mothers of conduct-disordered boys and with mothers of normal boys, conduct-disordered boys elicited negative parenting from both sets of mothers. (This experimental setting controls for genetic effects and shows that characteristics of the child contribute to parenting.) Van den Boom (1994) trained lower-SES mothers to respond sensitively to their children; in this way, they modified mothers' negative responses to their child's irritability, and they reduced avoidant attachment in distress-prone children. Similar experiments attest that parenting is malleable and that change in parenting predicts change in children's language (Goldstein, King, & West, 2003), attachment (Heinicke, Rineman, Ponce, & Guthrie, 2001),

aggressiveness (Patterson, Dishion, & Chamberlain, 1993), behavior management (Webster-Stratton, 1990), and school adjustment (Forgatch & DeGarmo, 1999).

Other, even invasive, psychobiological experiments are increasingly common. Intranasal administration of neuropeptides can reach the central nervous system, and OT is known to play a key role in regulating social behavior and supporting the parent-infant bond in mammals (MacDonald & MacDonald, 2010). Naber, van IJzendoorn, Deschamps, van Engeland, and Bakermans-Kranenburg (2010) videorecorded fathers during a play session with their toddlers once following intranasal OT administration and then after intranasal placebo administration. Fathers increased their support for learning and exploration with respect for the child's autonomy following OT administration. Utilizing a double-blind, placebo-controlled crossover design, Weisman, Zagoory-Sharon, and Feldman (2012) observed fathers and their 5-month-old infants twice in a face-to-face still-face paradigm following administration of OT or placebo to the father. OT administration increased fathers' salivary OT and key parenting behaviors that support parent-infant bonding. Moreover, parallel increases were found in infant salivary OT and engagement behavior, including social gaze, exploration, and reciprocity. In other words, OT administration had parallel effects on the treated parent and untreated child.

*Parenting interventions qua experiments.* Interventions with parents have two construals. Near the end of this chapter, interventions are discussed as practical guides to improve parenting clinically and to inform policy. Intervention trials also can be interpreted as experimental manipulations that test theoretical models of parenting effects (Cowan & Cowan, 2002; van Doesum, Riksen-Walraven, Hosman, & Hoefnagels, 2008). An intervention designed to facilitate maternal responsiveness enhanced children's language skills (Landry, Smith, Swank, & Guttentag, 2008); a second to improve parents' behavior support found positive effects on key indicators of children's school readiness (Lunkenheimer et al., 2008); and a third to boost parents' positive behavior practices reduced problem behaviors in young children (Dishion et al., 2008). Thus, many interventions focus on parents, but the ultimate outcome is a concern with children (DeGarmo, Eddy, Reid, & Fetrow, 2009; Powell, 2006). Forgatch, Patterson, and DeGarmo (2005) found that fidelity to a therapy intervention protocol predicted change in parents' practices and children's behavior, and Cowan, Cowan, Ablow, Johnson, and Measelle (2005) enrolled parents in classes on effective parenting just

prior to their children's kindergarten entry and later recorded better and lasting school adjustment and higher academic achievement for children in kindergarten and first grade, compared to children of parents who attended a comparable series of discussion groups without the effective-parenting emphasis.

### Challenges to Parenting Effects From Behavior Genetics and Group Socialization Theory

In the context of this methodological diversity of support and robustness of findings, it is surprising to find critics who contend there is still little that children's parents do which influences child development, but they rather believe that heredity and peers hold sway. It is illogical and nonscientific to assert the preeminence of one cause when there are many and each in its own way contributes to some effect. The constructive enterprise is really to understand how all the relevant forces might work in concert. The following brief evaluations cumulate over the hard-won knowledge of several critiques (see, e.g., Collins et al., 2000; Lerner, Rothbaum, Boulos, & Castellino, 2002; Maccoby, 2000; Vandell, 2000). The arguments for genetic and peer influences on child development complement, but do not supplant, the force of parenting effects. That said, these twin contentions hold water and have made it incumbent on socialization researchers to demonstrate parenting effects taking each into consideration.

*Behavior genetics.* Behavior genetics (BG) seeks to understand biological sources of variation in human characteristics (Plomin, DeFries, McClearn, & McGuffin, 2008). By studying individuals of varying genetic relatedness (identical and fraternal twins, biological and adopted siblings who share or do not share the same experiences), behavioral geneticists attempt to estimate the amount of variation (the heritability;  $h^2$ ) in characteristics that can be explained by genetic endowment contra socialization. Heritability denotes inheritance of DNA and refers to the "main effect" of genetics on individual differences, but does not necessarily imply genetic determinism; for discussions of interpretations and misinterpretations of heritability, see Plomin et al. (2008), Rutter (2006), and Visscher, Hill, and Wray (2008). BG assumes that sources of variation in a child characteristic can be separated into independent genetic (G) and environmental (E) components that together (with error variance) add to 100% of the variance in a characteristic. G effects are additive (A) and dominant (D), and E effects are shared (C) and non-shared plus error (E). (E is not usually measured directly,

but estimated to be the residual variance not accounted for by G; see Caspi, Taylor, Moffitt, & Plomin, 2000.) Some BG research contends that (a) genetic endowment accounts for child characteristics better than socialization; (b) children with different genetic predispositions elicit different reactions from their parents; and (c) nonshared environments (conceptualized as experiences in and out of the family that differentiate individuals) play a greater part in child development than shared factors (conceptualized as experiences in and out of the family that are common to individuals). Oddly, perhaps, parenting is often only included in the shared environment.

A full consideration of this literature vitiates many central BG claims. For example, G and E do not account for any child characteristic in a zero-sum way (Gottlieb, 1995; Rose, 1995; Turkheimer, 1998). The prevailing relational bioecological perspective on human development “stresses the interactive and synergistic, rather than additive and competitive, nature of the links between the family and other influences” (Collins et al., 2000, p. 227). Everything that human beings are or do is an ineluctable joint function of their genes and their life experiences (Elman et al., 1996). Furthermore, experience may contribute to development at the same time heritability is at work. Some environmental factors affect a group without altering the rank order of individuals within the group. Correlations between parenting and child characteristics may reflect genetic linkages (Finkel & Matheny, 2000) but also bidirectional reciprocal interactive processes. BG assigns both child and parent parts of parent-child covariances to the genetic component in the  $G + E = 100\%$  formulation. It may be that the child's part in parent-child covariance (so-called evocative effects) is genetic, but assigning the parent contribution to genetics is debatable (Maccoby, 2000). In a developing transactional relationship, such as the one between parent and child, the child influences the parent and the parent influences the child.

Furthermore, BG designs in themselves exhibit evidence of parenting effects. For example, using a parent-offspring BG design, Deater-Deckard et al. (2006) found for both genetically related and adoptive mother-child dyads that corporal punishment and child externalizing behaviors were positively correlated (even if only in dyads that were low in maternal warmth). O'Connor, Deater-Deckard, Fulker, Rutter, and Plomin (1998) identified two groups of adoptees: one at genetic risk for antisocial behavior (their biological mothers had a history of antisocial behavior) and the other not at risk. At several points during the adoptees' childhood, O'Connor et al. assessed the children's

characteristics and the adoptive parents' child-rearing methods. Children carrying a genetic risk for antisocial behavior were more likely to receive negative socialization from their adoptive parents, but parental negative behavior made an independent contribution to children's externalizing, over and above the children's genetic predispositions. Maternal expressed emotion is an environmental risk factor for children's antisocial behavior problems. Horn and Loehlin (2010) reported that the IQ of adopted children approximates the IQ of their adoptive parents and exceeds the IQ of their biological parents. This effect follows from how adoptive caregivers parent. In a similar way, Neiss and Rowe (2000) found that parents' education was associated with adopted adolescents' verbal IQ.

Twin studies aim at partitioning the population variance due to G and E effects by comparing monozygotic (MZ) and dizygotic (DZ) twin correlations or concordances (O'Connor & Croft, 2001). In various twin studies, the quality of the parent-child relationship has been shown to contribute to child outcomes independent of genetic factors (Peña & Champagne, 2012). For example, using a nationally representative birth cohort of twins, Caspi et al. (2004) accounted for behavioral differences between MZ siblings growing up in the same family after genetic influences on children's behavior problems were taken into account by assessing which child received more negative emotional expression and which received more warmth. Within pairs, the twin receiving more maternal negativity and less warmth had more antisocial behavior problems. Twin data support the hypothesis that family environments make substantial contributions to child development (Plomin et al., 2008; Wong et al., 2010). Genetically informed research designs support socialization effects.

BG assumes that parenting is a shared experience for siblings, and because shared environment effects have sometimes proven to be small, parenting effects must be small. However, even within the same family and home setting, parents do not behave toward different children in the same way, parenting is not perceived by different children in the same way, and parenting does not affect different children in the same way (Suitor et al., 2009; Turkheimer & Waldron, 2000). Nonshared environmental effects refer to the influence of events specific to an individual's life, such as specific parenting, illness, or particular friends, which are not shared by other family members. The distinction between shared and nonshared environmental effects is based on whether such environmental influences make siblings more or less alike. BG offers two explanations to account for individual variation among siblings. The first

is within-family environmental differences, and the second is differential experience outside the home. To the extent that siblings perceive differential parental treatment, they experience different environments, which increases the likelihood that they also develop differently. Genes may contribute to making siblings 50% alike, but (as is universally recognized) siblings are normally very different from one another, and it is widely held that siblings' different experiences (their nonshared environments) in growing up contribute to making them distinctive individuals. In a study of 1-year-old twin pairs (Bokhorst et al., 2003), only nonshared environmental factors accounted for the variance in twin concordances of disorganized versus organized attachment, while both shared and nonshared environmental effects accounted for the variance in secure versus insecure attachment.

The following additional considerations stoke the socialization fires (Charney, 2012). Heritability estimates are themselves often indeterminate and variable (Klahr & Burt, 2014), as estimates vary depending on the dependent construct, source of information, and other methodological factors; genes may function differently in different environments and at different times (Naumova, Lee, Rychov, Vlasova, & Grigorenko, 2013; Szyf & Bick, 2013); and exposure to specific environments may be influenced by the individual's genetic make-up (Rutter, Moffitt, & Caspi, 2006). Estimates derived from twin studies might exaggerate genetic contributions because MZ twins have more similar environments than do even same-gender DZ twins. Meta-analyses show that heredity rarely accounts for as much as 50% of the variation among individuals in a particular population (Klahr & Burt, 2014; McCartney, Harris, & Bernieri, 1990). In genetically informed adoption and twin research, degree of biological relatedness between individuals, not specific markers of genetically linked characteristics in the two individuals, is often the primary focus. However, it has proven difficult to identify actual genes responsible for the heritability of complex traits, the so-called missing heritability problem (Plomin, 2012). In the view of some, even powerful BG methods have so far failed to reveal a single *bona fide* replicable gene effect pertinent to the normal range of variation in human intelligence and personality (Wahlsten, 2012). Work on the epigenome, the dynamic part of the genetic code that can be altered by environmental conditions, opens the door widely to parenting effects (as noted earlier). For example, poor quality parenting results in DNA methylation that influences gene expression in a manner that undermines children's mental health (Monk, Spicer, & Champagne, 2012).

Intelligence and personality have been the child outcomes that are the focus of most heritability studies, but genetic contributions might be greater for some human characteristics (intellect, temperament) than for others (religion, politics), and contemporary parenting studies are concerned with a much broader range of issues, so the case for parental influence may be greater for many of children's learned behaviors. Parents are concerned not only with the "final product" of their parenting. They live with their children and are involved in quotidian processes of parenting and cope with a constantly changing set of childrearing challenges. Children's fruit and vegetable consumption is shaped, not just by children's taste preferences, but also by their mother's nutritional knowledge, by her conceptions of the health benefits of eating more produce, and by her own consumption of fruits and vegetables (Galloway, Fiorito, Lee, & Birch, 2005). Many of these concerns of parenting are not addressed by BG.

*Group socialization theory.* We change when we participate in peer group interaction (Lewin, 1947; Steinberg, 2011), and J. R. Harris (1995, 1998) asserted that experiences outside the home, and especially within the peer group, constitute the major environmental source of influence on children's development. According to Harris (1995, p. 463), group socialization affects children's behavior, language, cognitions, emotions, and self-esteem, whereas dyadic relationships with parents (or teachers or mentors) have minimal effects on these psychological characteristics. Harris went so far as to ask, "Do parents matter?"

The challenge Harris explicitly raised was subsequently addressed in several empirical efforts (many of whose titles incorporate direct responses to her question). For example, Galambos, Barker, and Almeida (2003) studied the relative influences of parenting practices of support, behavioral control, and psychological control versus deviant peers on trajectories of externalizing and internalizing problems in adolescents. They found that parents' firm behavioral control halted the upward trajectory in externalizing problems among adolescents, which suggests that parenting exerts an important influence on adolescents' lives and does so even in the face of potentially negative peer influences. Subsequently, Wood, Read, Mitchell, and Brand (2004) compared the influences of parenting cognitions (disapproval versus permissiveness for drinking) and parenting practices (nurturance and monitoring) versus peer influences (alcohol offers, social modeling, and perceived norms) on alcohol abuse in older adolescents. Parental influences moderated peer influences such that higher levels of perceived parental involvement were associated with

weaker relations between peer influences and adolescent alcohol abuse, which indicates that parental influences are continuing. Hoque and Ghuman (2012) demonstrated similar parental versus peer effects on adolescent alcohol use in a South African sample. A. Harris and Goodall (2008) even showed that parents, teachers, and pupils agree that parents' engagement in learning in the home is most likely to lead to positive learning outcomes. Although 12- and 14-year-olds may turn to peers to fulfill attachment functions of proximity seeking and safe haven, 10-year-olds describe more trusting and communicative relationships with parents than with peers, and children at all three ages report that their parents serve as their primary secure base (Nickerson & Nagle, 2005). These are just a few (among many; Udel, Donenberg, & Emerson, 2011) studies that answered Harris's question in the affirmative, replying that *vis-à-vis* peers *parents do matter*.

Several additional counterarguments to the radical peer socialization proposition mitigate its claims: Parents and peers exert joint influences on the developing child (Bornstein, Cote, Haynes, Suwalsky, & Bakeman, 2012). Masten, Juvonen, and Spatzier (2009) found that perceived parent values predict children's academic and social behaviors over a range of ages, whereas peer group norms predict social behavior over the same range but academic behavior only for older children. The proclivity in children to select, think, and behave as their like-minded peers do might account for some similarities between them and their friends. However, children are not randomly assigned to peer groups; rather, parents and parent-child relationships influence which peers are available to children and which peers children select. Group socialization might apply to some (likely transient), but probably not to other (likely enduring), beliefs and behaviors. Also, children vary in their susceptibility to peer influence, and parenting is a likely source of children's differential susceptibility. In most cases, moreover, infants and very young children are hardly exposed to meaningful peer influence (with the exception of siblings).

Social relationship theory posits that multiple associations are important to children because they meet different developmental needs (Vandell, 2000). Parents may serve as a source of love, affection, security, protection, advice, and limit setting. Siblings may offer opportunities related to social understanding, conflict management, and differential status. Peers may provide mutual commitment, support, and trust. Teachers and nonparental caregivers may be influential for their expertise and access to opportunity. In the end, Harris (1995) conceded:

It is important to note that [group socialization theory] does not imply that children can get along without parents. Children are emotionally attached to their parents (and vice versa), are dependent on them for protection and care, and learn skills within the home that may prove useful outside of it; these facts are not questioned. (p. 461)

In short, many individuals in children's lives influence their development; children's parents are likely first among possible equals.

## Summary

Whereas weaker correlational designs once dominated the study of parenting, contemporary investigators have turned to a panoply of genetically informed and experimental designs to demonstrate parenting effects more robustly and conservatively. Even parenting's most strident critics now acknowledge that parents serve important socializing functions in children's lives: "Parents are the most important part of the child's environment and can determine, to a large extent, how the child turns out" (Harris, 1998, p. 15). Of course, biological mothers and fathers contribute directly to the nature and development of their children by passing on heritable characteristics. At the same time, all prominent theories of development put experience in the world as either the principal source of individual growth or as a major contributing component (Lerner et al., 2011; Wachs, 2000). Thus, evidence for heritability and peer influences neither negates nor diminishes equally compelling evidence for effects of parenting. It falls to parents (and other caregivers) to shape the preponderance of children's experiences, and parents directly and indirectly influence children in multiple meaningful ways.

Thinking and research in parenting today are guided by a relational bioecological developmental systems perspective. The size of reported parenting effects reflects the fact that parenting is part of a complex multivariate system that encompasses parents' and children's own capacities and proclivities (intellect, personality), their social relationships (with siblings, peers, teachers, neighbors), and contexts (home, school, neighborhood, socioeconomic class, culture). Within complex developmental systems like that between parent and child, it is unlikely that any single factor can be expected to account for substantial amounts of variation. Parenting effects are also conditional and not absolute (i.e., true for all children under all conditions). More nuanced conceptualizations that incorporate larger numbers of influential variables will explain parenting effects better than minimal ones with fewer variables.

Multiple sources of shared and nonshared environmental influences affect a child's life course.

It would be short-sighted, therefore, to lose perspective on how parenting, even early in life, reverberates across the life span. Automakers and dealers spend nearly \$33 billion a year to influence how people decide what kind of car to purchase. However, consumers are most likely to buy the same brand of car their parents recently chose (Anderson, Kellogg, Langer, & Sallee, 2012). Perceived maternal favoritism in the nuclear family continues to shape the quality of sibling relationships at least into midlife; regardless of which sibling was favored, recollections of favoritism in childhood reduce closeness among siblings, and siblings who have better relationships believe that they were treated equitably by their parents (Suitor et al., 2009). An fMRI study that examined adults' responses to their mothers' and fathers' faces versus the faces of male and female celebrities or strangers revealed that mothers' faces elicited the most activation in core and extended brain regions involved in familiar face processing (Arsalidou, Barbeau, Bayless, & Taylor, 2010). B. A. Shaw, Krause, Chatters, Connell, and Ingersoll-Dayton (2004) analyzed data from a nationally representative sample of 3,000 adults, 25 to 74 years old, from the National Survey of Midlife Development in the United States. They found that parental support during early childhood was a principal factor associated with decreased levels of depressive symptoms and of chronic illness in adulthood. Associations between early parental support and adult health persisted into peoples' 70s. With parenting so demonstratively important, the question to ask should be not whether parents matter, but what makes a good parent.

## THE MULTICAUSAL ORIGINS OF PARENTING

A vital step on the path to fully understanding parenting is to evaluate the many forces that shape it. The origins of individual variation in maternal and paternal caregiving, whether of cognitions or practices, are extremely complex, and it has long been explicitly acknowledged that parenting is multiply determined. Evolution and history; designed and natural ecology; social class and culture; educational, legal, medical, and governmental institutions; formal and informal support networks; family configuration; children themselves; and the biology, intellect, personality, and the idiosyncratic history of the parent work in tandem to construct a parent. Consistent with a relational developmental bioecological orientation (Belsky, 1984; Bronfenbrenner

& Morris, 2006; Farnfield, 2008), this vast array of causes can be grouped roughly according to their proximity to the parent from proximal to distal: (a) intrapersonal and intrapsychic characteristics of parents, (b) actual or perceived characteristics of children, and (c) contextual characteristics. A thorough and thoroughly up-to-date meta-analysis sought to quantitatively synthesize what twin and adoption studies have to say about the etiology of parenting (Klahr & Burt, 2014). Unsurprisingly, this exhaustive attempt to definitively catalogue genetic and environmental sources of parenting identified effects attributable to parent, child, and the environment. Reasons of space constrain a full accounting of all possibilities (see Bornstein, in press, for a more detailed, contemporary, and comprehensive treatment), and so the following exposition is illustrative rather than exhaustive. For heuristic purposes, the ensuing considerations of parent, child, and contextual origins of parenting also treat each factor as a determinant, and each has been investigated as such; however, readers should consider that parenting also affects each factor, and untangling direction of effects is a persistent vexing concern. Qua antecedents, each is moreover thought to influence parenting directly and, indirectly through parenting, children.

### Characteristics of Parents Affect Parenting

Even if most parents face the formidable challenges of parenthood with a degree of psychological naïveté, parents do not meet the task totally unprepared. Biological and psychological characteristics, such as their own genetic endowment, hormones, brain function, age, intellect, personality, and the legacy of their family of origin equip parents to interpret and respond to the kaleidoscopic requirements and pressures of parenting and children.

### Biology and Parenting

Because securing the survival of offspring underlies evolutionary selection, it is likely that specific biological processes evolved in the service of parenting. Expressions of parenting have been shown to reflect genetic endowment, neurohormonal circulation, and central nervous system structure and function. Lytton and Gallagher (2002) and McGuire (2003) introduced and discussed BG research on the heritability of parenting beliefs and behaviors. On the assumption that parenting is itself a phenotype, in the BG view it is therefore a reflection of nature and nurture. Genetic contributions to parenting are conceptualized as evidence of genotype-environment correlations (*rGE*).

Early BG studies showed significant heritability for parenting measures, but the results differed by dimension (McGuire, Segal, & Hersherberger, 2012). Kendler and Baker (2007) meta-analyzed child- and parent-based BG studies of genetic contributions to measures of parenting and found that weighted heritabilities varied for warmth, protectiveness, and control but never exceeded 50%. A succeeding review (Klahr & Burt, 2014) arrived at similar conclusions with respect to heritabilities for different dimensions of parenting in mothers and fathers based on child and parent adoption and twin designs.

Although the literature on possible genetic contributions to parenting is building, it is still new, and the genes involved as well as their processes of action still need identification and unravelling. BG-informed designs implicate genetics but do not (yet) identify molecules; molecular genetic studies, as noted earlier, are challenged to pinpoint and catalogue genetic sources of human phenotypes, such as parenting (although this might be changing: see Bakermans-Kranenburg & van IJzendoorn, 2008; Burkhouse, Gibb, Coles, Knopik, & McGeary, 2011; S. S. Lee et al., 2010; Mileva-Seitz et al., 2011; van IJzendoorn, Bakermans-Kranenburg, & Mesman, 2008). For example, the dopamine (DA) system is an important biological regulator of mothering (Champagne et al., 2004). Indirect evidence has pointed to involvement of the DA system in human mothering; fMRI studies, exposing mothers to infant stimuli, found brain activity patterns that coincide with regions of the mesocorticolimbic DA system (Barrett & Fleming, 2011). Mileva-Seitz et al. (2012) studied genetic variation in both *DRD1* and *DRD2* genes in a community sample of mothers in relation to maternal behaviors during a mother-infant interaction at 6 months postpartum. Two *DRD1* single-nucleotide polymorphisms were associated with maternal orienting away from the infant, and two *DRD2* SNPs were associated with maternal infant-directed vocalizing. As to how genes might manifest in parenting, it is possible they do so through hormones implicated in childbearing and child rearing or because they contribute to the mental and emotional composition of the parent (both of these determinants of parenting are discussed below).

Many reproductive neurocrines, OT, AVP, and PRL, are at least homologous in females and males (Bales, 2014; Corter & Fleming, 2002); estradiol plays a role in regulating maternal behaviors in female animals, and the conversion of testosterone (T) into estradiol is involved in regulating paternal behavior in male animals (Trainor & Marler, 2001, 2002). For example, OT is consistently

implicated in attachment and positive parenting in different species from rat (Champagne, Diorio, Sharma, & Meaney, 2001) to monkey (Maestripieri, Hoffman, Anderson, Carter, & Higley, 2009) to human (Feldman, Gordon, & Zagoory-Sharon, 2011). Feldman et al. (2012) assayed OT from adults who were also genotyped for oxytocin receptor (*OXTR*) and *CD38* risk alleles associated with social dysfunction (*CD38* is an ectoenzyme that mediates the release of brain OT). Parent-infant interactions were microcoded for touch and gaze synchrony, and participants reported on parental care in childhood. Reduced plasma OT and both *OXTR* and *CD38* risk alleles were related to less parental touch, and parents reporting greater parental care showed higher plasma OT, low-risk *CD38* alleles, and more touch, suggesting that peripheral and genetic markers of the extended OT pathway might underpin core behaviors associated with human parenting. In one extension of this work, the same research team observed associations between baseline OT levels in mothers and fathers and different parenting behaviors (engagement, affect synchrony, and communication). OT revealed differential associations with sexually dimorphic patterns of parental behavior discussed earlier: Mothers' baseline OT levels were positively correlated with affectionate but not stimulatory contact, whereas fathers' baseline OT levels were positively correlated with stimulatory but not affectionate contact (Feldman, Gordon, Schneiderman, Weisman, & Zagoory-Sharon, 2010; Feldman et al., 2011).

Increases in PRL levels are implicated in the expression of parenting in females as well as males, and fathers have higher PRL levels than nonfathers (Gettler, McDade, Feranil, & Kuzawa, 2012); AVP, and perhaps PRL and T, may constitute endocrinological bases of paternal care (Fernandez-Duque et al., 2009). In men, T is elevated during mate acquisition or conspecific competition but downregulated in parenting (Fleming, Corter, Stallings, & Steiner, 2002; Gettler, McDade, & Kuzawa, 2011): Men with higher T levels report less sympathy in response to an infant cry (Fleming & Li, 2002), and fathers with higher T engage in less caregiving (Alvergne, Faurie, & Raymond, 2009; Kuzawa, Gettler, Muller, McDade, & Feranil, 2009). A large representative study in the Philippines showed that among single nonfathers men with high waking T were more likely to become partnered fathers by the time of follow-up 4.5 years later. Men who became partnered fathers then experienced large declines in waking and evening T, which were significantly greater than declines in single nonfathers (Gettler, McDade, Feranil, & Kuzawa, 2011). Estrogen has been implicated in unique

emotional responses to infant faces (Sprengelmeyer et al., 2009), and increased estrogen in fathers is associated with more paternal activity after the baby is born (Fleming et al., 2002).

Virgin female and male rats rarely exhibit parental responses, suggesting that the changes that accompany reproductive experience prime the brain to be sensitive to a new and unique set of stimuli (Lambert & Kinsley, 2012). It is well to remember in considering the possible implications of pregnancy-related hormones, however, that many individuals who do not give birth to children—like fathers, grandparents, in-laws, and adoptive parents—not only parent them but come to love and develop strong emotional bonds with them too (Rilling, 2013).

Just as endocrinology is wrapped up in parenting, so are the structure and function of the brain (Bridges, 2008; Brunton & Russell, 2008). Nonhuman animal studies show functional and morphologic sex differences in neural forebrain circuitry and specific behaviors during nursing and care of offspring (Champagne et al., 2001; Corter & Fleming, 2002; Sheehan & Numan, 2002; Simerly, 2002). Another cresting area of research is the “neuroscience of parenting” (Bornstein, 2013a). Using visual (usually faces) and auditory (usually cries or laughs of own and unfamiliar infants and children), imaging studies from EEG to ERP to MEG to fMRI have begun to divulge neural activation patterns in specific regions of the brain that are associated with select parenting cognitions and practices leading to incipient models of a complex brain network hypothesized to mediate human parenting (Swain, Lorberbaum, Kose, & Strathearn, 2007). Since Bartels and Zeki (2000, 2004), programmatic research with own versus other baby photographs and videos (Bornstein, Arterberry, & Mash, 2013; Leibenluft, Gobbin, Harrison, & Haxby, 2004; Noriuchi, Kikuchi, & Senoo, 2008; Ranote et al., 2004; Strathearn, Li, Fonagy, & Montague, 2008; Swain, Leckman, Mayes, Feldman, & Schultz, 2006) and with cries of own infant versus standard cries versus control noises (de Pisapia et al., 2013; Montoya et al., 2012; Ranote et al., 2004; Venuti et al., 2012) has revealed enhanced activations in regions of mothers’, fathers’, and nonparents’ brains associated with empathy, responsiveness, and emotion recognition and evaluation. First-time mothers activate mirror-neuron regions of the brain more strongly when observing and empathizing with their own compared with unknown infants (Lenzi et al., 2009). Connecting brain activation with cognitions, mothers viewing smiling pictures of their own versus unfamiliar infants yields brain activation that is correlated with pleasant mood ratings

and mothers’ affective responses to their infant (Nitschke et al., 2004). Experience-independent and -dependent neuroplastic alignments of the human brain likely subserve the biological requirements of child care and play critical parts in bonding, in securing offspring survival and well-being, and perhaps in fostering reproductive fitness in subsequent generations (Bornstein, 2013a; P. Kim, Leckman, Mayes, Feldman, et al., 2010; Rilling, 2013).

Papoušek and Papoušek (2002) advanced the notion that some parenting practices are biologically wired in human beings. Intuitive parenting involves responses that are developmentally suited to the age and abilities of the child and that likely have the goal of enhancing child adaptation and development. Parents regularly enact intuitive parenting programs in an unconscious fashion; such programs do not require the time and effort typical of conscious decision making, and, being more rapid and efficient, they utilize less attentional reserve. An example of such intuitive parenting (mentioned earlier) is child-directed speech (Soderstrom, 2007) whose special characteristics vary from adult-directed speech along prosodic, simplicity, redundancy, lexical, and content dimensions. Cross-cultural study attests that child-directed speech is (essentially) universal (Jacobson, Boersma, Fields, & Olson, 1983; Snow, 1977; but see Ratner & Pye, 1984). When communicating with their children, even deaf mothers modify their sign language the way hearing mothers use child-directed speech (Erting, Prezioso, & Hynes, 1994). Indeed, parents find it difficult to resist or modify such intuitive behaviors, even when asked to do so (Trevvarthen, 1979). Additional support for the premise that such interactions with children are intuitive comes from observations that nonparents (males and females) who have little prior experience with children modify their speech as parents do when in the presence of a young child and even when asked to imagine speaking to one (Jacobson et al., 1983). Many parenting cognitions and practices are likewise unconscious, habitual, and possibly automatic, and they are enacted by nonparents and parents alike (Senese et al., 2013).

### *Age and Stage of Life in Parenting*

The contemporary demographics of parturition in the United States indicate that the rate of teenage (15–19 years) motherhood is epidemic (329,772 babies in the United States in 2011; J. A. Martin, Hamilton, Ventura, Osterman, & Matthews, 2013), as approximately one in three girls becomes pregnant by the end of their 19th year. At the same time, increasing numbers of adult women are

delaying conception, extending the age range for pregnancy and birth (J. A. Martin et al., 2013). These demographic trends might be ascribable to several factors that contribute to the decision to postpone childbearing. For example, the aging of the baby boom generation translates into greater absolute numbers of women in their late 30s and 40s than in previous decades, which is compounded by delayed marriage, the pursuit of advanced education, careerism, and high rates of divorce. In addition, advances in birth control have made it possible to delay becoming pregnant, and advances in assisted reproductive technologies (ART; such as IVF) have made it possible for older women to become pregnant and parent (Ganong et al., Chapter 4, this *Handbook*, this volume; Golombok, 2002, 2013).

These demographics, in turn, raise questions about effects that may obtain among parent age or stage of life, parenting, and child development. The psychosocial impacts of early childbirth are fairly well established. Adolescent mothers experience more pregnancy and delivery problems, birth less healthy babies, express less desirable and realistic childrearing cognitions, and parent using less favorable practices than do adult mothers (Berlin, Brady-Smith, & Brooks-Gunn, 2002; Bornstein & Putnick, 2007; Bornstein, Putnick, Suwalsky, & Gini, 2006; Demers, Bernier, Tarabulsky, & Provost, 2010; Moore & Brooks-Gunn, 2002; Pomerleau, Scuccimarri, & Malcuit, 2003). Not inconsequentially, young maternal age at parturition uniquely predicts pervasive educational and psychosocial outcomes in children—from reduced chances of graduating from high school to enhanced chances of becoming a teen mother (for girls) or being incarcerated (for boys; National Campaign to Prevent Teen and Unplanned Pregnancy, 2013). At the opposite pole of the parent age continuum, a 35-year-old woman has a 1 in 400 chance of conceiving a child with Down syndrome, and this likelihood increases to 1 in 110 by age 40 and then to 1 in 35 by age 45 (National Down Syndrome Society, 2012). Tending and rearing children are physically challenging, and “gerontological primiparas” may command fading physical capacities to meet those demands (Mirowsky, 2002). Fathers’ age matters as well: A monotonic association obtains between advancing paternal age and risk of ASD in children (Reichenberg et al., 2006), and a study of genome-wide mutation rates by sequencing the entire genomes of a sample of Icelandic parent-offspring trios revealed that the diversity in mutation rate of single nucleotide polymorphisms is dominated by the age of the father at a child’s conception, implicating increases of about two mutations per year (Kong et al., 2012). However,

older mothers are also more likely to adhere to good diets, gain weight appropriately during pregnancy, and begin prenatal care in the first trimester of pregnancy, and they are less likely to smoke. Age is often conceived of as a marker for maturity, perspective, and patience; older adult mothers possess experience and information their younger counterparts do not, and they may feel psychologically ready to assume responsibilities of child rearing. Garrett, Ferron, Ng’andu, Bryant, and Harbin (1994) learned that an especially important factor in mothers’ readiness to be a parent was her maturity as indexed by her age at childbirth.

These age-related factors apply to becoming a parent. Others apply to being a parent. Parents age as their children do, and they face unique developmental needs along the parentway. Parents may be 40 or older when their first child enters adolescence, and parents at midlife encounter their own challenges, for example providing significant support to an emerging adult (as nearly one-in-three parents do now; K. Parker & Patten, 2013) even as they care for their own aging parents (Bornstein, Jager, & Steinberg, 2012).

It was once standard to believe that optimal childbearing takes place between about 20 and about 30 years of age (Rindfuss & Bumpass, 1978), and Rossi (1980) proposed a “timing-of-events” model that suggested that socially off-time childbearing results in a raft of curvilinear relations between age and parenting cognitions and practices. Thus, having a child when very young or very old might represent “off-time” (versus “on-time”) variations in the progression through this key phase in the life cycle. The association between parenting stress and age appears to be curvilinear, with teenage and older mothers tending to report higher levels of parenting stress compared to mothers in their 20s and early 30s (Östberg & Hagekull, 2000). The age at which a parent has a child shapes the child’s cognition and even risk for mental illness, and it appears that this risk is curvilinear as well, with both age extremes associated with decreased intelligence and increased prevalence of some neuropsychiatric disorders. Associations between parental age and child gray matter volume, adjusting for offspring age, gender, intelligence, and parental social class, show  $\cap$ -relations (P. Shaw et al., 2012).

Whether and how chronological parent age relates to parenting cognitions or practices or child development appears to depend on specifics, including the assessment of parent and outcome in child (Bornstein & Putnick, 2007; Bornstein et al., 2006). For example, mothers of all ages possess implicit beliefs (Holden & Buck, 2002), and mothers of all ages engage equally in child-directed speech (Papoušek & Bornstein, 1992). However, the more

mature, experienced, and well-to-do mothers are, all factors attendant to age, the more appropriate and optimal their parenting cognitions and practices are likely to be (Bornstein et al., 2012; Demers et al., 2010).

Of course, age is a “social address” (Wachs, Chapter 21, this *Handbook*, this volume), and at present, there is no comprehensive theory of women’s adult psychosocial development. For this reason age usually stands as a reasonable proxy. More proximal intrapersonal factors likely play the meaningful roles in parenting, and it is possible to identify some critical developmental phenomena that would help to mark mature caregiving. For example, age-related developing executive functions (discussed below) coordinate cognitive and metacognitive processes through monitoring and controlling the use of knowledge and strategies (Barkley, 2012; Yeager & Yeager, 2013).

### ***Cognitions in Parenting***

Parents’ attentiveness, intelligence, mental functioning, and (as we see later) even memories of their own childhood help to create a larger cognitive framework of parenting. German policewomen report enhanced vigilance following the birth of their first child (Fullgrabe, 2002), and women’s assessed attentional processing of infant emotion during pregnancy influences their relationships with their infant (Pearson, Lightman, & Evans, 2011). Mothers with better attention and working memory are more sensitive and prompt when responding to their infants (Gonzalez, Jenkins, Steiner, & Fleming, in press). Using data from the Massachusetts site of the NICHD Study of Early Child Care and Youth Development, Mulvaney, McCartney, Bub, and Marshall (2006) found that mothers’ verbal intelligence predicted the effectiveness of their scaffolding collaborations with children (which in turn uniquely predicted cognitive capabilities of the children). Already discussed, parents’ belief systems relate to certain behavior choices and help to determine how much time, effort, and energy to expend in parenting. For example, perceived self-efficacy is likely to affect parenting positively because parents who feel competent are reinforced and thus motivated to engage in further interactions with their children, which in turn provides parents with additional opportunities to read their children’s signals fully, interpret them correctly, and respond appropriately. Culturally distinct parenting beliefs provide parents with a framework for interpreting their children’s behaviors, guiding parents’ interactions with their children, and determining the activities and opportunities that parents supply for their children’s development. Ethnographic interviews of mothers with infants between

the ages of 2 and 18 months disclose that some mothers avoid using physical punishment with infants because they believe that infants are not able to clearly understand right and wrong, whereas other mothers believe that infants can misbehave intentionally and need to be punished to stop their bad behavior and learn to respect the mother’s authority. Subsequent quantitative analyses reveal that mothers who express concerns about bad behavior and spoiling interact less positively with their infants during free-play interactions (Burchinal, Skinner, & Reznick, 2010).

Normally, executive functions (defined above) include self-regulation, sequencing, flexibility, response inhibition, planning, and organizing behavior. The orderly approach to problems, maintenance of problem solving sets for future goals, flexibility and effectiveness of verbal self-regulation, skillful use of strategy, and behaviors that alter the likelihood of later events are all executive functions—and nicely describe many requirements of parenting. In short, executive functions exert powerful influences on social behavior, and immaturity or impairment of executive functions can lead to demanding and self-centered behavior, lack of social tact and restraint, impulsive speech and actions, disinhibition, and indifference, all of which are hallmarks of dysregulated parenting.

The neuropsychological underpinnings of executive functions are usually assigned to the prefrontal cortex and its extended networks (Pennington, Bennetto, McAleer, & Roberts, 1996). Notably, individuals with localized prefrontal injury display poor parenting (Eslinger, Grattan, Damasio, & Damasio, 1992). Consider patient DT, who:

proved unable to anticipate and meet her child’s needs, such as planning meals, changing clothing, and providing nurturance and comfort.... Her performance [was] erratic, impulsive, and marked by poor follow through on required tasks, failure to learn from mistakes, and very negative reactions to criticism.... [She had] very limited capacity for empathic understanding, inadequate identity development, difficulties in vocational adjustment, and a concrete level of moral reasoning. (Grattan & Eslinger, 1992, p. 185)

DT shows how the want of executive functions profoundly undermines parenting in an individual who otherwise possesses normal motor and sensory functions and broadly normal intellect, perception, language, and memory. To this point, it is important to note that the prefrontal cortex shows a prolonged course of development, with changes in synaptic density detectable even into the mid-20s (P. Shaw et al., 2006) and so could very well underlie the challenges commonly associated with

adolescent parenting. Younger mothers score lower than older mothers on a construct called “cognitive readiness to parent” (aggregated parenting knowledge, attitudes, and style), and cognitive readiness to parent predicts parenting during infancy (Whitman, Borkowski, Keogh, & Weed, 2001) and attachment security at 1 year and accounts for relations between early maternal interactions and 1-year attachment (Lounds, Borkowski, Whitman, Maxwell, & Weed, 2005).

Civitas Initiative et al. (2000) conducted a survey of 3,000 adults regarding what parents know about child development. Specific areas of misinformation included expectations of young children at different ages and stages, and spoiling and spanking. A report from the Commonwealth Fund subsequently indicated that mothers want simple and easily accessible materials about their child's development and about easing the pressures of child rearing (Kannel & Perry, 2001). Mothers' specific knowledge of childrearing and child development explains variations in their emotional relationships with their young children (Bornstein, Jager, et al., 2012). Parents' knowledge guides health-related decisions, as the SIDS knowledge-versus-compliance example (recounted earlier) importantly illustrates (Centers for Disease Control and Prevention, 2014b). Parenting cultural knowledge is often conceptualized as naive theories about how children progress toward idealized social roles, what influences their development, how skills are acquired, and the parts of different adults and environments in the developmental process (Keller et al., 2006; Rosenthal & Roer-Strier, 2001).

### ***Personality in Parenting***

Personality has a significant part to play in parenting: “One cannot take the ‘person’ out of the parent” (Vondra, Sysko, & Belsky, 2005, p. 2). This idea has been acknowledged formally at least since Sigmund and Anna Freud and was continued by Winnicott, Spitz, and others in the psychoanalytic psychodynamic tradition (described earlier). Contemporary views derived from personality psychology assert that some parenting cognitions or practices should reflect general and stable personality characteristics (Belsky & Barends, 2002). Bronfenbrenner and Morris (2006) opined that personality factors constitute person “force characteristics” likely to influence children's development because personality affects parenting directly and because it shapes other social contextual factors that influence parenting, including spouse selection, marital relationships, occupational experiences, and friendships and social supports. Two general orientations have guided theory and

research linking personality to parenting: One concerns the five factors that identify the composition of normal personality, and the other concerns less typical personality characteristics from anxiety and stress to depression and psychopathology.

Personality has been conceptualized as a profile of five broad-band factors (the “Big Five”) each of which has lower-level facets (McAdams & Pals, 2006), and Allik and McCrae (2004) maintained that this nomothetic trait structure provides a comprehensive map of personality and may be “universal” (McCrae et al., 2005). *Openness to experience* reflects a tendency to have a broad perspective and to approach life in intelligent, creative, philosophical, and inquisitive ways. *Neuroticism* reflects a proneness to psychological distress, unrealistic ideas, excessive cravings or urges, maladaptive coping responses, and a perturbable, insecure, and vulnerable orientation to life. *Extraversion* reflects the quantity and intensity of interpersonal interaction, activity level, need for stimulation, capacity for joy, control, and assertiveness. *Agreeableness* reflects an interpersonal orientation in feelings, thoughts, and actions along a continuum from compassion to antagonism, the high end of which is characterized as cooperative, trusting, and warm. *Conscientiousness* reflects the extent to which a person is well-organized, responsible, decisive, dependable, hardworking, and even ambitious.

Prinz et al. (2009) meta-analyzed associations between the Big Five personality factors and parenting. Results tend to show small effects moderated by age, study design, and so forth; many personality features are associated with both positive and negative parenting; and most studies focus on mothers (and fewer on fathers; Cabrera, Fitzgerald, Bradley, & Roggman, 2007). For example, mothers high in extraversion and conscientiousness are more likely to display nurturance and support (Clark, Kochanska, & Ready, 2000; Smith et al., 2007), but extraversion has associations with internalizing, and extraverted mothers are also more controlling (Clark et al., 2000). Conscientious mothers provide more structure and use less forceful disciplinary styles than less conscientious mothers, however conscientiousness is also associated with restrictive and over-controlling childrearing (Clark et al., 2000; Neitzel & Stright, 2004; Verhoeven et al., 2007). Along with Kotov, Gamez, Smith, and Watson (2010), other meta-analyses have reported that conscientiousness shows associations with both internalizing and externalizing psychopathology (Decuyper, De Pauw, De Fruyt, De Bolle, & De Clercq, 2009; Ruiz, Pincus, & Schinka, 2008). Agreeable mothers express high levels of positive affect, support, and warmth

with their children, are more sensitive and responsive to their children's needs, and are less likely to be affectively negative, uninvolved, and over-reactive (De Haan et al., 2009; Smith et al., 2007); however, agreeableness has associations with externalizing (Kotov et al., 2010; Ruiz et al., 2008). Mothers who are high in neuroticism display high levels of negative affectivity toward their children, are less responsive to their children's needs, engage in more physical and verbal power assertion, and are less encouraging of their children's autonomy (Clark et al., 2000). Kotov et al. (2010) also found that neuroticism shows small to moderate associations with internalizing and externalizing psychopathology (Decuyper et al., 2009; Ruiz et al., 2008) as neuroticism is a robust predictor of negativity/rejection toward children, and mothers high in the personality characteristics of negative emotionality and disagreeableness are rated by observers as being more rejecting of their children (Clark et al., 2000). In fathers too, high levels of neuroticism indicate depression within the first year of their baby's life (Matthey, Barnett, Kavanaugh, & Howie, 2001).

Only a few studies have assessed all of the five personality factors simultaneously in relation to parenting thereby allowing evaluation of the unique role of each. In one, factor analysis of a personality inventory completed by a community sample of European American mothers of first-born 20-month-olds replicated extraction of the Five-Factor model of personality. Mothers also responded to measures of parenting cognitions (knowledge, self-perceptions, and reports about behavior) and were observed in interaction with their children to yield measures of parenting practices (language, sensitivity, affection, and play). Controlling for sociodemographic characteristics, the five personality factors (as variables and in patterns as clusters) related differently to diverse parenting cognitions and practices (Bornstein, Hahn, & Haynes, 2011). In a parallel cross-cultural study, mothers of firstborn 20-month-olds from seven countries (Argentina, Belgium, Israel, Italy, Japan, South Korea, and the United States) completed all of the same procedures (Bornstein et al., 2007). The Five-Factor structure was extracted when the cross-cultural data were analyzed, and again the Big Five were found to relate differently to diverse aspects of parenting. C. L. Smith et al. (2007) examined longitudinal relations among maternal personality, emotional expressions, and parenting (sensitivity and intrusiveness): Conscientiousness and agreeableness were positively associated with observed positive emotional expressions at T1, and agreeableness, openness to experience, and extraversion at T1 were

positively related to positive emotional expressions at T2. T1 and T2 maternal positive emotional expressions, in turn, were associated with more sensitive behavior observed at T3. In addition to first-order associations between maternal personality and maternal parenting, other factors (e.g., emotional expressiveness) may constitute possible pathways for explaining second-order relations between personality and parenting. Maternal personality is often neglected in parenting research, but appears to be a significant factor in normative parenting, child development, and family process.

Other features of normal personality favorable to good parenting likely include empathic awareness, predictability, nonintrusiveness, and emotional availability; lack of self-centeredness and adaptability might also be especially pertinent to parenting. Adult adaptability is likely vital in the first few months, when infants' activities appear unpredictable and their behaviors undifferentiated, and self-centered parents may be less likely to put children's needs before their own; so women who are more pre-occupied with themselves, as measured by physical and sexual concerns, show less effective parenting in the first postpartum year.

Some states of mind, still in the normal range but troubling, are regularly associated with poor parenting (Whisman & Baucom, 2012; Zahn-Waxler, Duggal, & Gruber, 2002). Stress, in its many forms, has a rich history of untoward influence on multiple aspects of well-being in parenting (Deater-Deckard, 2004). Stress as in coping with daily hassles predicts less maternal positivity (Crnic & Low, 2002); depressed mothers experience more parenting stress (Coyl, Roggman, & Newman, 2002); and stress disrupts the parent-child relationship (Ciciolla, Crnic, & West, 2012; Crnic, Gaze, & Hoffman, 2005). Parenting stress affects children as well: Parenting stress is related to specific parenting behaviors, which are, in turn, related to specific domains of self-concept in adolescence (Putnick et al., 2008). Mothers and fathers report increased parenting stress across their child's transition to adolescence, driven by parent-child interactions rather than qualities of the parent or the child per se (Putnick et al., 2010). Abidin (1992) conceptualized parenting stress as resulting from many different relationships and contexts. Parents who are more stressed in the parenting role are more likely to be categorized as authoritarian (Tan, Camras, Deng, Zhang, & Lu, 2012), whereas parents who report low levels of stress are more likely to be categorized as authoritative (Woolfson & Grant, 2006). More stressed parents are more likely to resort to harsh discipline (Anjum & Malik,

2010; Fang, Wang, & Xing, 2012; Pinderhughes, Dodge, Bates, Pettit, & Zelli, 2000) and under chronically high conditions even child abuse (Taylor, Guterman, Lee, & Rathouz, 2009), whereas less stressed parenting has been linked with better parent-adolescent communication (Joshi & Gutierrez, 2006). Prospective studies reveal that the effects of stress begin surprisingly early: Stress during late pregnancy predicts child birth weight and is associated with increased emotional and antisocial problems in young children, even when controlling for important confounds (Rice et al., 2007; Swanson & Wadhwa, 2008; Talge et al., 2007). Some child factors, such as low birthweight, prematurity, illness, and ASD, are associated with parenting stress (Kuhn & Carter, 2006; Saigal & Doyle, 2008), and (unsurprisingly) the more severe the child's symptoms the greater the degree of parenting stress (Williford, Calkins, & Keane, 2007). Stability of stress (Lecavalier, Leone, & Wiltz, 2006; Putnick et al., 2010) likely maintains these adverse influences (Östberg, Hagekull, & Hagelin, 2007).

Whereas psychological well-being is associated with parenting competence (Fujiwara, Okuyama, & Izumi, 2012), psychological distress (anxious or depressive symptomatology short of outright psychopathology) appears to undermine parenting. Maternal anxiety predicts self-reported lower warmth toward children (Drake & Ginsburg, 2011), and anxious mothers may be disengaged or intrusive and over-stimulating (Feldman et al., 2009; Kertz, Smith, Chapman, & Woodruff-Borden, 2008; for a meta-analysis see van der Bruggen, Stams, & Bogels, 2008). Children of mothers with high levels of anxiety during mid to late pregnancy are more likely to display emotional and disruptive behavior problems (Beesdo-Baum & Knappe, 2012; Huizink, Mulder, & Buitelaar, 2004; O'Connor, Heron, Golding, Glover, & ALSPAC, 2003), even controlling for confounds (O'Connor, Heron, Glover, & ALSPAC, 2002; van den Bergh & Marcoen, 2004), and older children of mothers with generalized anxiety disorder exhibit flatter emotional tone and are more withdrawn (Stein et al., 2012).

Whether fleeting, as in response to the birth of the baby or economic circumstances, or chronic, depression adversely affects parenting (Field, 2010; Morse, Buist, & Durkin, 2000; Murray, Halligan, & Cooper, 2010; Zahn-Waxler et al., 2002). Epidemiologically, postnatal depression is surprisingly common with a prevalence of as much as 15% (Gavin et al., 2005). Depressed mothers fail to experience—and convey to their children—much happiness with life. Depression's associated mood disturbance, worry, and rumination compromise mothers'

ability to attend, diminish responsiveness, and discoordinate interactions with infants and children (Manian & Bornstein, 2009; Murray et al., 2010; Pearson et al., 2012; Stein et al., 2012; Tronick & Reck, 2009), and depressed parenting is thought to have short- as well as long-term adverse consequences for children (Dix & Meunier, 2009). Mothers who present with depression likely show negative affect and beliefs, apathy and lack of energy, and so decreased and compromised engagement with their children (Campbell, Matestic, von Stauffenberg, Mohan, & Kirchner, 2007; Kertz et al., 2008; Mertesacker, Bade, Haverkock, & Pauli-Pott, 2004; van Doesum, Hosman, Riksen-Walraven, & Hoefnagels, 2007). Meta-analysis points to small, significant associations between maternal depression and negative (coercive, intrusive) and disengaged (withdrawn, uninvolved) parenting (Lovejoy, Graczyk, O'Hare, & Neuman, 2000). Although maternal postpartum depression has been the major focus of study, depression's effects are not exclusive to mothers. Prenatal and postpartum depression manifests in about 10% of men (Paulson & Bazemore, 2010), and postpartum paternal depression is predicted by maternal depression (Beck, 2001; Goodman, 2004; Wee, Skouteris, Pier, Richardson, & Milgrom, 2011). Happily, most cases of postpartum depression remit; unhappily, treatment of depression is less than successful in repairing parent-child relationships (Forman et al., 2007).

Psychopathology, such as mental illness, phobias, substance abuse, and antisocial behavior, seriously impairs thinking, affect, and behavior, and consequently parenting cognitions and practices. Vesga-López et al. (2008) estimated prevalence of postpartum psychopathologies to range from 12% for substance use to 15% for mood disorder. Fewer studies of such outright psychopathologies and parenting populate the literature (Berg-Nielsen, Vikan, & Dahl, 2002). However, mothers diagnosed with major psychopathologies display detached parenting, spend less time with their children, show less affection, and provide less structure (Brook, Brook, Ning, Whiteman, & Finch, 2006; Champion et al., 2009; Gerdes et al., 2007; Suchman & DeCoste, 2012); meta-analysis indicates that maternal psychopathology is a likely antecedent of infant disorganized attachment (Madigan et al., 2006); and mothers who engage in antisocial behavior are less likely to employ optimal parenting practices (Jaffee, Belsky, Harrington, Caspi, & Moffitt, 2006) and more likely to demonstrate hostility toward children (Bosquet & Egeland, 2000) or even abuse them physically (Kim-Cohen, Caspi, Rutter, Tomás, & Moffitt, 2006; Kim-Cohen, Rabbitt, Henry, & Gold, 2012).

### *Intergenerational Transmission of Parenting*

Complete maternal deprivation in rats, through artificial rearing (AR), produces deficits in maternal behavior of the offspring. In adulthood, AR mothers engage in poorer parenting (fewer pup retrievals and less pup licking, but more nonmaternal tail chasing, digging, and hanging/climbing). Daughters of AR and maternally reared (MR) mothers that were observed after the birth of their own litters in adulthood showed patterns of parenting behavior that mimicked patterns shown by their respective mothers (Gonzalez, Lovic, Ward, Wainwright, & Fleming, 2001). Moreover, AR mothers show the same deficits in maternal behavior towards MR foster pups as they do with their own pups (Palombo, Nowoslawski, & Fleming, 2010). Thus, maternal behavior deficits in dams that had been raised in isolation are primarily attributable to the direct effects of early experience on mechanisms regulating their maternal behavior and not to offspring effects. Finally, maternal deprivation impairs performance on social learning tasks, but not spatial learning. AR animals make no distinction between a new and a previously presented juvenile conspecific, and AR animals respond less rapidly than MR animals at tests for maternal behavior 2 weeks after postpartum experience with pups (Lévy, Melo, Galef, Madden, & Fleming, 2003).

Through intergenerational transmission, via interlocked genetic and experiential pathways, purposefully or unintentionally, one generation (G1) appears to influence the parenting beliefs and behaviors of the second (G2) that in turn shape child development in the third (G3; see Belsky, Conger, & Capaldi, 2009, and their introduction to the special section of *Developmental Psychology*). Fraiberg, Adelson, and Shapiro (2003) once referred to these influences as “ghosts in the nursery.” Ruoppila (1991) reported significant correlations between grandparental and parental child rearing in a Finnish sample, and Vermulst, de Brock, and van Zutphen (1991) documented similarities in parental functioning across generations in a Dutch sample. Kovan, Chung, and Sroufe (2009) recorded interactions of parents and their 2-year-olds and then waited and recorded interactions of those 2-year-olds as parents of their own 2-year-olds. Even accounting for confounds, a relatively strong correspondence emerged in parenting practices between generations. Various studies now document similarities across generations for harsh parenting (Capaldi, Pears, Patterson, & Owen, 2003; DiLillo & Damashek, 2003) and poor supervision (Smith & Farrington, 2004) as well as for positive (Hofferth, Pleck, & Vesely, 2012;

Thornberry, 2005; Thornberry, Freeman-Gallant, Lizotte, & Krohn, 2003) and constructive parenting (Z. Chen & Kaplan, 2001; Kerr, Capaldi, Pears, & Owen, 2009). More significantly, maritally dissatisfied couples are more likely to have had unhappily married parents (Amato & Booth, 2001); marital violence in the family of origin tends to repeat in the successive generation (Stith et al., 2000); and when parents abuse their children the children are at risk of repeating the pattern as parents with their own children (Cicchetti, Toth, & Maughan, 2000; Newcomb & Locke, 2001; Pears & Capaldi, 2001). Thus, physically aggressive and punitive techniques in G1 toward G2 predict similar behaviors in G2 toward G3 and antisocial behavior in G3 (Murphy-Cowan & Stringer, 1999). The emerging literature is clearly suggestive that parenting children can exert long-term direct effects on those children parenting their own children. Moreover, the roots of such effects appear to penetrate deeply: Perceived quality of maternal care in childhood is associated with brain structure and functional responses to salient infant stimuli among human mothers in the first postpartum month. That is, mothers who reported higher maternal care in childhood showed larger gray matter volumes, and in response to infant cries these mothers exhibited higher activations, vis-à-vis mothers reporting lower maternal care (Kim, Leckman, Mayes, Newman, et al., 2010).

The Adult Attachment Interview (AAI; George, Kaplan, & Main, 1985) assesses an adult’s internal working model of his or her own relationships with his or her parents. Strong predictive links have emerged between the G2 mother’s AAI classification and the G3 child’s attachment with the mother (P. K. Smith & Drew, 2002). G2 mothers who report having secure and realistic perceptions of their attachments to their G1 mothers, for example, are themselves more likely to behave sensitively with their G3 children and have securely attached G3 children (Cummings & Cummings, 2002). Van IJzendoorn (1995) reviewed AAI studies and reported very high concordance between the parent’s autonomous/nonautonomous classification and a child’s secure/insecure classification in Ainsworth’s Strange Situation. Indeed, some researchers claim that G2 maternal attachment to her primary G1 caregiver is a better predictor of her parenting skills than G2 representations of her G3 child or experiences directly with the G3 child (Biringen, Matheny, Bretherton, Renouf, & Sherman, 2000).

Just collecting two- or three-generation data is formidable, so it is to be expected at this stage that the field is far from settled on the mediational processes

by which parenting transmits intergenerationally. Both genetic and experiential pathways of various flavors have been proffered. For example, a parent's experiences with and memories of his or her own parents may reverberate in his or her parenting via direct (possibly ascribable to G2's observational learning of G1 parenting) or indirect (experiencing G1 parenting as a child might shape interactive behaviors with others, including one's own children) pathways (Campbell & Gillmore, 2007; Capaldi et al., 2003; van IJzendoorn, 1992). Parents draw on the legacy of their families of origin for models of parenting, often emulating the same patterns of parenting and couple interaction they were exposed to as children, so mothers' positive memories of their family of origin's coparenting relationship are associated with their own supportive stance (Stright & Bales, 2003).

In brief, many biological and psychosocial factors in the parent help to shape parenting cognitions and practices. Others not addressed here, such as the parent's birth order or physical health (Houck, Rodrigue, & Lobato, 2007) do so too. To parent well, parents' own needs must be met: When women are inadequately nourished, for example, their health and social development may be compromised, and their abilities to bear and rear healthy children are jeopardized.

### Characteristics of Children Affect Parenting

Phonemes (the meaningful sound units of speech) are constructed of subelements (distinctive features). Jakobson (1941/1969) observed that the order of appearance of these distinctive vocal features in a Babel of languages including English, Swedish, and Japanese may be relatively fixed in babies. Infants first produce front oral-cavity consonants (/m/, /p/) and mid- to back-vowels (/a/). Consonant-vowel combinations of these pairs are therefore frequently the earliest phonemes that appear in infant vocalizations. Notably, two of these early and frequently appearing pairs, viz. /ma/ and /pa/, acquire particular meaning quite early in life. Murdock (1959) tallied the use of front-consonant/back-vowel phonemes as parental descriptors in 1,072 languages and compared their frequency with other combinations (e.g., front-consonant/front-vowel, back-consonant/back-vowel, etc.) Fifty-seven percent of languages use front-consonants/back-vowels for parental kin terms. That is, adults appear to adopt infants' first utterances as terms for their parenting role.

Thinking about parent-child relationships naturally highlights children's parents as agents of their socialization,

and there is ample evidence, especially in the early years, that, between parents and children, children have little agency and parents exert more sway (Kochanska & Aksan, 2004; Maccoby, 1992; Vygotsky, 1978). However, as just illustrated in regard to the signal impact of infant utterances, to a considerable degree parenting is a two-way street, and children actively select, modify, interpret, and create their own environments, including their parenting (Bell, 1968; Scarr & Kidd, 1983).

From the start, the birth of a child stirs the emotions and rivets the attention of adults. By their very coming into existence, children alter the sleeping, eating, and working habits of their parents; and they change who parents are and how parents define themselves. In point of fact, parent and child activities are characterized by intricate patterns of transactions and attunements (Bornstein, 2009, 2013a). Infants cry to be fed and changed, and when they wake, they let parents know they are ready to play and to learn; through social referencing and attachment relationships, infants and young children regularly use others as agents. Many parenting initiatives are proactive; very often, however, children's parents behave reactively. When, recall, Anderson et al. (1986) experimentally paired conduct-disordered boys with mothers of normal boys, the mothers behaved negatively. For some, adolescent problem behaviors may more powerfully determine parenting practices than parenting practices provoke subsequent adolescent problem behaviors (Huh, Tristan, Wade, & Stice, 2006).

In effect, many subtle as well as not so subtle biological and physical, psychological and social characteristics of children influence parenting (Hodapp & Ly, 2005; Karraker & Coleman, 2005). Parents and their children continuously interact with one another over time to mutually construct parenthood (as well as childhood). Some "child effects" are universal and common to all children; others are unique to a particular child or circumstance. For example, certain shared physical features of children likely affect parents everywhere, perhaps in similar ways. By 18 to 20 weeks of gestation in their first pregnancy (earlier in repeated pregnancies), fetuses are felt to move in utero ("quickening"), a significant marker in the lives and psyches of the child's parents (Cunningham et al., 2010). Newborns have large heads dominated by disproportionately large foreheads, widely spaced sizable eyes, small snub noses, exaggeratedly round faces, and small chins. The ethologist Konrad Lorenz (1935/1970) hypothesized that these physiognomic *Kindchenschema* incite adults to express species-general nurturant reactions. Human infant faces elicit activity in select brain regions associated with empathy, reward,

and responsiveness (such as the orbitofrontal cortex, OFC; Caria et al., 2012; Glocker, Langleben, Ruparel, Loughhead, Valdez, et al., 2009), and these responses in adults are rapid (detectable after only ~130 ms; Kringelbach et al., 2008), affectively positive (Parsons, Young, Kumari, Stein, & Kringelbach, 2011; Senese et al., 2013), and motivating of caregiving and even willingness to adopt (Glocker, Langleben, Ruparel, Loughhead, Gur, et al., 2009; Volk & Quinsey, 2002). From the moment of birth, certain baby signals effectively influence parenting: Infant crying alters hormonal circulation, heart rate, blood pressure, skin conductance, and attention, and arouses adults to approach and soothe (Konner, 2010; Soltis, 2004; van Anders, Tolman, & Volling, 2012), and infant smiles encourage proximity and trigger brain areas associated with reward and motivation (Eibl-Eibesfeldt, 1989; Konner, 1991; Mascaro et al., 2013). As to be expected in an alloparental species such as ours (Hrdy, 2009), many of the same parental nervous and behavioral systems that are galvanized in mothers are in fathers (Kuo, Carp, Light, & Grewen, 2012; Wittfoth-Schardt et al., 2012) and in nonparents (Caria et al., 2012; Glocker, Langleben, Ruparel, Loughhead, Valdez, et al., 2009).

Other structural characteristics of children affect parenting and the quality of parent-child interactions; child health status, gender, and developmental age are three significant examples. Regarding the first, child health, for example, preterm children often have difficulty regulating engagements with parents, as evidenced in increased gaze aversion, decreased play, and lower levels of joint attention. In compensation, mothers of preterms tend to be more active and directive (Goldberg & DiVitto, 2002). Infant faces may elicit solicitude, but the face of an infant with a cleft lip, a minor change to one facial feature, disrupts activity in the OFC (Parsons et al., 2013) and parenting (Murray et al., 2008).

A second structural characteristic is gender. Although there is evidence that parenting girls and boys is surprisingly similar in many ways (Hyde, 2014; Leaper, 2002), child gender broadly organizes parents' descriptions, impressions, and expectations of children from the start of life (Bornstein, 2013c): Newborn nurseries are outfitted with gender-appropriate blankets, accessories, and so forth; baby showers are dutifully respectful of the child's gender; and infants are fastidiously dressed in gender-stereotyped clothing. Parents have been reported to purchase gender-typed toys for their children within a few months of the child's birth—prior to when children could express gender-typed toy preferences themselves—so

just the fact of gender is an active ingredient in parenting (Pomerleau et al., 1990). Parents speak more frequently about emotions with their girls than with their boys, they speak about emotions differently, and differentially reward and punish emotional expression in daughters versus sons (Garside & Klimes-Dougan, 2002). Boys tend to receive less parental oversight and more freedom than girls (Kroneman, Loeber, & Hipwell, 2004). Even when girls and boys may be equivalent by objective assessment, they may be parented differently: recall Mondschein et al. (2000) on mothers' differential estimations of girls' and boys' motor skills; in the temperament domain, mothers respond differently to their "difficult" sons than to their "difficult" daughters (Else-Quest, Hyde, Goldsmith, & Van Hulle, 2006). Some investigators have even hypothesized that individual parent-child gendered dyad combinations might betray distinct dynamics: mother-son, mother-daughter, father-son, and father-daughter. For example, Daughters, Gorka, Rutherford, and Mayes (2013) reported that maternal distress tolerance predicts adolescent distress tolerance in daughters, but not sons.

On the third structural characteristic, the age and stage of the child's development dictates plainly many parental beliefs and behaviors. Childhood is change—development involves rapid growth in biological, mental, emotional, and social spheres; understanding, anticipating, and responding to dynamic ontogenetic change continuously challenge parents. Parents need to know about and keep vigilant to all the complications and subtleties associated with their child's development. Not unexpectedly, the sheer frequency with which children are exposed to parent-related actions, objects, and events evolves markedly from infancy to adolescence (Bradley, Corwyn, McAdoo, & García Coll, 2001). For example, mothers and fathers alike show high levels of preoccupation during the first postpartum month that decline by the third postpartum month while their positive thoughts about parenting and the infant reciprocally increase (P. Kim, Mayes, Feldman, Leckman, & Swain, 2013). Mothers of infants in many cultures use affect-laden speech, but as children achieve more sophisticated levels of motor exploration and cognitive comprehension mothers increasingly orient, comment, and prepare children for the world outside the dyad by infusing their speech to children with increasing amounts of information (Bornstein et al., 1992). Parents of preschool children spend more quality time and time in childcare activities than do parents of school-age children (Price, 2008; U.S. Bureau of Labor Statistics, 2013), and parents grant older children greater autonomy than younger children (Leventhal, Dupéré, &

Brooks-Gunn, 2009). Similarly, children's achieving certain milestones, standing upright and walking for example, exhaustively alters the nature and quality of adult caregiving (Campos et al., 2000; Karasik, Tamis-LeMonda, & Adolph, 2014), and the elevation in parent-child conflict is timed to firstborns' transition to adolescence (Shanahan, McHale, Osgood, & Crouter, 2007). With each child rite of passage, moving from "lap child" to "yard child," going to school for the first time, receiving communion or getting bar or bat mitzvahed, driving and dating, attending college, getting married, and all the events in between, parenting changes.

Idiosyncratic characteristics of individual children are equally compelling to parents. Every child is an original, and general developmental functions unfold in the context of wild individual variation. Some individual differences are rooted at deep biological levels. For example, a polymorphism of the *DRD4* gene is associated with disorganized attachment (Gervai et al., 2005; Lakatos et al., 2000, 2002). Among carriers of the 7-repeat *DRD4* allele, there is no relation between quality of maternal communication and infant attachment disorganization; however, a strong relation exists between maternal disrupted communication and attachment disorganization in infant carriers of the *DRD4* 7-repeat genotype. That is, a genetic character in the child moderates the relation between maternal caregiving and infant attachment (Gervai et al., 2007). Similarly, low maternal sensitivity in infancy predicts higher levels of mother-reported externalizing behavior problems at 2 to 3 years of age but only if infants carry the 7-repeat allele of the *DRD4* gene (Bakermans-Kranenburg & van IJzendoorn, 2006). In the Dunedin study, Caspi et al. (2002, 2003) found that the relation between childhood maltreatment and later psychological maladjustment is moderated by genetic factors. The functional polymorphism of the regulatory region of the monoamine oxidase A (*MAOA*) gene moderates the relation between early maltreatment and later antisocial behavior, and a regulatory polymorphism of the serotonin transporter (*5-HTT*) gene moderates the effect of early maltreatment on adult depression (see also Foley et al., 2004; Kaufman et al., 2004; Kim-Cohen, Caspi, Taylor, et al., 2006).

Other surface domains of development show equally impressive variation and exercise strong psychological and behavioral impressions on parents. Children's cognitive development at age 2 predicts their mothers' language at age 3, controlling for maternal language at 2 (Song et al., 2013). Child temperament and behavior engender maternal feelings of competence (Dixon & Smith, 2003; Kiff,

Lengua, & Zalewski, 2011; Putnam et al., 2002) and elicit consequent parenting (Anderson et al., 1986; Larzelere, 2000), just as children's information disclosure affects parental monitoring (Kerr & Stattin, 2000; Stattin & Kerr, 2000). Children's problem behaviors unnerve parents: For example, infants' cry-fuss/sleep difficulties contribute to maternal depression and stress, and repeated problems have a greater impact than antecedent or concurrent ones (St. James-Roberts, 2007). Goldberg (1977) taxonomized three salient child characteristics that likely affect parents: (1) *responsiveness*, the extent and quality of child reactivity to stimulation; (2) *readability*, the definitiveness of child behavioral signals; and (3) *predictability*, the degree to which child behaviors can be reliably anticipated. Each child varies on each dimension, and each possesses his or her unique profile of them all, and in consequence how they will influence how parents treat the child. An "easily read" child produces unambiguous cues that allow parents to recognize the child's state of arousal quickly, interpret signals promptly, and thus respond contingently.

Normal development may be nonlinear in nature, stalling sometimes, or even regressing temporarily (Bever, 1982; C. C. Harris, 1983; Strauss & Stavey, 1982). Parenting a child is thus akin to trying to judge a moving target, the ever-changing child developing in fits and starts at his or her own pace. A major challenge parents face is that, at base, they are constantly trying to divine what is inside their children's heads, what they want, what they know, how they feel, and what children will do next vis-à-vis the things and people around them. Thus, parents seem constantly in search of patterns, often inferring them on the basis of single transient events or child expressions.

In brief, child effects are pervasive and thoroughgoing and potent in parenting. In the presence of children, most adults will curb their language and modify their behavior, and to set examples they will eschew the immoral and illegal and strive to heed the better angels of their nature. Moreover, a transactional or reciprocal effects model asserts that parenting affects child growth and development but that children also affect parenting. This relational developmental systems view prevails in parenting theory and research.

### Contextual Characteristics Affect Parenting

In addition to parent and child characteristics, social and societal factors, such as the parent's family structure, support networks, socioeconomic status (SES), and ethnicity and culture, engender and encourage or discourage diverse parenting cognitions and practices. Again, these represent

only a few of many possible contextual factors that likely influence parenting; neighbors, workmates, media, and ecology, for example, do so as well. It is also important to recognize that childrearing cognitions and practices evolve and change with time (Bronfenbrenner, 1958; French, 2002)—in classical Rome the *pater familias* could dictate the life and death of his children, where today's laws tend to favor mothers—and so the attitudes and actions of parents at any one time may differ from those characteristic of parents of different eras.

### ***Family Structure and Parenting***

Parenting is influenced by family configuration broadly construed. For example, dramatic changes in family dynamics take place when a second baby is born into the family (roughly 80% of mothers in the United States will have more than one child; Dye, 2010), and parenting remains similar but also differs in diverse ways for first- versus laterborns in the same family (Furman & Lanthier, 2002). Analysis of data from the American Time Use Survey revealed that in two-child families the firstborn receives about 25 more minutes of quality time with mothers and 20 more minutes with fathers each day than does the second-born at the same age, leading to an aggregate difference of about 3,000 hours from age 4 to 13 (Price, 2008). A quality-quantity trade-off is also pervasive in preindustrial societies, where larger family size has been linked to poorer survival and growth outcomes of later offspring (Strassman & Gillespie, 2002), and in Western societies, where larger family size is associated with less direct parental involvement in key childcare activities (Lawson & Mace, 2009). Quantitatively, mothers engage, respond, stimulate, talk, and express positive affection more to first- than to laterborns, even when first- and laterborns show no differences in their behavior, indicating that some parenting reflects pure parity and not child effects (Belsky, Gilstrap, et al., 1984). However, in primates survival rates for infants are higher among multiparas compared with primiparas (Hrdy, 2009): for baboon infants of first-time mothers 29%, versus 63% for infants born to experienced mothers (Altmann, Hausfater, & Altmann, 1988). Human first-time parents report more intense preoccupation with newborns than do experienced parents (Kim et al., 2013), and when parent-adolescent relationships are assessed at the same age for two siblings, parents report experiencing less conflict with their secondborn as compared with their firstborn adolescent and exhibit greater knowledge of their secondborn's daily activities as compared with their firstborn's daily experiences (Whiteman, McHale, & Crouter,

2003). The latter kinds of results are consistent with the notion that parents learn from their previous childrearing. Parents may also act toward children in the same family differently because children differ in age, intellect, or personality. Combined with variation in genetic makeup (the 50% siblings do not share), within-family variation in parental thinking and treatment is a potent factor in accounting for why children in the same family may differ from one another (Caspi et al., 2004; Jenkins, Rasbash, & O'Connor, 2003).

Other equally dramatic variations and changes in family structure (some not usually so positive) may have diverse consequences for children's parents and their parenting and for children's development. Preterm, developmentally disabled, and ill children (Goldberg & DiVitto, 2002; Hodapp, 2002; Zuckerman & Keder, Chapter 15, this *Handbook*, this volume) and multiple births (Damato, 2005; Lytton & Gallagher, 2002) are examples that spring to mind. If, as the CDC's Autism and Developmental Disabilities Monitoring Network estimates (Centers for Disease Control and Prevention, 2014a), about 1 in 88 children in the United States is diagnosed with an autism spectrum disorder (ASD), consider the world those parents face (Hjalmarsson, 2013; Salas, 2012). New high rates of U.S. American mothers participating in the labor force (two in three mothers; U.S. Department of Labor, 2011; Repetti & Wang, 2014), single parenthood (four in 10 families; Marquardt, Blankenhorn, Lerman, Malone-Colón, & Bradford-Wilcox, 2012; J. A. Martin et al., 2013; Weinraub, Horvath, & Gringlas, 2002), as well as separation and divorce (one in two marriages; Hetherington & Stanley-Hagan, 2002) certainly alter or disrupt parenting and upset and complicate family processes, as do transitions to stepparent and foster family status (Ganong et al., Chapter 4, this *Handbook*, this volume; Haugaard & Hazan, 2002; Hofferth & Anderson, 2003). Notable in this connection, and a dire observation calling for research as well as remediation, is the great incidence of child abuse in the stepparent population (Daly & Wilson, 1988). Still other vicissitudes of life (financial stress, death of a parent, military deployment, and the like) alter family structure and so parenting and child development (Duncan, Magnuson, & Votruba-Drzal, Chapter 14, this *Handbook*, this volume; Ganong et al., Chapter 4, this *Handbook*, this volume).

### ***Support Networks and Parenting***

Integration or isolation from potential support networks facilitates or hampers parenting. Support refers to the psychological and tangible resources available to individuals

through their relationships with family, friends, neighbors, work associates, and others. Normally, supportive networks have positive effects on children's parents. Support from family members and other groups is associated with successful transition to parenthood (Bird, Peterson, & Miller, 2002; Elek, Hudson, & Bouffard, 2003), and afterward mothers who report supportive relationships with "secondary parents" (grandparents and the like) are less harried and less overwhelmed, have fewer competing demands on their time, and as a consequence are more available to their children and are more competent and sensitively responsive to their children than are those bereft of such relationships (Crnic & Greenberg, 1990; Grych, 2002). Benefits of support could obtain because support affords parents regular positive experiences and so bolsters overall well-being, because support provides a sense of predictability and stability in one's life situation and recognition of self-worth, or support buffers stress and mental health issues (Bird et al., 2002). Members of support networks can also teach and encourage parents in more developmentally appropriate caregiving.

Several significant questions have motivated work in the area of parent support. One concerns sources of support. Emotional and childcare support from a spouse (if not from other family members) are associated with well-being, greater life satisfaction, and more positive affect and competence (DeLongis, Capreol, Holtzman, O'Brien, & Campbell, 2004). In the Civitas Initiative et al. (2000) national survey, 70% of mothers of children under 3 reported that they relied on their spouse and 66% on their mother for support. Other people, especially in-laws, exerted an impact on fathers' commitment to parenthood and satisfaction with being a parent (Solantaus & Salo, 2005). Marital status and father presence in the home are critical to the young mother's well-being (Brown, Goslin, & Feinberg, 2011) and account for the quality of maternal-child emotional relationships (Bornstein, Cote, et al., 2012). Fathers who felt less supported by their partners, and those noticing a greater change in their partner and in their relationship postpartum, held a more negative attitude toward fatherhood and indicated more deleterious adaptive problems postpartum (Letourneau, Duffett-Leger, Stewart, Dennis, & Tryphonopoulos, 2011). Friends and relatives constitute a major base of information for younger parents with little child-rearing experience. Although health care professionals are less immediately accessible, they constitute an important reserve for all ages and social classes of parent but are the most often consulted about emergent or specific medical problems (Hickson & Clayton, 2002; Hulbert,

2003). In the Civitas Initiative et al. (2000) survey, 54% of mothers reported that they relied frequently on their child's doctor/pediatrician, 25% on nurses, and 20% of childcare providers for information and advice. At the same time, parents report that many anticipatory guidance topics are not covered in well-child visits, and that, even after such visits, they can still use more information (Golan et al., 2008; Sanghavi, 2005). Although it sometimes conflicts with information in other messages or from health care professionals and can be inaccurate, more and more contemporary parents turn to the Internet for quick and practical solutions; the child-rearing concerns mothers express in chat rooms and on message boards relate most often to feeding or eating, sleep, development, discipline, toilet-training, and mother-child relationships (Porter & Ispa, 2012).

A second question in this literature concerns the types of support and the relative importance of the objective amount of support available to a parent versus the parent's perception of support. Support is multidimensional and may be educational, emotional, inspirational, tangible, or structural (Bryant, 2012). Supports may be informal (extended family) or formal (parent education programs); both influence parenting (Cochran & Niego, 2002) and so children. Quantitatively, more childcare support is associated with higher-quality face-to-face interactions between mothers and babies (Levine, García Coll, & Oh, 1985). However, greater perceived support (both global and parenting support in particular) has been linked with lower levels of parenting stress, more positive parenting and relationships with children, and fewer negative interactions with children (Bonds, Gondoli, Sturge-Apple, & Salem, 2002; Ensor & Hughes, 2010; Izzo, Weiss, Shanahan, & Rodriguez-Brown, 2000; Suzuki, Holloway, Yamamoto, & Mindnich, 2009). The majority of existing research links global perceptions of support to parenting competence and well-being and suggests that it may matter more that parents feel support of some sort from some source rather than the amount, type, or basis of support.

### *Socioeconomic Status and Parenting*

Socioeconomic status comprises income, education, and occupation of householders and is broadly influential in parenting (Bornstein & Bradley, 2003). Although parents in different strata behave similarly in certain ways, SES orders a wide variety of cognitions and practices of parents toward children as it does the home environment (Bornstein, Hahn, Suwalsky, & Haynes, 2003; Bradley & Corwyn, 2002; Hoff, Laursen, & Tardif, 2002). SES-related variation in parenting affects the likelihoods that parents

read books on childcare and read books to their children (Bornstein et al., 2010).

Higher-SES mothers converse with their children more, and in more sophisticated ways, than do lower-SES mothers (Hart & Risley, 1995, 1999; Hoff, 2003), and mothers' encouragement in language undoubtedly facilitates self-expression in children; higher-SES children produce more gestures and sounds and later more words than do lower-SES children (Rowe & Goldin-Meadow, 2009). Parents in higher socioeconomic strata also change more flexibly and more rapidly in response to changes in developmental theory than do parents in lower socioeconomic strata (Bronfenbrenner, 1958). Reciprocally, low SES and poor education are risk factors in parenting and children's development on many accounts. Low SES adversely affects mothers' psychological functioning and is associated with stress and harsh or inconsistent disciplinary practices (McLoyd, Aikens, & Burton, 2006). Around the globe, low- compared to middle-SES parents typically provide children fewer opportunities for variety in daily stimulation, have less appropriate play materials on hand, and engage in less total stimulation (Bornstein & Putnick, 2012). Kohn (1979; see Weininger & Lareau, 2009) hypothesized that social class differences in parents' child-rearing values spring from differences in the requirements and expectations parents need to succeed in their jobs. Lower-SES parents tend to believe they have less control over their children's development and profess a "natural growth" approach to child development where higher-SES parents fill children's "leisure time" with structured didactic activities (Lareau, 2003).

Education, maternal education especially, appears to be a potent ingredient in SES vis-à-vis parenting (Bornstein et al., 2003). For example, more-educated parents spend more time with their children (Guryan et al., 2008) and possess more understanding of child rearing and child development (Bornstein et al., 2010). They command great knowledge about factors that reduce risks and illness, and they implement practices at home to improve child health. Not surprisingly, parent education links to many child health and psychosocial outcomes (E. Chen et al., 2002; Duncan et al., Chapter 14, this *Handbook*, this volume). Maternal education has significant effects on birth weight and gestational age from the start (Currie & Moretti, 2003), and in the long-term higher levels of maternal education are associated with better cognition and higher education in children, net household income and other demographic characteristics (Duncan & Brooks-Gunn, 1997). In short, the positive characteristics of caregiver (especially

maternal) education vis-à-vis child development are profound and ubiquitous. In many low- and middle-income countries (LMIC) around the globe, maternal education, net of other family socioeconomic indicators, is positively related to the mother's own health care utilization as well as the nutritional status and health care utilization for her children (Abuya, Ciera, & Kimani-Murage, 2012; Ahmed, Creanga, Gillespie, & Tsui, 2013; Burchi, 2012). Unfortunately, instructional capital there in the form of maternal education is limited: In 39 LMIC, the median years of education for women aged 25 and over was only about 5 in 2010 (Barro & Lee, 2010).

Overall, financial stresses associated with low SES adversely affect the general well-being and health of parents and demand attention and emotional energy from them (Magnuson & Duncan, 2002). In McLoyd et al.'s (2006) analysis, stress on impoverished parents stemming from day-to-day struggles to find the resources that afford food and shelter, and the stress of trying to cope with living in deteriorated housing and dangerous neighborhoods undermine parenting skills and contribute to disorganizing family life (Toldson & Lemmons, 2013). These circumstances, in turn, may reduce parents' attentiveness, patience, and tolerance toward children (Crnic & Low, 2002). As reviewed earlier, stress on parents is associated with decreased sensitivity to child cues, more negative feelings toward children, and harsher parenting styles (Seigny & Loutzenhiser, 2010). The deterioration of parenting in low-SES circumstances is believed responsible for many adjustment difficulties of children growing up in impoverished families. The effects of parental poverty might be moderated by age, gender, or other individual-difference characteristics of the child, however; and, what's noteworthy, parenting in upper social strata does not absolutely protect children from risks of disadvantage, problem behaviors, or even substance use (Luthar, 2003; Luthar & Barkin, 2012; Luthar & Latendresse, 2005; Racz, McMahon, & Luthar, 2011).

### ***Ethnicity, Culture, and Parenting***

Like social class, issues of ethnicity and culture permeate how children's parents view parenting and how they parent (Bornstein & Lansford, 2010; LeVine, 2003). Variation in beliefs and behaviors is always impressive, whether observed among different ethnic groups in one society or across cultural groups in different parts of the world. Regarding misbehavior of their children, for example, African American parents convey strong and immediate messages, European American parents emphasize

problem solving and negotiate consequences, and Native Americans have children spend time with extended family (Lubell, Loften, & Singer, 2008; McBride Murry, Hill, Witherspoon, Berkel, & Bartz, Chapter 11, this *Handbook*, this volume). As mentioned earlier, European American mothers endorse the importance of independence and self-assertiveness when asked to describe their ideal child, whereas Latina American mothers accentuate obedience and respect for theirs, and each parents in accord with those beliefs (Tamis-LeMonda & McFadden, 2010). Ethnic differences pervade parenting cognitions, practices, and effects as well as parent-child relationships (Hofferth, 2003; Park & Bauer, 2002). Likewise, expected timetables for child development in new mothers in Australia of Australian versus Lebanese heritage differ, showing that culture-of-origin shapes parenting much more than other seemingly more immediate factors, such as experiences observing their own children, comparing them to other children, and advice from friends and experts (Goodnow, Cashmore, Cotton, & Knight, 1984).

The role of culture in parenting—what we can learn from the way parents in cultures not our own rear their children—has persisted in popular fascination from the Classical period of Greece, when Xenophon and Aristotle were captivated by *agoge*, the Lycurgan system of Spartan childrearing, to the present day “Tiger Mother” (Chua, 2011) and purported “wisdom” of French parents (Druckerman, 2012). Culture influences children’s parents and so child development from very early in life in terms of who parents, how parents conceive of childhood, the ways parents care for children, and so forth (Benedict, 1938; Selin & Stone, 2009; Whiting, 1981). In some cultures, children are reared in extended families where care is provided by many alloparents; in others, children and their mothers are isolated from almost all social contexts. In some, fathers are treated as irrelevant social objects (“honored guests”); in others, fathers assume complex and continuing responsibilities for children (“house husbands”). European American parents enjoy eye contact, lavish praise, foster language development in their children, are responsive to crying, and generally avoid physical punishment; Gusii (Kenya) parents gaze avert, explicitly reject praise, regard it as silly to talk to a baby, are angered by cry, and cane children as a way to instill control (Quinn, 2005). Parents in some cultures believe that play with children affords important development-promoting experiences, parents in others see play primarily as child amusement, and parents in still others do not include play at all in their job description (Bornstein, 2007). Cultures

also differ vastly in who is responsible for young children and, consequently, for the estimated 163 million children around the world who do not live with a biological parent (Leiden Conference on the Development and Care of Children Without Permanent Parents, 2012) whether or not children benefit from their diverse informal caregiving arrangements (Leinaweaver, 2014).

Different ethnic or cultural groups possess parenting ideas, approach parenting tasks, and value parenting outcomes differently (Cote, Bornstein, Haynes, & Bakeman, 2008; Goodnow & Lawrence, Chapter 19, this *Handbook*, this volume). Japan and the United States maintain reasonably similar levels of modernity and living standards, and both are child-centered societies, but the two differ dramatically in terms of history, beliefs, and behaviors with respect to parenting. Traditional Japanese mothers expect early mastery of emotional maturity, self-control, and social courtesy in their offspring, whereas U.S. American mothers expect early mastery of verbal competence and self-actualization in theirs. U.S. American mothers promote autonomy and organize social interactions with their children so as to foster physical and verbal assertiveness and independence, and they promote children’s mastery of the external environment. Japanese mothers organize social interactions so as to consolidate and strengthen closeness and dependency within the mother-child dyad, and they tend to indulge young children (Bornstein, Cote, et al., 2012; Morelli & Rothbaum, 2007). Li, Fung, Bakeman, Rae, and Wei (2013) compared conversations between European American and Taiwanese mothers and children (6–10 years) about good and poor learning. European Americans mentioned mental activities and positive affect more, whereas Taiwanese mentioned learning virtues and negative affect more.

The general cultural climate moderates parenting effects. In diverse domains of development, parenting practices relate differently to children’s adjustment depending on the broader cultural context. A study of associations between corporal punishment and children’s adjustment in China, India, Italy, Kenya, the Philippines, and Thailand disclosed that more frequent corporal punishment is linked to higher levels of child aggression and anxiety in all six countries, but the connection weakens where the use of corporal punishment increases in cultural normativeness (Lansford et al., 2005). Culturally defined beliefs are so powerful that parents sometimes act on them as much as or more than on their own senses (or what their good sense) tells them about their own children. Parents in Samoa, for example, reportedly think of young children as having

an angry and willful character, and, independent of what children might actually say, parents consensually report that their children's first word is *tae*, Samoan for "shit" (Ochs, 1988).

Ethnic and cultural differences notwithstanding, children's parents also share some striking commonalities in their cognitions and practices. Bringing up children is a universal task, and in the end parents everywhere must nurture, protect, and promote the growth of children if their children are to survive, there are only so many mechanisms available to socialization, and (as noted earlier) all well-intentioned parents possess similar aspirational goals for their children, including physical health, emotional security, intellectual achievement, and social adjustment, if their children are to thrive. Some cross-cultural similarities in parenting may reflect shared biological bases of caregiving, others the historical convergence of parenting styles, and still others increasing unanimity on account of worldwide migration or dissemination via mass media.

The moderation of parenting by ethnicity and culture calls for several caveats and qualifications. First, the greater part of the contemporary database in parenting refers to Western, educated, industrialized, rich, and democratic populations (Bornstein & Lansford, 2010; Henrich et al., 2010) and has not often enough situated parenting by specific ethnic groups or within specific cultural traditions. This situation is changing (see, for example, the introduction to the special issue of *Parenting: Science and Practice* on parenting attributions and attitudes across cultures, Lansford & Bornstein, 2011; Selin, 2014). Neither ethnicity nor culture is homogenous or monolithic either (Calzada, Hunag, Anicama, Fernandez, & Brotman, 2012). For example, child age is influential in Latino/a parenting practices; parenting with preschool children is usually indulgent or permissive, but once children become older, parenting is guided by stricter standards (Halgunseth, Ispa, & Rudy, 2006). Specialized meanings attend ethnicity and culture. Low-income African American mothers in Early Head Start use physical discipline but adopt distinctive terminology and conceptions for different forms: "spank" and "slap" are correctives and not abusive, but "whup" and "switch" connote beating (Ispa & Halgunseth, 2004). In a related way, finally, the child-rearing cognitions and practices of one's own group seem to have exaggerated moral force and appear quite natural to parents when they may actually be rather unusual when compared with those of other groups. We tend to be instinctively critical of, and resistant to, childrearing regimens different from our own (Quinn, 2005). This observation extends to parents in one

ethnic or cultural group conceiving of a given parenting behavior as normative that parents in another conceive of as harsh or abusive.

In brief, parenting is conditioned by multiple contextual spheres of influence in which the parent-child dyad is embedded, including the family's structure, network, class, ethnicity, and culture. Other contextual factors, such as religious affiliation (Gaunt, 2008; Mahoney, 2005; Mahoney, Pargament, Tarakeshwar, & Swank, 2008) and neighborhood residence (Leventhal, Dupéré, & Shuey, Chapter 13, this *Handbook*, this volume) not addressed here directly, likewise exert molding influences on children's parents.

### A Methodological Consideration

The literature concerning endogenous and exogenous sources of influence on parenting is burgeoning. However, antecedents to parenting have typically been studied in isolation, and few investigations evaluate multiple influences simultaneously. Thus, the overlap of different antecedents vis-à-vis the unique contribution of any one influence on parenting remains essentially unexplored. For example, young parent age may exert untoward effects on parenting (and on children) because people who have children early in their life career are more likely to have associated problems (low education, low SES) that also adversely affect parenting and children. With this limitation in mind, family systems theorists have emphasized the importance of considering the possible independence *and* interdependence of multiple organismic, environmental, and experiential determinants of parenting. Furthermore, the size of the effect for any one antecedent-outcome relation, or for contingencies that operate across different components of the family system, might be small in magnitude. This is not a statement about the unimportance of small effects, but rather of the need to build models of parenting that focus on the ways small effects might combine or grow in magnitude over time.

### Summary

To understand variation in parenting, information about multiple sources is required, including biological and psychological characteristics of each individual in the family, relationships with parents' families of origin, relationships between parents and between parents and each child, and relationships between nuclear family members and key individuals or institutions outside the family (friends, peers, work, childcare, school, ethnicity, culture).

Parenting stands at the confluence of many rivulets of influence; some flow from within the individual, whereas others spring from sources external to the parent in the child and in the landscape that situates children and their parents.

## PRACTICAL PARENTING

Practically speaking, parenting has positives, such as intimacy, nurturance, and rewards, which we want to enrich, but is also encumbered with negatives, such as frustration, anger, and violence, which we want to prevent. To the good, through diverse analyses Bianchi (2000), Sayer, Bianchi, and Robinson (2004), and Aguiar and Hurst (2007) concur that adults in the United States and elsewhere in the world (Gauthier et al., 2004) are spending more time with their children today than in the past. Still, nearly one-half of a national sample of parents rue that they spend too little time with their children (Bianchi, Robinson, & Milkie, 2006).

It is also a sad fact of everyday life that parenting children does not always go well or right. Infanticide was practiced historically, and although it is rare today, it is not unknown (Hrды, 1999). Short of that, vulnerable young are too commonly the victims of neglect (forgotten in locked cars on hot days, never immunized, or left to waste away in orphanages) and abuse (born drug addicted, put in harm's way, or trafficked). Infant cries draw a parent's attention but also trigger shaken baby syndrome (Lee, Barr, Catherine, & Wicks, 2007) and assaults (Cavanagh, Dobash & Dobash, 2007). Every year, child-protection agencies in the United States alone receive 3 million referrals for child neglect and abuse involving about 6 million children younger than 5. About 80% of the children in investigated neglect and abuse cases are not removed from their home, although about 80% of perpetrators are parents, the vast majority biological parents. According to the National Research Council (2013), neglect and abuse amount to an estimated \$80 billion per year in direct costs of hospitalization, law enforcement, and child welfare and indirect costs of special education, juvenile and adult criminal justice, adult homelessness, and lost work productivity. Three factors increase the risk of child abuse: parental depression, parental substance abuse, and whether the parents were neglected or abused as children.

Although usually protected, we see that children are still too often exposed to relatively hostile and emotionally negative climates in the home, and parents in the front seat of the car fail to heed that children in the back

seat overhear what they say. By the current standards of meta-analytic evidence, parents contribute to their children's internalizing and externalizing behavioral problems (Fearon, Bakermans-Kranenburg, van IJzendoorn, Lapsley, & Roisman, 2010; Groh, Roisman, van IJzendoorn, Bakermans-Kranenburg, & Fearon, 2012). Moreover, many parents resort to harsh verbal and physical treatment and even corporal punishment. Exposure to domestic violence as well as caregivers' psychological aggression and violence are risk factors for children's mental health problems, physical injuries, and even death. Aggression against children is all too common in the United States (Gershoff, 2002) as it is in other countries around the world (Lansford et al., 2005; Mejia, Miewer, & Williams, 2006). From Finland and Denmark to Kenya, child-rearing violence in one year predicts child-externalizing behavior later (Peltonen, Ellonen, Larsen, & Helweg-Larsen, 2010; Skinner, Oburu, Lansford, & Bacchini, 2013). The American Academy of Pediatrics (AAP) has declared that "physical discipline is of limited effectiveness and has potentially deleterious side effects," recommending that "parents be encouraged and assisted in the development of methods other than spanking for managing undesired behavior." The AAP reaffirmed that pediatricians encourage parents to use alternate age-appropriate forms of nonaggressive discipline, such as distraction, time-outs, and offering explanations. Internationally, United Nations documents such as the Convention on the Rights of the Child have identified violence toward children as a problem to be eliminated at a national level. The use of corporal punishment toward children has now been legally banned in all settings in 34 countries, and legislation is pending in several others (Global Initiative to End All Corporal Punishment of Children, 2013).

Strong secular and historical trends operating in modern society—industrialization, urbanization, poverty, increasing population growth and density, and especially widespread dual parental employment—constitute centrifugal forces on parenting. Society at large is also witnessing the emergence of striking permutations in parenthood and in the constellation of the family structure that have plunged the family generally, and parenthood specifically, into an agitated state of question, flux, and redefinition (Ganong et al., Chapter 4, this *Handbook*, this volume; Solomon, 2012). Because these society-wide developments exert many unfortunately debilitating influences on parenthood, on parenting, and, consequently, on children and their development, a significant proportion of parents needs assistance to identify more effective

strategies to optimize child care and to create more satisfying family relationships. Not surprisingly, a one-time U.S. commissioner of education preached that every child has a right to a “trained parent.” Parents are usually the most invested, consistent, and caring people in the lives of their children, so providing them with knowledge, skills, and supports will help parents respond more positively and effectively to social and child-related challenges.

Only a fraction of parents who need such services receive them, however. Thus, organizations at all levels of society increasingly feel they ought to intercede in child rearing and right social ills through parenting preventions and interventions. As a result, contemporary parenting has witnessed an explosive growth in information and support programs. One implication of the increasingly sophisticated view of the origins and conduct of parenting is that many aspects of parenting are compliant to education and intercession; thus, what we learn about parenting holds the promise of far-reaching practical implications. In the view of some critiques, this trend also paradoxically leads away from a focus on parents as the proximal protectors, providers, and proponents of their progeny and toward entrusting childrearing to experts and the state.

Contemporary parents from families along multiple risk continua might become more effective. Preventions and interventions designed to help parents come in a variety of venues (psychotherapy, classes, media), settings (homes, schools, health clinics, houses of worship), and formats (individual, family, group) and with a variety of goals (universal versus specific). For example, child-focused programs are based on theories that emphasize biological and psychological processes of change within the child; parent-focused programs primarily target parents’ cognitions and practices; translational programs combine child- and parent-focused perspectives to improve the quality of parent-child relationships.

Competences are knowledge, skills, abilities, personal characteristics, and attitudes, and competencies to adequately perform a task, duty, or role are (usually) learned (Roe, 2002). Competent parenting, crucial to child welfare and well-being, can be learned. Profession-specific competencies provide motivation and direction for learning as well as a means to judge the adequacy of parenting programs (Epstein & Hundert, 2002). Many experimental trials and parenting intervention programs have been devised. A review of 46 randomized trials provides evidence of prevention of a wide range of problem outcomes from 1 to 20 years later. However, this literature offers

a paucity of evidence concerning processes that account for program effects (Sandler, Schoenfelder, Wolchik, & MacKinnon, 2011). Interventions to promote positive parenting have been touted to offer positive outcomes for children, but they often consume substantial resources and require rigorous appraisal. Biglan, Mrazek, Carnine, and Flay (2003, p. 438) called for the integration of more science into societal parenting practices to prevent youth behavior problems and to promote “agreement on a set of consensus standards for selecting disseminable preventive interventions.” An example is Triple P, the Positive Parenting Program, a popular multilevel behavioral family intervention (Prinz, Sanders, Shapiro, Whitaker, & Lutzker, 2009; Sanders & Kirby, 2010; Sanders, Markie-Dadds, & Turner, 2003; Wilson et al., 2012). Systematic reviews and meta-analyses comparing Triple P with wait-list or no-treatment comparison groups reveal relatively small maternal and smaller paternal outcomes that do not differ from control conditions.

Some interventions succeed. For instance, targeted interventions are known to improve maternal mentalizing and sensitivity (Juffer, Bakermans-Kranenburg, & van IJzendoorn, 2007; Sadler et al., 2013), and the Family Check-Up, an intervention designed to prevent young children’s problem behavior via improvements in parents’ positive behavior, reported improvements on key indicators of children’s school readiness (Lunkenheimer et al., 2008). Unhappily, however, most interventions fail and do so for a wide variety of reasons, as when parents short-shrift intervention “homework” assignments or program staff fail to help parents access needed services or measurement is biased or a control group is contaminated through unintended diffusion of the parenting intervention (Bodenmann, Cina, Ledermann, & Sanders, 2008; Fixen, Naoom, Blase, Friedman, & Wallace, 2005; Goodson, Layzer, St. Pierre, Bernstein, & Lopez, 2000; Hebbeler & Gerlach-Downie, 2002; Okagaki & Bingham, 2005; Pinquart & Teubert, 2010; West, 2009; see Kaminski, Valle, Filene, & Boyle, 2008, for a meta-analysis of training programs).

By deconstructing those reasons critically, we can learn ways that future interventions might succeed. Happily, Powell (2013) provides solid and timely guidance on central aspects of undertaking and evaluating parenting interventions, including preliminary work, sampling, research design, options for comparison conditions, measurement of implementation fidelity, and analysis of outcomes (Boutelle, Cafri, & Crow, 2011; DeGarmo & Forgatch, 2005; Flay et al., 2005; McCall & Green, 2004;

Sandler et al., 2011; Shadish, Cook, & Campbell, 2002). To summarize some main points of that tutorial, parenting interventions should be based on theoretical and empirical models that specify the overarching goal of the intervention with regard to anticipated improvements in specific child outcomes, how change in malleable parenting variable(s) targeted by the intervention is expected to improve child outcomes, and how intervention components are expected to change focal parenting variable(s). Development of a coherent, measureable theory of change and articulation of a precise logic model are critical to an intervention functioning as intended. Randomly assigning intervention and comparison conditions to parents or to larger units in which parents are based (e.g., schools) will provide the strongest evidence of intervention effectiveness, assuming the outcome study is well implemented. Parenting interventions that assess both parent and child outcomes make more robust contributions than those that only assess parenting outcomes. Likewise, intervention studies should routinely determine whether intervention effects are sustained beyond the intervention period (Olds et al., 2002). Provision of some level of support to comparison group participants is consistent with intervention researchers' ethical responsibilities, particularly with vulnerable populations (Celano, Holsey, & Kobrynski, 2012; Sieber, 2012). One can be certain that intervention fidelity—the degree to which a program has been implemented as planned—will be less than 100% ensured (Durlak & DuPre, 2008; Korf-macher, O'Brien, Hiatt, & Olds, 1999); but fidelity to an intervention protocol predicts change in parents' practices and children's behavior (Forgatch et al., 2005). Finally, no single intervention fits all (Barrera, Castro, & Steiker, 2011), so, as an Institute of Medicine report (O'Connell, Boat, & Warner, 2009) recommended, interventions that successfully adopt and integrate cultural mazes will experience the likeliest successes with both consumers and community agents (see Takanishi & Bogard, 2007).

Higher reflective functioning is associated with sensitive parenting and improved child development (Pajulo et al., 2009). Core concepts of reflective functioning and mindful parenting include, in addition to understanding mental states and intentions, full presence, nonjudgmental stances, emotional awareness, self-regulation, and compassion (Duncan, Coatsworth, & Greenberg, 2009), and certain mindfulness tools can help to address pressing parenting requirements successfully. Central ingredients include:

- Children's parents benefit from knowledge of how children develop. Therefore, the normative patterns

and stages of children's physical, verbal, cognitive, emotional, and social development should be part of the knowledge base for parenthood.

- Children's parents need to know how to observe children and how to interpret and use what they learn. Informed child watching helps to clarify a child's level of development in relation to what parents want children to learn and to accomplish. Observing also allows parents to identify potential trouble early and may help parents respond to it more meaningfully.
- Children's parents need all manner of skills for managing their children's behaviors. Knowledge of alternative methods of discipline and problem avoidance, for example, is basic.
- Children's parents need to understand the tremendous impact they have on their children's lives through the simplest things they do: their attention, expressed pleasure, listening, and interest.
- Children's parents need to know how to take advantage of everyday settings, routines, and activities to create learning and problem-solving opportunities that enhance childhood and parenthood.
- Children's parents need to be patient, flexible, and goal-oriented—to call on their personal resources and extrapersonal sources of support—and they must command an ability to extract pleasure from their encounters with children.

The responsibility for determining the child's best interests rests first and foremost with parents. Parents are children's primary advocates and their frontline defense. Parents are the corps available in the greatest numbers to lobby and labor for children. Few ethical or sentient parents want to abrogate their child-rearing responsibilities (Baumrind & Thompson, 2002). Insofar as children's parents can be enlisted and empowered to provide children with experiences and environments that optimize their development, society is positioned to obviate after-the-fact remediation. In the dedication of *Some Thoughts Concerning Education* to "Edward Clarke, of Chipley, Esq.," John Locke (1692) wrote: "The well educating of their children is so much the duty and concern of parents, and the welfare and prosperity of the nation so much depends on it, that I would have every one lay it seriously to heart." On these grounds, the doctrine of parental rights remains a fundamental premise to child rights. Parents sometimes don't know what to do, but they can find out; they sometimes do know what to do, but still do not get into the trenches and do it.

## CONCLUSIONS

There is no such thing as an infant.

—*D. W. Winnicott (1965, p. 39)*

Evolutionary theory places parenting at the pinnacle of the pyramid of human needs, above immediate physiological needs as well as needs for affiliation, esteem, and mate acquisition (Kenrick, Griskevicius, Neuberg, & Schaller, 2010). In turn, parents intend much in their interactions with their children: They foster their children's emotional regulation, development of self, social sensitivities, and participation in meaningful relationships and experiences inside and outside of the family through the models they portray and the values they display, and they promote their children's mental development through the structures they create and the meanings they place on those structures. The complex of parent cognitions and practices is divisible into domains, and parents tend to show individual variation in how they express their cognitions and practices as they do a core consistency in certain of those domains. Some aspects of parenting are frequent or significant from the get-go and wane as children develop; others wax in importance over the course of children's development. Although not all parenting is critical, and single events are rarely formative, parenting certainly has long-lasting effects. The interactive and intersubjective aspects of parent and child have telling consequences for the person's future, and little and big consistencies of parenting aggregate over childhood to help construct the person. Common public misperceptions about parenting—that all different ways to parent work equally well, that people naturally know how to parent, and that parenting cannot be taught—are falsehoods in need of correction. Researchers and theoreticians today do not ask whether parenting affects child development, but which parent cognitions and practices affect which aspects of child development when and how; they are interested also to learn the ways in which individual children are so affected, as well as the ways individual children affect their own development (Bornstein, 2013b).

Human development is too complicated, nuanced, and dynamic to assert that children's parents alone determine the course and outcome of their ontogeny; parenthood does not fix the route or the terminus of child development by itself. Status in maturity is shaped by the attitudes and actions of individuals themselves across the life span. Children bring unique, physical, mental, and social lives to everyday encounters with adults that shape their caregiving

experiences. Children also alter their environment as they interact with it, and they interpret their world in idiosyncratic ways. These intrapersonal factors and extrapersonal contexts play important roles in determining the nature, function, and effect of parenting. Additionally, a full understanding of parenting depends on the several ecologies in which parenting is embedded. Family composition, social class, ethnicity, and culture all exert salient influences on how parents behave toward their children and what they believe about their children as they grow. So, parent and child convey distinctive characteristics to every mutual interaction, and both are changed as a result. Parent and child actively create one another through time.

Children's parents have central parts to play in their physical growth, cognitive advance, emotional maturation, and social development. A better understanding of the nature of the human being is afforded by examining parents' cognitions, practices, and their consequences—the unique and specific influences of the individual's parents. Successful parenthood ultimately means having facilitated a child's self-confidence, capacity for intimacy, achievement motivation, pleasure in play and work, friendships with peers, and continuing intellectual success and fulfillment. Parenting experiences within the family exercise a major impact over each of these spheres of development.

When a rat dam is given a choice between a chamber that has been associated with pups and one where she received an injection of cocaine, there is a period of time after parturition when new dams prefer pups, spurning even the power of narcotics in favor of offspring (Mattson, Williams, Rosenblatt, & Morrell, 2001; Pereira, Seip, & Morrell, 2008; Seip & Morrell, 2007). As judged by psychoanalysis, ethology, psychology, and neuroscience, children's parents engage in a peculiar kind of life's work: Parenting is a delicate blend of empathy, altruism, and prosociality, blind devotion and selflessness, marked by constantly challenging demands, changing and ambiguous criteria, and all too frequent evaluations. Defining principles of parenting, such as specificity, moderation, transaction, and thematicity as well as indirect and direct effects, render parenting less than straightforward. Parenting also entails both affective components, in terms of commitment, empathy, and positive regard for children, and cognitive components—the how, what, and why of caring for children. Thus, different tasks are more or less salient and compelling at different points over the life course of childrearing. The path to achieving satisfaction and success in parenting is not linear or incremental, but tends to meander.

It is obvious that parenthood is central to childhood, to child development, and to society's long-term investment in children. Children's parents are fundamentally committed to their survival, socialization, and education. But parenthood is also a major phase and constituent ingredient of mature adulthood. So the motivation to know about the meaning and importance of parenthood and parenting exists as much for each individual as out of the desire to improve the lives of children and the welfare of society. For the majority of humankind, parenting is a process that formally begins before pregnancy and continues through the balance of the life span. Practically speaking, *once a parent, always a parent*.

## OVERVIEW

What makes a family diverse? Which families emerge as we think about “diverse families”? Developmental scholars often highlight ethnic variability when using *diversity* as an adjective describing families, but that is not the focus of this chapter (see McBride Murry, Hill, Witherspoon, Berkel & Bartz, Chapter 11, this *Handbook*, this volume,

for a review of ethnically diverse families). Instead, we concentrate primarily on structural variability of families, on multiple ways in which families are created and maintained, and familial processes that accompany structural variations.

In this chapter we examine several types of diverse families as environmental contexts within which children develop: families headed by unmarried and cohabiting parents, children who have had a parent die or whose parents have divorced, stepfamilies, families headed by gay and lesbian individuals, grandfamilies (grandparents

---

We thank Ashton Chapman for her assistance in preparing this chapter.

raising grandchildren), and parents who utilized assisted reproductive technologies (ART). These categories are not homogeneous, so when feasible, we examine the state of the scholarship within subcategories of these larger family types. Most of the research we review was conducted in North America, but we also include studies from Europe, Australia, and New Zealand.

The diverse families we review in this chapter are only some of the family types that could have been included. Space constraints forced hard decisions about what to include. Not included were children who are adopted, in foster families, or whose parent(s) are incarcerated, in military service, or institutionalized. Also not included were families who are considered diverse by virtue of non-normative family interactions (e.g., child abuse, parental mental illness). We focused on family structures we have studied (e.g., unmarried, cohabiting, divorced, stepfamilies, grandfamilies) and family structures that personally interested us (e.g., the bereaved, gay and lesbian parents, and ART families).

We open this chapter by defining family diversity, followed by an examination of theoretical and conceptual perspectives. Next are brief examinations of research on children's development in our selected types of diverse families. We close by offering observations about developmental trends in research trajectories and methodological challenges and concerns in the study of children in diverse families.

## DEFINING DIVERSE FAMILIES

Diverse families, unlike traditional families, often are not formed by marriage, and when they are, the marriage may not be the first for at least one of the adults. The children, therefore, may be genetically related to only one parent, and sometimes to neither parent. Diverse families also may include more than two adults who serve in parental roles, or only one adult, not always a genetic parent, may be rearing children. Legal connections between parents and children, like genetic bonds, also vary widely in diverse families, which potentially has both direct and indirect effects on children's development (Biblarz & Stacey, 2010; Ganong & Coleman, 2004).

In addition, unlike in first-marriage (nuclear) families, families and households are not always equivalent in diverse families. That is, family membership and membership of the households in which the children reside may not coincide. The children often belong to more than one

household and are reared by coparents who live apart from each other. Their families include individuals who are not legally or genetically related to them but are nonetheless involved in helping rear them.

Finally, diverse families may be structurally similar to nuclear families, but the dynamics of the family make them divergent from the "standard." For instance, stepfamily households may appear to be structurally comparable to first-marriage families (i.e., two adults and children), but these appearances may be misleading; many children in stepparent households still have two biogenetic parents involved in raising them, along with one or two stepparents (Ganong & Coleman, 2004). Even when stepchildren have no contact with a divorced parent, there are substantive differences in interpersonal and family dynamics that distinguish stepfamilies from the families of children reared by two continuously married parents (Ganong & Coleman, 2004).

Children in diverse families, therefore, have often a divergent life course from children reared in other family forms (Ganong & Coleman, 2004). In fact, many children reside in more than one type of diverse family as unstable parental unions and changes in household membership may result in a series of family formations. These divergent personal and familial histories create challenges for developmental scholars faced with designing studies and utilizing theories that allow them to adequately assess these assorted pathways of family life.

## THEORETICAL AND CONCEPTUAL PERSPECTIVES

For decades, scholars have shown interest in examining socialization practices and children's development in families called, among other things, *nontraditional*, *deviant*, *alternative*, and *nonnuclear*. When scholars study child development in diverse families the implication is that these families diverge from some standard or normative form of family life. Although Lerner (2006), in the sixth edition of this *Handbook*, asserted that developmental scholars no longer ignore context and instead account in their scholarship for the variable effects of time, place, and interpersonal influences on individuals, he also recognized that there continues to be research on human development in which models are proposed "that *a priori* sets one group as the standard for positive or normative development and where another group, when different from this normative one, is therefore defined as being in deficit" (p. 7).

This deficit-comparison approach to developmental science continues to be a norm in the study of children (and parents) in most types of diverse families.

The standard by which all other families are compared has most often been labeled the “traditional family” (e.g., Lamb, 1982), but also has been known by other labels, including the Standard North American Family (SNAF; Smith, 1993), nuclear families, first-marriage families (Ganong & Coleman, 2004), natural families (Farber, 1973), and intact families. These “traditional” families typically are characterized by two parents, one of each sex, and their genetic offspring, with all family members residing in one household. For some scholars, these characteristics are enough for a family to be considered as traditional, but for most scholars distinctive family dynamics also must be in place (e.g., parental roles assigned by sex, primary childrearing done by the parents). For example, in an edited volume, *Nontraditional Families*, published over 30 years ago, which included chapters on dual-earner couples, families with children in daycare, shared coparenting among married parents, cohabiting couples, post-divorce families, and stepfamilies, Lamb (1982) identified four principal axioms or beliefs related to the presumed superiority of traditional families as places to rear children: (1) children need a mother and father, (2) fathers should be the primary or sole economic providers and mothers should be the main caretakers, a division of labor that is reflected by societal norms, (3) mothers are naturally more suited to raising children than are fathers, and (4) children should be reared by kin rather than by family outsiders. Although families in industrialized nations have changed considerably, these decades-old axioms persist to some degree.

In the United States and other Western industrialized nations, the continuation of heterosexual, first-marriage, nuclear families as the comparison standard for other families and for the well-being and development of children has been influenced not just by science, but also partly by societal and religious norms. For instance, since the beginning of the 21st century, the U.S. government has spent millions of dollars promoting the creation and maintenance of “healthy marriages and families,” a code term for first-marriage heterosexual families, primarily because such families are seen by religious, political, and social conservatives as the best or only form of family to enhance the well-being of children and adults (Acs, 2007). As we review research and theory about children in diverse families in this chapter, we attend not only to the application of scientific principles in these bodies of literature, but also to the role that cultural and personal

values have played, at least in some of the reviewed areas of scholarship.

### Epistemic Values

Over two decades ago, Clingempeel, Flescher, and Brand (1987) argued that the study of the effects of parental remarriage on children was influenced by two types of firmly held values, epistemic and nonesepistemic. Epistemic values about how research on children and their families should be conducted are the scholarly standards each social and behavioral science discipline attempts to inculcate in students via research methods courses, research practicum experiences, theses, dissertations, and other mentored experiences. Clingempeel et al. (1987) identified three such epistemic values that they asserted were limiting what was known about stepchildren: (1) a between-groups comparison bias, (2) a disciplinary ethnocentrism bias, and (3) the rational objectivity bias. The *between-groups bias* limited researchers to questionable choices of comparison groups in studies of stepchildren. Unlike true experimental designs in which researchers can randomly assign children to groups and control the independent (causal) variables to determine effects, naturally occurring family groups often differ from other families on multiple dimensions. They may be inherently nonequivalent in important, but perhaps unknown, ways that affect the outcomes of the dependent variables of interest (Clingempeel et al., 1987). This is known as the selection effect, and Clingempeel and colleagues thought that scholars neglected this when designing studies of stepchildren, particularly in choosing comparison groups of children and families.

The *disciplinary ethnocentrism bias* refers to conventional barriers to learning about and understanding methods, theories, and ways of conceptualizing research taught in other disciplines in which children and their families also are studied. For example, sociologists emphasize different dimensions of research and take different approaches to children and families than do psychologists. Disciplinary ethnocentrism occurs when scholars do not take a multidisciplinary lens to children and their families and “consequently, important research questions which lie at the cross points of several disciplines may remain unexamined, and the development of an integrated knowledge base may be impeded” (Clingempeel et al., 1987, p. 243).

Finally, the *rational objectivity bias* refers to adherence to a philosophy of science in which researchers strive for

detached distance between research subject and scientist. This bias, rooted in logical positivism, contends that researcher objectivity is a reachable goal that scientists may achieve by following accepted guidelines for studying children and families. We revisit these specific epistemic values later in this chapter after reviewing research on multiple forms of structurally diverse families, but for now we focus on the relevant notion that research on the effects on children of living in diverse families may be influenced by researchers' epistemic values. The fact that this is not "news" to most developmental scholars makes it no less significant when considering this vast body of research.

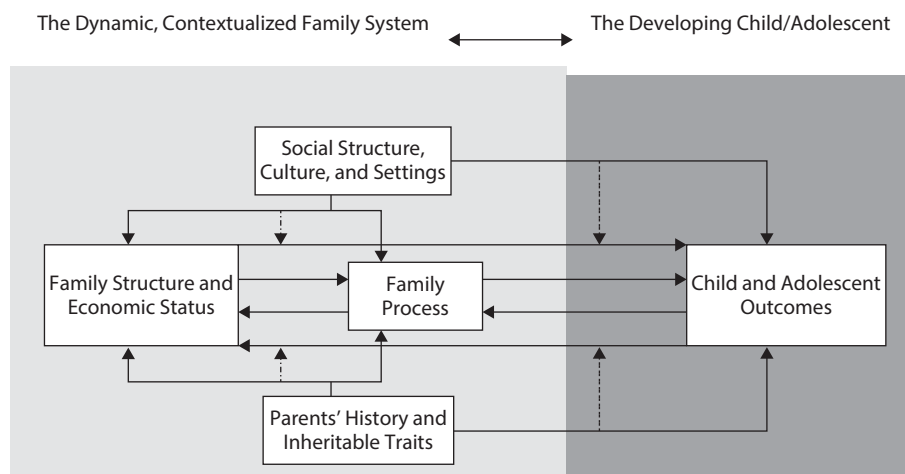

### Nonepistemic Values

In developmental sciences, epistemic values intersect with what Clingempeel et al. (1987) called *nonepistemic values*. These values are personal beliefs held by scholars, acquired via socialization by parents and other family members, religious and educational institutions, mass media, and other societal agents. The four assumptions about children's development that Lamb (1982) identified are good examples of nonepistemic values that may influence researchers. Of course, not all researchers within given areas of investigation adhere to common sets of personal values. Nonepistemic values are often based on cultural beliefs and usually represent widely held societal norms. There is variability in scholars' adherence to societal norms, however, and scholars who study children and their diverse families represent a wide array of cultural and

subcultural groups. We should expect to find some variability in the nonepistemic values found in any given body of literature. However, researchers are self-selected into their disciplines in general and into their programs of research in particular, driven by a plethora of motivations to study certain groups, to ask specific questions, and to employ some theories over others (Luker, 2008). As we have noted, the study of diverse families is an area of investigation heavily laden with personal and cultural values.

### Relational Developmental Systems Perspectives

Strong theory can offset personal biases and societal values, and a number of theoretical perspectives have been employed in the study of children's diverse families. Many of these theories or conceptual frameworks fit comfortably under the metatheoretical umbrella of relational developmental systems (Lerner, Lewin-Bizan & Warren, 2010). This family of theories includes Bronfenbrenner's bioecological model of development, life course perspectives (see Elder, Shanahan, & Jennings, Chapter 2, this *Handbook*, this volume), resilience models of development (see Masten, Narayan, Silverman, & Osofsky, Chapter 18, this *Handbook*, this volume), and Crosnoe and Cavanagh's (2010) integrative model for research on children and adolescents (see Figure 4.1). This metatheory embraces diversity, plasticity, and multiple levels of systemic influences, with the focus of the theory being the mutually influential relations between the developing individual and the multiple levels of the individual's changing context. Family is a primary context for individual development,

**Figure 4.1** Integrative model for research of families with children and adolescents.

Source: "Families with Children and Adolescents: A Review, Critique, and Future Agenda," by R. Crosnoe and S. E. Cavanagh, 2010, *Journal of Marriage & Family*, 72, pp. 594–611.

and changes to family structure or processes are of crucial importance in understanding how children develop, just as changes in children influence alterations in their familial contexts (Lerner & Overton, 2008). The relational developmental systems metaperspective is a logical framework for the study of children's development in diverse families, with other systems included in study designs as well: children and their families embedded in neighborhoods and broader communities, interacting with school, legal, work, and faith systems, and being affected by societal and cultural influences. Several other chapters in this *Handbook* focus on these nonfamilial contexts; here, we focus mostly on family as context.

Among scholars who have focused on family structure diversity, there has been a general convergence across disciplines and across bodies of literature on how children in diverse families should be studied. This convergence reveals implicit but broadly held conceptual and theoretical agreements on how family structure, economic status, and family processes intersect with social contexts and parental variables to influence children's outcomes (Crosnoe & Cavanagh, 2010). This integrative model is clearly within the relational developmental systems metatheory family.

An important feature of the relational developmental systems perspective is a holistic view that rejects dichotomies, including the distinction between basic and applied research (Lerner & Overton, 2008). This is pertinent because there are multiple reasons to apply findings from developmental science to policy and interventions with diverse families, as well as motivations to conduct research on programs designed to facilitate developmental adaptations for children and their families. We examine several such research efforts in this chapter.

## CHILDREN LIVING WITH UNMARRIED PARENTS

Here we focus on children living with unmarried parents, both single (i.e., living alone) and cohabiting biological parents. Reviewing research on children living with either unmarried single parents or with unmarried cohabiting parents—and together considered as one type of diverse family—is somewhat problematic because this categorization schema conflates marital status (single) and relationship status (unmarried and alone or unmarried and cohabiting). We treat these families as one form of family diversity with two subgroups, in part because researchers often examine children from these two subgroups in the

same studies, and also because of the fluidity with which unmarried parents dissolve and enter relationships make it logical to jointly consider these subgroups.

Among the most widespread changes in children's living arrangements in Western industrialized nations over the past 30 years have been the large increases in unmarried childbearing by single women and by unmarried cohabiting parents (Popenoe, 2009). By far the largest group of children living with a single parent (12% of the total number of U.S. children under 18) resides with a mother or a father who has never been married (U.S. Census Bureau, 2011). In the United States, about 40% of births are to unmarried mothers; the number of American children born to single mothers has tripled in 25 years (Martin et al., 2009), and increased by 800% since 1960 (Ventura, 2009). The proportion of unmarried births has increased even more in Australia and in several western European nations (Popenoe, 2009). The number of childbearing cohabitating unions also has dramatically risen. For instance, approximately 20% of American children were born to unmarried cohabiting parents at the start of the 21st century (Kennedy & Bumpass, 2008).

These demographic data indicate that marriage and childbearing have become disconnected for a substantial segment of the population. This decoupling has been due, in part, to declining economic and cultural incentives to marry and reduced stigma and social sanctions associated with unmarried parenthood (Ellwood & Jencks, 2004). In the United States, particularly among low-income individuals, marriage has taken on such symbolic importance as an achieved status that young adults postpone marriage, but not having children, until they feel they have reached certain economic and relationship standards (Edin & Kefalas, 2005). Consequently, unmarried parenthood is an emerging family form that is chosen most often by low-income individuals (Wu, 2008). These families are known as *fragile families*, in part because of the extreme instability of household membership among unmarried and cohabiting parent households, and in part because of an influential longitudinal U.S. research project known as the *Fragile Families and Child Well-Being Study* (<http://www.fragilefamilies.princeton.edu/>).

Although marriage and parenthood have become disconnected in most of the Western world, in Europe unmarried and cohabiting parents are far more likely than those in the United States to be middle class, well educated, and in stable unions (Allan, Hawker, & Crow, 2001). In this section we focus primarily on unmarried families in the United States.

### **Characteristics of Unmarried Mother and Unmarried Cohabitation Households**

Unmarried mothers who give birth, alone or within the context of cohabiting unions, are more likely than married mothers to be young, Hispanic or African American, and have lower levels of education (Kennedy & Bumpass, 2008; Wu, 2008). In general, single mothers and cohabiting parents more often live in poverty than do married parents (Kreider, 2008).

#### ***Households Headed by Single Parents***

Children born to unmarried mothers tend to reside with their mothers; nearly 80% of the American children who lived with one parent in 2004 lived with a single mother, and only 10% lived with a single father (Kreider, 2008). Given this unequal distribution, even in large national studies, the numbers of children in single father families are often too small to analyze. Consequently, less is known about children living with single fathers.

Although a greater percentage of unmarried mothers are delaying or avoiding marriage than in the past (Gibson-Davis, 2011), they do not lack romantic involvement with one or more partners. Determining how many partners single parents have had, however, is difficult. Cross-sectional designs often provide information only about the current relationship status of parents, and even longitudinal data sets seldom afford researchers the opportunities to assess parental relationship histories. One exception is the Fragile Families Study (FFS); Osborne and McLanahan (2007) examined the number of romantic partnerships new mothers had over a 3-year period. Unmarried mothers who lived apart from their children's biological fathers at birth were far more likely to have had relationship transitions than were married or cohabiting mothers, and to have substantially more relationships (Osborne & McLanahan, 2007). Over 20% of mothers who had visiting (noncohabiting) boyfriends when children were born, and 30% who were unpartnered at the child's birth, had three or more romantic relationships in the 3 years after giving birth. African American and Hispanic children experienced more maternal partnership transitions than European American children.

#### ***Cohabiting Parent Households***

Children in cohabiting parent households are about twice as likely as children of married parents to undergo a parental breakup, particularly at a young age (Manning, Smock, & Majumdar, 2004). Although European American

cohabiting parents who married each other increased the odds of family stability for children, Hispanic and African American cohabiting parents who married did not increase family stability (Manning et al., 2004). These ethnic differences may be related to economic resources. Married parents generally have greater economic resources than cohabiting parents, but marriage boosts economic resources for Hispanic and African American families less than for European Americans (Manning & Brown, 2006), which may reduce the protective effect or so-called marriage benefit them.

The instability of household membership in unmarried single and cohabiting parent households means more than frequent family transitions—it also means children have a much greater likelihood than those in married-parent households of having more complex families as a result of their parents' reproducing with multiple partners (Cancian, Meyer, & Cook, 2011). Multiple partner fertility is common among fragile families; 60% of children born to unmarried mothers have at least one half-sibling through either one or both parents (Cancian et al., 2011). The presence of half-siblings enhances the odds that household membership will fluctuate.

An estimated 46% of all U.S. children are expected to spend some of their childhood years in a household with a cohabiting mother and her partner (Kennedy & Bumpass, 2008), but this estimate includes cohabitating biological parents and stepparent-parent cohabitations. About half of the children in U.S. cohabiting households live with both of their biological parents (Kreider, 2008). The remaining half consists of children of divorced, bereaved, or never-married parents, almost always a mother, sharing a residence with the parent's romantic partner. Here we focus mainly on children living with unmarried biological parents (children in cohabiting stepfamilies are included in the stepfamily section of this chapter).

### **Child Outcomes: Children With Unmarried Mothers**

The research evidence is clear that unmarried parenthood and the multiple family transitions that often follow are related to poorer developmental well-being for children compared to children living with married parents (Waldfoegel, Craigie, & Brooks-Gunn, 2010). Children living with unmarried mothers are more at risk than children with married parents to perform poorly in school (Crosnoe & Wildsmith, 2011), to have mental health problems, and to exhibit internalizing and externalizing behavior problems (S. L. Brown & Rinelli, 2010). They also are more likely to

have sexual intercourse at younger ages than children born to married parents and to bear children outside of marriage themselves (Hognas & Carlson, 2012).

### **Child Outcomes: Children With Cohabiting Biological Parents**

Research on children living with their cohabiting biological parents is relatively meager, but in general, researchers have found that children living with two unmarried biological parents in cohabiting unions fare worse, on average, than children living with married parents (Artis, 2007; S. L. Brown, 2004, 2006; Gibson-Davis, 2008; Manning & Brown, 2006), and about the same as children in cohabiting stepfamilies (Artis, 2007; S. L. Brown, 2004, 2006; Dunifon & Kowaleski-Jones, 2002; Manning & Brown, 2006) and children living with a single mother (S. L. Brown, 2004). These family structure differences are widespread. For instance, S. L. Brown (2006) found that children in cohabiting families had more emotional and behavioral problems than children with married parents and had less motivation to do well in school. Children living with cohabiting parents are more at risk than children with married parents to be less physically healthy (Schmeer, 2011), to have more mental health problems (Artis, 2007; Waldfogel et al., 2010), to exhibit more internalizing and externalizing behavior problems (Hofferth, 2006; Schroeder, Osgood, & Oghia 2010), and to perform more poorly in school (Crosnoe & Wildsmith, 2011).

### **Explanatory Models**

Several theoretical perspectives have been used to explain why children living with unmarried and cohabiting biological parents fare worse than do children living with both married parents. These models focus on (a) economic resources, (b) parenting skills and parental effectiveness, (c) fathers' involvement, (d) family stability and change, and (e) selection.

#### ***Economic Resources***

Some of the differences in developmental outcomes between children with married and those with unmarried cohabiting parents are due to relative differences in financial resources, parental education, and related social capital available to married parents (Crosnoe & Wildsmith, 2011). Because household incomes are lower, unmarried parents have fewer resources of all kinds to invest in

their children (McLanahan, 1997). Parents may have to work longer hours outside the home to earn enough to survive, which gives them less time to monitor, check homework, play with, and socialize their children (Kendig & Bianchi, 2008). When at home, these parents, often tired from working at physically demanding, low-wage jobs, may have less energy for their childrearing responsibilities (Carlson & Corcoran, 2001).

Lower household incomes disadvantage children in many ways, from having fewer books, computers, and educational toys in their homes to living in poor-quality housing in dangerous neighborhoods and having to attend under-resourced public schools. Cohabiting biological parents are less likely to be employed than married parents, and when employed, their lower educational levels seldom allow them to earn as much as dual-earner married parents for the same number of working hours (Manning & Brown, 2003). They also are less likely to pool their incomes and spend money on children than are married couples (DeLeire & Kalil, 2005).

Resource management is difficult for low-income unmarried mothers and cohabiting parents. In addition to the challenges of trying to manage a household and maintain family members' health and well-being on limited incomes, for parents who have reproduced with multiple partners, decision making about resource allocations often becomes more complex. Parents may have to make difficult judgments about how to distribute their finite resources to multiple children in two or more households. Nonresidential fathers are less likely to support their children after mothers have reproduced with other men (Meyer & Cancian, 2012), which may result in even fewer resources available to children living with single or cohabiting mothers. In addition, nonresidential fathers provide less support for children over time, often because they have additional children to support with new partners (Meyer & Cancian, 2012). Although negative effects of unmarried parent families may be mostly attributed to poverty (Crosnoe & Wildsmith, 2011), there are other factors, many of which have to do with parents' effectiveness and involvement in rearing their children.

#### ***Parental Skills and Effectiveness***

It is more difficult for unmarried mothers and fathers to engage in effective parenting practices than it is for married parents—strains related to the lack of economic resources, poorer parental mental health, and coparental conflicts negatively affect unmarried parents' effectiveness at raising children (Cavanagh & Huston, 2006). Unmarried and

cohabiting parents are less likely than married parents to engage in authoritative parenting practices and more likely to be either punitive or detached parents (Waldfoegel et al., 2010). When they do practice authoritative parenting, however, their children do better in school and exhibit fewer behavioral problems than children in cohabiting households with less-warm parents who set fewer rules (Dunifon & Kowaleski-Jones, 2002).

Living in poverty is stressful, and stress affects parents' mental health (S. L. Brown, 2004). There is evidence that single and cohabiting mothers are more likely to be depressed than mothers in other family structures (S. L. Brown, 2004). Because they may be less effective parents than mothers who are not depressed, their children's needs may not be met (Klausli & Owen, 2009). Parental anxiety also interferes with how effectively parents interact with their children (Carlson & Corcoran, 2001). Evidence from the Fragile Families Study indicates that partner instability increases mothers' and fathers' anxiety, particularly after a relationship transition (Waldfoegel et al., 2010).

How well unmarried coparents cooperate, particularly when making decisions about children, is predictive of children's well-being (Klausli & Owen, 2009). Coparental conflicts are harmful to children's emotional well-being (Cummings & Davies, 2002), and unmarried mothers' relationships with dating or "visiting" partners and unmarried cohabiting parents' relationships are less cooperative and more conflicted than married parents' relationships (S. L. Brown & Booth, 1996). There also may be indirect benefits for children when parents' romantic relationships are of higher quality—satisfaction with partner relationships may enhance parenting effectiveness and reduce household stress, which consequently benefits children (Waldfoegel et al., 2010). Having a partner or coparent may allow parents to monitor, supervise, and be more involved with children than when they are the sole parent (Demuth & Brown, 2004). Single mothers, but not mothers in cohabiting couples, spend less time with their children than do married mothers (Kendig & Bianchi, 2008).

### **Fathers' Involvement**

Given the economic and other resource deficits experienced by most unmarried mothers and by many cohabiting parents, the possibility that greater father involvement in childrearing would be related to benefits for children's well-being makes sense theoretically (King, 2009). Involved fathers potentially make additional resources available to children and augment their care by mothers. Greater investment of father's time and economic resources

in parenting should enhance children's well-being (Waldfoegel et al., 2010). Conversely, father involvement harms children if (a) fathers do not share economic resources with children, (b) they drain household assets rather than add to them, (c) they physically abuse children, mothers, or both, or (d) they have mental health issues or substance abuse problems (King & Sobolewski, 2006). When non-residential fathers are actively engaged with children and have close ties to them, children's well-being is enhanced (Amato & Gilbreth, 1999; King, 2009; King & Sobolewski, 2006). Secure attachment between children and nonresidential fathers can help children adapt to changes in family structure (Schroeder et al., 2010). King and Sobolewski (2006) found that strong relational ties to nonresidential fathers were related to children having fewer behavioral problems and making better grades, but weak ties to fathers were related to more behavioral problems unless the children were close to their mothers. Being close to mothers was almost as positive for children's well-being as being close to both parents. Being close to fathers only was helpful, but not as helpful as close maternal ties.

Involvement in childrearing by residential biological fathers has also been found to be positively related to children's well-being in unmarried cohabiting families (L. M. Berger, Carlson, Bzostek, & Osborne, 2008; Carlson, 2006). Residential fathers' effects are greater than those of nonresidential fathers (Carlson, 2006). Involvement by residential stepfathers, often called *social fathers* in the research on children of unmarried parents, can also benefit children's development (Bzostek, 2008), but the inclusion of a new romantic partner in an unmarried parent household complicates childrearing (Carlson, 2006). For instance, nonresidential fathers often reduce involvement with their children when a social father starts living with them (King, 2009; Meyer & Cancian, 2012). Nonresidential fathers and social fathers have been known to "swap" children (Furstenberg, 1995). That is, they parent the children they live with but reduce or cut ties with their biological children living elsewhere. Mothers encourage social fathers to assume parental responsibilities for their children (Burton & Hardaway, 2012), making a point to select men who are willing to do so (Tach, Mincy, & Edin, 2010). The net effects on children of these complex mother-father-child relationships are not entirely clear. Much more research is needed on the effects of multiple parent-figures, particularly multiple father figures, on children living with unmarried parents.

Finally, a study by Hawkins, Amato, and King (2007) has called into question the direction of effects of father

involvement and adolescent well-being. Their study, using nationally representative longitudinal data from the Add Health data set, did not support a nonresidential father-effects model; instead, levels of adolescent well-being influenced how involved fathers were in their children's lives. This child-effects model indicated that adolescents' problem behaviors caused fathers to disengage, rather than fathers' engagement contributing to better adolescent behavior. These effects should be examined with other data sets and with children from other family structures.

### *Family Stability and Change*

Given the greater instability of unmarried and cohabiting parent households, deconstructing the effects of family instability from family structure effects is difficult (Wald-fogel et al., 2010). Most researchers have reported that greater instability in parental romantic relationships or in household membership are related to greater negative effects on children's development (e.g., Cavanagh & Huston, 2006; Osborne & McLanahan, 2007). There is evidence that it may not be the number, but the types of family transitions children experience that is developmentally relevant (Manning et al., 2004). For example, in one study the dissolution of cohabiting unions was less harmful for children than divorce (Wu, Hou, & Schimmele, 2008).

In general, losing a parent's presence in the home is more stressful for children than living with one parent only (Liu & Heiland, 2012). Not all studies, however, have reported worse outcomes for children transitioning from cohabiting two-parent to one-parent households (S. L. Brown, 2006; Schmeer, 2011; Schroeder et al., 2010). Transitions that result in the absence of a disruptive household member may enhance children's development rather than harm them (S. L. Brown, 2006). Conversely, the addition of an involved stepparent who brings social capital and other resources into the family may be a benefit that results in better developmental outcomes for children. Consequently, gaining a stepparent in the household can either negatively or positively affect children's well-being and behavior (S. L. Brown, 2006; Schroeder et al., 2010).

The effects of household transitions vary somewhat by ethnicity (see McBride et al., Chapter, 11, this *Handbook*, this volume). Osborne and McLanahan (2007) reported that partnership instability negatively affected Hispanics more than European American children, and Fomby and Cherlin (2007) reported that changes in parents' cohabitation status were related to increased behavioral problems for European American, but not African American children. Being reared

by an unmarried parent may be harder on European American children than African American and Hispanic children (Dunifon & Kowaleski-Jones, 2002). These ethnic differences in transition effects may be related to cultural variations in the extent to which community supports unmarried parenthood (Fomby & Estacion, 2011).

Nock (1995), borrowing a concept Cherlin (1978) applied initially to remarried stepfamilies, called cohabiting families incomplete institutions that lacked broad cultural and societal support, which made family life more stressful and, therefore, more prone to conflicts and dissolutions. The meanings attached to dissolution of nonmarital unions or the creation of a nonmarital stepfamily may differ for family members belonging to different ethnic communities (Fomby & Estacion, 2011). More research is needed on how ethnicity mediates family transitions and family structure effects.

### *Selection Effects*

Selection effects refer to observed and unobserved influences on children, parents, and families that differ from first-marriage families as the standard and that also may affect children's development. These preexisting characteristics or attributes may obscure effects on children due to family structure. Thanks to analytic strategies that allow for more careful examinations of possible selection effects, such as fixed effects analytic models and difference-in-difference approaches (Berger et al., 2008; Meyer & Cancian, 2012), and statistical matching models (Liu & Heiland, 2012), more researchers are addressing selection effects. Fixed effects analytic models, in which invariant characteristics of children and families are statistically removed in an attempt to control for unobserved differences, have been used to control for selection effects. Unfortunately, these approaches cannot identify specifically the unobserved differences between family types if selection effects are found, and they can lead to somewhat different results within the same investigation (Meyer & Cancian, 2012).

Potential selection effects in the study of children with unmarried and cohabiting parents include parental values and beliefs about childrearing, marriage, and family life that may differ from parents in other family structures. Motivations to enhance children's educational attainment and knowledge about healthy childrearing practices may vary as a consequence of parental education, age, income, and neighborhood resources (Kowaleski-Jones & Dunifon, 2006). Ethnicity also may be related to preexisting conditions that affect parents and children from diverse family

structures in different ways (e.g., Fomby & Estacion 2011; Kowaleski-Jones & Dunifon, 2006).

### *Interventions With Unmarried and Cohabiting Parents*

Findings related to children's outcomes when parents are single or cohabiting have led to concentrated efforts to enhance children's well-being by changing their parents' marital status (Acs, 2007) and by teaching couple and coparenting skills to low-income unmarried parents (Wood, McConnell, Moore, Clarkwest, & Hsueh, 2010). Although a focus on teaching parental skill building is not new, the U.S. Healthy Marriage Initiative, started under George W. Bush and continued by President Obama, has been a policy initiative that funneled millions of federal dollars into training programs for low-income unmarried parents (Wood et al., 2010). In general, there is little evidence that such educational interventions improve parents' skills long-term or that children indirectly benefit from such parent education efforts (Wood et al., 2010). Similarly, programs designed to enhance fathers' engagement with their children and with coparents have not consistently yielded affirming results (Wood et al., 2010). Unfortunately, most interventions with unmarried parents have not been carefully evaluated with control groups and sound measurements, so interpretation of the findings from this body of work has been challenging.

### *Methodological Concerns*

Reviewing research on the well-being of children who live with an unmarried parent is challenging for two reasons. First, in many studies it is not clear who is included in the category of "children with unmarried parents." Some study samples include children and adolescents living with divorced or bereaved single parents as well as never-married parents. Despite sharing the social address of living with a single parent, these children have had quite different life courses. Unless researchers deconstruct the category of single-parent families into subtypes for analyses, it is likely that the category of single-parent families in some studies is not homogeneous. There are ways to analyze data to either statistically control or to examine differences between types of unmarried parent households (e.g., fixed effects analytic strategies), but not all researchers have employed such strategies.

A second challenge is related to the relationship instability of unmarried mothers and fathers—cross-sectional study designs can miss children's transitions into and out of various types of two-adult household configurations. It is possible for researchers to assess these transitions in

longitudinal studies, but if data collection periods are far apart, and survey questions do not account for transitions between time periods, some transitions may be missed.

Child well-being differences between married and cohabiting parent households sometimes disappear when controls are added (e.g., Manning & Brown, 2006; Wu et al., 2008). For instance, Manning and Brown (2006) found that marriage benefited European American children more than children of color. Artis (2007) found that without statistical controls, children of married parents exhibited greater well-being (i.e., school performance, sadness/loneliness, and self-control) than children in cohabiting biological and stepfamilies, but with economic resources, maternal depressive symptoms, and parenting practices added to statistical models as controls, family structure differences were found only in reading skills. In most studies of children's development in unmarried cohabiting households, however, structural differences between family types remained after controls were added.

### *Summary of Research on Children in Unmarried and Cohabiting Households*

There is consensus that well-being is lower for children living with unmarried or cohabiting parents, compared to those residing with married parents. These outcomes are likely due primarily to the harmful effects of poverty and family transitions, both phenomena predictive of negative outcomes for children (see Acs, 2007). Poverty and household transitions are stressful for family members, and parenting quality and engagement are diminished by them and by related environmental conditions (e.g., relocations, work hours, dangerous neighborhoods). There is growing evidence that specific aspects of family transitions affect children—relationship quality, who leaves and enters the household, whether resources are added or subtracted from the children's household, the developmental timing of transitions, and frequency of changes. There is widespread concern about improving the well-being of parents and children in low-income unmarried and cohabiting families, but interventions generally have not been effective.

## **BEREAVED CHILDREN**

Approximately 4% of U.S. children under the age of 18 live with a widowed parent (U.S. Census Bureau, 2011). The death of a parent is among the most stressful experiences a child can have (Yamamoto et al., 1996). It permanently

disrupts a significant attachment relationship and, consequently, may have profound effects on children's sense of identity and security. There is a long, substantial body of research establishing bereaved children's vulnerabilities to a multitude of negative consequences, including grief (Melhem, Porta, Shamseddeen, Payne, & Brent, 2011), emotional and psychological distress (Silverman & Worden, 1992), depression (Cerel, Fristad, Verducci, Well, & Weller, 2006; Melhem et al., 2011), separation anxiety (Lin, Sandler, Ayers, Wolchik, & Luecken, 2004), delinquent and criminal behavior (Draper & Hancock, 2011; Wilcox et al., 2010), alcohol and substance abuse (Brent, Melhem, Donohoe, & Walker, 2009), other health-compromising behaviors (Wilcox et al., 2010), and changes in identity and self-esteem (Brent et al., 2009). Although most children do not develop clinical symptoms following parental death (Kaplow, Layne, Pynoos, Cohen, & Lieberman, 2012), or continue to suffer serious long-term negative effects (Luecken & Roubinov, 2012), the loss of a parent is a profound, life-changing experience, often accompanied by other changes in children's lives (e.g., relocations, changes in routines, loss of parental support, financial deprivations). It is not surprising that the research focus has been on negative child outcomes.

### *Cause of Death and Outcomes*

For most children and adolescents, parental death is an unexpected life course event. Findings are mixed as to whether the negative effects are more intense and longer lasting when parental death is anticipated (e.g., terminal illness), or when the demise is sudden (e.g., suicide, violent death, accident). Some evidence suggests unexpected death trauma is greater for children than anticipated loss of life (Brent et al., 2009; Cerel, Fristad, Weller, & Weller 1999, 2000), but not all researchers found child effects differences due to suddenness of the fatality (A. C. Brown, Sandler, Tein, Liu, & Haine, 2007); some found longer anticipations of death were related to poorer child adjustments (Saldinger, Cain, Kalter, & Lohnes, 1999).

Several studies have focused exclusively on children whose parents committed suicide (Wilcox et al., 2010). Suicide is described as a "confusing death" (Cerel, Jordan, & Duberstein, 2008, p. 39) because of assorted reactions of family members and the wider community. Suicide is stigmatized in Western societies, which results in less social support from outsiders than other bereaved individuals; social network members feel awkward and unsure about how to offer emotional support. Family members also may try to keep the cause of death a secret due

to feelings of shame (Cerel et al., 2008). A propensity for children to blame themselves and other family members for suicide has been noted by researchers, and following suicide there may be more interpersonal conflicts, less clear communication, and less mutual support within families throughout the grieving process than after parental death by other causes (Cerel et al., 2008; Ratnarajah & Schofield, 2007). Premorbid family dynamics and the mental health of family members may distinguish these families from other bereaved families, and these potential premorbid differences have implications for children's grieving and adjusting (Cerel et al., 1999, 2000). Others have argued, however, that "pre-suicide and post-suicide family functioning that are either protective or risk factors for [child] adverse outcomes are simply unknown" (Cerel et al., 2008, p. 41).

### *Demographic Predictors*

In addition to cause of death, numerous other child or family demographic characteristics have been examined as predictors of post-bereavement risk and vulnerability, such as age and sex of children and family income. These variables have not been found to consistently predict children's reactions to parental mortality.

### *Theories of Child Bereavement*

Although several theories have been proposed to explain family bereavement processes (Rothaupt & Becker, 2007), they ignore developmental differences between adults and children in cognitive understanding of death, emotional maturity, identity, and other intrapersonal phenomena that likely affect grieving processes. Research on bereaved children suggests that their grieving processes are different from adults' due to cognitive differences in how death is understood and experienced (Kaplow et al., 2012). For example, effects of unexpected death on children are less clear than effects on adults, who fare worse than children (Kaplow et al., 2012).

Most studies on childhood bereavement have not been explicitly framed from a theoretical perspective. The common assumption of virtually all researchers, however, that parental death is traumatic and stressful for children lends itself to the widespread use of risk and resilience perspectives. A few studies have been based on attachment theory, and there have been grounded theory studies on bereavement, examining how parents may assist children in remembering the deceased parent (Nickman, Silverman, & Normand, 1998).

### ***Risk and Resilience Perspectives***

Among scholars using a risk and resilience framework there is general recognition that studying children's outcomes in response to parental death without considering family functioning, community effects (sociocultural and environmental mediators), and intrapersonal mediators (e.g., constructing meaning from the death) is inefficient (see Masten et al., Chapter 18, this *Handbook*, this volume; Ratnarajah & Schofield, 2007). Family functioning variables include the quality of family relationships prior to parental death (Cerel et al., 2008), interactions between the surviving parent and child (Haine, Wolchik, Sandler, Millsap, & Ayers, 2006), the mental health (Kalter et al., 2002) and adjustment to loss of the surviving parent and that parent's abilities to maintain family routines and meet children's needs (Caughy, Huang, & Lima, 2009). Family stressors such as parental substance abuse, domestic violence, and marital separations also are seen as relevant to understanding children's adjustment to parental death (Gray, Weller, Firstad, & Weller, 2011). Community system supports such as support groups and grief counseling are seen as relevant considerations (Cerel et al., 2008). How children cognitively and emotionally process a parent's death is relevant (Ratnarajah & Schofield, 2007; Shear & Skritskaya, 2012).

Based on a review and critique of the childhood bereavement literature, Luecken and Roubinov (2012) proposed a risk and resilience model of how the stress of parental death disrupts children's biological regulatory systems and increases the risk of long-term physical health problems. In this model, parental death affects the distal risk and protective factors of parent-child relationship quality, along with caregiver mental health and other negative life events that often co-occur with parental death. These factors in turn affect children's self-esteem, self-efficacy, and social relations. The effects of these distal factors on long-term physical and mental health are mediated by children's threat perception and appraisal, emotion regulation, emotional reactivity, and biological stress reactions. Parts, but not all, of this model have been examined by researchers (Luecken & Roubinov, 2012).

### ***Research Limitations and Challenges in Studying Bereaved Children***

Studying bereaved children is challenging. Death is a sensitive and emotionally charged topic, and there are ethical concerns about studying bereaved children and surviving parents, which creates methodological limitations.

First, the research often has been characterized by small convenience samples, which lowers statistical power and reduces researchers' ability to generalize findings (Luecken & Roubinov, 2012). Samples of bereaved children are hard to obtain, so researchers usually rely on newspaper ads, obituaries in newspapers, funeral homes, and clinical rosters from hospitals and clinics to obtain samples (Cerel et al., 2006; Gray et al., 2011). It is often impossible to determine how representative such samples are, and the frequent overreliance on clinical groups confounds multiple risk factors (Kaplow et al., 2012). There are exceptions, such as Draper and Hancock's (2011) use of the U.K. National Child Development data set and Wilcox et al.'s (2010) use of national registers in Sweden, but most are convenience samples.

Small samples lead to problems—for instance, seldom included are enough children from ethnic minority groups to allow researchers to examine possible cultural differences in how grief and loss are experienced (see Bornstein, Jager, & Putnick, in press, for a review of sampling problems in developmental science). Because samples of children of different ages are too small to examine separately, researchers' have limited abilities to compare grief and adjustment to parental mortality across developmental periods.

Although longitudinal designs are rare (for exceptions see Cerel et al., 1999; Melhem, Moritz, Walker, Shear, & Brent, 2007; Sandler et al., 1992), a consensus has formed among researchers that the normative course of grieving and recovery from parental death is a period of acute sadness and distress, followed by a gradual return to healthy functioning without evidence of impairment (Luecken & Roubinov, 2012). Little is known, however, about the effects of later transitions in family structure (e.g., parental remarriage, cohabitation) on children and the cumulative effects of bereavement and other family changes. Furthermore, without developmental evidence from well-controlled longitudinal studies that include appropriate comparison groups, researchers are challenged to distinguish between normative grief reactions and clinically significant prolonged psychological and social maladjustment and complicated grief (Kaplow et al., 2012). Across studies, about 5% to 10% of children develop clinically defined problems over time as a result of parental death (Kaplow et al., 2012). More research is needed to delineate the predictors of adaptive and complicated grief.

Since researchers have focused predominately on negative outcomes for children, we know little about positive responses to parental mortality. Researchers rarely

examine the possibility of children experiencing long-term positive outcomes after parental death (for an exception see Wolchik, Coxe, Tein, Sandler, & Ayers, 2008). Biological stress responses are seldom measured (Luecken & Roubinov, 2012). Expansion of the types of outcomes measured would yield a more complete picture of children's grieving processes.

Comparison groups also have been problematic. Some studies had no comparison groups, or comparison groups were obtained via convenience sampling. Often, the samples have been a mixture of community-based (from schools, churches, community groups) and clinically identified children (e.g., depressed children at a university clinic), or nonbereaved children, a group much larger and more demographically diverse than the target group of bereaved children. As in many studies of children in diverse families, the appropriateness of the comparison groups depends on the research questions being addressed. In many studies of bereaved children, the comparison group was children living with both parents, with the only difference between groups being parent mortality.

Finally, with few exceptions (e.g., Nickman et al., 1998), intervention studies have not been conducted on effective ways of assisting children to cope with parental death. The Family Bereavement Program has been one of the few to investigate interventions with bereaved children. Using an experimental design, 244 children and caregivers from 156 families participated in 12 sessions of family activities and small group activities designed to enhance positive coping strategies, reducing negative thoughts, and communicating to children that caregivers and others understood their grief and other feelings (Sandler et al., 1992). Short-term and longer-term (11 months) follow-ups indicated benefits to children from participating. Another study from this team found that posttraumatic growth was positively related to active coping, seeking support from surviving parents, threat appraisals, and internalizing and externalizing problems (Wolchik et al., 2008).

### ***Summary of Bereaved Children***

Empirical evidence from the past two decades on children in postbereavement single-parent families has been generated primarily from three projects: The Family Bereavement Program (A. C. Brown et al., 2007; Sandler et al., 1992; Wolchik et al., 2008), the Grief Research Study (Cerel et al., 1999, 2000, 2006; Gray et al., 2011) and the Impact of Parental Death Study on Children (Brent et al., 2009; Hamdan et al., 2012; Melhem et al., 2011). The preponderance of evidence is that children adapt to

this loss over time and surviving parents' coping helps children adjust (Nickman et al., 1998), but more research is needed on the mechanisms by which parents and other caregivers can assist children in mourning.

## **CHILDREN IN SINGLE-PARENT FAMILIES AFTER DIVORCE**

Divorce rates in the United States reached a peak (5.2 divorces per 1,000 population) in the 1970s, and then leveled off to around 3.6 divorces per 1,000 population, where it remains (U.S. Census Bureau, 2011). In 2011, over 5 million children lived with a divorced single mother, and approximately 1.2 million lived with a divorced single father (U.S. Census Bureau, 2011). Because so many children are affected by parental divorce, it has been studied extensively, with nearly 2,000 articles listing divorce as a key topic published since 2000 (Amato, 2010).

### **The Effects of Divorce on Children**

Children of divorced single parents are most often compared in studies to children in continuously married nuclear families, often utilizing large national datasets (e.g., National Longitudinal Study of Youth, National Survey of Families and Households). Effect sizes from these studies are often small, and longitudinal studies have found that the majority of children in postdivorce families do well over time (Amato, 2010). Research on the effects of divorce on children in the United States has continually shown, however, that children with divorced parents compared to children with continuously married parents do less well on social, emotional, behavioral, academic, and health outcomes. For example, children whose parents divorced are more aggressive (Osborne & McLanahan, 2007), engage in more antisocial behavior (Strohschein, 2005), are more prone to delinquency (Videon, 2002) and depression (S. L. Brown, 2006), are less socially engaged (S. L. Brown, 2006), have lower cognitive achievement (Fomby & Cherlin, 2007), and have poorer psychological well-being compared to children with married parents (Amato & Sobolewski, 2001). The most consistent divorce effects are externalizing behavior problems and lower-quality relationships with non-residential fathers (Lansford, 2009).

### **Theories Used to Explain Divorce Effects**

Although feminist theory, attachment theory, attribution theory, symbolic interactionism, family systems theories,

life course perspectives, and social capital models have been employed, most researchers have relied on stress and coping models to explain divorce effects on children (Amato, 2010). The process of divorce is stressful for all family members and involves multiple changes, such as declines in parental economic and emotional support, lack of adequate parental monitoring, loss of time spent with parents (especially nonresidential parents, usually fathers), conflicts between parents, and poor parental adjustments to separation and divorce (Amato, 2010; Sandler, Miles, Cookston, & Braver, 2008). Researchers have focused on transition effects, coparental functioning, and parent-child relationships.

### **Transitions**

Courts in North America and Europe often award joint physical custody to divorcing parents (Emery, 2011), so many children in “single parent households” actually reside part-time concurrently with both biological parents. Periodic changes in household membership due to custody arrangements are accompanied often by new parental partnerships and other household changes (Ganong & Coleman, 2004). More family structure transitions are positively related to greater internalizing and externalizing problems (Osborne & McLanahan, 2007).

### **Coparental Cooperation**

How parents negotiate new roles as nonromantic coparents may affect how children adjust following divorce. Qualitative and small quantitative studies suggest parents who either cooperate or coparent in a business-like fashion experience better child outcomes than disengaged or hostile divorced coparents (Ahrons, 2006). Not all studies agree, however; Amato, Kane, and James (2011) reported little evidence that cooperative coparenting buffered children from the negative effects of divorce on well-being or academic achievement. Study design differences might account for some discrepancies in findings, but more research is needed on the effects of postdivorce coparenting on children.

There is agreement, however, that coparental conflict increases negative outcomes for children (Emery, 2011; Fabricius & Luecken, 2007), and children in joint-custody arrangements whose parents report high conflict experience more psychological problems than do children in sole-custody arrangements (Lee, 2002). Conflict may mediate the relations between divorce and children’s internalizing and externalizing behaviors and interpersonal problems (Amato, 2005).

### **Parent-Child Relationship Quality**

Researchers have generally found that parent-child relationship quality is related to children’s negative internalizing and externalizing behavior (Amato & Sobolewski, 2001; Sandler et al., 2008). Children whose postdivorce relationships with both parents are close exhibit fewer problem behaviors and have higher self-esteem than when one or both parental relationships are not close (Amato & Sobolewski, 2001).

### **Nonresidential Fathers**

Findings from studies in the United States and Europe on fathers’ roles in children’s adjustment postdivorce have been mixed. Some suggest father involvement enhances children’s adjustment (Amato et al., 2011), others find father involvement not related or negatively related to child adjustment (Kalil, Mogstad, Rege, & Votruba, 2011). Father involvement quality appears to be more important than contact time in predicting positive child outcomes (Amato & Gilbreth, 1999). Overall, when divorced nonresidential fathers actively engage with children there are increased positive outcomes and less negative internalizing and externalizing behaviors, as well as delinquency (Amato & Gilbreth, 1999; Sarkadi, Kristiansson, Oberklaid, & Bremberg, 2008). When fathers do not engage in authoritative parenting practices, however, increased contact with them may be detrimental to children’s well-being (Amato & Gilbreth, 1999), particularly among low-income urban youth, who engage in more delinquent behavior when fathers are in contact more (Coley & Medeiros, 2007).

### **Selection Effects and Preexisting Conditions**

To isolate the influence of divorce on children’s outcomes, researchers have investigated selection effects and effects of preexisting conditions, factors that might have differentiated children from divorced families from children in first-marriage families prior to the divorce. Several longitudinal studies have found that increases in negative externalizing (acting out, aggression) and internalizing (depression, anxiety) behaviors often begin to appear as early as 8 to 12 years before parental separation, implying that parents may not avoid negative effects on children by staying together (Furstenberg & Kiernan, 2001; Robbers et al., 2011). Possibly preexisting effects are exacerbated by anxieties that arise during the process of parental separation or divorce. Sun and Li (2002), using pooled time-series models to evaluate data from the National Education Longitudinal Study (NELS), found that children

whose parents divorced had a U-shaped pattern in their academic aspirations, self-esteem, and locus of control compared to peers in continuously married families, with the dip in children's outcomes evident three years before, and a return to higher levels beginning roughly three years after, parents' legal divorce. These findings indicate that some negative outcomes associated with divorce may become exaggerated around the time of the legal divorce but dissipate after children adjust to new family patterns and roles. Such a pattern of effects could explain the disparity sometimes found in fixed effect models attempting to account for selection effects because the possibility that time since parental divorce (or separation) has a curvilinear relationship with child adjustment is unaccounted for in most models (Amato, 2010; Sun & Li, 2002). In some studies using fixed effect models, no associations were found between children whose parents have divorced and those whose parents have been continually married, although others suggested causal impacts of divorce on children (Amato, 2010). Few studies have used fixed effects models, however.

### ***Processes, Moderators, and Mediators of Divorce Effects***

Increasingly, researchers have explored mediators of the relations between divorce and childhood outcomes in attempts to identify factors that differentiate between children who eventually adjust to postdivorce family life and those who do not. Much of this research has focused on how parents manage the coparenting transition after divorce and how parent-child relationship quality and contact, in particular between children and nonresidential fathers, affects child outcomes. There also have been investigations into children's age at divorce (Amato, 2005), exposure to parental conflict (Amato, 2005; Emery, 2011), and the parents' physical or substance abuse (Cummings & Davies, 2002) as mediators and moderators of the links between divorce and child well-being.

### ***Age at Divorce, Sex, and Ethnicity***

Studies have been mixed regarding the effects of divorce timing on children. Infants and toddlers have little understanding of divorce; it is the disappearance of a parent that makes them insecure and anxious (Lamb & Kelly, 2009). There have been concerns among scholars that infants and toddlers may be unable to form secure attachments with caregivers after parental divorce (Emery, 2011), although evidence is mixed. Children generally benefit from being allowed to develop a secure base, while having brief but frequent contacts with nonresidential parents (Emery, 2011;

Pruett, Ebling, & Insabella, 2004), but researchers comparing attachment among children from divorced families with those in continuously married families have seldom found differences in rates of secure attachment (Hamilton, 2000). Though very young children lack the capacity to articulate adjusting to divorce transitions, they may still experience loss and confusion regarding family changes (Clarke-Stewart & Brentano, 2006). Some researchers have concluded that younger children have more difficulty adapting to divorce because they lack cognitive capacity to understand it or to access outside resources to help them cope (Hetherington, 1999). Other researchers, however, have found that risk related to parental divorce escalates with older children (Chase-Lansdale, Cherlin, & Kiernan, 1995). Lansford et al. (2006) found that children whose parents divorced when they were in kindergarten to fifth grade had more internalizing and externalizing symptoms and poorer grades when they were in Grades 6 to 10. Parenting behaviors are more important to children's adjustment to divorce, however, than is age. Although results of studies vary, there are no consistent sex differences related to divorce (Kelly, 2012). Similarly, findings regarding ethnic differences in children's responses to parental divorce are inconsistent, and few studies have examined if there are ethnic differences (Amato, 2010).

### ***Interventions to Support Children Following Parental Divorce***

In the United States, most intervention programs designed to support children and parents following divorce have been initiated by the courts. Typical intervention goals are to enhance coparenting, reduce conflicts, and lower relitigation rates (Wolchik et al., 2002). Few interventions have been evaluated carefully, so effects are often unclear, although a few well-designed intervention studies have shown promise in maintaining and strengthening mother-child relationships, consequently reducing children's mental health problems and externalizing behaviors (Wolchik et al., 2002), and enhancing cooperative coparenting skills, thereby contributing to improved child well-being (Sandler et al., 2008; Sullivan, Ward, & Deutsch, 2010).

### ***Summary***

Although research on divorce effects generally continues to be informed by early characterizations of these children as "troubled, drifting, and underachieving" (Wallerstein, 1991, p. 353), significant progress has been made toward more nuanced understandings of divorce as a complex

process in the lives of children and adults. Early research designs were characterized by simple comparisons between children in nuclear families and those whose parents divorced. Over time, stepchildren, children in cohabiting families, and other groups were included as comparisons, controls were added, and data were explored for mediators and moderators of divorce effects on children. Large representative data sets combined with qualitative and mixed methods designs contributed to a better grasp of the effects of the divorce process on children.

Amato (2010, p. 658) argued “researchers should focus less attention on mean differences between children with divorced and continuously married parents and more attention on the factors that produce variability in children’s adjustment following divorce.” With increased focus on the role of stress, risks and resilience, the effects of multiple transitions, preexisting conditions, and potential moderators or mediators on children’s adjustment to divorce, researchers are better able to understand how divorce affects children and what differentiates those who adjust from those who continue to struggle. Recently, more attention has been paid to selection factors and genetic effects, and longitudinal studies of children pre- and postparental divorce are contributing to clearer, more sophisticated models of divorce effects on children. Although genetically informed designs that explore genetic influences on children’s responses to divorce (e.g., studying offspring of twins and adopted children) have been inconclusive, “future research on gene x environment interactions may help explain why some children are vulnerable and other children are resilient in response to parental divorce” (Amato, 2010, p. 654). Finally, better evaluation of interventions and preventative programs meant to ease the adjustment process of children of divorce are evolving.

## EFFECTS OF STEPFAMILY LIVING ON CHILDREN

In the early 1970s, the most frequent precursor to stepfamily formation in the United States changed from bereavement to divorce (Ganong & Coleman, 2004). Previously, stepparents often were seen as substitutes or replacements for a deceased parent, and stepfamily households typically resembled first-marriage households (i.e., two adults, one of each sex, and one or more children, all residing together under one roof). It gradually became obvious, however, that postdivorce stepfamilies were qualitatively different from postbereavement stepfamilies. Roles in these stepfamilies

were often ambiguous, as were stepparents’ relationships with stepchildren, and clinicians noted that adults and children often struggled to adjust (Ganong & Coleman, 2004).

### *Demographics of Stepchildren*

A child becomes a stepchild when a parent marries or cohabits with a person who is not the child’s other parent. The new partner becomes a stepparent to the child. Accurate demographic data on U.S. stepfamilies have become hard to obtain, but reasonable estimates from Europe (Steinbach, 2008), North America (Kreider, 2008), and Australia (Forster-Jones, 2007) are that 10% to 20% of minor age children live in households with a parent and a stepparent. An estimated one-third of U.S. children will spend at least some of their childhood living with a stepparent (Bumpass, Raley, & Sweet, 1995), and 47% of Americans in a national survey (Parker, 2011) reported having a close step-relative (e.g., stepparent, stepchild). Demographics generally underestimate the numbers of stepchildren because they assess stepchildren in stepparent households only. Stepchildren who reside primarily with a single parent but also have a nonresidential stepparent are not included in demographic statistics of stepchildren, such as those collected by the U.S. Census Bureau.

Because most contemporary stepfamilies are formed after parents’ divorce or the dissolution of cohabiting parents, it is possible that children can have two stepparents concurrently if both biological parents repartner, but there are no reliable estimates of this phenomenon. Given that the divorce rate for remarriages in the United States is higher than that of first marriages (Teachman, 2008), and that about 10% of marriages are third or higher remarriages for at least one spouse (National Center for Health Statistics, 1993), it is probable that some stepchildren have had a series of stepparents throughout their childhood years (Monte, 2011). Increased fertility among cohabiting adults and what has become known as *multiple partner fertility* also have led to increased numbers of children being reared by a series of stepparents in cohabiting stepfamilies (Carlson & Furstenberg, 2006).

### *Stepfamily Structural Complexity*

Stepfamilies are structurally diverse. The simplest stepfamily household structure is when one of the adults is a stepparent to the child or children in residence. *Simple stepfamily households* are most often stepfather households because mothers typically have primary physical custody of children (Kreider, 2008). *Complex stepfamily households*, sometimes called *blended households*, are

those in which both adults are stepparents to each other's children from prior unions. Blended stepfamilies also may contain children from the current union, creating half-sibling relationships (Gennetian, 2005).

When the entire network of stepfamily relationships is considered, and not just the stepparent household, there can be at least 30 structural configurations based on the residence of children from prior unions of both adults and whether or not the adults have reproduced in the new union (Ganong & Coleman, 2004). These structural variations create problems for researchers because it takes enormous samples to be able to examine potential differences in children's development between the diverse varieties of stepfamily structures. Perhaps because of problems in obtaining adequate samples to examine all types of stepfamilies, researchers generally have focused on stephouseholds only (for exceptions, see Amato & Keith, 1991; King & Sobolewski, 2006), and have limited distinctions between simple or complex households, or to whether they contain a stepfather, a stepmother, or both (Ganong & Coleman, 2004). Unless samples are large, researchers often limit studies to stepfather households.

The complexity is exacerbated when variable custody arrangements mean that stepfamily households gain and lose children on a weekly (or other) basis, as some children leave stepparent households to spend time with their other parent while children who primarily reside elsewhere enter the stepparent household to spend time (Ganong & Coleman, 2004). It is feasible, for example, for a simple stepfather household to become a complex household during summers or on alternative weekends when the stepfather's biological or adopted children spend time in the household. In other words, stepchildren in simple stepfamily households may actually be part of a complex stepfamily, with siblings, half-siblings, or stepsiblings living some or most of the time elsewhere (Ganong & Coleman, 2004).

Adding to this complexity is the diversity of sibling relationships stepchildren may experience (Gennetian, 2005; Halpern-Meekin & Tach, 2008). Stepchildren may have many combinations of stepsiblings, half-siblings, and full siblings. Stepsiblings are children of a stepparent, half-siblings are children with whom a child shares only one parent; some half-siblings may be products of the current parental union or they may be the offspring of one parent's prior unions. In a study based on the U.S. National Longitudinal Study of Adolescent Health data set, 15% of the respondents had half-siblings, almost 3%

had stepsiblings, and 1% had both half-and stepsiblings (Tillman, 2008).

### *Stepchildren and Family Transitions*

Most stepchildren have experienced multiple family structures before acquiring a stepparent. For example, most stepchildren lived in a single-parent household before becoming a stepchild, and many initially resided with both of their parents in a married or cohabiting household prior to living in a single-parent household. In addition, some stepchildren were born to single, never-married parents who later repartnered or wed a person who was not the child's other parent. The three major pathways to becoming a stepchild—(1) the dissolution of biogenetic parents' relationships, (2) the death of one parent, (3) and the repartnering of never-married parents—are important in understanding familial contexts of stepchildren and previous family transitions they have experienced (Sweeney, 2007). There is evidence that stepchildren's well-being is negatively related to the number and type of previous family structure transitions they have experienced (Cavanagh & Huston, 2006; Sweeney, 2007). It is likely that the reasons for structural transitions are relevant for understanding stepchildren's development (Monte, 2011).

### *Stepchildren's Outcomes*

Researchers concerned about stepchildren's development generally compare stepchildren to children living with both biological parents and to those living with only one parent (Coleman, Ganong, & Fine, 2000). Less common have been comparisons to children living in other types of families such as adopted children or children living with neither parent (exceptions include Laubjerg, Christensen, & Petersson, 2009). A few researchers have compared children in cohabiting stepfamilies to those in remarried stepfamilies (Raley, Frisco, & Wildsmith, 2005). Also uncommon have been within-group studies of changes over time for stepchildren (Shriner, Mullis, & Schlee, 2009).

Although a few studies have reported no differences between stepchildren and children from other family structures (Wen, 2008), stepchildren generally have been found to fare more poorly than children living with both of their parents. Although the effect sizes of these differences have been small (Amato, 1994), they have been consistent. In general, stepchildren's outcomes have been similar to children living with a single parent (Ginther & Pollak, 2004). On average, stepchildren achieve less well than children living with both parents in academic performance

(Tillman, 2008) and completed schooling (Wojtkiewicz & Holtzman, 2011). Dropout rates may be due to stepchildren leaving home to cohabit (Goldscheider & Goldscheider, 1998) and marry (Aquilino, 1991).

Compared to children in nuclear families, stepchildren on average have been found to exhibit more internalizing behavior problems, such as depression (Barrett & Turner, 2006) and emotional problems (Hanson, McLanahan, & Thomson, 1996; Laubjerg et al., 2009). Adolescent stepchildren generally have displayed more externalizing behavioral problems than children living with both parents, such as using drugs, alcohol, and tobacco (Brown & Rinelli, 2010), engaging in sexual behaviors (Upchurch, Aneshensel, Sucoff, & Levy-Storms, 1999), nonmarital childbearing (Astone & Washington, 1994), and engaging in illegal, delinquent, or aggressive behaviors (Kowaleski-Jones, 2000).

Findings about sex differences in stepchildren's reactions to stepfamily living have been mixed, although more studies report sex differences in stepchildren's developmental outcomes (e.g., Benson & Johnson, 2009; Mandara, Rogers, & Zinbarg, 2011), than do not (Gunnore & Hetherington, 2004). Girls appear to have more difficulty adjusting than do boys (Ganong & Coleman, 2004). Similarly, indications are that stepmothers have a harder time raising stepchildren than do stepfathers (Schrodt, 2008), but some have found no differences between children residing with stepmothers and those residing with stepfathers (Demuth & Brown, 2004).

The increase in cohabitating stepfamilies worldwide has triggered a few studies comparing stepchildren in remarried and cohabiting stephouseholds. Findings are mixed; children in cohabiting stepfamilies and those in remarried households have similar developmental outcomes (S. L. Brown, 2004), except in school performance, where children with remarried stepparents do better (Raley et al., 2005). No differences have been found in well-being of children living in cohabiting stepparent households and cohabiting two-biological parent households (Artis, 2007; Dunifon & Kowaleski-Jones, 2002). Complicating comparisons, at least in the United States, are socioeconomic and ethnic differences between cohabiting and married stepfamilies (Manning & Brown, 2006). Much of the U.S. research on cohabiting stepparents and stepchildren has been limited to families in poverty, which complicates comparisons to married stepfamilies.

Despite hundreds of published studies, researchers continue to raise questions about stepfamily effects on children. For these researchers, intrigued by generally

small effect sizes (Amato, 1994) and the fact that most stepchildren (75–80%) fare well after parental remarriage (Hetherington & Kelly, 2002), the persistent questions have become, “What variables mediate the effects of stepfamily living on children?” and “What individual, interpersonal, and contextual (social) factors contribute to stepchildren's development?” These questions cannot be addressed with study designs that simply compare stepchildren to children from other family structures, and so stepfamily scholars have used increasingly elaborate designs. Quantitative studies have become more sophisticated, with increasing efforts to statistically control for unobserved factors that may bias the association between family structure and children's outcomes through the use of fixed effects methods (Sweeney, 2010). Considerations of stepfamily structures have become more complex as well, with more attention to the influences of various types of siblings on children's development (Gennetian, 2005). Increased numbers of qualitative studies also have enhanced the understanding of stepchildren's lived experiences and the family processes that affect them (Baxter, Braithwaite, & Bryant, 2006; Ganong, Coleman, & Jamison, 2011), such as how stepparents develop close ties with stepchildren (Ganong, Coleman, Fine, & Martin, 1999) and the contexts under which stepchildren respond to stepparents (Ganong et al., 2011).

## **Theoretical Explanations for Stepparent Effects on Stepchildren**

### ***Stress Effects***

The negative consequences of family and individual stress are at the core of several explanatory models of stepfamily effects on children. These models have generally focused on the stressful effects of family structural changes on children and economic demands. Stress effects on children's development related to poor quality or conflicted interpersonal relationships have been examined, but we discuss them as family process effects.

### ***Structural Change and Family Instability***

The *change and instability* perspective proposes that the multiple changes experienced by children as their families undergo structural transitions lead to impaired cognitive and academic performance (Tillman, 2008), internalizing and externalizing problem behaviors (Barrett & Turner, 2006; Cavanagh & Huston, 2006; Sweeney, 2007), and more distant relationships with parents and other family

members (DeLongis & Preece, 2002). Parental remarriage or cohabitation often results in many changes for children, such as moving to a new residence, perhaps changing schools, adapting to new household members, and facing new household routines and rules (Ganong & Coleman, 2004). Children frequently have fewer contacts with non-residential parents after either parent repartners (Ganong, Coleman, & McCaulley, 2012), which is often experienced as a loss by children. Most stepchildren experience multiple structural transitions in their families, and researchers have found support for a *cumulative effects hypothesis* that as parental marital and relational disruptions increase, family members' stress escalates, causing children to exhibit more internalizing and externalizing problems (Martinez & Forgatch, 2002).

### ***Economic Stressors***

Another stress-related explanation is the *economic deprivation hypothesis*, which proposes that stepchildren are disadvantaged compared to children living with both parents because of economic hardships experienced living in a single-parent household before entering a stepfamily household (Manning & Brown, 2006). Although parental remarriage generally brings household incomes close to that of first-marriage households, the financial problems and conditions that accompany poverty, such as inadequate schools, dangerous neighborhoods, and parents working long hours may have already been experienced. Evidence supporting the economic deprivation hypothesis has been mixed; when researchers control for differences in household income or socioeconomic status, stepfamily effects are sometimes but not always attenuated (Heard, Gorman, & Kapinus, 2008; Hoffmann & Johnson, 1998; Pong, 1997), and although stepparents often increase household income, they may be financially supporting biological children living elsewhere, so they bring demands on the stepfamily's resources as well as assets.

### ***Family Processes Effects***

Another set of explanations focuses on the effects of stepchildren's relationships with stepparents and biological parents. Most family process explanations emphasize (a) parenting and stepparenting behaviors, the dimensions of warmth and control, (b) stepparent involvement in childrearing (c) the quality of parent-child and step-relationships, and (d) direct and indirect effects of other family relationships on stepchildren, particularly marital and coparental conflicts, nonresidential parent-child relationships, and half-and stepsiblings.

Some researchers have speculated that stepchildren have more problems than other children because they receive inadequate parenting and adult support (Carlson, 2006). Parents' abilities to competently rear their children may be compromised because they are investing time and energy in building relationships with new partners rather than in childrearing (Hoffman & Johnson, 1998). Support for this *reduced social capital model* has been found in studies of academic achievement (Pong, 1997) and behavior problems (Carlson, 2006; Kim, Hetherington, & Reiss, 1999). Parental stress also contributes to compromised parenting: parents who cannot monitor children's behavior, participate in school activities, or interact with children at levels they did prior to remarriage or cohabiting (Phythian, Keane, & Krull, 2008).

Researchers have hypothesized that stephousehold adults were more controlling and less warm than bioparents in two-parent households, thereby placing stepchildren at greater risk for problems. There is evidence of more authoritarian parenting in stepfamily households than in nuclear families (Benson & Johnson, 2009), but not all investigators have found differences in parenting style (Bulcroft, Carmody, & Bulcroft, 1998).

In general, researchers have found that stepparents spend less time with and are less involved than parents (e.g., Hofferth & Anderson, 2003). The main explanations for this come from economic models and evolutionary psychology. The *social capital model* states that stepparents invest their time and energy on the repartnered couple's shared relationship or on children from prior unions rather than on stepchildren (e.g., Gorman & Braverman, 2008). From evolutionary scholars, the *parental investment/parental discrimination proposition* that stepparents invest little in their stepchildren because they are not genetically related, discriminating in favor of their genetic offspring, has received some research support (e.g., Schnettler & Steinbach, 2011). Evolutionary theory and parental discrimination also have been employed to explain stepchild abuse. Children in households with nonrelated adults, particularly stepfathers, mothers' boyfriends, and other men, have been found to be at greater risk for sexual abuse (Margolin, 1992) and physical abuse (Daly & Wilson, 1996) than children living in households with parents only.

However, not all researchers have found reduced investment in stepchildren by stepfathers (Bulcroft et al., 1998). In fact, the *added adult hypothesis*, that stepchildren benefit when stepparents are engaged with stepchildren in positive ways, also has received support from researchers

(e.g., Bulcroft et al., 1998; Sweeney, 2007). When stepfathers demonstrated to stepchildren that they matter to them, internalizing and externalizing behavior problems are reduced (Schnettler & Steinbach, 2011); when stepparents spend more time with stepchildren, step-relationships are closer and children benefit emotionally (Schenck et al., 2009; Schrodt, Soliz, & Braithwaite, 2008).

Other potential explanations for why stepparent involvement in childrearing has been more limited than residential parents' involvement include the following: (a) stepfathers may find it hard to break into tightly knit mother-child systems because both mothers and children work to keep them at a distance (Bray & Kelly, 1998), (b) some mothers want romantic partners but not coparents and may discourage childrearing involvement by stepfathers (Ganong et al., 2012; Weaver & Coleman, 2010), and (c) nonresidential parents may discourage active involvement by stepparents out of jealousy and fears that they might be supplanted by the stepparent in their children's lives. Stepchildren's reactions to stepparents' efforts to engage have been found relevant for stepparent involvement; stepchildren reject stepparents who engage in discipline and control early in the relationship (Bray & Kelly, 1998; Ganong et al., 1999).

### ***Quality of Parent-Child and Stepparent-Stepchild Relationships***

Children who maintain close emotional ties with residential (Planitz, Feeney, & Peterson, 2009) and nonresidential (Schenck et al., 2009) parents have better developmental outcomes than children whose bonds are less close after parental remarriage. Stepchildren also benefit when parents let stepchildren and stepparents bond (King, 2006).

Although many stepchildren have affectionate and close relationships with stepparents (Ganong et al., 2011), not all do. Stepchildren generally are less close to stepparents than to parents (Heard et al., 2008; Schnettler & Steinbach, 2011). Stepparents who intentionally try to develop positive relationships by engaging in friendship-developing actions and who maintain those behaviors over time have warmer, closer bonds with stepchildren than other stepparents (Ganong et al., 1999). A key may be stepchildren recognizing and reciprocating stepparents' affinity-seeking efforts (Ganong et al., 1999; O'Connor, Hetherington, & Clingempeel, 1997).

Conflicts between stepparents and stepchildren may be a source of stress that affects child development (Klaus, Nauck, & Steinbach, 2012). Step-relationships are characterized by more disagreements than are parent-child relationships, particularly when stepchildren

are adolescents (Barber & Lyons, 1994). Even when positive stepparent-stepchild relationships are established when children are preadolescents, conflicts may arise when children get older (Hetherington, 1993). Higher rates of early home leaving by stepchildren have been attributed to stepchild-stepparent conflicts (Heard et al., 2008).

### ***Marital and Coparental Relationships***

*Coparental conflicts* between children's biological parents and conflicts between bioparents and stepparents negatively affect behavioral and psychological outcomes for stepchildren (Feinberg, Kan, & Hetherington, 2007). Coparental conflicts affect children more in stepfamilies than in nuclear families (e.g., Hanson et al., 1996), which may result from these conflicts escalating into triadic processes that include children (Baxter et al., 2006; Weaver & Coleman, 2010). Loyalty conflicts, disputes involving coparents and a child or a parent-stepparent-child triad, have been found to affect stepchildren's sense of well-being (Baxter et al., 2006). Stepchildren are placed "in the middle" of these emotionally tinged struggles between adults, which is stressful, and harmful to their emotional and psychological development (DeLongis & Preece, 2002).

### ***Stepsiblings and Half-Siblings***

The presence of stepsiblings and half-siblings may negatively affect stepchildren's development (Gennetian, 2005; Tillman, 2008). When there are half- and stepsiblings, stepfamily dynamics become more complex and parental resources are spread thinner than in simple stepfamilies.

### ***Selection Effects***

There is some support for the selection argument that differences between stepchildren and children living with both parents are due to individual or familial factors that predated parental remarriage or cohabitation (Cavanagh & Huston, 2006; Hawkins et al., 2007). Although scholars have used fixed effects models and other statistical techniques to control for unmeasured preexisting factors the results suggest "both socialization and selection processes matter" (Cavanagh & Huston, 2006, p. 576).

### ***Summary of Research on Stepchildren***

Research on stepchildren has become increasingly sophisticated methodologically and theoretically (Sweeney, 2010). Large national data sets or large representative samples in the United States and Europe have allowed researchers to better assess demographic characteristics of

stepchildren and their families and to examine variables that might mediate or moderate the effects of living with a stepparent, such as socioeconomic status, age when the step-relationship began, coparental conflicts, relationship quality, and the sexes of stepparents and stepchildren. There is some research consensus that stepchildren's well-being is partly a function of closeness to residential parents and stepparents, coparental conflicts, and stepfamily financial status. The employment of fixed effects analytic strategies has helped researchers unpack selection factors from the effects of family structure and family process (Sweeney, 2010), but qualitative studies also are being done, resulting in greater insights into family dynamics and providing a complement to quantitative investigations. For instance, stepparents and stepchildren's efforts at relationship building with each other contribute to positive relationships and children's emotional well-being, as do high stepparent warmth and limited efforts to discipline.

## CHILDREN REARED BY GAY AND LESBIAN PARENTS

For many years, the prevalence of children reared by parents in gay and lesbian relationships was a matter of speculation. Reliable data were difficult to obtain because of stigma against gays and lesbians in some communities, and the serious negative consequences for adults identified as homosexuals in those communities made gay and lesbian parents and their children reluctant to identify themselves in surveys (van Dam, 2004). In some countries, however, it is now possible to determine if a household is headed by couples in a same-sex relationship and if there are children under the age of 18 in the household who belong to at least one of the adults by birth, marriage, or adoption (Gates & Cook, 2011; Rosenfeld, 2010). In the United States in 2010, 646,464 same-sex-couple households were identified, and of these, 17% had children residing with them (Gates & Cook, 2011). An estimated 1% to 12% of children in the United States have a gay or lesbian parent, and one in five gay men are raising children (Gates & Cook, 2011). Gay couples are more likely than opposite-sex couples to have a nonrelated child in their households, often an adopted child (Krivickas & Lofquist, 2011). Although demographic estimates of households headed by gay or lesbian couples have improved, the numbers of children with gay or lesbian parents are likely higher than reported. The U.S. Census does not assess the number of children whose nonresidential parents are in same-sex relationships, and it is impossible from

the U.S. Census to determine the number of single-parent households headed by gay or lesbian parents.

## Diversity Among Gay and Lesbian Families

Families of children who have gay and lesbian parents are structurally diverse (Patterson, 2009), partly due to the variety of ways in which gay and lesbian individuals become parents: (a) reproduction in a previous heterosexual relationship before "coming out," (b) adoption, (c) donor insemination, or (d) employing surrogates. The pathways to becoming parents are relevant to understanding children's development in these families because they differ on critical variables, including (a) presence or absence of a biological parent living elsewhere, (b) physical custody of children, (c) parents' and coparents' legal rights and responsibilities, (d) number of adults claiming some type of parental status, and (e) motivation to become parents or to rear children. These pathways also differ in the degree to which parenthood was planned; gays and lesbians who adopt, employ in-vitro fertilization, or use a surrogate to bear a child for them generally do so after having acknowledged their sexual orientations. They are referred to by researchers as having *planned* to rear children (e.g., Chan, Raboy, & Patterson, 1998). In contrast, homosexual parents who reproduced in marriages or other heterosexual relationships prior to coming out may have planned to have children, but not to rear them as a gay or lesbian parent (Lynch, 2004; Moore, 2008).

Demographic data on gays' and lesbians' trajectories to parenthood are nonexistent, although researchers contend that most homosexual parents reproduced in prior marriages or cohabiting relationships (Moore, 2008). Sex differences exist in the extent to which homosexual men and women select pathways to parenthood; fewer gay men than women adopt, and lesbians are more likely than gay men to become parents via assisted reproductive technology (Stacey & Biblarz, 2001). There also are sex differences in the technology employed, with lesbians using in-vitro fertilization with donated sperm or sperm banks (Vanfraussen, Ponjaert-Kristofferson, & Brewaeys, 2003), and gay men more likely employing surrogates.

## Raising Children Born in Previous Heterosexual Relationships

Children whose gay or lesbian parents reproduced in heterosexual relationships before coming out may (a) reside in households headed by a single parent, (b) reside in households headed by a parent and his or her "new"

same-sex partner, or (c) spend time in the households of both biological parents (Lynch, 2004). It is likely, given beliefs about the best interests of children after parents dissolve relationships, that most children will have contact with both parents (Hequembourg, 2004). In the United States, parents are increasingly awarded shared legal custody and physical custody (Emery, 2011), which means that both parents are involved in making decisions about children and that children will spend time in both parents' households. This arrangement is substantively different from familial contexts of children residing full-time with same-sex comothers or cofathers, or with single gay or lesbian parents (Hequembourg, 2004; Lynch, 2000).

### *Single Homosexual Parents After Dissolution*

Little is known about children being reared by single gay or lesbian parents after dissolution of a heterosexual union (Biblarz & Stacey, 2010). Because of small samples these children often are included in the same category for data analysis with children of partnered gay and lesbian parents.

### *Gay and Lesbian Stepfamilies*

When gay and lesbian parents who bore children in prior heterosexual unions remarry or repartner, they create what may be called *gay and lesbian stepfamilies* (Hequembourg, 2004; Lynch, 2004; Moore, 2008). They meet the definition of stepfamilies (i.e., one or both parents have a child from a previous union; Ganong & Coleman, 2004), and many family dynamics in these families resemble heterosexual stepfamilies more closely than they do planned gay and lesbian families (Moore, 2008; van Dam, 2004). For example, children in gay and lesbian stepfamilies may feel closer to biological parents than to stepparents, may spend time in two households (i.e., mom's house, dad's house), and may have three or more adult caregivers (biological parents and stepparents) who interact with them in these households (Lynch, 2004; Moore, 2008).

Many lesbian and gay stepfamilies, however, do not define themselves as stepfamilies, preferring instead to think of themselves as similar to married heterosexual families (Lynch, 2000). In addition, unrelated comothers and cofathers often see themselves as equal parents rather than as stepparents (Lynch, 2000). The view that same-sex stepfamily households are just another form of nuclear family household may be a feasible coconstruction of family realities if children are very young when the household is formed and if they have no contact with their other biogenetic parent. For older children, and for children with at least some contact with nonresidential parents, however,

this view may be less realistic. For older children and those with contact with both biogenetic parents, emotional bonds with biological parents tend to be stronger than bonds to stepparents (Moore, 2008).

In stepparent same-sex households, children usually make clear distinctions between their relationships with their biological parent and the other household adult (Moore, 2008; van Dam, 2004), in contrast to gay and lesbian couples who adopt a child together, have surrogates, or reproduce via in-vitro fertilization (IVF). In most of those families, both adults simultaneously become coparents of the child and may have more equal relationship statuses and histories with the child than in gay and lesbian stepfamilies.

Most children in gay or lesbian stepfamily households have a biogenetic parent living elsewhere, which affects children (see the section on stepchildren in this chapter for a lengthier explanation of these family dynamics) who may be involved with three or four parental figures and may spend time in two households. This aspect of family life has been ignored in research on children whose parents are in same-sex relationships. Virtually all the research has been on family members in the household, not the broader family units.

Nonresidential parents can affect same-sex coparents, and parents' homosexual orientation has been the focus of custody battles (Patterson, 2009). Fear of legal reprisals by angry former spouses has contributed to tendencies for children not to disclose a parent's homosexuality, the keeping of secrets, and parent-child coalitions against the straight parent (Goldberg, 2007a, 2007b; van Dam, 2004). Little is known about how these family dynamics affect children.

Stepparents or "social," nonbiogenetic parents in gay and lesbian stepfamilies cannot legally make decisions about children's education, health care, or other areas of a child's life in which legal guardianship status is relevant (Shapiro, Peterson, & Stewart, 2009), and although second-parent adoption is an option for homosexual stepparents, in most, but not all, legal jurisdictions (Meezan & Rauch, 2005) it is relatively rare, partly because of biases against gays and lesbians and the presumed damages that would be inflicted on a child (Crowl, Ahn, & Baker, 2008). Second-parent adoption by homosexual adults may be more common in some European nations (e.g., Spain, United Kingdom), Canada, New Zealand, and Australia.

Planned homosexual parenthood typically requires effort, time, and expense. Assisted reproductive technologies (ART) can be costly. Couples who use ART are older, wealthier, and have fewer children than other parents

(Tasker, 2010). Adoption also is expensive and adoptive parents must undergo rigorous reviews.

The challenges involved in becoming a homosexual parent are relevant to children's well-being. It is probable that gays and lesbians who adopt or use ART to become parents are highly motivated to rear children, and they may have advantages in raising children compared to the general population of heterosexual parents, who often become pregnant without planning.

### **Children's Developmental Outcomes in Gay and Lesbian Families**

There is widespread agreement by most scholars that children of gay and lesbian parents are similar to children of married parents on nearly all developmental outcomes (Biblarz & Stacey, 2010). An APA commission concluded: "Research suggest(s) that the development, adjustment, and well-being of children with lesbian and gay parents does not differ markedly from that of children with heterosexual parents" (<http://www.apa.org/about/policy/parenting.aspx>). Sociologists have asserted that there is a "rare degree of consensus that unmarried lesbian parents are raising children who develop at least as well as their counterparts with married heterosexual parents" (Biblarz & Stacey, 2010, p. 5).

Most researchers have framed studies from either a resilience perspective or have made efforts to not assume a priori that children in heterosexual, two-parent families will fare better than children reared by gays and lesbians (Biblarz & Stacey, 2010; Goldberg, 2007a, 2007b). They have pointed out potential advantages of children reared by homosexual parents, such as potentially greater motivations to rear children compared to heterosexual parents (Biblarz & Stacey, 2010; Tasker, 2010). Researchers also have speculated that children of lesbians may benefit from a "double-dose" of mothering (Biblarz & Stacey, 2010; Crowl et al., 2008).

#### ***No Differences***

Studies of children's cognitive development (Crowl et al., 2008), school performance (Rosenfeld, 2010), psychological adjustment and well-being (Brewaeys, Ponjaert, van Hall, & Golombok, 1997; Chan et al., 1998; Gartrell & Bos, 2010; Wainright, Russell, & Patterson, 2004), externalizing behaviors (Bos, van Balen, & van den Boom, 2007; Wainright & Patterson, 2008), and social relationships (Chan et al., 1998) generally have reported that children of gay and lesbian parents fare as well developmentally

as children living with both biological parents. Most researchers reported that family processes such as parental warmth (Wainright et al., 2004), interparental conflict (Chan et al., 1998), or coparental satisfaction (Bos et al., 2007) were more important to children's well-being and development than parents' sexual orientation.

#### ***Differences in Sexual Identity and Parent-Child Relationships***

Some researchers have reported small differences between children reared by gay and lesbian parents and those reared by heterosexual parents in sexual identity and behavior and in parent-child relationships (Crowl et al., 2008). Children reared by lesbian mothers were more likely to have flexible attitudes and self-perceptions about sexual identity compared to children with heterosexual parents (Goldberg, 2007a; MacCallum & Golombok, 2004). Although these findings are not uniform across all studies (Brewaeys et al., 1997 and Golombok et al., 2003 found no differences in sex identity), they are worth examining.

Tasker and Golombok (1997), in a longitudinal study, found no differences between sons reared by lesbians and by heterosexual mothers, but daughters were more likely to have engaged in or considered a same-sex relationship. A Dutch study had similar findings; no differences in sexual identity for sons but lower heterosexual identity for daughters of lesbians than for daughters of heterosexual couples (Bos et al., 2007). Biblarz and Stacey (2010) speculated that it was not mothers' sexual orientation but the absence of fathers in the lives of children of planned lesbian mothers that contributed to the greater flexibility in sexual attitudes and identities. Without fathers, children had less pressure to conform to sexual stereotypes and cultural norms (Biblarz & Stacey, 2010). The lack of information about children of gay fathers makes drawing conclusions difficult, but there is evidence that gay fathers encourage less gendered identities in their children (Bigner, 1999) similarly to lesbian mothers (Berkowitz & Ryan, 2011).

Not all studies report differences in parenting or parent-child relations by family type, but when they do, differences tend to support more positive relationships with lesbian mothers than between children and heterosexual mothers and fathers. Compared to heterosexual parents, lesbian mothers use less corporal punishment (Golombok et al., 2003), have fewer disputes with children (Golombok, Tasker, & Murray, 1997), show greater warmth and affection (Bos et al., 2007; MacCallum & Golombok, 2004), exhibit more positive parenting skills such as concern, problem-solving, availability (Bos et al., 2007; Brewaeys

et al., 1997), share parental responsibilities among coparents (Bos et al., 2007; Patterson, Sutfin, & Fulcher, 2004), engage in play and shared interests with children (Golombok et al., 2003; MacCallum & Golombok, 2004), and enforce less strict conformity to sex norms (Golombok et al., 2003). Researchers have tended to attribute these findings to children benefiting from having two mothers (e.g., Crowl et al., 2008).

Most studies on children in same-sex parent households have been of children with lesbian comothers. The few investigations of coparenting gay fathers suggest that two men raising children function more like two women than they do a man and a woman (Mallon, 2004; Stacey, 2006). It is risky to make inferences about similarities and differences, however, because there are so few studies comparing gay and lesbian parenting.

### **Research Methods on Children Reared by Gay and Lesbian Parents**

Despite general consensus on findings, research on children in gay and lesbian families has been criticized for study design problems, mostly centering on sampling strategies, the appropriateness of comparison groups, measurement issues, and other methodological shortcomings. Critics contend that research designs are so seriously flawed that no valid conclusions may be drawn about children's developmental outcomes (Regnerus, 2012a; Schumm, 2012). Both critics and proponents often recognize similar study limitations but differ in the implications these limitations have for validity of findings. In the background of this debate lie moral and religious values about homosexuality.

#### ***Sampling and Samples***

Both critics (Regnerus, 2012a) and scholars sympathetic to the challenges of gay and lesbian families (e.g., Wainright et al., 2004), have pointed out that most studies of children's development are characterized by small samples of lesbians and less often of gay men and their children, that are obtained through convenience or snowball sampling methods. Small samples lack adequate statistical power to determine statistically significant differences between children with gay and lesbian parents and other groups of children, so Type II errors may occur. Small samples are less challenging for qualitative researchers (Zanghellini, 2007), yet most work on children with homosexual parents has been quantitative (Biblarz & Stacey, 2010).

Another problem with small samples is representativeness. Drawing random samples of children in gay and lesbian families is expensive because such families are

relatively rare. Even with large samples, subsets of children with gay and lesbian parents may be too small for statistical analysis (Wainright et al., 2004). Users of secondary data often have to rely on multiple questions to determine how many adults are in the home, the relationship status of those adults, and sometimes the types of relationships the adults have with the children or with a focal child in the household. It should be noted that in studies drawn from secondary data sets, single gay or lesbian parents are not identified and neither are nonresidential gay and lesbian parents.

The stigma associated with being gay or lesbian, which in some communities is heightened when the individual is a parent (Berger, 2000), is challenging for researchers. Gay and lesbian parents are often reluctant to identify themselves to researchers, fearing negative consequences of exposing their children and themselves by doing so (e.g., discrimination, threats). Consequently, researchers have employed a variety of ways to seek participants through gay and lesbian social networks and organizations, by recruiting participants from businesses that serve gay and lesbian clientele, by advertising in media outlets that target gays and lesbians, and via word of mouth (e.g., Berkowitz & Ryan, 2011; Goldberg, 2007a; van Dam, 2004). As a result of nonrepresentative sampling methods, however, it is often difficult or impossible to determine how close these convenience samples resemble the population of gay and lesbian parents and their children. Samples of homosexual parents tend to be primarily female, European American, middle-class, and urban (Biblarz & Stacey, 2010). Gay fathers are undersampled, probably because lesbian mothers are more likely than gay fathers to have children in their homes and are more willing to participate in family research than are men. There is evidence from Rosenfeld's (2010) study of parents drawn from the U.S. Census that samples of same-sex couples in most U.S. studies are less economically and ethnically diverse than the general population of American same-sex-couple households. Critics contend that convenience sampling selects gay and lesbian parents with above-average abilities and resources that mask the kinds of problems children might have in the general population of homosexual parents (Regnerus, 2012b; Schumm, 2012).

#### ***Comparison Groups***

Most studies of children of gay and lesbian parents have compared them to married heterosexual parents or to other two-parent households. Biblarz and Stacey (2010; Stacey & Biblarz, 2001) argued that few study designs allowed researchers to differentiate the effects of parents'

sexual orientation from a number of other potentially relevant effects, such as number of parents, their marital status, their sex, and their relationship to children (genetic or social parents). These five variables—parental sex, number and marital status of parents, parental sexual orientation, and biogenetic relationships between parent and child—interact with children’s development in complex ways, and yet are difficult to discern because they are conflated by most study designs (Biblarz & Stacey, 2010). Consequently, it is difficult to tease out developmental outcomes due to sexual orientation of parents from these conflated potential effects.

Tasker (2010) also has pointed out the necessity to control for “methods of conception” when comparing children of gay and lesbian parents to larger groups of children with heterosexual parents. A common problem is that the larger comparison groups may contain more diverse families. A solution has been to match comparison groups, but there are limits to the number of variables by which families, children, and parents can be matched, and matching reduces the ecological validity of study designs.

### **Measurement Issues**

One main measurement challenge with this body of literature has been in operationalizing sexual orientation of parents. For example, Regnerus (2012a) used questions about parents’ sexual or relational behavior asked of offspring: “From when you were born until you were 18 (or until you left home on your own), did either of your parents ever have a romantic relationship with someone of the same sex?” Others have relied on respondents’ self-identified status as lesbian (e.g., Bos et al., 2007) or gay (Berkowitz & Ryan, 2011). Some scholars have pointed out that sexual orientation may not be categorical (Zanghellini, 2007), and others argue that there are qualitative differences in the experiences of children whose parent *ever* had a same-sex relationship and those who have only known life with two mothers or two fathers (Gates et al., 2012).

### **Data Collection Methods**

Most studies have been based on self-reported data from parents, although there have been exceptions where children completed self-reports (e.g., Wainright et al., 2004) or were interviewed in qualitative studies (Goldberg, 2007a, 2007b). Reliance on parental self-report is potentially a critical issue; reviewers have concluded that parent-child relationships were significantly better in same-sex families than in heterosexual families when parents were reporting but not when children were reporters (Crowl et al., 2008;

Tasker, 2010). Given the social stigma associated with same-sex unions, it might be understandable if social desirability affected gay and lesbian parents’ responses to questions about how well their children were developing. Children also might be somewhat defensive or unwilling to openly talk about their parents, reflecting interpersonal strategies learned in families existing at the margins of society (Goldberg, 2007b).

There have been a few studies in which observational data were collected (e.g., Bos et al., 2007), and a few qualitative studies (e.g., Berkowitz & Ryan, 2011; Goldberg, 2007a, 2007b). Scholars have called for more qualitative work and a shift in research paradigms from scientific positivism to recognition of the importance of qualitatively understanding family processes effects on children in gay and lesbian families (Berkowitz, 2009; Zanghellini, 2007).

### **Few Longitudinal Studies**

There have been only a few longitudinal studies, all of lesbian parents and their children; the U.S. National Lesbian Longitudinal Family Study (NLLFS) has followed 84 planned lesbian families over five waves of data collection (e.g., Gartrell et al., 1996; Gartrell, Bos, & Goldberg, 2012), a small sample of children of lesbians in the United Kingdom has been followed into adulthood (e.g., MacCallum & Golombok, 2004; Tasker & Golombok, 1997), and there is a small Belgium study of planned lesbian parenthood (Brewaeys et al., 1997; Vanfraussen et al., 2003). None of these longitudinal projects had representative samples, but all had comparison groups of heterosexual parents, matched for specific family characteristics. The fact that these studies are from different cultures and from essentially the same historical cohort allow for some cross-cultural comparisons (Bos et al., 2007), and all have shown that children in planned lesbian families were similar to children from heterosexual families.

### **Gaps in the Research Literature on Children With Gay and Lesbian Parents**

There are several lacunae in research about children reared by gay and lesbian parents. Perhaps the most serious shortcoming is the small number of studies of gay fathers (Regnerus, 2012a). Lesbian parents who have children via donor insemination and gay men who employ surrogates provide a sort of natural experiment by which researchers could study the effects of parental sex as well as sexual orientation. There have been few studies about the effects of legal unions for same-sex parents and the attendant social and policy-related advantages of such institutionalized

support on children. There is some cross-national evidence that legal unions affect parents' sense of well-being (Shapiro et al., 2009), and other cross-cultural work that suggests legal issues may affect how lesbian parents thought about sperm donor involvement (Ryan-Flood, 2005) and thus has implications for raising children. Little is known, however, about the effects on children of being reared in married homosexual households. Changes in laws and public policy in the United States and elsewhere should make it easier for researchers to examine these potential effects on children's development.

### **Theory**

Most studies of children of lesbian and gay parents have been informed by psychological developmental theories such as social learning and cognitive development theory, but many studies seem to be atheoretical. Developmental theories appear in studies of children's sexual identity, sexual orientation, and gender development. Scholars have called for studies using queer theory and other conceptual frameworks oriented toward gay and lesbian life (Berkowitz, 2009). Queer theory is a constructivist approach that questions the binary categorization of humans as heterosexual and homosexual; the focus in queer theory is heteronormativity, the belief that heterosexuality is normative and should be supported by societal institutions, with other orientations seen as deviant and problematic (Berkowitz, 2009)

### **Summary**

Most studies find the well-being of children of gay and lesbian parents to be comparable to children living with married parents, and greater than children in other family structures. Critics of these studies cite numerous methodological problems to discount the entire body of work. It is difficult to disentangle politics and values from developmental science when evaluating research on children with gay and lesbian parents.

## **Politics and Values in the Study of Children of Gay and Lesbian Parents**

### **Politics**

The study of children of gay and lesbian parents is an undertaking with high political stakes. In some countries policy makers and politicians have turned to social and behavioral science scholarship to bolster their beliefs about homosexuality, marriage, and parenthood (Meezan & Rauch, 2005). More than do most areas of developmental

and family study, scholarship on the effects of gay and lesbian parenthood on children appears to reflect the personal values of researchers.

Although the U.S. Supreme Court decided that the federal government must recognize same-sex marriages, numerous states prohibit adoption by homosexuals and deny them parental rights on the grounds that homosexual parenting is not in children's best interests. Although there is an international trend to legally recognize the rights of gay and lesbian parents (e.g., Canada, Spain, France, The Netherlands), the issue of gay and lesbian parenthood continues to be an ideological battleground (Goldberg, 2007b). Attempts to explore how the presence or absence of legal ties affect homosexual parents and their children have been rare (see Biblarz & Stacey, 2010), but this may be a subject of increasing interest to researchers.

### **Nonepistemic Values**

Beliefs about the innate benefits of children being reared by a married mother and a father appear to be a cornerstone of the nonepistemic values of the critics of gay and lesbian parenthood. This value presumes that "mothering and fathering involve gender-exclusive capacities" (Biblarz & Stacey, 2010, p. 4). Children missing one of the sex influences are seen to be at a developmental disadvantage. The "essential father" is another nonepistemic value that affects research on fatherless children from a variety of family structures (Biblarz & Stacey, 2010). The essential father belief is that fathers provide masculine role modeling benefits for the development of sex role identities for sons and for daughters, and that fathers are the primary disciplinarians, so without a father's guidance and limit setting, children struggle with a variety of developmental and behavioral challenges. This is an aspect of heteronormativity, a system of social control that sets heterosexual relationships as natural and normal, and is "an ideological composite [that] fuses together a gender ideology, a sexual ideology, and a family ideology into a singular theoretical complex" (Oswald, Blume, & Marks, 2005, p. 144). Zanghellini (2007) argued that most proponents of gay and lesbian parenthood unknowingly accept these nonepistemic assumptions by engaging in the discourse of whether or not gay and lesbian parenthood harms children.

### **Epistemic Values**

The prevailing epistemic value of using heterosexual married parents and children as the standard by which other families must compare is a value that some scholars have argued dominates and constrains research on children of

homosexual parents (Berkowitz, 2009; Goldberg, 2007a; Zanghellini, 2007). Assuming that sex and sexual orientation in general and homosexual identity in particular are categorical variables that represent homogenous groupings is another epistemic value in this literature (Goldberg, 2007a). As a result, the variability of these concepts and the meanings attached to them are seldom considered in research on children in these families, and so context often is lost in the debates about what is good or bad for children.

Critics of prevailing epistemic values of developmental science suggest the use of feminist standpoint theorizing, critical theory, queer theory, and other conceptual approaches that reject heteronormativity. Like queer theory, feminist standpoint and critical theories emphasize conducting research through the lens of homosexuality in efforts to better understand the experiences of gay and lesbian parents and their children, without comparing them to heterosexual parents and children with expectations of difference and deviance (Berkowitz, 2009; Goldberg, 2007a). These theories advocate using more interpretive, qualitative methods that allow researchers to more fully assess the contexts within which “queer” parents rear children (Berkowitz, 2009; Berkowitz & Ryan, 2011). Proponents argue that such approaches open researchers to more nuanced understandings of the experiences, thoughts, and feelings of children (Goldberg, 2007a) and parents (Berkowitz & Ryan, 2011) in homosexual families.

## **FAMILY DIVERSITY AND ASSISTED REPRODUCTIVE TECHNOLOGIES**

The term assisted reproductive technology (ART) can be applied to any use of equipment to fertilize an embryo or create a pregnancy without sexual intercourse. ART includes in-vitro fertilization, embryo and gamete donations (sperm, egg, or both may be donated), and surrogacy. In-vitro fertilization is when the mother’s eggs are fertilized with the partner’s sperm in a laboratory and the fertilized embryo is placed back into the mother’s womb to be carried to term. Embryo donation (donor insemination or gamete donation) is similar to in-vitro fertilization except that the donated embryo, egg, and/or sperm come from a third party other than the child’s intended legal or social parents. Surrogacy involves aspects of in-vitro fertilization and donor insemination, the primary difference being that pregnancy is brought to term by a woman other than the child’s intended legal or social mother. The sophistication of ARTs range from self-fertilizing with donated sperm

using a turkey baster to a lengthy series of medical consultations, hormone treatments, and surgeries involved in zygote intrafallopian transfer. ARTs may have been used since biblical times, but they gained widespread attention in 1978 after the birth of Louise Brown, the first child conceived in a Petri dish (Robertson, 1994).

In 2003, European national registries reported that 284,765 ART treatments had been performed (Andersen et al., 2007). By 2012, the approximate total of ART births since 1978 had reached over 5 million children, and the International Committee for Monitoring Assisted Reproductive Technologies (ICMART) estimated that annually 350,000 children are born through ARTs (ICMART, 2012). Both the demand for and success rate of these procedures is increasing substantially (Centers for Disease Control and Prevention, 2013).

Demographic variables that distinguish between women who experience infertility problems and make use of ARTs and those who do not have identified that ARTs users tend to be older (between the ages of 35 and 44), married, non-Hispanic European Americans, who likely have an income at least 300% of the poverty level and a college degree (Stephen & Chandra, 2000). ART is more expensive than poor women or couples can afford.

ARTs have been controversial. Reproduction without sexual intercourse is seen by many as unnatural (Nerlich, Johnson, & Clarke, 2003) and the disconnection of gestational and genetic relationships between parents and children with some ARTs worried clinicians and ethicists (Golombok, 2013). Infertile individuals, gays and lesbians wanting children, and other single adults wanting to become parents welcomed ARTs (Golombok, 2013).

Because ARTs have been somewhat stigmatized, parents have tended not to disclose to children how they were conceived for fear of harming parent-child relationships (Golombok, Murray, Brinsden, & Abdalla, 1999). Disclosure to school age or younger children appears to have little effect on them, but adolescents and young adults tend to be upset upon learning about their origins. Many seek contact with donors (Jadva, Freeman, Kramer, & Golombok, 2010) and often engage in more negative internalizing behaviors and are more distressed than peers who are unaware of their status or whose status was disclosed at earlier ages (Colpen & Soenen, 2002).

### **ART Effects on Children**

Studies of gay and lesbian parents who used ART were discussed in an earlier section of the chapter so here we

limit discussion to ART children of infertile couples and single mothers by choice. Findings regarding the physical or cognitive effects on children conceived via ART have been mixed, with some researchers reporting no differences between ART children and other children in congenital malformations (Ludwig & Katalinic, 2002) and psychomotor development (Jongbloed-Pereboom, Middleburg, Heineman, Bos, & Hadders-Algra, 2011), whereas others found significantly greater risks for children conceived using ARTs in lower birth weight (Sutcliffe et al., 2001), and younger gestational age at birth (Stromberg et al., 2002).

Overall, researchers have reported no differences in psychological or behavioral problems between children born via donation of sperm (Golombok et al., 2002), egg (Golombok et al., 2006), or embryo (MacCallum, Golombok, & Brinsden, 2007), and children who were spontaneously conceived, adopted, or conceived via IVF (Golombok, MacCallum, & Goodman, 2001). Similarly, children born via surrogacy have not been found to differ in emotional, behavioral, or psychological adjustment compared to other ART children or to spontaneously conceived children (Golombok et al., 2006). Few studies have focused on single mothers using ART by choice; a longitudinal investigation of infants and toddlers found no emotional or behavioral differences between children of single ART mothers and married mothers of spontaneously conceived children (Murray & Golombok, 2005).

### ***Theory in Studying Children Born to Parents Using ARTs***

Attachment theory has been used in some studies, but for the most part ART studies have been atheoretical. Although researchers have explored the possibilities that parents who used ARTs engage in different parenting styles than do parents in other types of families, in general no differences have been found between ARTs and spontaneously conceiving parents in regards to maternal negativity (Golombok et al., 2011) and quality of parent-child interactions (Steel & Sutcliffe, 2009). Some investigators found that ART parents score higher on control and involvement with children than do spontaneously conceiving parents (Colpen & Soenen, 2002), and that new ART parents often display and report higher levels of warmth, joy, and attachment to their newborn children than do spontaneously conceiving parents (Golombok et al., 2006, 2011; Hahn & Dipietro, 2001). Finally, researchers have studied ARTs from an identity theory approach, exploring how offspring make meaning of their relationships and reinterpret their

conception and birth history as they enter adolescence and adulthood.

### ***Methods***

Cross-sectional studies on adolescents and young adults often have recruited samples from online message boards and support groups for children attempting to gain contact with their biological parents (Jadva et al., 2010). ARTs children who find out about their birth status before the age of 18 often engage in such searches out of curiosity and perhaps to resolve identity issues that arise; in contrast, those informed after 18 tend to search for pertinent medical information (Jadva et al., 2010). Most researchers on ART's effects on children have utilized longitudinal designs (Brewaeys, 2001; Hansen, Bower, Milne, de Klerk, & Kurinczuk, 2005). In some European countries, regulations regarding the use of ARTs and centralized registries have allowed researchers to follow large cohorts of children born using ARTs synchronously with adopted children or children conceived through vaginal intercourse (Nekkebroek et al., 2010). In contrast, researchers in countries with less centralized health care systems (e.g., United States) have had to gather convenience samples, often from a single hospital or clinic (Ellison et al., 2005).

Policy research on ART has primarily dealt with legal ownership of donated genetic material, the parentage of live births that result from such donations, and whether governments or clinics have the legal obligation or ability to limit the number of cycles of treatment an individual or couple may undertake. The ownership of donated material has become a salient concern to ethical and legal scholars largely due to fears regarding the birth of children who lack clearly identified genetic parents, which in most U.S. states forms the basis of legal family frameworks (Sparrow, 2012). Although some courts in the United States have privileged the parental rights of intended legal parents of children conceived through ART, legal parentage remains dominated in most countries by presumed genetic parenthood.

Experimental research in ARTs families is still dominated by comparisons of conception methods among couples facing fertility difficulties (e.g., comparing couples that elect for surrogacy, IVF, adoption, or spontaneous conception; Golombok, 2013; Van Steirteghem, Bonduelle, Devroey, & Liebaers, 2002). Although some researchers and practitioners have recommended that ART physicians and legal professionals should inform prospective parents about potential risks associated with ARTs, systemic

research on interventions that might be beneficial to parents electing to use ARTs and their children does not exist.

### *Summary of ART-Conceived Children*

Like many other diverse families in this chapter, study of children born using ARTs has followed a trajectory of descriptive studies, comparisons to spontaneously conceived children in nuclear families, to more complex within-group explorations of family processes that may affect child development. There appears to be some consensus that despite somewhat increased risks for low birth weight and low gestational age, children born using ARTs follow similar developmental trajectories to their peers in other family forms. Additionally, the resilience of children born via ARTs is often buffered by the likelihood of their parents having ample economic resources and a high commitment to childrearing. Important questions currently under investigation include whether, when, and how a child's ART status ought to be disclosed, and what role surrogates and donors ought to enact in the lives of children whose birth they helped create. Within-group studies and continued use of longitudinal designs to examine changes over time are trends within the field that will contribute to improving knowledge about children born using ARTs.

Advancements in technology suggest that there will be increasing complexity in techniques used by fertility specialists and families in regards to human reproduction. Via ART, children now may have up to five parents—a sperm donor, an egg donor, a surrogate mother to carry the child through pregnancy, and two parents. New technologies raise the possibility of a third genetic parent, as researchers have fused genetic material from two mothers among mice to alter genetic codes for specific results (Ralston & Rossant, 2005). Identity issues for children, therefore, may become increasingly salient (Jadva et al., 2010). Relationships with half-siblings linked by a donor also may become more important to emerging adults, as donor sibling registries and other methods of connecting to kin are devised (Golombok, 2013).

## **CHILDREN REARED BY GRANDPARENTS**

Families in which grandparents are raising their grandchildren are commonly referred to as grandfamilies, and about 2% of children in the United States live with a grandparent with no parent in the household (U.S. Census Bureau, 2011). These grandparents are known as custodial grandparents, a label that refers to children's physical residence

rather than legal status, although some residential grandparents are legal guardians of grandchildren (Dunifon, 2013).

Grandfamilies are formed when, for a variety of reasons, parents are either not available (e.g., incarceration, military deployment, death) or they are not able to care for children (e.g., mental health problems, substance abuse, poverty; Edwards, 2006; Strong, Bean & Feinauer, 2010). Grandparents are often among the first persons called upon to assume caregiving responsibilities for children when parents cannot, and they assume these responsibilities largely because they would rather grandchildren reside with them than in care facilities or nonfamilial arrangements such as foster care (Weber & Waldrop, 2000). African American children are more likely to live in grandfamilies than are European American or Hispanic children (Kelch-Oliver, 2011).

The availability of large numbers of healthy grandparents, many of whom are middle aged or younger, also has contributed to the rise of grandfamilies (Bernal & Anuncibay, 2008). Increases in longevity and additional years of good health allow grandparents to serve in caregiving roles for extended periods.

The creation of grandfamilies often follows a crisis or series of stressful events linked to the parents' inability or unwillingness to rear their children (Strong et al., 2010). Children in grandfamilies thus have experienced stressors that, along with the absence of parent(s), may contribute to feelings of sadness, anger, fear, and confusion (Poehlmann et al., 2008).

Grandfamilies are often poor, in part due to financial burdens that accompany custodial grandparenthood (Baker & Mutchler, 2010). Even middle-class custodial grandparents find financial demands related to childrearing expenses stressful. Incomes also may be affected if custodial grandparents in the workforce have to reduce hours to fulfill caregiver roles. Additionally, custodial grandparents may be stressed by legal issues and housing concerns; their homes may have inadequate room for grandchildren (Baker & Mutchler, 2010). If grandparents are informal rather than legal guardians of grandchildren, negotiations with social service agencies, schools, and other institutions may be complicated (Letiecq, Bailey, & Porterfield, 2008). Grandparents also may be unsure of how to interact with these groups, and this uncertainty may hinder their efforts to seek external support for their grandchildren (Letiecq et al., 2008). Although nonresidential parents are sometimes involved with children (Dolbin-McNab & Keiley, 2009), involvement is often inconsistent and may add stress for children and grandparents (Messing, 2006).

### Effects on Custodial Grandchildren

Although a few researchers have found that custodial grandchildren are healthier than children living with one or two biological parents (Solomon & Marx, 1995), most have concluded that residing in grandfamilies poses physical and mental health risks for children (Billing, Ehrle, & Kortenkamp, 2002; Bramlett & Blumberg, 2007; Silverstein & Vehvilainen, 2000). Given the likelihood that grandfamilies live in poverty, it is not surprising that custodial grandchildren may experience food insecurity and may experience negative developmental outcomes related to chronic malnourishment (Baker & Mutchler, 2010).

In most studies, custodial grandchildren, compared to children living with both parents, were at increased risk for emotional and behavioral disorders (Billing et al., 2002; Bramlett & Blumberg, 2007; Leder, Grinstead, Jensen, & Bond, 2003), and were more likely to experience posttraumatic stress disorder, depression, anxiety disorders, and/or developmental delays, likely due to trauma exposure that preceded their transition into the grandfamily (Fergusson, Maughan, & Golding, 2008). Custodial grandchildren also are more likely than children living with both parents to experience moderate to severe difficulties with emotion regulation, concentration, behavior management/conduct, peer relations, and depression/anxiety (Bramlett & Blumberg, 2007). Those in infancy or early to middle childhood were at an increased risk of experiencing attachment disruptions (Poehlmann et al., 2008).

Teachers and custodial grandparents perceived grandchildren as experiencing more emotional and behavioral problems in the classroom than other children (Edwards, 2006), and they were more likely than children living with both parents to fail a grade (Solomon & Marx, 1995), perform poorly on reading and math evaluations (Sawyer & Dubowitz, 1994), and be less engaged with school (Billing et al., 2002). Custodial grandchildren were more likely than peers to receive clinical treatment and support due to hyperactivity, depression, oppositional behavior, attention deficit hyperactivity disorder, temper tantrums, mood swings, and social isolation (Grant & Kucera, 1998), and they were more likely than other children to receive special education services (Edwards, 2006).

### Explanatory Mechanisms

The reasons posited to explain why custodial grandchildren are at a developmental disadvantage when compared to peers from two-parent and single-parent households,

include attachment disruptions (Strong et al., 2010), lack of social support for grandparents raising grandchildren (Leder et al., 2003), family instability (Edwards, 2006), poverty (Baker & Mutchler, 2010), and psychological trauma related to parental absence (Weber & Waldrop, 2000). As with other diverse families, it is difficult to delineate between stressors affecting children's development prior to living in a grandfamily from effects due to living in a grandfamily (Strong et al., 2010).

### Gaps in the Literature

Many of the studies about grandfamilies have had small samples and cross-sectional designs. Longitudinal research is needed to examine long-term effects of grandfamily living on children, with foci on ways custodial grandparents can serve as protective buffers for grandchildren in times of stress (Dunifon & Bajracharya, 2012). Greater attention also should be paid to ethnic diversity, and how grandchildren's and grandparents' ages are related to child outcomes (Weber & Waldrop, 2000). Nonresidential parents' roles in the children's lives also should be explored (Dunifon, 2013). Finally, researchers would benefit from improved understanding of the differences between stable, well-functioning grandfamilies and high-risk grandfamilies that require intensive clinical treatment; this information could inform intervention programs aimed at promoting grandfamily resilience.

Among the primary challenges researchers have identified for grandparents raising grandchildren are increased psychological and economic stress placed on grandparents as care providers. Consequently, efforts have been made to develop interventions. Multimodal home-based interventions delivered by nurses, social workers, and legal professionals have been found to increase social support and reduce stress for caregiving grandparents (Kelley, Whitley, & Campos, 2013).

The relative effectiveness and benefits to children of grandparents providing foster care compared to foster care provided by nonrelatives have little research support. Though many advocates for kinship care suggest that grandparents (and other kin) can provide more continuity in children's lives, and therefore more benefits, children in kin arrangements often face more difficult circumstances (i.e., fewer economic resources, less food security) compared to peers in traditional foster care (Ehrle & Geen, 2002). Many states have adopted a preference for kin care, however, because it is less expensive and legal precedents favor kinship placement (Leos-Urbel, Bess, & Geen, 2000).

### Summary

Grandchildren reared by grandparents generally have lower well-being than their peers living in other family structures. Grandchildren often face multiple stressors (e.g., poverty, loss of parents) and frequent, multiple transitions. Research into grandfamilies is still in the early stages, and much more needs to be known about children in grandfamilies and effective interventions for them and their grandparents.

## CHILDREN IN DIVERSE FAMILIES: A SUMMARY

In general, children in diverse families do not fare as well developmentally as children growing up with two continuously married parents. There are exceptions to this, with children reared by gay or lesbian parents, children born as a result of ART, and most bereaved children over time, being comparable to children in nuclear families on the common outcomes measured—internalizing and externalizing behaviors, cognitive and school performance, health, and interpersonal relationships. Of course, not all studies find that children in diverse families are deficit compared to those in first-marriage families, and in some studies (e.g., stepchildren), effect sizes are often small. There is not yet consensus among scholars on the causal reasons behind these differences. Leading candidates are explanatory models that include family socioeconomic status, transitions (i.e., the number, timing, and nature of transitions), stress and coping variables, the quality of family relationships (e.g., between coparents, parents and children, children and nonparental caregivers), and societal support (e.g., stigma, institutionalization, socioenvironmental factors). Intrapersonal factors (e.g., mental health, genetic predispositions, substance abuse) also should be considered as likely relevant explanatory constructs. Progress has been made in understanding how family status and family processes interact to affect children, but there is still work to be done.

### The Developmental Trajectory of Research on Children in Diverse Families

When a community of scholars begins studying an identified group of children and their families who are seen as experiencing or presenting problems to society, there is a recognizable research trajectory that has four phases. The *first phase* consists of descriptive and demographic studies identifying the group and the issues experienced by that group. This is a *social address* approach in which the

target group of diverse families is treated as homogeneous. Simple comparisons are made between the target group and two-parent married families, often using small samples. For instance, early researchers of stepchildren, categorized children from stepmother, stepfather, and complex, blended households together as a single group, with scant attention paid to controlling for years in the stepfamily, precursors (parental death or divorce) to stepfamily living, and other relevant variables. Stepchildren were then compared to children in first-marriage families and, sometimes, to children living with a single parent. In initial studies of specific types of structurally diverse families, theories are rarely employed.

In the *second phase* of a research trajectory on diverse families, researchers employ larger, more representative data sets and more sophisticated study designs. For instance, variables known to differ across family types are controlled, and attempts are made to assess family dynamics as well as family structure. During this phase, the intersections of family processes and family structures are explored, and there is some effort to use theories to guide variable selection. Researchers also become more aware of data set limitations in being able to control for important variables or to examine potentially relevant family processes. For instance, stepchild researchers began limiting samples to stepfather households only because enough stepmother households to include in statistical analyses could not be located.

Researchers also begin utilizing longitudinal data sets to search for changes in children over time, and begin considering selection effects as an explanation for differences between children in diverse families and other children. Also, a rise in small qualitative studies designed to explore processes within the specific type of diverse families are seen. Intervention studies also appear in the literature, but they tend to consider the target diverse families as mostly homogeneous, and interventions are “one-size-fits all” designs. Bereaved children and grandfamilies are generally in this phase of the research trajectory.

In the *third phase* of the research trajectory, there is greater reliance on longitudinal studies, sometimes framed from the perspective of multiple family members (data collected from children, parents, and sometimes teachers or others). The efforts by researchers to control for inherent differences in family structures are more sophisticated and greater attention is given to contexts, such as the number and timing of transitions, the types of transitions, and precursors to current family type. Greater attention is paid to gender issues (e.g., gay and lesbian families,

stepfamilies), and researchers take care in deconstructing parents' marital and relational statuses (e.g., unmarried and cohabiting parents).

Also in this third phase, research questions become more nuanced and gradual "truths" about children in various family structures become known through replication of findings in multiple settings with diverse samples from the target population (e.g., stepchildren). In studies of some family forms, researchers begin looking beyond households as they conceptualize family membership (e.g., nonresidential parents were included in studies of stepchildren and children in divorced families; half-siblings and stepsiblings that did not share a residence with target children also got some attention), and researchers' conceptualizations become more complex and more closely reflect the realities of children's and families' lives. Research on children of gay and lesbian parent families and ART families are in this phase.

In the *fourth phase*, researchers continue examining the interactions of family structure and family processes (particularly parenting, parent-child relationship dynamics), using theoretically informed and analytically sophisticated designs. Selection effects are examined in various ways, including the use of fixed effects analytic designs, differences within differences approaches, and matching of children and parents in diverse families to children and parents in nuclear families. Multiple theoretical explanations are examined in this phase. There is the start of work examining biogenetic and genomic effects on children in diverse families, as well as examinations of children's effects on parents and on their own developmental processes. Qualitative research in this phase is focused on illuminating processes within family structures, leading to grounded theories, testable quantitative hypotheses, and more understanding of how context affects children and their families. There are more mixed methods designs. Of the types of diverse families presented in this chapter, the bodies of research on unmarried families, postdivorce families and stepfamilies are in this phase.

Crosnoe and Cavanaugh (2010) were referring to this latter phase of research when they asserted that "we stand on the cusp of a paradigm shift in which we will be able to establish causal pathways and unpack actual processes better than ever before" (p. 594) in the study of families with children and adolescents. The increasing sophistication of analytic models, the availability of large, representative longitudinal data sets from multiple nations, and refinements in qualitative research approaches suggest that the study of children in diverse families is on the verge of significant

growth. This does not suggest, however, that challenges do not remain.

## Challenges and Concerns in the Study of Children in Diverse Families

### Comparison Groups

Who are appropriate comparison groups for children in structurally diverse families? Should children living with married biological parents always be the standard of comparison? Clearly, for most researchers the choice of two-parent nuclear families as the comparison for diverse families is the default, but this epistemic value does not always make conceptual sense and may lead to designs that conflate number of parents, sex of parents, biogenetic relationships between parent and child, and marital status of parents (Biblarz & Stacey, 2010). Social and political conservatives generally have treated first-marriage nuclear families as the norm to which all other families are compared and found wanting. Social and behavioral scientists too often have either embraced or accepted this view, perhaps because they share these nonepistemic values about family structure or because theories and conceptual frameworks implicitly support this view. Whatever the reason, researchers need to think clearly and be explicit about their decisions regarding comparison groups. There is evidence that more researchers are employing family structure comparisons that are not limited to first-marriage nuclear families (see research on children living with unmarried cohabiting parents, for instance). A few researchers have begun using designs comparing well-functioning and poorly functioning children and families from given family structure types (e.g., stepfamilies).

### Sampling

Finding samples of children in diverse families is challenging (e.g., bereaved children, gay and lesbian families). Stigma and self-definitions contribute to making these children and their parents hard to locate. Some children and parents prefer not to be identified as members of diverse family structures (e.g., gay and lesbian families, stepfamilies, divorced single parents, ART) because of perceived stigma associated with membership. In addition, family members define their relationships and statuses in ways that do not always coincide with researchers' definitions. The socially constructed nature of family status may influence how individuals identify themselves to researchers. For example, children who perceive their stepfathers to be

their fathers may not identify themselves as stepchildren. In a methodological study based on the National Study of Families and Households longitudinal data sets, White (1998) found that 15% of family membership changes were based on respondents' social constructions of family life.

### ***Design Diversity***

More qualitative research and mixed method designs are needed that will allow scholars to examine family experiences and meanings held by family members. There also is a need for thick description of the contexts within which children and their diverse families live and for qualitative studies that elucidate internal family processes with in-depth analyses. Quantitative studies capture certain types of family process variables, but qualitative data are needed to augment what we are learning from large secondary data sets of children and parents in diverse families. Children and adolescents as well as parents and other family members should be included in these qualitative efforts.

More varied approaches are needed in studying children in diverse families. The current literature is dominated by self-report methods (i.e., interviews, questionnaires), often of only a single family member, usually a mother. Data collected from multiple respondents are needed, as are observational studies and investigations that combine multiple methods.

### ***Transition Effects***

Family instability makes it hard for researchers to unpack the effects on children of living in diverse families from the effects of family transitions. In some families, transitions occur so often that even in large-scale, longitudinal data sets, it is possible to miss some transitions experienced by children. More longitudinal studies are needed that allow researchers to attend to the number, sequence, and type of transitions, and also be able to assess the potential effects of particular family structure precursors to living in specific types of diverse families. Many children live in multiple family structures before they reach adulthood. Family structure is more often a fluid phenomenon than it is a fixed property or stable family factor. This not only challenges researchers, it also presents an opportunity for programmatic research into the specific effects of transitions on children.

### ***Structural Overlaps***

Not all diverse families are discrete structural forms. For instance, many gay and lesbian families are a type of

stepfamily, with issues and dynamics that fit stepfamilies as well as families headed by same-sex parents. Similarly, some cohabiting families are stepfamilies and some are not. These overlaps challenge researchers to be clear about whom and what they are studying and the family processes they expect to affect children.

### ***Theory-Methods Connections***

Stronger connections are needed between theory and methods in studies of children in diverse families. Across the families types reviewed in this chapter, a limited number of explanatory mechanisms have been proposed. Most of these are neither theories nor even conceptual frameworks, but propositions drawn from prior investigations. The availability of national and other large, representative data sets might help strengthen theory-methods connections, as should the greater use of statistical techniques such as growth curve modeling. Qualitative researchers are also generating testable hypotheses from their work (e.g., stepfamily dynamics), which should enhance future research and theory linkages.

### ***Genetic Influences***

Developmental research on children in diverse families is heavily focused on nurture and environmental influence, and less on genetic influences. This is a serious methodological and theoretical gap; models of parental influences on children may be missing genetic influences if they are not examined along with environmental effects (Crosnoe & Cavanagh, 2010). The researchers that have examined genetic connections between children and parents support a gene  $\times$  environment model and make a strong case for including genetic relatedness as a factor to be considered in studies of children in diverse families (e.g., Reiss, Neiderhiser, Hetherington, & Plomin, 2000).

### ***Selection Effects***

Selection effects continue to be an issue in the study of diverse families. More scholars need to try to account for selection effects and, more specifically, identify when selection effects occur, and why and how they affect children's development.

### ***Households Are Not Families***

Although seldom stated explicitly by developmental scientists, a common assumption implicitly made about children's families is that all relevant family members share a residence. Consequently, it is not unusual in developmental studies for families to be operationalized as those

individuals sharing a household. A narrow research focus equating households and families precludes scholars from being able to assess and understand the complete contexts in which children's development occurs. For instance, nonresidential fathers have been examined in some diverse family types (e.g., unmarried, post-divorce, stepfamilies), but more attention is needed on the influences of siblings, grandparents, and parents (including mothers) who do not share a child's household.

### *Including Fathers*

Fathers are relatively ignored in studies of diverse families. Notwithstanding the attention paid to nonresidential fathers in some bodies of literature, more attention should be paid to fathering and father's effects on children. Little is known, for instance, about gay fathers and children living with fathers only.

### *Including Ethnic Minorities*

Ethnic minorities are often underrepresented in samples. Research in the last decade has more successfully assessed ethnic differences in family processes across diverse family structures (e.g., in studies of unmarried parent families, grandfamilies), but samples in studies of bereaved children, children reared by gay and lesbian parents, and ART contain little ethnic diversity. Even the body of research on divorced families and stepfamilies lacks ethnic diversity in samples. In addition to studying how ethnicity interacts with family structures and family processes, researchers need to explore variability in the meanings of parenting and other family processes across ethnicities (Crosnoe & Cavanagh, 2010).

### *Policy and Intervention Studies*

Although some attention has been paid to the effects of public policy and legal issues on children in diverse families, particularly in work on children of divorced parents and children in gay and lesbian families, this research is still in its infancy.

More intervention studies that include well-designed evaluations are needed for almost every type of diverse family. Effective family interventions are challenging to implement because families within a given social category vary so greatly that a "one size fits all" approach, although more cost-effective to deliver, is less effective than more nuanced approaches of what works, and when, how, and with whom. Small bodies of intervention research exist for bereaved children, stepchildren, and for children who have divorced parents, but these studies often were characterized

by small samples, the absence of comparison groups, and inadequate measurement of outcomes; most interventions of children in diverse families have not been replicated.

## **A FINAL WORD**

In the chapter introduction we discussed how epistemic and nonepistemic values affect research on children in diverse families (Clingempeel et al., 1987; Lamb, 1982). Over the past 25 years, the prevailing epistemic values have evolved so that family structure and family process variables now are most often combined as indivisible parts of a whole perspective. Gradually, scholars from the many disciplines that study children and families appear to have created a set of multidisciplinary epistemic values presenting an integrative view that includes family structure, parents' mental health, parenting processes, relationship quality (e.g., parent-child, coparents), stress related to family functioning and economic hardships, the presence or absence of community support, and, less often, biological and physiological variables. Guided by relational developmental systems metaframeworks (Lerner, 2006; Lerner et al., 2010), scholars using quantitative, qualitative, and mixed methods have embraced this perspective. These multidisciplinary epistemic value changes bode well for the future study of children in structurally diverse families.

Nonepistemic values have also changed, but researchers are not free from their influence. For example, potential study participants are affected by cultural beliefs about the relative goodness and badness of various family forms, and, as we noted earlier, perceived stigma about divorce, stepparent or stepchild status, homosexuality, and artificial reproduction make it harder for researchers to locate study participants who may be reluctant to expose themselves and their family members to discrimination or worse.

Researchers' beliefs also are relevant. Although most researchers may be abandoning parents' marital status as a causal variable affecting children's well-being, and focusing more on interactions between family structure and process (Crosnoe & Cavanagh, 2010; Smock & Greenland, 2010), cultural values still hold marriage as a valued status believed to have positive effects on children and their parents. For instance, the U.S. government's Healthy Marriage Initiative spent millions for programs to encourage and strengthen marriage. These widely held values about children and their families affect both research participants' responses (e.g., social desirability) and researchers' analyses of data. The debate on children's outcomes in

gay and lesbian families (e.g., Regnerus, 2012a) is a clear example of the influence scholars' (and research funders') nonepistemic values about families have on how research is conducted and the conclusions that are drawn.

Diverse family structures are not new, but widespread trends, such as the decoupling of childbearing and marriage, increases in unmarried parenthood and multiple partner fertility, and greater family structure instability, are accelerating the pace of change. What is new is that "today's family scholars have multiple sources of rich data and useful methodological tools with which to try to understand such changes and their implications" (Smock & Greenland, 2010, p. 589). In addition, developmental and family scholars more often seek "to specify and test individual  $\leftrightarrow$  context relations that are linked developmentally to health and positive functioning" (Lerner & Overton, 2008, p. 247), instead of simple comparisons of children in diverse families to those in nuclear families. Understanding how children and their families change in positive directions and learning how to proactively enhance those changes are among the key tasks for the field.

## INTRODUCTION

One of the coauthors of this chapter has had the opportunity to live with groups of same-age children and adolescents for years at a time. As a coach of groups of elite hockey players who have ranged in age from 7 to 20-plus years, these ethnological encounters have made it rather clear that peer interaction, relationship, and group experiences play significant roles in the social, cognitive, social-cognitive,

emotional, and, in these particular cases, physical lives of each individual participant. In many ways, the informal observations of the coauthor/coach have been formally supported by the research that readers will review as they make their way through this chapter. Take the following informal observations of an ice hockey team as examples:

At the beginning of each season, children, many of whom are in unfamiliar social territory, try out for a given team. During these tryouts, participants are observed by

a selection staff as they demonstrate particular *individual* and team skills. Eventually, a team is chosen and a *group* is formed. One immediate result of failing to make the team pertains to the construct of social comparison. It is often the case that individuals come to believe that they are not good enough, and they consequently come to exclude themselves from *interacting* with their more “successful” peers. To make matters worse, in some cases, members of the successful group tease those who have not been selected. *Rejection* and *exclusion* may occur; *rejection sensitivity* may be experienced. Depending on individual characteristics (e.g., temperament/personality; social-cognitive acumen) and the relationship experiences each “unsuccessful” participant has experienced in the past, the individual may continue to pursue other possibilities that will allow participation in the sport (e.g., try out for another team; participate at a lower level of expertise); others may decide to turn to another activity altogether. The point is that from a rather early age, children compare themselves to their age-mates on all manner of characteristics, abilities, and beliefs. These social comparisons can affect how one interacts with others, who one may befriend, and how one thinks and feels about the self.

Over the course of a season, *friendships* develop between members of the selected team. And *cliques* are formed as well. There appear to be good reasons for the formation of close dyadic relationships within the group; for example, friendships emerge between those who have similar interests beyond the confines of the arena; others develop friendships because they happen to be similarly skilled (*homophily*). And one begins to identify friendships simply by observing who it is that the participants sit near as they ready themselves for practices or games; who they join at the restaurant tables after a game is played; or in the case of adolescents who travel out of town for league games, who they ask to room with.

As the season progresses, the group develops a team “mentality.” Although there are clearly defined subgroups, when the larger group is engaged in competition, they band together to support each other, on and off the ice. They become the “ingroup” with an established set of norms and values that often have absolutely nothing to do with ice hockey. For example, the team may choose to wear specific modes of dress or listen to particular kinds of music that distinguishes the larger group from the “outgroup”—the competition. These norms and values are often “handed down” by those who are older and who have played on the team in an earlier year. In some cases, it becomes clear that some participants are more “central” to the group and

viewed by their teammates as leaders (and as *popular*). Also, within the group as a whole, disagreements and/or disputes may occur between its individual members. When the disputing members are friends, it is likely that some form of negotiation will occur that leads to an acceptable outcome for both partners. In other cases, one member appears to have his/her way in the dispute/disagreement. From observing the disagreements/disputes that occur over the course of the season, the observer is able to identify a *dominance hierarchy* within the group.

In the dressing room, prior to practices and games, it becomes readily apparent that some of the individuals are quieter than others; some are gruffer and more belligerent; some are more emotionally reactive both on and off the ice; some of the emotionally reactive individuals have difficulty regulating affect (thus spending much time in the penalty box) whereas others have little difficulty doing so; yet others promote coordination, inclusion, and collaboration. Typically, the members of the latter group become group leaders. Relatedly, each team member brings with her or him a set of individual characteristics that may play a role in determining the nature of interactions and relationships that occur within the group (and away from the arena). Often, *depending on age and gender*, members of the first two groups (the quiet and belligerent ones) become “outsiders,” rejected by the group as a whole. They may be members of the same team, but they are nevertheless rejected because their behaviors do not coincide with that which has become expected by the group as a whole. Whether these rejected individuals continue to make positive contributions to the group likely depends on the support (or lack thereof) that they receive from their friends on the team. If those who are rejected lack friends, their contributions to the team, on and off the ice, may well be limited and they may decide to isolate themselves from the group or quit the team. In either case, their intrapersonal selves will suffer. And this is when the typical coach must begin to think like a developmental scientist or psychologist. Failure to do so can lead a highly talented group of individuals to underachieve (and that may well be why, at all level of sporting activity, coaches are dismissed!).

Some individuals may make seemingly disparaging comments to their teammates, while at the same time, smiling at and laughing *with* their putative “victims.” Some of these victims return the smile and respond with similarly disparaging comments. Often physical or communicative roughhousing ensues, but the participants continue to display positive affect and recognize that these incidents are not truly antagonistic—and, it is clear to

most who are familiar with the participants, that this is not aggression! To the developmental scientist, the label applied is “rough-and-tumble” play. Nevertheless, there are likely to be members of the group who cannot recognize the nonliteral meanings of the disparaging comments and roughhousing. They assume that the protagonists are predators who mean them harm; they conclude that they are disliked by these cruel teammates. Often these assumptions could be the worst mistakes that an individual can make during the course of what can be a very long season. Thus, the ways in which each individual interprets the activities, overtures, and goings on within and outside of the dressing room will determine how pleasant or unpleasant the group experience will be.

## CHAPTER GOALS

For non-sports-minded readers, the goal of beginning this chapter with a description of what may go on behind the closed doors of youth hockey teams has been to illustrate some of the many social, emotional, biological, and cognitive factors that interact to determine the nature of peer relations. Some factors describe children’s individual characteristics (e.g., age, sex, temperament); some help define the meanings of interaction that may occur within and between groups (e.g., literal versus nonliteral meanings; cultural interpretations of behaviors and interactions); and some are focused on the nature of the relationships between the children (e.g., Is the relationship characterized by mutual like or dislike?), and their standing within the peer group (e.g., Are some children clearly “central” to the group? Are some children rejected by the group? Do some of the group members feel rejected by the group as a whole?). In moving beyond the example provided earlier, one may conclude that careful observations of children interacting with one another can only reveal clear “meanings” if one has knowledge of children’s individual characteristics, their relationships, their group memberships, and the communities and cultures within which they are dwelling (Hinde, 1987, 1995). In this regard, the understanding of children’s peer interactions, relationships, and groups is a complicated business.

The central goal of this chapter is to provide insights from extant theory and research on peer relations that will make the seemingly complicated, somewhat comprehensible. We begin this chapter with brief definitions of the constructs that will guide our review. In this first section, we describe, very briefly, the history of peer relations

research and the *raison d’être* for studying children’s peer interactions, relationships, and groups, and then we present the central theories that have helped to guide research on children and their peers.

In the second section, we introduce a conceptual model that guides our review of the extent literature on children’s peer interactions, relationships, and groups. We provide definitions and examples from each level of social complexity in the model and introduce the notions that context and culture *must* be considered if one is to understand children’s behavior and relationships with peers. Also, we note that one cannot understand any one level of complexity (e.g., children’s social interactions) without considering how it effects or is affected by each of the other levels (e.g., relationships, groups). In the third section, we consider the different methods and measures used to examine children’s peer interactions, relationships, and groups. Thereafter, we explore the nature of children’s relationships with peers and their impact on psychosocial adjustment. For example, we describe both dyadic (e.g., friendships) and group relationships and their effects on developmental outcomes; we also explore the literature on children’s intrapersonal thoughts and feelings about peer group processes. The chapter concludes with a discussion of future theoretical and empirical research directions.

## DEFINITIONS, HISTORY, AND THEORY

The term *peer relations* refers to the broad set of direct and indirect experiences that individuals of all ages have with their nonfamilial age-mates. Peer relations include an extensive array of phenomena including forms of behavior, affect, cognition, motivation, and relationships. In contrast to experiences within the family, experiences with peers are, at least by definition, more likely to be egalitarian, voluntary, and transitory. Due to their differences from adult-structured social domains, the peer domain presents children and adolescents with unique socialization experiences. The peer system is known to complement and supplement, rather than replicate, family-related experiences.

During the past 50 years, developmental scientists have come to learn through rigorous research and novel methodologies, that, in conjunction with the family, the peer system is a significant developmental force. The features and effects of peer experiences are developmental in at least two important ways: (1) they vary as a function of age, and (2) they can be the antecedents, or causes, *and* the consequences of other phenomena. In truth, theorists

and researchers have attempted to identify and measure the most essential features of children's peer experiences and to understand the central processes by which these experiences affect development for well beyond 50 years. In previous versions of this chapter in this *Handbook* (Rubin, Bukowski, & Parker, 1998, 2006), we described the historical origins of contemporary research on peer relations. Research on peer relations continues to be an area of remarkable activity and growth within developmental science. For instance, during the past decade, the time period covered by this chapter, well over 1,500 papers on aspects of peer relations have been published in archival journals, and many books have been focused specifically on peer relations (e.g., Bagwell & Schmidt, 2011; Cillessen, Schwartz, & Mayeux, 2011; Prinstein & Dodge, 2010; Rubin, Bukowski, & Laursen, 2009).

Research on peer relations is multidisciplinary. The dynamics and processes involved in peer relations fall within several traditional scholarly domains including developmental, clinical, and social psychology; sociology; education; neuroscience; anthropology; psychiatry; economics; cultural and media studies; and sport science. New directions in the study of peer experiences involve paradigms drawn from behavior and molecular genetics, social developmental neuroscience, and cultural models. These multidisciplinary approaches help to acknowledge that experiences with peers have extensive links with other domains of functioning as either antecedents to change or as the results of what has happened in them.

### Why Study Peer Relations?

The intense interest in peer relations has been motivated by several concerns and circumstances. They include (a) theoretical proposals regarding peer relations as a contributor to, and a manifestation of competent human functioning (e.g., Tomasello, Melis, Tennie, Wyman, & Herrmann, 2012) and multidisciplinary interests in the origins and significance of extrafamilial social cooperation (Nowak, Tarnita, & Wilson, 2010); (b) applied interests in the promotion of well-being and the prevention of problematic outcomes; (c) recognition that youth live in peer-rich social worlds in which their interactions with age-mates can occur around the clock via multiple modes of interaction; and (d) the presence of peer-related themes throughout contemporary popular culture and media.

Regarding these latter two points, children and adolescents often find themselves surrounded by peers. In increasing numbers, many children, beginning soon after

birth, spend a substantial portion of their weekdays in age-stratified social contexts within which they outnumber adults. Government policy initiatives in many jurisdictions in Europe, the Americas, Asia, and Oceania have promoted opportunities for contact with peers via daycare, prekindergarten education, and after-school programs for school-age children and young adolescents. For many children and adolescents, the peer world is the domain within which they spend the majority of their waking time during the week. Just as importantly, recently developed forms of communication technology and web-based social media programs have provided new forums for peer interaction. Youth can now have contact with each other more extensively, more quickly and thoroughly than anyone could have imagined as recently as 5 years ago. These opportunities touch on multiple processes related to communication between peers. In some ways, the extensive adoption of Internet-based social media sites has changed the peer landscape in radical and fundamental ways.

These social changes have occurred in conjunction with an increased presence of peer themes in many expressive genres of contemporary Western culture. Via books, movies, and television shows, peers have captured the attention of the general population in both positive and negative ways. On the positive side, children, adolescents and their friends have had central roles in many of the most successful movies and works of fiction from the past decade. For example, the central theme of the charming and complex *Harry Potter* books (and movies) is not wizardry and other forms of fantasy but rather the interactions and relationships among a group of peers who offer each other companionship, help, loyalty, and security as they make their way together through the challenges of growing up.

On the negative side, hardly a day goes by when there is not a report in the print or electronic media about adverse forms of peer experience in primary and secondary school contexts. Extreme cases of negative peer experiences have been identified by some journalists as the cause of such destructive outcomes as school shootings and suicides. Furthermore, the harmful effects of some experiences with peers have been portrayed extensively in popular TV shows (e.g., *Glee*, *iCarly*) and movies (e.g., *Mean Girls*, *Diary of a Wimpy Kid*, *The Perks of Being a Wallflower*). In contemporary cultural consciousness, peers relations are a constant fixture in the lives of young people that can be a source of joy and a source of pain.

Of course the most powerful motivation to study peer relations derives from theory that emphasizes the importance of peer experiences as antecedents of multiple forms

of development and adjustment. Peer-based processes are implicated in a wide range of theories intended to explain the processes that account for multiple aspects of development. References to the critical roles of peers can be seen in empirical work regarding the development of language (Justice, Petscher, Schatschneider, & Mashburn, 2011); basic cognitive skills (Rogoff, Goodman Turkkanis, & Bartlett, 2001); achievement motivation (Wigfield et al., Chapter 16, this *Handbook*, Volume 3); social cognition (Killen & Smetana, Chapter 17, this *Handbook*, Volume 3); fundamental forms of social interaction such as cooperation (Eisenberg, Spinrad, & Knapfo, Chapter 15, this *Handbook*, Volume 3) and aggression (Eisner & Malti, Chapter 19, this *Handbook*, Volume 3); emotion and its regulation (Calkins & Mackler, 2011); sexuality (Zimmer-Gembeck, Siebenbruner, & Collins, 2004); and physical well-being (Salvy, de la Haye, Bowker, & Hermans, 2012). A final motivation for studying peer relations stems from extensive evidence that peer relations predict subsequent behavioral and affective maladjustment. For several decades it has been known that multiple aspects of peer relations are prospectively associated with several forms of maladjustment (see Parker, Rubin, Erath, Wojslawowicz, & Buskirk, 2006, for a review). Working largely within a developmental psychopathology framework, researchers have been keen to identify those aspects of peer experiences that function as risk factors; are causally associated with behavioral and affective maladjustment; and function protectively to minimize the likelihood of problematic outcomes that result from other experiences with peers or from other domains. Consistent with the view that peer experiences contribute directly to the growth of competence and well-being, clinically oriented researchers have devised peer-based interventions to promote effective functioning and to minimize maladjustment (e.g., Bierman, 2004).

### A Brief Note Regarding Classical Theories

The most basic and important questions about the roles of peers in child and adolescent development concern the processes by which social experiences with peers influence affect and behavior. In the past decade, there has been a decline in the explicit emphasis on particular "grand" theories, such as the ideas of Piaget and the concepts drawn directly from social learning theory. Instead, research has been driven by more focused concepts whose roots can be found in the extant "grand" theories, but are no longer perceived to be tied directly to them. An ironic consequence of this distance between current ideas and past grand theories

is a heightened importance of recognizing the broader conceptual frame of present approaches to studying peer interactions, relationships, and groups. Most relevant grand theories have been described extensively in prior *Handbook* chapters (Rubin et al., 1998; Rubin, Bukowski, et al., 2006) as well as in other recent sources (see Rubin, Bukowski, et al., 2009 for relevant reviews). Several of these theories have pointed to the behavioral, emotional, and social cognitive processes that underlie the development of competent functioning within the peer group. These processes can be drawn from the developmental models proposed by psychoanalytically oriented theorists, the symbolic interactionists, genetic epistemologists, and cognitive, social learning and social cognitive theorists. In the present chapter we attempt to situate current research within these larger theoretical approaches.

## INDIVIDUALS, INTERACTIONS, RELATIONSHIPS, GROUPS, AND CULTURE: A MODEL OF LEVELS OF COMPLEXITY IN CHILDREN'S PEER EXPERIENCES

For more than 30 years, recognition of the multiple levels of analysis that comprise the peer system has greatly increased. Especially significant in this regard has been the contribution of Robert Hinde (e.g., 1987, 1995) who outlined the features and dialectical relations between successive levels of social complexity. Hinde's model considers the types of interactions that may (or may not) occur given particular contributions of individual characteristics. From these interactions, relationships are formed (or avoided), and those relationships that develop come to exist within social groups that have their own particular characteristics. Significantly, groups exist within communities and cultures that bring with them generally agreed upon sets of norms and values.

### The Individual

The level of the *individual* refers to the person-related characteristics that children bring to and take away from their experiences with peers. Individual level variables include age, sex, race, and ethnicity; temperament and patterns of physiological response to arousal (e.g., behavioral inhibition; exuberance; sociability; emotion reactivity and regulation); developmental history; reputations that the individual has within given peer groups; social-cognitive skills and social competence (reflective interpersonal

problem-solving skills; consequential thinking; social information processing skills; the ability to achieve social goals in acceptable ways); self and relationships perceptions (e.g., self-perceptions of social skills; internal working models of relationships; the understanding of relationship constructs; the individual's thoughts and feelings about how others may think and feel about, and act toward them in given situations); and social goals and needs. The important point about variables at the level of the individual is that they pertain to the person *per se*.

Recently, at least two new perspectives have emerged in the study of individual characteristics and their relations to peer interactions, relationships, and groups. The first derives from the study of differences in the extent to which individuals prefer to approach or to avoid social situations. As outlined by McNaughton and Gray (2000), children possess two neural-based systems—the Behavioral Activation System (BAS) that motivates approach behaviors via sensitivity to reward and the Behavioral Inhibition System (BIS) that inhibits behavior in response to conditioned aversive stimuli. Although the BAS and the BIS were initially regarded as independent systems, it has been proposed that the two systems intersect to control behavior. Thus, children who are high in BIS and low in BAS are motivated to avoid social situations, whereas those who are low in BIS and high in BAS are motivated to approach others in social situations. Research on BAS/BIS sensitivity has shown that high levels of BIS are associated with poor perceptions of peer relations and consistently associated with several measures of internalizing problems such as depression, anxiety, and behavioral avoidance (e.g., Kingsbury, Coplan, Weeks, & Rose-Krasnor, 2013). Furthermore, the interaction between the BIS (low) and the BAS (high) predicts social/emotional competence (Kingsbury et al., 2013).

The emphasis on basic mechanisms of reward and inhibitory control is apparent also in recent theory regarding the role of changes in individual level characteristics and developmental changes in sensitivity to peer effects. Steinberg and his colleagues have proposed a neural-based developmental model of peer influence. This approach is predicated on the recognition that reward-sensitive aspects of neural functioning develop earlier than neural mechanisms related to control. Accordingly, the effects of peer influence are stronger during early adolescence at the time when reward mechanisms develop than they are in late adolescence after the control mechanisms emerge (e.g., Chein, Albert, O'Brien, Uckert, & Steinberg, 2011).

In a related advance, it is proposed that emotional reactivity and regulation can predict children's social interactions, which, in turn, may affect their peer relationships

(e.g., Degnan et al., 2011). For example, researchers have shown that the child's tendency to be emotionally dysregulated, when combined with dispositionally based unsociability, predicts the frequent enactment of socially reticent behavior among preschoolers (e.g., Rubin, Coplan, Fox, & Calkins, 1995). On the other hand, preschoolers who are emotionally regulated and unsociable are more likely to display exploratory and constructive solitude rather than anxious withdrawal in the classroom. And those who are sociable and unable to regulate their negative emotions (e.g., anger) are more likely to engage in aggression behavior than their age-mates who are sociable, yet well regulated (Rubin et al., 1995).

Another example of the significance of the effects of individual level biological factors on social interaction (or the lack thereof) derives from recent research by Barhight, Hubbard, and Hyde (2012). These researchers assessed emotional reactivity as an individual level construct that might predict children's actions in situations involving bullying. They posited that individuals who are highly aroused physiologically (high heart rate when witnessing videos of bullying) would be more likely than their age-mates who were unemotional, to intervene and disrupt bullying when it occurred in the classroom. Their findings that confirm this hypothesis point to the value of reactivity as an important individual level variable in peer relations research.

A second nuance in the study of individual-level characteristics that may affect peer functioning derives from recent research in neuroscience. Researchers have begun to show that neural mechanisms may mediate the relations between such individual characteristics as social anxiety and the ability to process social cues pertaining to peer rejection. It is now well known that children and adolescents who are socially anxious tend to demonstrate heightened amygdala sensitivity when confronted with instances of peer rejection or exclusion (often assessed during socially dynamic, simulated peer interactions such as "cyberball," wherein the participant is "excluded" by hypothetical peers, e.g., Guyer, Choate, Pine, & Nelson, 2012). And recently, researchers who study children who have experienced traumatic brain injuries have found that the brain structures of those who have mutual best friends in school vary from those who are friendless (Yeates et al., 2013). In both of these latter neuroscience programs of research, the investigators have relied on neuroimaging procedures. Given the current *neuro-Zeitgeist*, we expect that with advances in neuroimaging technologies, the study of brain-behavior relations will significantly advance knowledge on the connections between individual characteristics and peer interactions and relationships.

## Interactions

The simplest order of social complexity of peer experience involves interactions. Interactions refer to what individuals actually do to or with each other (Hinde, 1987). Behaviors that simply (and only) complement one another (such as riding on either end of a teeter-totter) would ordinarily not be considered true interaction unless it was clear that they were jointly undertaken. Instead, the term *interaction* is reserved for dyadic behavior in which the participants' actions are interdependent such that each actor's behavior is both a response to, and stimulus for, the other's behavior. Conversational turn taking is a paradigm-case illustration of interaction. For example, Child A requests information from Child B: "What's your name?"; Child B responds. "My name is Isabella. What's yours?"; Child A replies: "Jonah, but some call me Spiderman"; Child B answers: "Yea, and lots of my friends call me Batgirl!"; and so on.

Such a simple exchange as that of Isabella and Jonah belies the richness and complexity of the ways that children of most ages communicate with and influence one another. In addition to "introducing" themselves, children in conversation may self-disclose, joke, play, cooperate, plan and decision-make, and engage in coconstruction. They may compete, respond to provocation, argue, fight, resolve conflict, gossip, and engage in a host of other behaviors that includes everything from rough-and-tumble play to highly structured sociodramatic fantasy. Interactions can have many characteristics (e.g., they can be short or enduring, balanced or imbalanced) and they may vary in their content (e.g., they can involve prosociality and cooperation or agonism and conflict).

Typically, researchers have been less interested in cataloguing the myriad of interactional experiences than in understanding the origins and consequences of three broad childhood behavioral tendencies: (1) moving toward others, (2) moving against others (externalizing behaviors), and (3) moving away from others (internalizing behaviors). As a consequence, our understanding of children's experiences at the interactional level may be disproportionately organized around the constructs of (a) sociability and altruism (caring, sharing and helping, e.g., Knafo & Plomin, 2006); (b) aggression, bullying, negative gossip, and interpersonal conflict (e.g., Murray-Close & Ostrov, 2009); and (c) withdrawal (avoiding interaction, e.g., J. C. Bowker & Raja, 2011).

It is clear that children engaged in interactions vary their behavior as a function of such *individual* factors as their short- and long-term personal goals, an understanding of their partner's thoughts and feelings in the situation,

the depth of their repertoires of alternative responses, and various "ecological" features of the context of the interactions (e.g., the presence of bystanders in a bullying situation). It is the demonstration of range and flexibility in responding to the challenges of interpersonal interaction that many think of as composing social competence.

## Relationships

One consequence of regularly finding oneself in the company of another person and either interacting or not interacting with that person is the development of identifiable *relationships*. Individuals form internal representations of relationships and their properties based on their interaction-based experiences with the dyadic partner. The type of relationship that is formed may be influenced by the *quality* of the interactions between individuals. For example, positive interactions may lead to the development of meaningful, supportive, secure, and constructive *friendships* (Bukowski, Motzoi, & Meyer, 2009) and *romantic relationships* (Collins, Welsh & Furman, 2009); negative interactions may result in enmity (Card, 2010) or bully-victim relationships (Salmivalli & Peets, 2009). In this regard, relationships are influenced by past and anticipated future interactions.

Of course, relationships also are determined by individual characteristics. For example, racial homophily is a particularly strong predictor of initial peer attraction and the formation of friendships (e.g., McDonald et al., 2013). As such, most child and adolescent friendships involve same-race peers (e.g., Joyner & Kao, 2000). Although racial homophily often characterizes friendships, scholars have proposed that increases in racial diversity within a community can lead to increases in social integration and improved intergroup attitudes (McGlothlin & Killen, 2005). Thus, it has been proposed that with increased diversity, the prevalence of cross-race friendships will also increase (Quillian & Campbell, 2003). However, there is mixed evidence that diversity increases the prevalence of cross-race friendships, with some studies finding increased cross-race friendship prevalence only for particular groups (e.g., majority children) and others finding that the effect of diversity is dependent on other contextual features, such as the amount of segregation in extracurricular activities and academic tracks (e.g., see McBride Murray, Hill, Witherspoon, Berkel, & Bartz, Chapter 11, this *Handbook*, this volume).

Researchers have also noted that the quality and stability of children's friendships is associated with the interactions and collaborative decision-making that occur within friendship dyads (e.g., A. Bowker, 2004; Poulin & Chan,

2010). In general, close friends' interactions and collaborations are more competent than those of nonfriend interactors or of those whose friendships are poorer in quality. This literature is reviewed extensively below.

### Groups

A *group* is a social network within which *individuals* interact and *relationships* are embedded (Kindermann & Gest, 2009; Santos, Vaughn, & Bost, 2008). Groups can differ on multiple dimensions including whether they are self-selected (e.g., a clique in a secondary school) or created by institutional or social forces (e.g., children who ride the same school bus), whether the members are brought together by an explicit reason (e.g., a school-based club; a competitive sports team) or by reasons that are not entirely clear (e.g., a neighborhood peer group), and whether it is formal (e.g., a school classroom) or informal (e.g., a group of friends). Accordingly, groups possess properties that arise from the manner in which the relationships are patterned but are not present in the individual relationships themselves. Examples of such properties include *cohesiveness*, or the group's internal structure or organization; *norms* or descriptive features (e.g., distinctive patterns of behaviors, interactions, and attitudes that characterize group members and differentiate them from members of other groups); *hierarchy*, or the extent of intransitivity in the ordering of the individual relationships along interesting dimensions (e.g., if Fred dominates Brian and Brian dominates Anthony, does Fred dominate Anthony?); and *homogeneity* or *homophily*, or consistency across members in the ascribed or achieved personal characteristics (e.g., sex, race, age, intelligence, attitudes toward school). Finally, groups can be small (e.g., a few friends who like to "hang around" together) or large (e.g., a culturally or politically defined context such as a city).

Not only can dominance structures describe individual standing within groups, but they can also identify smaller groups within the larger peer structure. For example, groups comprise core and marginal members (Hogg & Reid, 2006). Within the group, core members are highly visible, popular, and socially powerful. Thus, core members have the power to persuade other group members to think like and agree with them. In some cases, status as a core member spans across a number of groups. For example, Sussman, Pokhrel, Ashmore, and Brown (2007) have identified a core group of "populars" who dominate the school setting. In contrast, marginal group members have relatively little status and power and their membership status within the group is more likely to fluctuate than that of a core member.

As noted above, the "glue" that holds groups together is drawn from shared values, attitudes, and behaviors of its constituent members (Kindermann & Gest, 2009). Thus, members in groups are interconnected through their dyadic relationships, while at the same time, sharing common interests and social conventions. These shared values and norms enforce appropriate within-group interactions between members.

Group norms can be used as a basis for distinguishing separate "crowds" within the networks of relationships among children in high school (e.g., Brown & Dietz, 2009). The emergent properties of groups also shape the experiences of individuals in the groups (e.g., Espelage, Holt, & Henkel, 2003). Thus, crowd *labels* constrain, in important ways, adolescents' freedom to explore new identities; *status hierarchies* influence the formation of new friendships; *segregation* influences the diversity of children's experiences with others; and *cohesiveness* influences children's sense of belonging. As such, the group can influence the individual. Indeed, many of the classic developmental studies focused on the peer group per se, including the Lewin, Lippitt, and White (1938) study on group climate, and Sherif, Harvey, White, Hood, and Sherif's (1961) examination of intragroup loyalty and intergroup conflict. In addition, recent theorists stressing the importance of children's peer experiences have generally conceptualized the group as an important developmental context that shapes and supports the behaviors of its constituent members (e.g., Xie, Cairns, & Cairns, 1999).

Returning to the intermix between levels of social complexity, some researchers have reported that boys are more likely to interact in groups, whereas girls are more likely to be exclusive in their relationships (see Rose & Rudolph, 2006, for review). Others report that girls value group membership more than boys and that they have more friends than boys. Yet others have failed to find significant sex differences in the extensivity of peer networks. This incongruence may be a function of the variety of methods used by researchers; for example, sex differences in the extensivity of networks and affiliation have been found when observational methods have been employed; but self-reports of group affiliations yield different results.

### Culture

It is important to recognize, that each of the levels described above falls under the all-reaching umbrella of the cultural macrosystem (e.g., Bronfenbrenner & Morris, 2006). Here the word *culture* means "the set of attitudes, values, beliefs,

and behaviors shared by a group of people, communicated from one generation to the next" (Matsumoto, 1997, p. 5). Cultural beliefs and norms help interpret the acceptability of individual characteristics and the types and ranges of interactions and relationships that are likely or permissible.

As it happens, the cultural and cross-cultural study of children's individual characteristics and their peer interactions, relationships, and groups has had a relatively brief history (see Goodnow & Lawrence, Chapter 19, this *Handbook*, this volume, for a full discussion of culture). A central question asked in this body of work is rather intriguing: Do the "meanings" and significance of given social behaviors or relationships differ from culture to culture or are there cultural universals in interpreting given social behaviors and relationships? This question focuses on the long-held distinction between *form* and *function*; that is, the psychological "meaning" attributed to any given (form of) social behavior is, in large part, a function of the ecological niche in which it is produced and exhibited (Bornstein, 1995). Given that cultures vary in their customs and belief systems, any particular individual characteristic, social behavior, interaction, or relationship may be interpreted differently across cultures. For example, if a given behavior is viewed as acceptable, then significant others (including peers) will attempt to encourage its development; if the behavior is perceived as maladaptive or abnormal, then attempts will be made to discourage its development. Of course, the very means by which people go about encouraging or discouraging the given behavior may be culturally determined and defined.

Another significant issue is the degree to which cultures allow or encourage peer interactions and relationships (see Chen & Rubin, 2011 for relevant discussions). All in all, the majority of the world's inhabitants do not reside in culturally "Westernized" countries; as such, cross-cultural work on peer interactions, relationships, and groups requires careful attention (see Chen & Rubin, 2011, for reviews).

### **Interdependencies Between Levels of the Multilevel Model**

As noted earlier, a critical point of the model derived from Hinde (1987, 1995) is interdependency. Although the constructs and processes at a particular level are conceptually distinct from those at other levels, they are interdependent in the sense that constructs at one level can be constrained by or influenced by constructs at other levels.

We focus on the construct of social withdrawal as an example of an individual characteristic (other relevant

constructs such as aggressiveness, temperament, theory of mind, and race and ethnicity are reviewed in various chapters in this *Handbook*). It is known that the extent to which one is anxiously withdrawn in the company of peers depends, in part, on features at the level of the *individual* (e.g., inhibited temperament, physiological markers such as vagal tone, heart rate, emotion dysregulation; e.g., Calkins & Mackler, 2011). When anxiously withdrawn children *interact* with peers, they make fewer attempts to initiate *interaction*, their initiations tend to be relatively undemanding, and they are more likely to be met with noncompliance than are their nonwithdrawn age-mates. On the other hand, they are more compliant and submissive to their peers' social overtures (see Rubin, Coplan, & Bowker, 2009, for a relevant review). Furthermore, it has been demonstrated that anxiously withdrawn children are more likely than typical children to be rejected, excluded, and victimized by peers and to have friendships that are of relatively low quality (all indices of *relationships*; e.g., Bukowski, Laursen, & Hoza, 2010; Rubin, Wojslawowicz, Rose-Krasnor, Booth-LaForce, & Burgess, 2006). Indeed, the extent to which one is rejected or excluded by peers and/or is friendless exacerbates *individual* trajectories of anxious, inhibited withdrawal (e.g., Booth-LaForce et al., 2012; Gazelle & Ladd, 2003; Oh et al., 2008).

Again, the interaction and transactions between levels is exemplified by the research indicating that anxiously withdrawn children who are rejected and/or friendless are at risk for developing negative thoughts and feelings about the self (e.g., depression, loneliness, hopelessness; Bukowski et al., 2010; Ladd, 2006; Nelson, Rubin, & Fox, 2005). Also, although anxiously withdrawn children appear to have as many friends as their typical age-mates (Ladd & Burgess, 1999; Rubin, Wojslawowicz, et al., 2006), they have been observed to interact with them in ways that vary from their typical age-mates (Schneider, 2009; Stewart & Rubin, 1995) and to think about their friendships differently than do their typical age-mates (Fredstrom et al., 2012; Schneider & Tessier, 2007). For example, anxiously withdrawn children are less talkative, more passive and submissive, and less competitive during their interactions with friends than nonanxiously withdrawn children (Schneider, 2009); and they also believe that their friendships are lacking in companionship, intimacy, and supportiveness (Rubin, Wojslawowicz, et al., 2006). In addition, socially withdrawn children are less mature in their conceptualization of the very meanings of friendship than are their typical age-mates (Fredstrom et al., 2012).

It is also the case that at the *group* level, both withdrawn children and their best friends are reported to be more victimized by the peer group (Hanish & Guerra, 2004; Rubin, Wojslawowicz, et al., 2006) and more submissive and low in the dominance hierarchy relative to their nonwithdrawn peers (Lease, Musgrove, & Axelrod, 2002). And finally, it is important to note that there are *cultural* differences in the ways in which behaviorally inhibited and shy-anxious children are perceived—by peers, parents, and teachers. In some cultures, inhibited, shy-withdrawn behavior is more prevalent than in others (e.g., Rubin, Hemphill, et al., 2006). And in some cultures, peers are more accepting (e.g., Chen, DeSouza, Chen, & Wang, 2006) or rejecting (e.g., Valdivia, Schneider, Chavez, & Chen, 2005) of their anxious withdrawn peers than in others. Of course, these differences may be accounted for by differing cultural “meanings” of the behavior. For example, in China, shy behavior is interpreted as an indication of reservedness, compliance, and conformity to adult expectations. These characteristics are considered typical and desirous. Given the significance attached to achieving and maintaining social order and interpersonal harmony within traditional Chinese culture, it makes sense that individuals are encouraged to restrain their personal desires and to behave in a sensitive, cautious, and inhibited fashion. Indeed, children who exhibit such tendencies are described as *guai hai zi* in Mandarin, which may be loosely translated as meaning “good” or “well behaved.”

At the same time, socially avoidant behavior in China is frowned upon. Cheah and Rubin (2004) found that when Chinese parents were asked directly how they would respond if they actually viewed their children behave consistently in a withdrawn fashion, they reported that mothers regarded such behavior in a very negative fashion. Cheah and Rubin argued that whereas shy, socially reserved sensitive behavior may eventually be conducive to harmonious group interactions, socially withdrawn behavior that removes the child from familiar others could undermine such goals. In this regard, socially withdrawn behavior could be perceived by Chinese mothers as “nonsocial” behavior that undermines the predominant collectivistic teachings of preschool caregivers, as well as the societal goals of group harmony and close interaction (Stimpfl, Zheng, & Meredith, 1997). Thus, as many others have noted beforehand, language and nomenclature are important in cross-cultural research. If one interviews or provides parents and children with questionnaires, a central rule of thumb must be that the construct one is interested in exists, has a label attached to it, and can be distinguished from related but different constructs. Social withdrawal,

social isolation, social avoidance, unsociability, preference for solitude, and shyness are related phenomena, and yet not considered the same constructs in the Western literature published in the English language (J. C. Bowker & Raja, 2011; Coplan et al., 2013; Wang, Rubin, Laursen, Booth-LaForce, & Rose-Krasnor, 2013); in cross-cultural research, one must surely ascertain whether given constructs go by the same or different names, or whether they, in fact, exist in various cultures.

### *Beyond Interdependencies*

It is important to recognize that at times the levels noted above can be antagonistic. The perception of one child as interacting frequently with aggressive behavior may prove attractive to a similarly inclined aggressive individual, thus promoting friendship (e.g., Bukowski, Sippola, & Newcomb, 2000); however, such a friendship dyad might prove to be a risk factor for effective functioning at the level of the group (Vitaro, Pedersen, & Brendgen, 2007).

A further implicit premise of the model is that children are motivated to function competently at each level of social complexity. At the level of the *individual*, children are motivated to successfully deal with several person- and self-related challenges such as functioning competently in a range of activities, developing a positive self-concept, being autonomous and feeling authentic, regulating one's emotions, and defending one's self from negative treatment by peers. At the level of the *dyad*, children are typically motivated to develop satisfying and lasting friendship relations and to avoid enmity. At the level of the *group*, most children are motivated to be accepted by peers, belong to a social network, and to be included in social activities. Inherent in this perspective is the tacit claim that a competent child or adolescent is one who can successfully interact at the level of the dyad *and* at the level of the group. Multilevel competence is challenging not only because it involves a potentially broad skill set but also because achievements at one level can lead to difficulties at others. For example, the initiation of a new friendship may lead to difficulties with an existing friendship network. Attainment of popularity may require adolescents to break-off friendships with less popular peers (Eder & Kinney, 1995). Managing interdependencies between the levels may be a critical defining characteristic of being identified as a socially competent individual.

As noted above, one challenge to Hinde's model is that some constructs appear at two levels simultaneously. Consider the construct of peer acceptance (i.e., the extent to which a child is liked by peers). It is one of the most

widely studied variables in peer relations research. In one respect, it is an *individual* level variable that refers directly to the status of a particular child. At the same time, it is a group level variable that indexes how many children in a given group like a particular peer. Accordingly, depending upon how it is conceptualized, a particular measure could be placed at a different level on the stratified model. Of course, this example (as well as others) does not invalidate the multilevel approach, but instead points to its complexity. Rather, this potential limitation can be addressed through the use of multilevel and transactional models that recognize the interdependence between individuals and the groups in which they are embedded (e.g., Kochenderfer-Ladd & Wardrop, 2001). Having a stratified structural model provides a way of thinking about peer variables that can aid in the development of comprehensive models to understand which aspects of the peer group are most important and how they affect well-being.

### Summary

To understand experiences with peers, researchers have focused on children's individual characteristics, the interactions they have with others, their involvements in peer relationships and groups, and the influences of culture on all of the above. Analyses within each level are, of course, scientifically legitimate and raise interesting questions. However, researchers have not always demonstrated a clear understanding of the important ways in which processes at one level are influenced by those at the others. As such, they have sometimes overlooked ways in which conclusions drawn at single levels of analysis can be limited. Clearly, research on peer relations would benefit from a consideration of (a) the underlying processes and motivations that account for the observed effects of peer experiences and (b) the differential significance of different forms of experience within the group (see also Wachs, Chapter 21, this *Handbook*, this volume).

Finally, our emphasis on multiple levels of analysis provides us with a basic conceptual model of social competence. Researchers have often treated measures of peer experiences at one level (e.g., peer acceptance; likeability) as indices of social competence. Our view is that social competence within the peer system refers to a child's capacity to engage effectively and successfully at each level of analysis and within his or her relevant culture. That is, a competent child will be able to (a) satisfy individual goals and needs successfully by interacting with peers in acceptable ways; (b) develop accurate and

productive means of understanding experiences in dyadic (e.g., friendships) and group relationships; (c) become engaged in relevant peer groups and participate in acceptable group-oriented activities; and (d) become involved in satisfying relationships derived from balanced and reciprocal interactions.

## STUDYING PEER INTERACTIONS, RELATIONSHIPS, AND GROUPS

To the extent that individual differences exist in children's adaptation or success with peers, such differences will be reflected in (a) their individual characteristics (e.g., gender; race/ethnicity; temperament; social cognitive skills); (b) their peer interactions; (c) their abilities to develop and sustain friendships; (d) their acceptance and status in peer groups; and (e) the groups within which they are members. Given that many of the individual characteristics relevant to children's peer interactions and relationships are reviewed in other chapters in this *Handbook*, we will leave that coverage to others. Herein, we examine procedures by which researchers have assessed peer interactions, relationships, and groups.

### Assessing Children's Peer Interactions

Although parents, clinicians, and archival data have all served as sources of information about the valence and nature of children's peer interactions, the most common sources are structured observations or the reports of other children or teachers.

#### *Observations of Behavior*

There is a long tradition of observing children in either naturalistic or laboratory-based play groups. For example, *observational procedures* have been used to index the frequency with which individuals (a) engage in particular behaviors (e.g., aggression, Bierman, Smoot, & Aumiller, 1993; deviant talk, Piehler & Dishion, 2007; reticence and behavioral inhibition, Rubin, Burgess, & Hastings, 2002; rough-and-tumble play, Smith, Smees, & Pellegrini, 2004; social pretense and rule-governed group games, Howe, Petrakos, Rinaldi, & LeFebvre, 2005; sharing, helping, and cooperating, de Guzman, Carlo, & Edwards, 2008; initiating or resolving conflict, Laursen, Hartup, & Koplas, 1996; gossiping, McDonald, Putallaz, Grimes, Kupersmidt, & Coie, 2007; talking negatively about oneself/ruminating, Schwartz-Mette & Rose, 2009); (b) adopt particular roles

vis-à-vis their partners (e.g., dominant versus submissive roles; teaching peers, learning from peers, and managing the behaviors of peers, Nelson et al., 2005); or (c) demonstrate social competence and interpersonal problem solving skills (Stewart & Rubin, 1995). Observations have also allowed the coding of the affect of interactions (positive, negative as well as the identity of the interactors (friends; children of the same/opposite sex; younger/older/same age). Typically, these observation protocols involve time or event sampling (e.g., Rubin, 2001).

Observational taxonomies have been used profitably to reliably distinguish between children along a variety of behavioral dimensions. In this regard, observations of peer *interaction* are used to identify *individual* characteristics. For example, observational taxonomies have been used to identify children whose behaviors (e.g., physical and relational aggression; anxious withdrawal) deviate from age-group norms. Observational taxonomies also have been used in studies to compare the social interactions of handicapped and typical children (e.g., Guralnick, Connor, & Johnson, 2011) and to compare the peer interactions of children in cross-cultural investigations (e.g., comparing the extent to which children from different cultures engage in sociodramatic play, Tudge, Brown, & Freitas, 2011).

Although observational methods offer many advantages over the assessments discussed next, they also have specific limitations. First, observations are time-, energy-, and money consuming. Whereas peer assessments can be conducted in minutes or hours, observations can require weeks or months of data collection. Second, as children get older, it becomes increasingly difficult to observe them during “naturalistic interactions.” Third, unless researchers carefully consider or control how social behavior is being influenced by setting demands, observation methods can lead to false conclusions of the willingness of certain individuals to engage in behaviors of interest. Fourth, observations may be reactive; for example, children who are aware that they are being observed may behave in atypical manners, perhaps suppressing negative behaviors or increasing the production of prosocial behaviors. Nevertheless, observational procedures represent “gold standards” that can be used to validate peer and teacher assessments of children’s social behavior. Recent reviews of these techniques can be found elsewhere (e.g., Rubin, Bukowski, et al., 2009).

### ***Peer Assessments of Social Behavior***

In lieu of direct observations, researchers have often relied on children for information about who behaves competently or incompetently (see Bukowski, Cillessen, &

Velasquez, 2012, for a review). Bukowski et al. have noted that there are several advantages of peer informants. First, as “insiders,” peers can identify characteristics of children and of relationships that are considered relevant from the perspectives of those who ultimately determine a child’s social status and integration within the peer group. Second, the judgments of peers are based on many extended and varied experiences with those being evaluated. Third, peer assessments of children’s behaviors represent the perspectives of many observers with whom the target child has had a variety of personal relationships. The chance that error will be introduced by some idiosyncratic aspect of any single reporter’s experience with the child is therefore correspondingly reduced.

In most peer assessment techniques, children are given a set of target behaviors and asked to nominate peers on the basis of a variety of behavioral roles or character descriptions (e.g., “shares with others”). Nominations received from peers are summed in various ways to provide indices of a child’s typical social behavior in the peer group. One commonly used peer assessment technique is the Revised Class Play (Masten, Morrison, & Pellegrini, 1985). Factor analysis of children’s nominations using this measure has yielded three behavioral factors—Sociability-Leadership, Aggressive-Disruptive, and Sensitive-Isolated. Recent advances in the use of peer assessments have provided a more refined articulation of the dimensions underlying children’s social behavior. For example, Rubin and colleagues (e.g., J. C. Bowker, Rubin, Buskirk-Cohen, Rose-Krasnor, & Booth-LaForce, 2010) developed a reliable and valid extension of the Revised Class Play to distinguish between different forms of social withdrawal and aggression, as well as to measure sociability, prosocial/altruistic behavior, exclusion, and victimization. Embedded items assess peer acceptance, perceived popularity, and rejection. An inherent problem with peer nomination techniques are potential biases due to variations in class size. A recently developed regression procedure provides a solution to this problem (Velasquez, Bukowski, & Saldarriaga, 2013).

A disadvantage of peer assessments is that once behavioral reputations consolidate they can be resistant to change (Hymel, 1986). Thus, even though a child’s behavior may have changed, their reputation for this behavior persists with peers. As such, the data reaching the researcher may not fully reflect the current state of “reality.” In addition, reputations are probably unduly influenced by infrequent but salient events (e.g., embarrassing social gaffs, poignant aggressive outbursts). Although characteristic of the child, the child’s reputation for this behavior may overstate

the frequency with which it appears in his or her social interchanges. Relatedly, there is evidence that children's recall of their peers' abilities and behavior is affected by their own behavioral reputation, level of peer status, age, and liking for the target; situational factors; and the target's gender, age, and sociometric status (e.g., Card, Hodges, Little, & Hawley, 2005). Finally, a main challenge to the study of peer assessments is the potential variance across cultural contexts in children's representations of social constructs (e.g., Chen & Tse, 2008).

### ***Teacher Assessments***

One advantage of teacher assessments over peer assessments is that the collection of data is more efficient and less time consuming. A second advantage is that, because they themselves are not members of the peer group, teachers may be more objective in their assessments of social behavior. On the other hand, teachers may bring with them an "adultomorphic" perspective that carries with it value judgments about social behaviors that might differ from those of children. Furthermore, teachers may carry with them biases that influence the ways in which they react to their pupils; such teacher reactions may strongly influence children's peer preferences and judgments (White & Kistner, 1992).

Many standardized teacher report measures presently exist and an excellent review of teacher ratings of child behavior may be found in Bierman (2004). Generally, these measures can be broken down into several socioemotional clusters or factors that fall along dimensions of social competence/sociability/likeability/leadership (Ladd, Herald-Brown, & Andrews, 2009); aggression/hostility/conduct disorder; (e.g., Polman, de Castro, Thomaes, & van Aken, 2009); hyperactivity/impulsivity; and anxiety/fearfulness/withdrawal (e.g., Coplan & Rubin, 1998).

### ***Agreement Among Sources***

Achenbach and colleagues (e.g., see Achenbach, 2006) have reported that the correlations between reports of children's behavioral problems average about .60 between informants seeing children under generally similar conditions (e.g., pairs of teachers; pairs of parents); .28 between different types of informants seeing the child under different conditions (e.g., parents versus teachers); and .22 between children's self-reports and reports by others, including parents and teachers.

Recently, De Los Reyes, Henry, Tolan, and Wakschlag (2009) have argued that informant discrepancies in reports of children's interactive behavior exist, in part, because

different informants observe children's behavior in different settings. As a result, parents and teachers (and peers) bring different perspectives of children into their appraisals. Parents are more likely to provide appraisals based on their experiences with their children at home or with family members; teachers may be better able to compare a given child with the many they have taught in the past, and thus provide a perspective that draws from a "normative sample"; and as noted earlier, peers have an "insiders" perspective on what a rated/nominated child is like when observed beyond the purview of parents and teachers (and trained laboratory observers). In this regard, De Los Reyes et al. (2009) have provided empirical support for an Attribution Bias Context Model in which it is suggested that when informant discrepancies arise, they indicate meaningful perceptual and situational differences among informants in how and under what circumstances they observe behavior.

From the perspective of De Los Reyes and colleagues, it may be appropriate to suggest that if it is the researcher's intention to examine how given children behave in school or in the surrounds of the school (e.g., the school yard; the school bus; the athletic fields and gym), then perhaps the most appropriate informants are peers. After all, peers possess the "inside" knowledge of what happens in and around the school and well beyond the vantage points of teachers and parents. Indeed, peers are likely to be the best informants about given children's behaviors during extracurricular activity as well. Of course, how this information is obtained must be guided by the ages of the child and his or her peers. However, the bottom line is that the goal is not to determine which assessment procedure yields the singular truth about the child, but to use what each one reveals about the child's functioning in particular areas or contexts.

### ***Assessing Peer Relationships***

#### ***Assessments of Friendship: Friendship Involvement***

The nature of the assessment of whether a child has a friend varies across periods of development. In early childhood, parents or teachers are often asked to identify whether a child is a friend of another child (Howes, 2009), and observations may be used to confirm that the two reported friends actually spend time together and share positive affect (Dunn, Cutting, & Fisher, 2002). In the assessment of friendships of elementary school-age children, children are thought to be the best informants on friendship. Therefore, children are typically presented with rosters or a set

of pictures of classmates and are asked to indicate which peers are their friends (e.g., Sebanc, Kearns, Hernandez, & Galvin, 2007). Similar procedures are used when studying the friendships of middle- or high school students, but researchers may simply ask adolescents to provide the names of their friends. Children and adolescents of all ages may also be asked to designate their “best” versus “good” friends. With these self-reported assessments of friendship, the pattern of friendship choices is subsequently examined to determine which friendship nominations are reciprocated or mutual and which children have mutual friends. Such assessments, in combination with peer nomination data, also may be used to identify the individual characteristics of children’s best and close friends (e.g., the aggressiveness or popularity of the friend; Ellis & Zarbatany, 2007; Wilson & Rodkin, 2011), and how the characteristics of children’s friends might impact their own adjustment (e.g., Vitaro et al., 2007).

However, there are several issues that may limit the validity of these measures. For instance, researchers do not typically provide informants specific criteria by which the presence of a friendship should be determined. Instead, it is often assumed that these informants share the researcher’s definition of friendship, which may not always be the case, and could impact the accuracy of the assessment. For example, a child may misinterpret the “meaning” of a friend and provide an over-inclusive set of nominations (e.g., by including the names of casual acquaintances). An example of such overinclusion may be gleaned from glancing at the number of “friends” adolescents and adults report having on their Facebook pages.

The “meaning” of a friend also may vary across cultures, which could lead to artificial differences in cross-cultural research studies. As French, Lee, and Pidada (2006) have shown, in cultures that ascribe considerable power or authority to the family system, the significance and meaning of friendship may differ substantially from the meaning of friendship in Western cultures. It is conceivable that friendship may even be seen as a threat to the expected structure and influence of the family. Accordingly, peer research needs to be increasingly sensitive to the cultural variations in the way that friendship is constructed and in the role that friendship is given in children’s lives.

Another issue concerns the restrictions that are often placed on who it is that children and adolescents can nominate as friends. For instance, limiting the total number of friendship nominations (e.g., three nominations), only allowing nominations for “best” friends, and restricting nominations to same-sex peers likely prevents many youth

from nominating peers who they consider friends and who may have a significant influence in their lives.

It is also common to limit friendship nominations to same-class, same-grade, or same-school peers (Berndt & McCandless, 2009). Although the same-classroom or grade peer group is typically a child’s most salient peer group, it is almost always the case that children have same-school friends who are outside of their own grade as well as friends who attend different schools (J. C. Bowker & Spencer, 2010; Kiesner, Poulin, & Nicotra, 2003). In sum, the restrictions placed on friendship nominations raises legitimate concerns; in many cases, it appears that the sizes of children’s and adolescents’ friendship networks are underestimated.

### *Assessments of Friendship: Friendship Quality*

Research indicates significant variability across friendship dyads in terms of relationship qualities or features (Bukowski & Hoza, 1989). That is, some friendships may be characterized by more positive relationship qualities, such as affection, companionship, aid, validation, and caring, than others. Significant variability in the extent to which conflicts occur, and are resolved, in friendships has also been documented (e.g., Simpkins & Parke, 2002). The most common approach to studying friendship quality involves assessment through children’s self-reports (for review, see Berndt & McCandless, 2009). Self-reports of friendship quality typically assess (a) the functions or provisions of friendships (e.g., degree of help and advice, intimate disclosure), (b) conflict and disagreements, and (c) the affective properties of the friendship (e.g., the degree of affection between friends). However, factor analyses consistently reveal that positive features of friendship (e.g., intimate disclosure) load on one factor and negative features of friendship (e.g., betrayal) load on another (Furman & Rose, Chapter 22, this *Handbook*, Volume 3).

Observational assessments of friendship quality are much less commonly used than self-report measures (e.g., Dunn et al., 2002; Simpkins & Parke, 2002), but may capture specific aspects of friendship that are less accessible through self-reports (e.g., the cognitive sophistication of play between friends; Simpkins & Parke, 2001; the extent to which gossip occurs; Menzer et al., 2012); and the ways in which friends communicate and co-construct solutions to social problems and issues, McDonald, Malti, Killen, & Rubin, 2014). As noted above, observational techniques are more labor- and time intensive than self-report techniques. However, the low-to-moderate associations between self-report and observations of the characteristics

of children's friendships (e.g., Simpkins & Parke, 2001) suggest that our understanding of the ways in which children's and adolescents' friendships differ qualitatively could be enhanced by studies that utilize both types of assessments.

### ***Assessments of Friendship: Cognitions About Friendship***

Finally, interview techniques have been the methodology of choice for investigators interested in children's beliefs and understanding of friendship. Examples of interview questions that assess friendship conceptions include: "What is a best friend?"; "What do you expect from a best friend?"; or "Why does a person need a good friend?" (e.g., Fredstrom et al., 2012). For example, Selman (1980) argued that children's friendship conceptions about various friendship issues (e.g., friendship termination) could be categorized into one of five developmental stages, which reflect increasingly complex perspective taking skills and social-cognitive sophistication. Hypothetical scenarios (in which the child is asked to imagine that the scenario involves a best or close friend) might also be used to study how children think about and evaluate various social situations involving close friends (e.g., conflict, betrayal, help-seeking; MacEvoy & Asher, 2012).

### ***Assessments of Peer Acceptance and Rejection: Children's Peer Acceptance***

Much of the increase in interest in children's peer relationships during the past 25 years can be traced to advances in *sociometry* (Bukowski et al., 2012). Techniques for measuring acceptance and rejection gave researchers a means of representing the extent to which a child is liked and disliked by peers. Much of the activity regarding sociometry is aimed at the challenge of developing valid and efficient measures of the two fundamental sociometric forces, specifically acceptance and rejection, and the measures that derive from them. *Acceptance* refers to how much a child is liked by peers; *rejection* refers to how much a child is disliked. The challenge of creating categorical measures results from the lack of independence between acceptance and rejection. These measures are neither the opposite of each other nor are they unrelated. Accordingly, a child high in acceptance is not necessarily low in rejection and a child high in rejection is not always low in acceptance.

A widely used method of assessing sociometric acceptance and rejection is to have children nominate peers in their classrooms or in their grades whom they "like" and "dislike." From these nominations, children are categorized into status groups based on the number of positive and

negative nominations they received from peers. Usually, only same-sex nominations are used to control for the other gender negative biases that occur in childhood.

From these nominations, derivative scores can be computed to index a child's general likeableness (i.e., sociometric *preference*) and the child's "visibility" in the peer group (i.e., sociometric *impact*). These scores have been used in various ways, most notably to make categorical assignments to the following sociometric groups: (a) *popular*—children who are high in acceptance and low in rejection (i.e., high impact, high preference); (b) *rejected*—children who are low in acceptance and high in rejection (i.e., high impact, low preference); (c) *neglected*—children who are low in both acceptance and rejection (i.e., low impact, mid-range in preference); (d) *average*—children who are average in acceptance and rejection (i.e., mid-range on both variables), and (e) *controversial*—children who are high in acceptance and rejection (i.e., high impact, mid-range on preference). Note that in the case of sociometric classifications, the term *popular* is used as a synonym for *accepted* rather than as an index of social prestige or status. Discussions of the stability of sociometric scores and classifications can be found in Bukowski et al. (2012).

Children's acceptance can also be assessed using *rating-scale* procedures. Rating-scale methods involve children rating each of their classmates (or a randomly selected group of grademates) on a scale (e.g., from 1 being *not at all* to 5 being *very much*) of how much they like to interact with each person. This method can be used to yield a continuous indicator of peer acceptance or to classify children into groups based on low, average, or high acceptance. An advantage of rating-scale measures is that each child in a class or grade receives an equal number of ratings rather than obtaining peer relationship data for only the prominent children in the group (e.g., those who happen to receive nominations for liking or disliking).

In contrast to the measurement of peer acceptance and rejection that is carried out with sociometric methods, *popularity* is measured with peer assessment techniques. Typically, in studies of perceived popularity, researchers ask children to nominate peers they believe to be most or least popular (Cillessen, 2009). Two basic premises, both related to the meaning that is ascribed to popularity, are implicit in this approach (see Bukowski, 2011, for a discussion of these issues). One is that the meaning of *popularity* is so well known to the participants that the inclusion of a definition is unnecessary to produce valid measurement of the construct. The second premise is that

there is a sufficient level of between-person agreement about the meanings of these words to justify the aggregation of nomination scores across individuals. The basic assumption of the peer assessment of perceived popularity is predicated on the assumption that all participants understand the meaning of the construct in the same way. It is not clear that the assumptions underlying these premises are always valid.

Nominations of peer-perceived popularity can be adjusted for biases due to variations in class size. Using these measures, children can be assigned to one of three possible groups: popular, unpopular, or average (all others). A continuous measure of perceived popularity may also be calculated by subtracting “not popular” from “popular” nominations, a procedure that makes the continuous measure of perceived popularity comparable to measures of social preference (e.g., Cillessen & Mayeux, 2004). Other researchers have asked teachers to nominate students who they believe are popular and have many friends (Rodkin, Farmer, Pearl, & Van Acker, 2006). Those who have simultaneously examined sociometric popularity and peer-perceived popularity have found that these two types of measurement may identify distinct groups of children and that correlations between acceptance and perceived popularity are moderate to strong (Cillessen & Mayeux, 2004; Hawley, 2003).

The use of sociometric techniques to assess the child's relationships within the peer group as a whole carries with it a number of limitations. Most noteworthy is the lack of practicality. Typically, sociometric procedures are used in schools because children spend the majority of their time in the company of peers. However, as noted earlier in our discussion of peer-nomination assessments of behavior, obtaining consent from everyone involved (i.e., school administrators, parents, teachers, children) is often difficult. If children nominate a classmate who has not agreed to participate, researchers are ethically bound not to use the data. Thus, for a researcher to obtain an accurate picture of a child's relationship status within any given classroom or grade requires obtaining consent from a large majority of the school-attending children (and parents; Cillessen, 2009).

### Assessing Peer Groups

The past decade has seen a substantial renaissance in concepts and methods related to the study of the peer group. These remarkable advances actually represent a return to many of the ideas and goals that were of interest

to researchers and theorists in the earliest waves of peer research in the mid-20th century. Indeed, early archival chapters on peer relations (e.g., Anderson, 1954) included extensive discussions of theory and available methods for studying the peer group *per se*. Since then, as attention has been directed to the levels of the individuals, interactions, and relationships, interest in the peer group as a phenomenon in and of itself has waned. This apparent lack of interest in the group is ironic as the classroom is frequently used as a natural context for research on peer relations. Although the classroom has been recognized as a “natural” context for experiences with peers, the properties of the context itself have been, until the last decade, largely overlooked by peer researchers. Although this neglect is not as extensive as it was a decade ago, it is still the case that the peer group *per se* receives relatively less empirical attention than is given to the individual, interactions, and dyadic relationships.

### *Why Has the Group Been Ignored?*

Several interrelated concerns point to the fundamental importance of assessing and accounting for the effects of the level of the group. The first derives from the statistical assumption that observations are independent from each other. Insofar as some children are grouped together with some peers (e.g., classroom peers) but not with others (e.g., children outside their classroom), this assumption of independence is violated when this group-based organization is not recognized and accounted for.

A second concern underlies the first. Because children within a group have a set of shared experiences, then they, as a group, differ from other groups of children in ways that may have consequences for their development. This second concern is predicated on the basic principles of theoretical models of social behavior and development. The need to integrate factors from multiple levels of social complexity has been a theme in social research for several decades beginning with Parsons and Shils (1951) and, closer to home, Bronfenbrenner and Morris (2006) and continuing to the present (e.g., Poteat, Espelage, & Green, 2007).

This lack of emphasis on group constructs (and measurement) can be traced to at least two intersecting limitations. One limitation is the lack of relevant theory to guide research on group contexts and their dynamics (Tseng & Seidman, 2007). This absence of theory may stem from several factors, including (a) the gap between the broad abstract features of theories that are designed to generally capture the fundamental components of contexts and the concrete and particular dynamics of specific environments

(see Bukowski & Lisboa, 2007, for a discussion); (b) the difficulty of using any particular theory, regardless of how expansive it claims to be, to explain the broad range of complex processes that make up social contexts such as classrooms; and (c) the need to match aspects of theory to available measurement and statistical tools, especially when methodological advances have outpaced the developments in theory (see Wachs, Chapter 21, this *Handbook*, this volume).

It is important to recognize that this conceptual limitation has two components. One has been the lack of explicit theory about how groups function to affect social development whereas the other is about the specific meaning of basic forms of group experience. This limitation is compounded by the historical tendency of peer relations research to be conducted by psychologists whose primary focus is on individual differences and on individual growth trajectories (e.g., those who may study equifinality and multifinality and yet neglect context and culture), because such theorizing at the group level may move many within the field of developmental science to ply their trade beyond their personal comfort zones.

The second limiting factor has been the lack of appropriate statistical tools for effective hypothesis-based integration of measures from different levels. Without user-friendly software to construct and evaluate complex multilevel models, research on the effects of groups was difficult. As Cairns (1983) noted several decades ago, the study of the group remained stuck in the 1930s and the sociograms produced by theorists such as Moreno (1934) were little more than premonitions of the abstract paintings of the 1950s and 1960s. Until recent developments in multilevel statistical software, distinguishing between and integrating effects at the level of the group and the level of the individual was nearly impossible. Most of these techniques were not possible until technical advances in computing power gave researchers the resources needed to make the complex calculations required to assess the multiple connections between group members. Currently advances in software have greatly facilitated the study of groups.

### ***What Are the Basic Features of Groups?***

Typically, the peer group context has been conceptualized according to considerations of structure and content (Gest & Kindermann, 2011; Tseng & Seidman, 2007). Whereas *structure* refers to the strength and patterns of associations between group members (Kelly, Ryan, Altman, & Stelzner, 2000), *content* refers to the behavioral and attitudinal

features or traits that characterize a particular group and that distinguish one group from another. Structure refers to the organization of the within-group links or forces that hold the members of the group together. Content refers to what the people in the group do, what they favor, and what they value.

Groups studied in peer relations research vary across a continuum anchored by these two phenomena. The ability to identify groups on the basis of *content* has been a mainstay of peer research for several decades. The identification of groups based on various “classic” parameters (e.g., means and standard deviations) has allowed researchers to compare groups of children who differ in the extent to which they show various peer related characteristics (e.g., aggression; Espelage et al., 2003). Although these techniques have been useful, they are not without their limitations. Such limitations include the methodological question of how to create cut-off scores on fundamental and derivative sociometric dimensions and the statistical problem of within group variability. In the past decade, researchers have replaced their use of these classic methods with latent variable models that can correct some of their drawbacks. Two techniques have been particularly useful: latent class analysis (LCA) and latent profile analysis. Each technique uses structural equation modeling to identify the presence of subgroups within a sample and to estimate the likelihood that each person in the sample belongs to each subgroup. The basic premise of these techniques is that unobserved subgroups exist within larger samples and that these latent subgroups are the categories of a categorical latent variable. These techniques offer many advantages such as reducing measurement error, avoiding the need to impose cut-off criteria on one’s data, and the capacity to combine measures from different latent constructs. An example of the application of LCA to a peer related variable can be found in Raufelder, Drury, Jagenowa, Hoferichter, and Bukowski’s (2013) identification of groups of young adolescents whose achievement behavior was differentially dependent on, or independent from, peer and teacher influence.

It is important to note that *content-based groups* are merely collections of individuals who have similar characteristics. They are not functioning groups in that each individual has an interpersonal connection to others. They are nevertheless important for peer research as they provide a means of identifying complex subgroups within the larger peer group context. Indeed, the most widely used categories in peer research have been content based. Sociometric groups comprise individuals with similar scores

on the basic dimensions of acceptance and rejection and derivative dimensions of impact and preference (Bukowski et al., 2012). For example, children in the “rejected group” have high scores on rejection and impact and low scores on acceptance and preference.

Descriptions of groups defined by *structural* features have been provided by Kindermann and Gest (2009). The purpose of identifying groups based on structural features is basically to find collectives of peers who have strong links to each other. The statistical programs used in the identification of structural groups employ dichotomous or, less frequently, continuous measures of connection between peers (e.g., friendship choice; affiliation). The algorithms maximize an index known as modularity (e.g., Kreager, Rulison, & Moody, 2011). Modularity comprises a ratio between within- and out-of-group connections. When all observed connections are between members of a group and none are to peers in other groups, the modularity score would be 1. Some of the most widely known procedures for identifying groups are UCINET (Borgatti, Everett, & Freeman, 2002), CROWDS (Kreager et al. 2011), and SIENA (Veenstra & Dijkstra, 2011).

Once a group has been identified, its internal structure and network characteristics can be assessed. For example, group size is a structural characteristic that simply requires quantification of members of the group. *Connectivity* can be assessed by examining group density, or the ratio of the number of within-group connections to the number of possible ties within that group. *Reciprocity* can be assessed by calculating the proportion of the within-group connections that are bilateral (e.g., mutual, reciprocated friendship choices). *Transitivity* can be computed by examining the proportion of within-group triads in which all three members are connected to each other. For examples of recent studies in which these indices were calculated and examined in relation to adjustment outcomes, see Dijkstra, Berger, and Lindenberg (2011), and Sijtsema et al. (2010).

Finally, group *cohesion* refers to the organization of the links between group members (Vacha, McDonald, Coburn, & Black, 1979). Cohesion can be measured objectively or with self-report measures. Direct or objective measures would assess the number and strength of the direct and indirect sociometric linkages between individuals. This measure would include an assessment of the overall level of liking among group members, an index of distance between group members in a class sociogram (Cillessen, 2009), and/or the proportion of mutual friendship nominations (Sherman & Cohen, 2002). Self-report measures could

include ratings of the classroom environment (Ghaith, 2003) or measures of collectivism and individualism such as those used by Santo et al. (2013).

## UNDERSTANDING PEER RELATIONSHIPS: FRIENDSHIP

Consistent with the premise that children’s experiences with their age mates will have a direct and powerful effect on well-being, researchers have devoted extensive attention to multiple forms of peer experience and their consequences for adjustment (see Bukowski et al., 2009, for a review). Whether particular types of peer experience are related to well-being is hardly an idle question. It holds importance for our understanding of the basic dimensions and processes of human nature, particularly the experiential mechanisms underlying adjustment, and for the development and implementation of policies and procedures to promote healthy development. Knowing which aspects of peer experience are most strongly associated with adaptive and maladaptive outcomes may be the most central question of peer research. Providing a clear answer to this question is not easy given that peer experiences occur across multiple dimensions whose significance are likely to vary across age and context. At the risk of simplification, peer experiences can differ in the extent to which they involve affect, behavior, or social inclusion.

In the next section, we describe research on the developmental significance of one specific form of children’s peer experiences, their *dyadic* relationships with peers. Children’s dyadic relationships with peers may take the form of friendships, romantic relationships, or antipathies. Theory and research on romantic relationships and mutual antipathies has been reviewed elsewhere (Card, 2010), including in this volume (Furman & Rose, Chapter 22, this *Handbook*, Volume 3). Therefore, we focus our review of dyadic peer experiences on children’s friendships.

The establishment and maintenance of close friendships represent challenging yet rewarding endeavors throughout childhood and adolescence. However, the constituent factors associated with friendship formation and maintenance vary with age; indeed, the very meaning of friendship undergoes developmental change. In the following sections we discuss the prevalence and functions of friendship; children’s changing understandings of friendship; friendship formation, maintenance, and loss; similarities between friends; children’s interactive behaviors with friends and nonfriends; gender-related issues in children’s friendships;

children without friends; and friendship and adjustment. An overriding theme is the significance of friendship in children's psychosocial development.

### Some General Observations

Friendships are common across the life span. From the existing corpus of investigations, one can safely conclude the following about friendships in childhood and early adolescence (see Bagwell & Schmidt, 2011, for an extensive review). To begin with, there appear to be three operationally defining features of friendship: First, each member of the dyad affirms the existence of the friendship. Second, the relationship derives primarily from mutual affection. Each partner views the other partner, and the relationship itself, as pleasant, fun, and likable. At the same time, the primary motivation for the relationship is not instrumental need. Third, the relationship is voluntary; it is neither obligatory nor prescribed.

Friendships serve several functions, such as providing emotional and social support, instrumental aid, intimacy, and affection; offering opportunities for intimate disclosure and for validation of interests, hopes, and fears; and providing prototypes for later romantic, marital, and parental relationships. Perhaps the most important function of friendships is to offer children an extrafamilial base of security from which they may explore the effects of their behaviors on themselves, their peers, and their environments (Rubin, Fredstrom, & Bowker, 2008).

Significantly, regardless of age or sex, most (60%–80%) youth have at least one same-sex mutually agreed upon friend (e.g., Laursen, Bukowski, Aunola, & Nurmi, 2007). The prevalence of friendship in adolescence is similar (Ellis & Zarbatany, 2007). Also, the prevalence of friendship appears to be similar across cultures (French, Purwono, & Rodkin, 2012). Another robust finding is that youth of all ages tend to form friendships with peers who are similar in sex (Mehta & Strough, 2009), race and ethnicity (McDonald et al., 2013), behavioral style (i.e., aggression, social withdrawal; Haselager, Hartup, van Lieshout, & Riksen-Walraven, 1998), and academic achievement (Altermatt & Pomerantz, 2003). Recent research has also revealed significant similarities between youth and their friends in internalizing symptoms (Giletta et al., 2011), externalizing problems (Hafen, Laursen, Burk, Kerr, & Stattin, 2011), popularity (Dijkstra, Cillessen, & Borch, 2012), social information processing (Spencer, Bowker, Rubin, & Booth-LaForce, 2013), religiosity (French et al., 2012), weight (de la Haye, Robins, Mohr, & Wilson, 2011),

and physical activity tendencies (Macdonald-Wallis, Jago, Page, Brockman, & Thompson, 2011).

### The Meanings and Understandings of Friendship

When asked to describe “a best friend” and expectations for friends, children of all ages describe best friendships as relationships that are characterized by reciprocity or mutual give and take (Bukowski & Hoza, 1989). Beyond this general agreement about the importance of reciprocity in friendships, however, there exist several notable developmental differences in how children and adolescents think about friendships. During early and middle childhood (4 to 8 years of age), friends are described as companions who share play preferences whereas during late childhood (10 to 11 years) they are described as having shared values, providing protection/instrumental aid and being loyal, and by early adolescence (11 to 13 years), friends are seen as sharing similar interests, making active attempts to understand each other, and willing to engage in intimate self-disclosure (Bukowski & Hoza, 1989; Schneider & Tessier, 2007).

Relatedly, Selman (1980) viewed children as mini-philosophers, for whom beliefs about friendship shaped both their friendship expectations and behaviors with friends. He identified six friendship issues: formation, closeness and intimacy, trust and reciprocity, jealousy, conflict resolution, and termination. Five developmental stages of friendship understanding were described within each issue, ranging from a view of friendship as a momentary physical interaction based on proximity, to an understanding that friendship develops through the integration of psychological dependency and independence. With development, children gain a better understanding of the psychological nature of friendship, acknowledge interdependency between friends, recognize the need to balance autonomy and intimacy, coordinate social perspectives, and show mutual respect for each other's viewpoint (Selman & Schultz, 1990). The developmental stage sequence proposed by Selman has been supported in a number of studies conducted in the North America and western Europe.

Of the limited extant cross-cultural research, it has been suggested that children come to understand the meanings of friendship in different ways and at different developmental rates across different cultures. For example, borrowing from the Selman taxonomy, Gummerum and Keller (2008) studied friendship reasoning among youth from China, Germany, Iceland, and Russia. For 7-year-olds, Russian

children were found to have the highest level of friendship understanding; Chinese and German youth were found to have the least sophisticated understanding of friendship. For 9-, 12-, and 15-year-olds, Russian *and* Chinese children were found to have the highest level of friendship understanding followed by the Icelandic and German children. These latter findings suggest that Chinese children appear to have a more dramatic change in friendship reasoning from Age 7 to 9. One might argue that the results reflect a stronger collectivistic, interdependency orientation in China and Russia—countries in which such group oriented, collectivistic phenomena, such as the organization Young Pioneers, are evident.

Taken together, it appears that children's understanding of friendship becomes increasingly sophisticated and their expectations become increasingly linked to intimacy with age. The underlying mechanisms that account for the developmental changes in children's conceptions about friendships are not clear, but possible explanations include developmental changes in perspective-taking abilities (Selman & Schultz, 1990), changes in children's understanding of reciprocity (Youniss, 1980), changes in cognition and relationship understanding due to accumulated social experience, and developmental changes in children's social needs (Rubin et al., 2008).

### Friendship Formation

There exist several different theories about with whom children and adolescents form friendships; such theories focus on issues pertaining to homophily (Byrne, 1971) and "social default" (Dishion, Andrews, & Crosby, 1995). As it happens, however, formation is a relatively understudied aspect of the friendship experience. This may be the result of the fact that at any given time, most children and adolescents are involved in at least one friendship with a history that encompasses a relatively brief period of time. Thus, empirically, it is challenging to find youth who are in the process of forming *new* friendships. Nevertheless, a study of "hitting it off" among unfamiliar preschoolers provides some insight into the friendship formation process (Gottman & Graziano, 1983), and so too do studies that consider new friendships that form following grade (Popp, Laursen, Kerr, Stattin, & Burk 2008) and school transitions (J. C. Bowker, Fredstrom, et al., 2010).

In an attempt to understand why some children form friendships and others do not, Gottman and Graziano (1983) paired unfamiliar preschoolers for three play sessions in one of the children's homes and audiotaped

their conversations. Of particular interest was whether certain coded conversational and social processes (such as communication clarity and connectedness, information exchange, and establishing common ground) explained which children "hit it off" or progressed toward forming a friendship, as assessed by mother-reports. The results produced a novel description of the friendship formation process. Specifically, information exchange, establishing a common ground, and minimizing conflict were found to be particularly important processes during the initial play session. However, as the children became better acquainted, other processes, such as self-disclosure, communication clarity, the exploration of similarity and differences, and conflict resolution, became increasingly predictive of which children were "hitting it off."

It is unknown whether this process model of friendship formation applies to older children and adolescents. However, recently, researchers have explored whether similarity *prior* to the formation of friendships predicts friendship formation across grade and school transitions. This research is guided by theory suggesting that individuals of all ages are more likely to be attracted to similar than dissimilar others (e.g., Byrne, 1971) and has demonstrated that youth and their soon-to-be friends are similar in peer victimization, popularity, aggressive behavior, delinquency, depression, and substance use *prior* to friendship formation (J. C. Bowker, Fredstrom, et al., 2010; Popp et al., 2008). In the Bowker, Fredstrom, et al. (2010) study, children who remained chronically friendless over time nominated dissimilarly behaved peers as their friends, suggesting that some children may fail at forming friendships because they direct their friendship bids to those who are unlike them (perhaps suggesting that they would prefer to be friends with those who they admire and who have positive characteristics that they, themselves, lack). Taken together, recent evidence indicates that one critical part of the friendship formation process for children and adolescents may be finding and pursuing similar peers. Of course, friendship is a dyadic process and some youth may not be able to choose and become friends with their preferred friends because they are rejected and disliked (Dishion et al., 1995; Hektner, August, & Realmuto, 2000). Youth who engage in prosocial and sociable behaviors appear to have the greatest opportunities to form new mutual friendships (J. C. Bowker, Thomas, Norman, & Spencer, 2011), perhaps because such behaviors improve the appeal and attractiveness of the youth as new potential friends who are enjoyable to be around.

### Friendship Maintenance and Termination

Once mutual friendships are formed, friendships at all ages show remarkable stability (Poulin & Chan, 2010). For example, two thirds of preschool-aged children who identify one another as friends do so again 4 to 6 months later (Gershman & Hayes, 1983). Berndt and Hoyle (1985) however found an increase in the stability of mutual friendships from Age 5 years (50%) to Age 10 years (75%) but not from Age 10 years to Age 14 years. In fact, it has been consistently found that only half of all young adolescent friendships are stable across one academic school year (A. Bowker, 2004; Wojslawowicz Bowker, Rubin, Burgess, Booth-LaForce, & Rose-Krasnor, 2006). This lack of increased stability during early adolescence may be accounted for by two factors. To begin with, friendships tend to become more exclusive with age—as such, children may allow some friendships to dissolve. As well, as children approach puberty, rapid changes in interests, and varying rates of development may result in a period of change in friendship choices (A. Bowker, 2004). However, the trend toward increasing stability in friendships continues into older ages (Cairns, Leung, Buchanan, & Cairns, 1995).

There is evidence suggesting that boys are more likely than girls to have stable same-sex (e.g., Hardy, Bukowski, & Sippola, 2002) and other-sex friendships (Chan & Poulin, 2007). Friendships involving individuals who interact both inside and outside of school are more stable than single-context friendships (Chan & Poulin, 2007). *Best* friendships tend to be most stable when they are positive in relationship quality (Branje, Frijns, Finkenauer, Engels, & Meeus, 2007), when the friendship partners are low in aggression and victimization (Hektner et al., 2000; Wojslawowicz Bowker et al., 2006), and when the friends are of the same-sex and same-race, and similar in behavior (Ellis & Zarbatany, 2007; McDonald et al., 2013). In addition, adolescents who have stable friendships are more similar to each other than those in unstable friendships in their choices of activities, delinquent behaviors, and such internal attributes as self-esteem and achievement motivation (e.g., Hafen et al., 2011). Due to socialization processes that accumulate over time, stable friendships appear to have greater influence on children's and adolescents' behavioral and psychological adjustment than unstable friendships (Brendgen, Vitaro, & Bukowski, 2000; Laursen, Hafen, Kerr, & Stattin, 2012).

Little research has focused specifically on friendship termination. J. C. Bowker (2011) reported that young

adolescents experience two types of best friendship termination or dissolution: (1) *complete dissolutions* (when a best friendship dissolves entirely and the adolescents no longer consider each other friends); and (2) *downgrade dissolutions* (when a best friendship becomes merely a “good” friendship). Downgrade dissolutions were more common than complete dissolutions, and more girls than boys experienced either type of friendship dissolution within the past several months. Previous research has revealed that friendship termination can place children and adolescents at risk for psychological distress and peer victimization, particularly if the dissolved friendship was not immediately replaced by a new friendship (e.g., Parker & Seal, 1996). However, J. C. Bowker (2011) found that it was young adolescents who experienced *downgrade* dissolutions (but not complete dissolutions) without best friendship replacement who reported the greatest loneliness. Thus, it appears that to fully understand the impact of friendship termination, a nuanced consideration of specific types of friendship dissolution, and new friendship replacement, may be required.

### The Effects of Friendship

The developmental significance of having friendship is clear. Studies consistently show that children with friends report higher levels of self-esteem and are less lonely than children without friends; also, having a friend promotes school satisfaction and academic engagement and protects children from peer victimization and its associated internalizing and externalizing costs (e.g., Erath, Flanagan, & Bierman, 2008). Friendships have also been found to protect children from hypothalamic-pituitary-adrenocortical axis dysregulation when negative peer experiences occur (Adams, Santo, & Bukowski, 2011; Peters, Riksen-Walraven, Cillessen, & de Weerth, 2011).

Children who are unable to form friendships, for whatever reason, appear to miss out on the social, psychological, and cognitive developmental benefits of interacting and negotiating with, and being supported by friends. Indeed, children without friends not only report higher levels of psychological distress (anxiety, depression, loneliness) than children with friends, but they are also consistently rated by their teachers, parents, and peers as lacking in social skills. The lack of social skills is likely both a cause and a consequence of their friendlessness. Significantly, approximately 15% of children are chronically without mutual friends; the results from several studies suggest that such children are at an elevated risk for internalizing

problems and peer victimization (Bowker, Fredstrom, et al., 2010; Ladd & Troop-Gordon, 2003). In addition, there is some evidence that the negative effects of being friendless during early adolescence may persist into early and middle adulthood. Bagwell, Newcomb, and Bukowski (1998) found that friendship involvement at 10 years predicted self-worth at 23 years.

In addition to examining the predictive associations between having mutual friendships and indices of adjustment/maladjustment, investigators have considered whether the *quality* of friendship explains variability in adjustment outcomes. In studies in which positive features of children's and adolescents' friendships are assessed (e.g., companionship, intimate disclosure, instrumental aid), these qualities are found to be concurrently and predictively associated with indices of psychological well-being (e.g., low levels of loneliness, depression, anxiety; peer victimization) and academic adjustment (e.g., Nangle, Erdley, Newman, Mason, & Carpenter, 2003). There is also some indication that having positive quality friendships buffers adolescents from the negative effects of group-level peer difficulties (e.g., low peer acceptance; Waldrup, Malcolm, & Jensen-Campbell, 2008), negative parenting (Lansford, Criss, Pettit, Dodge, & Bates, 2003), and qualitatively negative parent-child relationships (Rubin et al., 2004). Friendships become increasingly intimate and supportive as children transition into early adolescence, and it is during the early adolescent developmental period that the strongest associations between positive friendship quality and psychosocial adjustment indices have been found (Furman & Buhrmester, 1992).

There do appear to be positive and negative trade-offs associated with some high-quality, positive friendships for certain children and adolescents. For example, co-rumination has been shown to predict both positive friendship quality and internalized distress (anxiety, depression) during late childhood and early adolescence (Rose, 2002; Rose, Carlson, & Waller, 2007). In a study of young adolescents, the strongest associations between self-reported self-consciousness and indices of psychological maladjustment (being sensitive to rejection experiences; social withdrawal) were found for young adolescents with high-quality, positive friendships (J. C. Bowker & Rubin, 2009). These results are consistent with results from other investigations that have revealed that seemingly high quality friendships can foster or support some psychosocial difficulties and problematic behavioral styles (e.g., Murray-Close, Ostrov, & Crick, 2007). For some children and adolescents, positive quality friendships may foster

a strong sense of togetherness and intimacy, which could be problematic if it encourages and reinforces negative ways of thinking, feeling, and behaving (J. C. Bowker & Rubin, 2009; Rose, 2002). Taking such findings together, it appears critical to consider more than one friendship "factor" in studies of friendship and adjustment.

### *Individual Characteristics and Friendship Consequences*

The ways in which friendship impacts adjustment also depends, in part, on the individual characteristics of the child. For example, although they tend to be more disliked than other children, most aggressive children have a mutual best friend and are as likely as well-adjusted children to have mutual friends (Vitaro, Brendgen, & Tremblay, 2000). Aggression, however, seems to be related negatively to friendship stability (Hektner et al., 2000). Moreover, aggressive children are more likely than their nonaggressive counterparts to have aggressive friends and their friendships tend to be confrontational and antisocial in quality (Dishion et al., 1995).

High levels of relational aggression (e.g., threatening friendship withdrawal) within the friendship, and high levels of exclusivity, jealousy, and intimacy characterize the friendships of relationally aggressive children. In contrast, overtly aggressive children direct their aggression outside their friendship dyads, and report low levels of intimacy (Grotzinger & Crick, 1996). Significantly, associating with deviant friends and peers often leads to subsequent behavioral and social difficulties through a process known as *deviancy training* (Dishion & Peihler, 2009). Deviancy training refers to the processes of praise, encouragement, imitation, and expectancy by which children and adolescents increase the level of aggression or antisocial behavior in their peers. Essentially, deviancy training occurs when children model aggression for, and reward the aggressive behavior of their friends; these exchanges are thought to increase individual tendencies in aggressiveness and to strengthen ties between aggressive and substance-abusing friends and delinquent peers. In recent years, deviancy training has been detected in at-risk children and their friends as young as 5 years of age, and deviancy training during *childhood* and *early adolescence* has been shown to predict the development and maintenance of antisocial and delinquent behavior in early, middle, and late adolescence, in samples of both boys and girls (e.g., Snyder, Schrepferman, Bullard, McEachern, & Patterson, 2012).

As noted above, there is some evidence that shy/withdrawn youth are as likely as their nonwithdrawn peers to have mutual and stable best friendships during childhood

and early adolescence (e.g., Rubin, Wojslawowicz, et al., 2006). Shy/withdrawn children are often lacking in social skills (Rubin, Coplan, et al., 2009). Yet, these behaviors do not appear to impact the formation and maintenance of their friendships, likely because shy/withdrawn youth form friendships with similarly withdrawn and similarly victimized peers (Rubin, Wojslawowicz et al., 2006). However, their shared internalizing problems and group-level peer difficulties may not allow for a positive and supportive friendship experience (Rubin, Wojslawowicz et al., 2006). In support of this notion, Oh et al. (2008) found that having a withdrawn friend predicted increases in social withdrawal during late childhood and into early adolescence. Yet, any mutual best friendship, especially if it is stable, may help withdrawn children navigate difficult times of transition and school change (Oh et al., 2008).

### Other-Sex Friendships

Friendships with other-sex peers during early and middle childhood and even early adolescence are so rare that they are often excluded from study (e.g., Peters, Cillessen, Riksen-Walraven, & Haselager, 2010). However, researchers have shown that throughout the adolescent period, the percentage of adolescents with other-sex friends (as distinct from romantic relationships) increases significantly (Arndorfer & Stormshak, 2008).

Same-sex friendships are generally perceived as more intimate than other-sex friendships during early adolescence, but other-sex friendships become increasingly intimate during the adolescent years as interaction and intimacy with other-sex peers increases in importance. Despite this increase in intimacy, it is still the case that the majority of other-sex friendships during adolescence are not considered to be best friendships (Poulin & Pedersen, 2007).

As other-sex friendships become more common, it is not surprising that they also become more influential on such adjustment outcomes as antisocial and delinquent behavior (e.g., Arndorfer & Stormshak, 2008). The risk associated with having other-sex friends has been shown to be stronger for girls than boys (e.g., Poulin & Pedersen, 2011), perhaps because girls appear to be more susceptible to peer influence in general and their other-sex friends tend to be older, with longer histories of delinquency. Indeed, the developmental risks of having other-sex friends is likely explained by the fact that most other-sex friends are older peers, with more experience with rule breaking and antisocial behavior. One recent exception to the suggestion that other-sex friendships during early adolescence

are “risky” derives from a study by Bowker and colleagues (Bowker, Thomas, Spencer, & Park, 2013). These researchers found that having an other-sex (same-grade) friend protected young adolescents who are sensitive to rejection, based on their physical appearance, from feelings of social anxiety. Notably, this protective effect was found after controlling for the effects of same-sex best friendship involvement and same-sex peer acceptance. The authors posited that having other-sex friendships during early adolescence may provide felt security regarding one’s appearance and foster social confidence, whereas lacking such friendships may exacerbate concerns about possible appearance-based rejection by other-sex peers. Thus, there may be developmental trade-offs associated with other-sex friendship involvement during early adolescence. Such friendships may contribute to delinquency but protect some adolescents from emotional and psychological difficulties.

## UNDERSTANDING PEER RELATIONSHIPS: PEER ACCEPTANCE, REJECTION, EXCLUSION, VICTIMIZATION, AND POPULARITY

For several decades, research on the group-level of social complexity was largely focused on the affective dimensions of peer experience, specifically the variables known as *acceptance* and *rejection* and the secondary measures (i.e., *impact* and *social preference*) derived from them (see Bukowski et al., 2012, for recent review). During the past decade, attention has been directed away from the affectively laden dimensions to the behavioral based dimension of *victimization* and the inclusion-related construct of *exclusion*. The distinctions between these constructs are not trivial in that they represent fundamentally different forms of experience and present different implications for intervention and prevention procedures.

### Peer Acceptance and Rejection

#### *Factors Underlying Acceptance and Rejection*

Children who are high in acceptance and low in rejection tend to have the social cognitive prowess that enables them to facilitate the initiation and formation of relationships. They are also skilled at paying attention to their peers in a manner that promotes the continuity of their interactions. In regard to particular forms of behavior, when entering new groups, well-accepted children are more likely than others to take the group’s frame of reference and say

something on topic without drawing undue attention to themselves; they are not disruptive of the group's activity (Putallaz & Gottman, 1981). In addition, well-liked children typically negotiate, compromise, and otherwise deal with peer conflict in competent ways (e.g., Troop-Gordon & Asher, 2005). They are seen as cooperative, friendly, sociable, prosocial, and sensitive by peers, teachers, and observers (e.g., Chen & Tse, 2008). They tend to be good athletes, good students, and have good senses of humor (e.g., Asher & McDonald, 2009). When accepted children do engage in aggressive behavior, it tends to resemble assertiveness rather than disruptiveness or harmful forms of action that are likely to impede the goals of their peers (Newcomb, Bukowski, & Pattee, 1993).

The overriding conclusion regarding rejection is that its primary antecedent is aggression. Relative to their more well-accepted peers, those who are rejected participate more often in three particular forms of aggression—disruptiveness, physical aggression, and negative behavior (e.g., verbal threats). These findings are especially strong for younger children (Cillessen & Mayeux, 2004). It is also the case that withdrawn behavior has been linked with peer rejection in numerous studies (e.g., Ladd, Kochenderfer-Ladd, Eggum, Kochel, & McConnell, 2011; Oh et al., 2008). It is argued that socially withdrawn children are rejected by peers because their demeanor runs contrary to age-specific norms and expectations for social interaction and relationship- and group-involvement (Rubin et al., 2009). Furthermore, researchers have argued that atypical behavior becomes more salient to the peer group with increased age, which may explain why the association between social withdrawal and peer rejection steadily increases throughout childhood (Ladd, 2006).

One reason that it is often difficult to arrive at a strong conclusion about the specific causes of acceptance and rejection derives from contextual variations. Groups have norms, or standards, regarding the “goodness” of particular acts. The acceptability of a behavior, and of the child who displays that behavior, is determined by whether the behavior conforms to the group's norms. If a behavior is universally valued, it should correlate with peer acceptance; if the normalcy of a behavior varies across groups, the extent to which the behavior is linked to acceptance and rejection should vary across these groups also. It is this logic that has provided the basis for much of the research on group and cultural variations in the antecedents and correlates of acceptance and rejection (see Chen & Rubin, 2011, for reviews).

### *The Consequences of Rejection: Externalizing Problems*

Results of longitudinal studies have consistently indicated that peer rejection in childhood predicts a wide range of externalizing problems in adolescence and beyond, including delinquency, conduct disorder, attention difficulties, and substance abuse (e.g., Prinstein, Rancourt, Guerry, & Browne, 2009). These findings are not particularly surprising given the well-established link between aggression and peer rejection, and especially given that aggressive rejected children are more likely to remain rejected over time. Importantly, research has shown that early peer rejection provides a unique increment in the prediction of later antisocial outcomes, even when controlling for previous levels of aggression and externalizing problems (e.g., Miller-Johnson, Coie, & the Conduct Problems Prevention Research Group, 2002).

Dodge et al. (2003) also found a developmental pathway in which peer rejection led to more negative information processing patterns (i.e., hostile cue interpretation), which led to increased aggression. Additionally, Prinstein and La Greca (2004) found that girls' childhood aggression predicted later substance use and sexual risk behavior, but only for those girls who were disliked or rejected in junior high school. Given that changes in peer acceptance tend to precede changes in aggression over time, but not vice versa, one can begin to understand the truly *transactional* nature of the relation between peer rejection and the development of externalizing problems over time (Prinstein et al., 2009).

Certainly part of the association between rejection and externalizing problems involves the network of peer involvement experiences by rejected children (e.g., Espelage et al., 2003). Involvement in a deviant peer group exposes them further to deviant models and restricts their opportunities to interact with nondeviant peers. Furthermore, deviant peers may reinforce delinquent acts through their positive responses to deviant behavior. For example, Brendgen et al. (2000) showed that rejected children were more likely than other boys and girls to associate with delinquent peers and that these associations accounted for their subsequent delinquency. These mechanisms also appear to account for the development of substance abuse problems (see Dishion & Piehler, 2009, for a review).

### *The Consequences of Rejection: Internalizing Problems*

Researchers have explored the unique role of peer rejection in the prediction of internalizing problems (for a review,

see Prinstein et al., 2009). In general, the strongest conceptual model that explains the relation between peer rejection and the subsequent development of such internalizing difficulties as anxiety, depression, loneliness, and negative self-regard is a transactional one (e.g., Parker et al., 2006). Consistently, researchers have reported that extremely shy and/or anxiously withdrawn children who are also rejected by their peers are at greater risk for the subsequent development of internalizing difficulties than are either withdrawn-non-rejected or non-withdrawn-rejected youth (see Rubin, Coplan, et al., 2009, for relevant discussion). In fact, those children who are, for whatever reason, socially withdrawn and whose peers actively dislike them have been shown to be at risk for the subsequent development of anxiety, depression, loneliness, and negative thoughts and feelings about themselves (e.g., Boivin, Hymel, & Bukowski, 1995). Socially withdrawn youth value peer relationships and yet struggle with peers. In addition, they are well aware of their social difficulties (Boivin et al., 1995). Thus, it is likely that withdrawn youths' shy and timid behaviors lead to peer rejection (and other peer difficulties), which in turn contribute to negative self-perceptions and increasing internalizing problems, and then, increasing withdrawn behaviors and problems with peers.

### ***The Consequences of Rejection: Academic Adjustment***

It has been shown that adjustment to school derives from several aspects of children's relationships with peers. Wentzel and Asher (1995) found that rejected/aggressive students, relative to average and rejected/submissive children, showed little interest in school, were perceived by teachers as dependent, and were seen by peers and teachers as inconsiderate, noncompliant, and prone to causing trouble in school. These findings were consistent with longitudinal findings reported by Ollendick, Weist, Borden, and Greene (1992) who showed that children who were actively disliked by their peers were anywhere from two to seven times more likely to fail a subsequent grade than better accepted children. Furthermore, Ladd, Herald-Brown, and Reiser (2008) have found that chronic peer rejection during the period between kindergarten and sixth grade predicts decreased growth in school participation and engagement. Given these longitudinal connections between peer rejection and later poor school performance, it is not surprising to learn that children who have troubled relationships with their peers are more likely to drop out of school than are other children (Ollendick et al., 1992).

## **Victimization**

### ***Victimization Versus Rejection: Definitional Issues***

Much of the research on victimization contrasts sharply with research on peer rejection. One obvious difference derives from the historical trajectories on the topics of peer research. Whereas research on acceptance and rejection attracted the attention of peer researchers during the 1980s and 1990s, interest in these constructs has been less expansive since the turn of the century as attention has shifted to such topics as victimization and exclusion. This increased interest in victimization has not been restricted to academic researchers; tragic victimization-related deaths and injuries are detailed almost daily in traditional and electronic media.

A second difference concerns the issue of definition. Although the definitions of acceptance and rejection are well known and relatively clear, definitions of victimization often vary from one study to another. Salmivalli and Peets (2009) recently argued for a definition of victimization that would emphasize behavioral features. They referred to victimization as the experience of being the target of any form of aggressive attack. Their emphasis on the component of attack appears to indicate that victimization is intentional, direct, and targeted. Despite the apparent specificity of this definition, the breadth of the experiences that can fall within this definition is substantial. Although inclusive definitions can have their advantages, too much breadth can be problematic as it brings together phenomena that derive from very different dynamics and whose effects occur via different pathways. For example, a broad definition of victimization could include acts of physical violence as well as moments of exclusion. In addition to the differences in their antecedents and effects, these experiences are likely to be affected by very different forms of intervention. This is not to say that a more specific set of definitions should be formulated. Instead it points to the importance for researchers to be continually cognizant of the problematic features inherent in broadly defined constructs. There is already some evidence of the value of distinguishing between the constructs of victimization and exclusion (Buhs, Ladd, & Herald, 2006).

A third distinction between the affectively laden construct of rejection and the construct of victimization concerns the multiple domains in which victimization is manifested. Just as there are multiple forms of aggression (e.g., physical, relational) and social withdrawal (anxious withdrawal, preference for solitude), there are multiple

forms of victimization and different types of victimized children. For example, some children appear to be victimized because they are aggressive and provocative elicitors of bullying. Others are withdrawn, submissive, passive “easy targets,” and do not explicitly invite victimization (Hanish & Guerra, 2004).

Moreover, victimization can occur under different contextual circumstances that vary in the degree to which they involve face-to-face interaction. Whereas victimization in a classroom or schoolyard requires direct contact between the bully and the victim, the cyber context does not require the victimizer to see the victim. This lack of direct contact is likely to limit the extent to which natural empathic responses inhibit bullying.

A fourth difference between sociometric rejection and victimization concerns their occurrence at difference levels of social complexity. Victimization can occur at the level of the dyad (Card & Hodges, 2006) and the group (Rosen et al., 2009). In contrast, sociometric rejection refers to the extent to which a child is liked within the peer group as a whole.

### *Predictors and Consequences of Victimization*

Two general conclusions can be reached about the factors that appear to predict both rejection and victimization. As noted earlier, the first is that these peer experiences are associated with aggression and social withdrawal (Salmivalli & Peets, 2009). Children who have elevated scores on these dimensions appear to be at highest risk for both victimization and rejection. Second, victimization and rejection are known to be similarly associated with other variables at the level of the individual and at the level of interaction. These factors include such intrapersonal phenomena as anxiety, low self-worth, and depressive symptoms as well as such interpersonal factors as friendlessness (Salmivalli & Isaacs, 2005). Although a comprehensive model to explain the processes that account for individual differences in rejection and victimization has not been developed, one assumes that it would emphasize the importance of characteristics that disrupt the goal-oriented behaviors of individuals and groups and that minimize the degree to which a person can defend or protect him- or herself.

Given that rejection and victimization are related to similar antecedents and insofar as both represent negative experiences within the peer group, it is not surprising that measures of these constructs are inter-related both concurrently and prospectively (e.g., Ladd & Troop-Gordon, 2003). Perhaps the best assessment of the prospective associations between victimization and rejection can be

found in Salmivalli and Isaac's (2005) longitudinal study of these constructs in a sample of young adolescents. They found that whereas peer rejection was related to subsequent victimization after the initial levels of victimization had been accounted for; victimization had no effect on subsequent rejection. Apparently rejection is an antecedent of victimization whereas victimization does not appear to affect subsequent rejection. Thus, rejection may be at the core of children's negative peer experiences.

In general, it has been found that being victimized by peers predicts internalizing problems (e.g., anxiety, depression, loneliness; Reijntjes, Kamphuis, Prinzie, & Telch, 2010), externalizing problems (aggression) as well as school adjustment problems (truancy; school participation; Reijntjes et al., 2011). However, much like rejection, the relations between victimization and negative outcomes can be described best as following a transactional course (e.g., Ostrov, 2010). For example, as noted above, there are groups of aggressive children who invite victimization (provocative victims); these children appear to be at the greatest risk for the development of both externalizing and school-related difficulties). Other groups of passive, submissive, withdrawn victims are at greatest risk for the development of hopelessness, helplessness, and depression. When negative events befall this latter group, they blame themselves for their plights, and the combination of passivity, submissiveness, victimization, and self-blame predicts problems of an internalizing nature (Salmivalli & Peets, 2009).

### *A Note About Interventions*

Perhaps the most striking difference between rejection and victimization is not seen in studies of their correlates, causes or consequences, but are seen instead in how researchers have developed interventions to minimize their occurrence. Procedures aimed at minimizing rejection have typically focused on the individual (see Bierman, 2004). The goals of these interventions are to improve the rejected child's social skills and/or to minimize predispositions (e.g., aggressive or withdrawn behavior; social cognitive deficits and information processing biases) that are believed to be the causes of the behavior (e.g., aggression; social withdrawal) that causes the child's rejected status. The implicit assumption of the individual-level intervention focus is that causes of rejection are situated within the child. Elimination of rejection is achieved by altering the causes and prevalence of the child's atypical behavior.

Interventions designed to eliminate victimization have typically taken a very different approach by emphasizing

properties of the social context. Context-focused interventions are based on the premise that victimization is a systemic problem that results from causes at the level of the individual, dyad, and group. Accordingly, there is a need to reform the context rather than to simply change the victim. Two exemplary interventions are the Kiva study (Kärnä et al., 2011) and the classroom reorganization study conducted by van den Berg, Segers, and Cillessen (2012). The Kiva study aimed at students, teachers, and parents. It is process-oriented in the sense that it consists of well-prepared activities to engage student participation. It also takes advantage of web-based materials. At the level of the person, it aims at empathy, self-efficacy, and supportive efforts to help victimized peers. The efficacy of this program has been demonstrated in a thorough evaluation (Kärnä et al., 2011). The van den Berg et al. (2012) project was much narrower in its approach. Its point of departure was the long-standing recognition that positive aspects of interpersonal experiences are inversely related to social distance. Their intervention consisted of altering classroom-seating arrangements such that peers who had a negative relationship would sit closer to one other. The observed effects of this intervention on victimization were roughly equal to the effect sizes observed with the more elaborate Kiva study.

## Exclusion

Less attention has been devoted to the study of peer exclusion than to peer victimization. Whereas victimization refers to negative, harmful behavior directed to an individual, peer exclusion refers to the processes by which someone is kept out of, or isolated by a group. In the following section, we discuss issues related to definition, the link between peer exclusion and other peer processes, and its association with other aspects of development.

### Defining Exclusion

Peer exclusion actively deters an individual from participating in group activity (e.g., Killen, 2007; Malti, Killen, & Gasser, 2012). Exclusion may be enacted by an individual or a group of individuals and may involve direct or indirect behaviors. For example, when an individual requests joining others in a play activity, the group may clearly decline and ignore their peer. Or, exclusion may be indirect and subtle. For instance, a child may speak to a group of peers who “respond” by pretending not to hear the child. Or, a child might find that the rules of a game have been intentionally altered so that he or she is no longer included. In each of

these examples, the behaviors have the effect of preventing the child from joining the group activity, thereby isolating him or her.

Although the act of exclusion has been studied as a type of relational or social aggression (Nixon, Linkie, Coleman, & Fitch, 2011) or isolation or neglect by peers (e.g., Elsaesser, Gorman-Smith, & Henry, 2013), findings from a recent observational study of preschool-aged children suggest that many instances of peer exclusion do not involve relationship manipulation or rumor spreading, two of the defining features of relational/social aggression and victimization (Fanger, Frankel, & Hazen, 2012). Moreover, although the terms *peer exclusion* and *peer rejection* are often used interchangeably, empirical findings suggest that the two constructs are related but distinct. Peer exclusion is a behavioral manifestation of peer rejection that helps to explain why peer rejection can be so damaging to the developing child (e.g., Buhs et al., 2006; Gazelle & Ladd, 2003). In other words, children exclude peers they actively dislike. Finally, ostracism is a very similar construct to peer exclusion; Williams (2007) defined ostracism as ignoring and excluding others. However, the study of ostracism originated in the field of social psychology, and to date, most studies of ostracism have focused on adults, with several notable exceptions (e.g., Gross, 2009). Another difference is that theory and research on ostracism tends to focus on being ostracized by *unfamiliar* others whereas the emphasis in research on peer exclusion tends to involve experiences of being left out or isolated by *familiar* age-mates.

Finally, much of the extant developmental research on peer exclusion tends to focus on how children reason about the isolation of others based on such individual characteristics as gender, race, age, or ethnicity (e.g., Killen, 2007) and how they think about in-groups and out-groups (Abrams & Rutland, 2008). This research is guided by several theoretical models, including social-cognitive domain theory and developmental subjective group dynamics model (reviewed in detail in Killen & Smetana, Chapter 17, this *Handbook*, Volume 3).

### Operationalizing Exclusion

Typically peer exclusion has been studied for three reasons. First, investigators have sought to determine whether peer exclusion is related to individual child characteristics (e.g., social withdrawal, aggression), and such adjustment outcomes as peer victimization. In these studies, children are asked to nominate same-grade or same-classroom peers in their schools who are left out of group activities, ignored

and avoided by classmates, and whose social initiation bids are frequently refused (e.g., Avant, Gazelle, & Faldowski, 2011; Buhs et al., 2006). Children who receive many nominations are identified as highly excluded by their peers. Given that exclusion is a peer group phenomenon that may often occur away from sight-lines of adults, it has been suggested that children are likely the most knowledgeable purveyors of information about who it is that is left out and ignored. But, the results of one study revealed modest agreement among peer-, self-, teacher-, and observer-reports of peer exclusion during middle childhood, suggesting that children, teachers, and objective observers may witness some of the same episodes of peer exclusion (Spangler & Gazelle, 2009). Other recent examples of studies that utilized teacher and/or other observations of peer exclusion include Fanger et al. (2012) and Murray-Close and Ostrov (2009).

Investigators who seek to determine how children *reason* about social exclusion typically present children with hypothetical scenarios in which social exclusion might occur. The characteristics of the child who might be excluded and the child(ren) who might do the excluding vary, depending on the investigators' questions of interest (e.g., adolescents' reasoning about interracial exclusion, Killen, 2007).

When in-group and out-group exclusion are of interest, hypothetical scenarios are also typically utilized, but the scenarios involve *normative* targets (such as Emily and Jack who are going to a school summer fair because they think the activity is important for the other children and their school and because they think it will be fun) and *deviant* targets (such as Alex who is not going to the fair because he or she would rather stay home; Abrams, Palmer, Rutland, Cameron, & Van de Vyver, 2013). Scenarios are typically followed by questions assessing children's own thoughts and feelings about the normative and deviant targets, their perceptions of other children's thoughts and feelings about the targets, and children's reasoning about other children's thoughts and feelings (e.g., "Why do you think the other children from your school would feel that way about [normative/deviant target]?" [Abrams et al., 2013]).

Finally, a third goal of exclusion research is to assess how children think and feel about and cope with peer exclusion when they actually experience it. This research is typically experimental, with children being exposed to simulated peer exclusion. Examples of this approach can be seen in the recent work on ostracism during childhood and adolescence (e.g., Gross, 2009), which most commonly utilizes the *cyberball* paradigm that was designed

for adults (e.g., Williams & Jarvis, 2006). In the cyberball game, participants are informed that they will play a ball tossing game on the computer with two virtual players (not actual players, but rather, part of the virtual game). The game begins with one of the "players" throwing the ball to the participant; the participant then chooses to which player he or she should "pass" the ball. There are two conditions: (1) the *ostracism* condition in which the participant receives the ball twice at the start of the game, and thereafter, never receives it again; and (2) the *inclusion/control* condition in which the participant receives the ball approximately the same amount of time as the other players in the game. Afterwards, participants are typically asked questions about how they felt during the game (to assess whether the manipulation was effective), additional neurocognitive (brain activation; Guyer et al., 2012), psychological (self-esteem, Gross, 2009) or behavioral (e.g., text messaging with others, Gross, 2009; food intake, Salvy et al., 2012) outcomes of interest are measured, and debriefing occurs. Another computer-simulated program used to assess peer exclusion is the Virtual School technique designed to assess the neural mechanisms mediating individual differences in social responses to uncertainty and exclusion in social contexts (Jarcho et al., 2013).

### *Who Is Excluded and Why?*

The construct of exclusion merits special attention in the study of social withdrawal. Socially withdrawn children and adolescents spend considerable time alone and away from peers because they actively remove themselves from and avoid their peers. Their withdrawal may be motivated by fear or anxiety or by strong preferences for solitude. Regardless of the motivation for solitude, early research on social withdrawal emphasized the importance of distinguishing socially withdrawn youth from peer excluded or isolated youth (e.g., Rubin & Mills, 1988). And yet, in peer relations research, exclusion is often considered as a correlate or outcome of social withdrawal (e.g., Avant et al., 2011; Gazelle & Rudolph, 2004).

The association between social withdrawal and peer exclusion appears to be strongest when two specific types of social withdrawal are considered: anxious-withdrawal or shyness (withdrawal that is motivated by fear or anxiety) and avoidance (withdrawal motivated by strong desires to be alone; Rubin, Coplan, et al., 2009). A small number of longitudinal studies provide evidence that the linkages between anxious-withdrawal and peer exclusion may be bidirectional such that anxious-withdrawal predicts increasing peer exclusion and peer exclusion predicts

increasing anxious-withdrawal over time (e.g., Gazelle & Ladd, 2003).

Social withdrawal is not the only behavioral factor associated with peer exclusion. A growing number of studies indicate that aggressive youth are also likely to be excluded by their peers (e.g., Ostrov, 2010). Both physical and relational aggression have been associated with relational victimization, and such relations have been found in early and middle childhood, as well as early adolescence.

The explanation for why socially withdrawn children are excluded by peers appears to be that their shy and timid behaviors are viewed as atypical and counter to social norms and expectations for peer interaction and relationship and group involvement (Rubin, Coplan, et al., 2009). Aggressive children are believed to be kept from group activities and avoided because their behaviors can be harmful and damaging (Salmivalli & Peets, 2009). Of course, the common feature explaining the associations between social withdrawal, aggression, and peer exclusion is the deviant or atypical nature of the behavior, a notion that dovetails well with the theory and research on children's and adolescents' reasoning about when intergroup exclusion is legitimate (see Killen & Smetana, Chapter 17, this *Handbook*, Volume 3).

Regardless of the reasons for peer exclusion, numerous studies, using both experimental manipulations and peer nomination assessments of exclusion, have revealed negative behavioral, academic, and psychological outcomes associated with being left out and ignored by peers (Avant et al., 2011; Buhs et al., 2006; Peake, Dishion, Stormshak, Moore, & Pfeifer, 2013). Even though the negative peer treatment may not be as direct as peer victimization, peer exclusion appears to have a negative impact on how children feel about themselves and their social worlds and to impair regulated coping efforts (Peake et al., 2013; Salvy, Bowker, et al., 2012). Such findings suggest that this construct deserves increased attention in the peer relations literature.

### Perceived Popularity

Although the word *popularity* has appeared in scholarly papers on peer relationships throughout the history of this research domain, the focus and clarity of this attention has never been stronger than in the years since the publication of the previous version of this chapter (Rubin, Bukowski, et al., 2006). During this period there has been a dramatic increase in research on popularity per se, enough to warrant the publication of a breakthrough book on the topic

(Cillessen et al., 2011). An important change that stimulated increased interest in popularity was largely conceptual. Certainly, popularity was hardly a new word for peer relationships researchers; however, the meaning ascribed to it has changed. Today, popularity refers to, and is assessed by, the extent to which a child is *perceived* to have a position of status within the group—a significant departure from earlier research in which popularity was defined by how much an individual was liked *and* disliked by peers as well as by the notoriety (“impact”) the individual has within the given group. In the next section, we review the correlates and consequences of *perceived* popularity.

### Who Is Perceived to Be Popular?

The apparently simple question of “who is popular?” can be rephrased to pose the question of what characteristics are ascribed to popular children by their peers. Thus, the concept under study is thoroughly perceptual in nature and the method by which it is assessed elicits children's viewpoints of what features characterize children who are viewed as popular in the peer group.

Over a decade ago, in a popular press book for parents, Rubin (2002) suggested that peers viewed two “types” of children and young adolescents as popular—those who are “decent” (kind, altruistic, trustworthy) and those who are “dominant” (arrogant, assertive, aggressive, mean-spirited). His suggestions were drawn from the research of Rodkin, Farmer, Pearl, and Van Acker (2000), as well as from (at the time), popular books and movies about “popular” groups of adolescents (e.g., “Queen Bees and Wannabees,” and *Heathers*). Rubin's challenge was whether parents should have a personal goal of socializing their children to be “popular” while at the same time wanting them to be individuals considered by others as trustworthy, helpful, fun-to-be-with best friends. Although researchers have not examined the stability and dyadic quality of the best friendships of children and adolescents perceived to be popular, there have been many studies suggesting that “popular as decent” and “popular as dominant” are empirically substantiated categories. For example, Rodkin et al. (2006) have identified two groups of children who are perceived by peers to be popular: “model” and “tough” children. “Model” children are perceived as being “cool” and at the same time are academically competent, physically skilled, sociable, and not rated as aggressive by teachers. “Tough” children are also perceived as “cool” but are highly aggressive and physically competent.

Generally, perceived popularity has been linked to a varied list of behaviors and characteristics. For example,

perceived popularity has been associated with both physical and relational aggression (Rose et al., 2004), as well as prosocial behavior (Cillessen & Mayeux, 2004). Perceived popularity has also been associated with having a good sense of humor, academic competence, athletic ability, being attractive, and being stylish and wealthy (Vaillancourt & Hymel, 2006). In a sample of young adolescents, Closson (2008) reported that for boys more than girls, perceived popularity was associated with being cool, athletic, entertaining, and risk taking; for girls more than boys, perceived popularity was associated with being fashionable, attractive, and sociable, and mean, snobby, and rude.

Researchers have suggested that relational aggression may be more central than physical or overt aggression to the establishment and maintenance of perceived popularity. In a longitudinal investigation, Cillessen and Mayeux (2004) found that children who are perceived as popular subsequently increase their use of relational aggression. They hypothesized that relational aggression may serve as a means to maintain social prominence during adolescence, especially so for girls. Furthermore, Rose, Swenson, and Waller (2004) found that the association between overt aggression and perceived popularity was fully explained through the association of both constructs with relational aggression.

It has been reported that the behavioral correlates of perceived popularity vary as children transition from elementary to middle school. Cillessen and Mayeux (2004), for example, found that aggressive behaviors become more strongly associated with perceived popularity after the middle school transition. Given that perceived popularity is relatively stable during late childhood and early adolescence, even across school transitions (e.g., Sandstrom & Cillessen, 2006), these combined findings suggest that changes (or the lack thereof) in the extent to which adolescents engage in positive and negative behaviors across the middle school transition might help to explain stability in high perceived popularity status.

Among the notable changes that occur as young adolescents move from elementary to middle school is the increasing acceptance of antisocial behavior. Adolescents' self-reported negative attitudes towards bullying decrease after the transition (Pellegrini & Long, 2002), and aggression becomes increasingly associated with social prominence (Bukowski et al., 2000). A related change is that the association between aggressive behavior and perceived popularity becomes particularly strong after the middle school transition (e.g., Cillessen & Mayeux, 2004; Rose et al., 2004). Additionally, there is a considerable

increase in substance use during middle school (Oetting & Beauvais, 1990) and perceived popular adolescents, in particular, are likely to increase their alcohol and drug use (e.g., Mayeux, Sandstrom, & Cillessen, 2008). Lastly, all adolescents face the challenge of reestablishing their group memberships and reputations after the transition, given that the move to middle school is accompanied by the introduction of many unfamiliar peers (Brown, McNeil, & Glenberg, 2009).

In a study designed to examine why it is that some youth maintain their perceived popularity status whilst others lose status and yet others gain stature among peers, Bowker, Rubin et al. (2010), followed a group of individuals as they made the transition from elementary to middle school. Peer-perceived increases in both aggressive and arrogant/conceited behavior together predicted both stability and increases in perceived popularity. This finding was consistent with evidence that aggression and arrogance are independently associated with perceived popularity during early adolescence (e.g., de Bruyn & Cillessen, 2006), and with suggestions that aggressive and other antisocial behaviors may reflect attempts to reestablish and gain new status in a new peer context (e.g., Cillessen & Mayeux, 2007).

Four important points can be derived from these findings. The first is that they situate popularity within a large set of variables related to a child's visible notoriety within the group. Second, among older children and young adolescents, aggression, especially, relational aggression, is seen a correlate of popularity, presumably as a means by which a position of status in the group is acquired and maintained. Third, popularity has been observed to be positively correlated with measures that are negatively related to each other. For example, it is positively correlated with both prosocial and aggressive behavior. The dual valence on the correlates of popularity is consistent with Hawley's (2003) bistrategic model of social competence that integrates motives to help and to control. Wargo Aikins and Litwack (2012) have argued that the capacity to skillfully combine these typically incompatible styles basically defines the competence of popular children. Fourth, although the overall construction of perceived popularity was quite consistent across samples, differences have been observed between boys and girls, with girls appearing to see perceived popularity more negatively than boys.

### ***How Do Popular Children Function Within the Peer Group?***

Whereas the studies discussed thus far have used empirical approaches to address the questions of "what is popularity"

and “who is popular,” other researchers have taken a more interpretive approach. At least two well-reasoned analyses of the features associated with popularity have suggested that the phenomenon is best understood as a form of social dominance and power (Pellegrini, Roseth, Van Ryzin, & Solberg, 2011; Sandstrom, 2011). As a result, Pellegrini et al. (2011) argue that the aggressive tendencies linked to popularity, especially the tendencies to act in a relationally aggressive manner, are a natural part of group processes by which some individuals strive to manage or control the activities of the group. Ironically, the putative purpose of their aggressive behavior is to achieve status within the group so as to establish within-group harmony and cohesion. Thus, Pellegrini et al. (2011) interpret popularity as an important means of stabilizing group dynamics. A little aggression on the part of the popular individual minimizes the likelihood that more serious aggression will emerge to upset or destroy the group.

Sandstrom (2011) focused on the role of popularity in the process of social influence. Implicit to Sandstrom’s interpretive approach is the claim that the prestige, status, and visibility that are part of the popularity rubric allow youth to control the social agenda (i.e., group norms) and to have influence over some of their peers. Sandstrom is careful to note that although one can demonstrate the influence that popular children can have over their peers, the processes that account for these effects and the contextual factors that moderate them are not well understood.

The intersection between popularity and power can be seen from another vantage point—the allure that being perceived as popular has for some children. In parallel to the recognition that some children are more concerned than are others with dominance within the peer group (Pellegrini et al., 2011), there is evidence that across the childhood and adolescent years some individuals are highly concerned with achieving and maintaining a position of status within the group. The desire for popularity has been observed to be strongest between the ages of 12 and 16 years and has been observed to be associated with the behaviors (e.g., aggression) that are critical for acquiring and maintaining status within the group (LaFontana & Cillessen, 2010).

#### ***How Is Perceived Popularity Related to Adjustment?***

Research on the effects of being popular has typically focused on changes in aggression that can be attributed to prior levels of popularity. Two studies in particular have shown that measures of status predict subsequent levels of aggression even after accounting for the original level of aggression (Cillessen & Mayeux, 2004; Rose et al., 2004).

Using similar 6-month longitudinal designs, Cillessen and Mayeux showed that a measure of perceived popularity predicted subsequent measures of physical and relational aggression for girls and boys whereas Rose et al. found this effect for young adolescent girls and boys using a measure of relational aggression. One can interpret these findings as evidence that the experience of power that is inherent in status has the insidious effect of allowing high-status persons to function outside of usual social norms such as the sanctions against aggressive behavior.

To our knowledge there have been no studies of the effect of status in the peer group on self-perceptions. It is reasonable to expect that the experience of power and dominance that derive from a position of status within the peer group will affect one’s sense of personal efficacy and influence. Whereas acceptance may promote a child’s affective sense of well-being and validation, popularity may affect one’s sense of power.

#### ***How Does Perceived Popularity Intersect With Other Aspects of Group Functioning?***

Two final issues regarding perceived popularity deserve some consideration. Both are related to the broad question that started this section of the chapter—specifically the question of what popularity is and how it fits together with other constructs. First, perhaps the most pervasive conclusion that can be drawn from the current literature is that popularity is firmly situated within the broader construct of status. Just as importantly, it is clear that popularity is intricately linked to a broad set of measures that are related to either prominence or notoriety in the peer group or issues of social dominance. This evidence of the complex set of measures with which popularity is associated has both conceptual and methodological repercussions. Conceptually, this vast set of associations with other measures raises the question of whether popularity should be studied on its own as a distinct form of status or whether it should be bundled with other aspects of status for purposes of theory development or for the creation of omnibus measures. Of course the methodological challenge of these associations is the interpretive issue that may be raised when one observes an association with a measure of popularity. Unless one has controlled for the many measures associated with popularity, an unequivocal interpretation of these associations will be, at best, difficult.

A second question concerns the extent to which popularity derives from natural or cultural forces. Researchers need to consider whether popularity is part of human nature, rooted in our atavistic past, with an ethological significance

that derives from its importance for the emergence of new leaders during adolescence, to promote the well-being and effective functioning of human groups, or whether it is a meme-like social construct that has worked its way into the culture of adolescent groups (at least in Western societies) and is handed down from one generation of adolescents to the next. Studies of cultural variations in the meaning and significance of popularity are needed to identify how youth from different countries and cultures define popularity and to explain why these differences may occur.

### **INTRAPERSONAL THOUGHTS AND FEELINGS ABOUT PEER PROCESSES**

Researchers have long posited that the children's standing in the peer group results, in part, from the ways in which they behave in various social situations. A related assumption has been that a child's thoughts about others, about the self, and about the larger social milieu account, in part, for why children behave as they do (Rubin & Rose-Krasnor, 1992). Thus, an indirect relation is hypothesized to exist between thinking about things social and peer reputation and status. In the following section, we review evidence for this relation.

#### **Social Information Processing (SIP)**

In this section, we review research in which the processing of social information has been associated with qualitative aspects of children's interactions and relationships with peers. The majority of this research has been guided by social information-processing (SIP) models, such as those of Rubin and Krasnor (1986), Crick and Dodge (1994), and Lemerise and Arsenio (2000) in which it has been argued that the ways in which children attempt to make sense of their social experiences with peers serves to determine, in part, the ways in which they interact with their peers and establish and/or maintain their relationships with them. Indeed, these models are part and parcel of transactional models suggesting that the relations between children's social cognitions, social behaviors/interactions, and reputations "snowball" in meaningful ways such that over time, these individual (social cognitions), interactional (social behaviors), and relationship (rejection/popularity; exclusion; victimization) become increasingly entrenched in the peer group.

Much research on social cognition and peer relationships has focused on aggressive children's deficits or

qualitative differences in performance at various stages of these SIP models. For instance, when considering the motives or intentions of others, aggressive children, especially those who are also rejected, are more disposed than their popular counterparts to assume that negative events are the product of malicious, malevolent intent on the part of others (e.g., Dodge et al., 2003). This bias is evident when children are asked to make attributions for others' behaviors in situations where something negative has happened but the motives of the instigator are unclear. In these ambiguous situations, rejected-aggressive children appear unwilling to give a provocateur the benefit of the doubt (e.g., by assuming that the behavior occurred by accident. This "intention cue bias" is often used as an explanation for aggressive and oppositional-defiant children efforts to solve their interpersonal problems in hostile ways.

But why would aggressive children think that when negative but ambiguously caused events befall them, the protagonist means them harm? In keeping with Lemerise and Arsenio (2000), a transactional perspective would suggest that aggressive children, many of whom are already rejected (and victimized) by their peers, believe that certain others do not like them, those others have a history of rejecting of them or acting mean toward them, and thus the negative act must be intentionally caused. This conclusion of intentional malevolence is posited to elicit anger and a rapid-fire response of reactive aggression. Many researchers have found that when asked how they would react to an ambiguously caused negative event, aggressive children appear to be hypersensitive and overly responsive to ambiguous social cues (Horsley, de Castro, & Van der Schoot, 2010), respond emotionally with dysregulated anger (e.g., de Castro, Verhulp, & Runions, 2012), and eventually with a choice and display of agonistic strategies (Dodge et al., 2003). And aggressive children also regard aggression to be an effective and appropriate means to meet their interactive goals (Vernberg, Jacobs, & Hershberger, 1999). The processes leading to the enactment of aggression may reinforce an already negative peer profile.

By the elementary and middle school years, many anxiously withdrawn children are also rejected and excluded by their peers (Rubin, Coplan, et al., 2009). Thus, it may not be too surprising that these children view their social worlds in ways that vary from those of nonwithdrawn and/or nonrejected and nonexcluded children. In early childhood, socially withdrawn children are less able than their non-withdrawn age-mates to understand the perspectives of others; also when socially withdrawn 4- and

5-year-olds are asked how they would go about obtaining an attractive object from another child, they produce fewer alternative solutions, display more rigidity in generating alternative responses, and are more likely to suggest adult intervention to aid in the solution of hypothetical social problems when compared to their more sociable age-mates (see Rubin, Coplan, et al., 2009, for a review).

Rubin and colleagues (Rubin, Coplan, et al., 2009) have argued that as a result of frequent interpersonal rejection by peers, anxiously withdrawn children may begin to attribute their social failures to internal causes. Consistent with Rubin and Krasnor's (1986) earlier report that extremely withdrawn children tended to blame social failure on personal, dispositional characteristics rather than on external events or circumstances, Wichmann, Coplan, and Daniels (2004) reported that when 9- to 13-year-old withdrawn children were presented with hypothetical social situations in which ambiguously caused negative events happened to them, they attributed the events to internal and stable "self-defeating" causes. Moreover, withdrawn children suggested that when faced with such negative situations, they were more familiar with failure experiences and that a preferred strategy would be to withdraw and escape.

Given the earlier noted conceptual associations between social withdrawal, victimization, and peer rejection, the findings by Wichmann et al. (2004) are reminiscent of work by Graham and Juvonen (2001). These latter researchers reported that youngsters who identified themselves as victimized by peers tended to blame themselves for their peer relationship problems. And Nolen-Hoeksema, Girgus, and Seligman (1992) have argued that self-blame can lead to a variety of negative outcomes of an internalizing nature, such as depression, low self-esteem, and withdrawal, thereby suggesting a self-reinforcing cycle of negative socioemotional functioning.

More recently, Burgess, Wojslawowicz, Rubin, Rose-Krasnor, & Booth-LaForce (2006) reported that aggressive fifth and sixth graders were more likely than their anxiously withdrawn and nonaggressive, nonwithdrawn (typical) counterparts to assign external blame in situations involving ambiguously caused negative events. However, like aggressive children, anxiously withdrawn children were more likely than typical children to indicate that they would feel angry if such events occurred. Anxiously withdrawn children were also more likely than typical children to suggest that they would cope with adversity by avoiding the provocateur.

In the same study, Burgess et al. (2006) found that whereas aggressive and withdrawn children exhibited

more maladaptive processing skills (e.g., external blame, anger, avoidant coping) than typical children in provocative situations involving unspecified peers, they demonstrated more adaptive processing (e.g., prosocial attributions, neutral emotions) if the provocative situations involved their best friends. These findings are particularly illuminating in that they question the suggestion that aggressive (and withdrawn) elementary school-age children have deficits in their abilities to process social information; it may well be that a key difficulty is performance- rather than competence-related and that the performance difficulty derives from an inability to regulate anger when negative events are experienced and viewed as caused intentionally. Also, within the friendship context, aggressive and anxiously withdrawn children are likely to have fewer experiences of being rejected, victimized, and otherwise intentionally hurt, which may explain why these children are able to process information in much the same way as typical children when the provocateur is a friend. In summary, these findings, as well as those by others (e.g., Peets, Hodges, & Salmivalli, 2008) strongly suggest that children's SIP differs across relationship contexts or according to the person about whom they are thinking, likely due to relationship-specific schema, expectations, memories, and affect that impact each step in the SIP model.

The relationship-specific ways in which children interpret and process social information are also noteworthy in light of recent evidence that friendship-specific SIP is related to actual friendship adjustment outcomes. For example, Rose and Asher (2004) found that the ways in which young adolescents interpret hypothetical help-giving and help-seeking friendship tasks relate significantly with the number and quality of their mutual friendships. Strategies such as avoidance and exclusion were found to be negative predictors of having friends and positive friendship quality. Rose et al. (2012) have also revealed significant linkages between children's and adolescents' outcome expectations about disclosing problems to friends and the extent to which they actually report disclosing to friends. And, Spencer et al. (2013) recently found homophily between young adolescents and their mutual friends in certain types of SIP; more importantly, the extent to which young adolescents and their friends were similar in aggression-related SIP was found to explain significant variability in the quality of their friendships. Thus, although SIP theory and research is typically concerned with explaining variability in behavioral outcomes such as aggression and withdrawal that are directed to peers in general, SIP models also appear to offer some

explanation about variability in behaviors directed at friends. In addition, they appear to provide some important clues about why some friendships during childhood and adolescence are more positive than others.

### Rejection Sensitivity (RS)

Also of relevance to understanding how social cognitions are related to peer interactions and relationships is the construct of *rejection sensitivity* (RS)—the tendency to defensively expect, readily perceive, and overreact to rejection (Downey, Lebolt, Rincon, & Freitas, 1998). Drawing from both attachment and SIP theories, the empirically-supported RS model states that experiences with rejection, from parents and/or peers, may sensitize children and adolescents to readily expect and perceive rejection in situations wherein rejection is possible (e.g., London, Downey, Bonica, & Paltin, 2007). Ironically, RS can lead to a self-fulfilling prophecy in which individuals' expectations of rejection lead them to engage in defensive actions (e.g., aggressing against or withdrawing from others; Downey et al., 1998), which in turn increases the likelihood of actual rejection.

Rejection sensitivity is typically assessed by presenting children with hypothetical scenarios and asking them how nervous or angry they would feel and how much they expect to be rejected in each situation. Downey et al. (1998) have hypothesized that expectations of rejection that are accompanied by anger may lead to aggressive behavior with peers and that (nervous or) anxious expectations of rejection may lead to internalizing or anxious behaviors with peers. In support of this hypothesis, Downey et al. (1998) found that angry expectations of rejection were positively associated with teacher-rated aggression and negatively linked with social competence. Furthermore, child and adolescent anxious expectations have been linked with social anxiety and social withdrawal (London et al., 2007). In general, RS has been linked both contemporaneously and longitudinally with psychosocial problems such as rejection, depression, and loneliness across development (e.g., McDonald, Bowker, Rubin, & Laursen, 2010). Longitudinal evidence also suggests that peer rejection predicts increases in rejection sensitivity over time (Wang, McDonald, Rubin, & Laursen, 2012). And recently, McDonald et al. (2010) revealed that anxious RS was uniquely associated with social anxiety and depressive symptoms whereas angry RS was not. These researchers also demonstrated that anxious RS was associated with depression, but only for

those adolescents with unsupportive friendships. Relatedly, Bowker et al. (2011) found that the associations between anxious RS and indices of social anxiety were strongest for young adolescents without mutual best friends and for those whose best friend was highly rejection-sensitive. Thus, it seems that anxiety-provoking expectations about rejection may not be linked with psychological distress for young adolescents who have supportive best friendships with nonrejection sensitive peers. Given that these latter studies were contemporaneous in nature, future longitudinal work on the buffering effects of best friendships is clearly warranted.

### Self-System Correlates of Peer Acceptance and Rejection

An important repercussion that has been ascribed to negative experiences with peers is their effect on the self-concept. For example, it has been reported that rejected-aggressive children overestimate their social skills and standing in the peer group relative to their non-rejected-aggressive age-mates (e.g., de Castro, Brendgen, Van Boxtel, Vitaro, & Schaevers, 2007). It has also been consistently reported that the combination of anxious withdrawal and peer rejection and/or exclusion fosters negative self-appraisals and negative self-esteem and to reinforce socially anxiety, social disengagement, and withdrawn behavior (e.g., Salmivalli, Ojanen, Haanpää, & Peets, 2005).

A further distinction between rejected children is the chronicity of their peer problems. Whereas rejection is temporary for some children, it is an enduring experience for others. Ladd and Troop-Gordon (2003) showed that chronic rejection was related to subsequent views of the self and that these negative self-perceptions partially mediated the relation between peer difficulties and internalizing problems and loneliness. Researchers have also reported that negative self-perceptions are associated with such peer difficulties as victimization (Salmivalli et al., 2005). In keeping with transactional models of the relations between peer interactions, relationships, and self-processes (e.g., Rubin, Coplan, et al., 2009), Salmivalli and Isaacs (2005) found that negative self-perceptions placed children at risk for victimization, rejection, and friendlessness. All in all, children who experience peer rejection, exclusion, and victimization, especially those who are characteristically anxious, withdrawn, and submissive, are at risk for the development of negative self-perceptions of their social skills and relationships.

## THE PEER GROUP AS A SOCIAL CONTEXT

In this section, we explore the structural and functional characteristics of the peer group within which friendships and social reputations exist. We also describe processes involved in group formation, and group norms and organization. Our discussion is focused on informal peer groups that are initiated and overseen by their participants; we will not discuss formal peer groups, which are usually under the supervision and direction of an adult.

### Peer Group Functions

From participating in peer groups, children are able to develop and fine-tune skills that are necessary for the maintenance of efficient group functioning. Group participation allows children to learn (a) how to engage in cooperative activity aimed at collective rather than individual goals; (b) about social structures within and across groups; (c) the skills associated with leading and following others; (d) to control hostile impulses towards in-group and out-group peers; and (e) to mobilize aggression in the service of group loyalty by directing it towards “outsiders.” Moreover, the peer group provides a social context within which close dyadic relationships may be developed. Another function of the peer group is to reinforce identity development. The association with peers who have similar views and normative beliefs allows children to develop a sense of identity within the broader peer group.

Lastly, it has been argued that peer group experiences may have a significant effect on the social, emotional, and behavioral functioning and adjustment of individuals within larger social settings. For example, the profile of peer networks significantly predicts changes in individual members’ academic motivation (Kindermann & Gest, 2009). Similar findings have been reported concerning the contributions of peer groups to such matters as school dropout, teenage pregnancy, and delinquency (see Brown & Dietz, 2009, for a review).

### A Developmental Perspective

As early as the preschool years, dominance hierarchies and affiliative networks exist (Santos et al., 2008). Many researchers have found that the social dominance hierarchy is an important organizational feature of the preschool peer group (e.g., Vaughn, Vollenweider, Bost, Azria-Evans, & Snider, 2003). And, researchers have argued that

dominance hierarchies develop naturally in groups to serve adaptive functions. In the case of preschool-aged children, dominance hierarchies appear to reduce overt aggression among members of the group. Observations of exchanges between children in which physical attacks, threats, and object conflicts occur reveal a consistent pattern of winners and losers. And children who are losers in object struggles rarely initiate conflict with those who have proven “victorious” over others or who have been victorious over them (Strayer & Strayer, 1976).

During the upper elementary school and middle school years, the structure of the peer group changes from a relatively unified whole to a more differentiated structure. In this new structure, children organize themselves into social groups, clusters, networks, or cliques. Peer networks and cliques are voluntary, friendship-based groups, and stand in contrast to the activity or work groups to which children can be assigned by circumstance or by adults. Cliques generally include three to nine same-sex children. By 11 years of age, most of children’s peer interaction takes place in the context of the clique, and nearly all children report being a member of one (for a review see Brown & Dietz, 2009).

Peer networks, whether identified observationally or via peer reports (see Kindermann & Gest, 2009, for a review), or whether identified in or out of school (Kiesner et al., 2003), are typically organized to maximize within-group homogeneity (Rodkin et al., 2000). Thus, in recent studies of preadolescents conducted in both Western (e.g., Canada, Finland, United States) and Eastern (e.g., China) cultures, group membership has been found to comprise children similar with regard to the following characteristics: aggression (e.g., Xie et al., 1999), bullying (e.g., Espelage et al., 2003), and school motivation and performance (e.g., Kindermann, 1993).

As in middle childhood, cliques are readily observed in adolescence, and group membership comprises individuals who are similar with regard to school achievement (Kindermann, 1993), substance use (cigarettes and alcohol; Urberg, Degirmencioglu, & Pilgrim, 1997), and delinquency (Kiesner et al., 2003). Whereas cliques represent small groups of individuals linked by friendship selections, the concept of peer subcultures, or “crowds” (Brown & Dietz, 2009), is a more encompassing organizational framework for segmenting adolescent peer social life. A crowd is a reputation-based collective of similarly stereotyped individuals who share the same image or status among peers, even if, in fact, they actually spend little time interacting with each other. Thus, crowd affiliation is

assigned through the consensus of the peer group and is not selected by the adolescents themselves.

Different behaviors may define membership and different consequences of membership may occur. For example, “jocks” are involved in athletics and tend to be popular as well as physically and romantically attractive; “brains” worry about their grades and have marginal standing with peers; and “druggies/burnouts” do poorly in school, are less socially competent, are hostile toward authority figures, and engage in risky health behaviors (e.g., La Greca, Prinstein, & Fetter, 2001). However, these outcomes may not generalize across school contexts due to the values of the school at large. For example, in a school within which academic proclivity is highly valued, “brains” may be members of the popular crowd; in schools wherein academics are not equally stressed by the student body, “brains” may be outsiders (Sussman et al., 2007).

Crowd membership is an especially salient feature of adolescent social life and adolescents’ perceptions of crowds change in important ways with age. For example, between the ages of 13 and 16 years, adolescents alter the ways that they identify and describe the crowds in their school (O’Brien & Bierman, 1988). Whereas young adolescents focus on the specific behavioral proclivities of group members, older adolescents center on members’ dispositional characteristics and values. This observation reflects broader changes that characterize developmental shifts in person-perception between the childhood and adolescent years.

The stigma that is placed on members of a particular crowd channels adolescents into relationships and dating patterns with those sharing a similar crowd label. This may prevent adolescents from the exploration of new identities and discourage shifts to other crowd memberships. There is recent evidence that the stigma associated with some large peer groups or crowds influences the judgments that adolescents form about their peers (Horn, 2003). In particular, Horn found that adolescents are biased in their use of reputational or stereotypical information about particular groups, particularly when presented with ambiguous situations. It is likely that these crowd-specific evaluations help to perpetuate group stereotypes and the structure of peer groups in a school.

Despite the differences that exist in the structures of peer groups, all of them inevitably disintegrate by late adolescence. This is largely due to the integration of the sexes that accompanies this period. To begin with, mixed-sex cliques emerge. By the mid high school years, mixed sex cliques become commonplace. Both girls and boys feel sufficiently

confident to approach one another directly without the support of clique membership. Another contributing factor to the decline in the importance of cliques and crowds results from adolescents developing their *own* personal beliefs and norms. In this regard, adolescents no longer see it necessary to identify themselves as members of particular social groups, whether they are cliques or crowds.

### Groups and Adaptation

As previously noted, group affiliation may be associated with adaptive and maladaptive development. For example, researchers have found a negative relation between peer group membership and externalizing/internalizing problems (Newman, Lohman, & Newman, 2007). Likewise, Prinstein and La Greca (2004) argued that being a member of a given peer group strongly enhances self-concept and may protect against the development of internalizing problems. Significantly, membership in stigmatized peer groups may be associated with maladjustment. In a longitudinal follow-back study, Prinstein and La Greca found that “populars/jocks” saw a decrease in internalizing problems over time whereas “brains” saw an increase in internalizing problems over time.

### Summary

In summary, peer groups provide children a unique social context in which they are able to learn about themselves, others, and relationships between people and groups. Children’s initial dyadic experiences with friends allow them to acquire the necessary skills for competent social interaction and peer acceptance. When children become members of social groups, and become accepted by group members, they may become active participants in cliques. At the same time, some adolescents become members of crowds. Cliques and crowds provide different social opportunities for adolescents. The former provides a context for adolescents to test and develop values and roles in the absence of adult monitoring; the latter offer extrafamilial support in the development of a sense of self.

### CONCLUSIONS AND FUTURE DIRECTIONS

In this chapter we have reviewed current theory and research on peer interactions, relationships, and groups. Our primary goal was to make the complicated business of peer relations more comprehensible. To meet this goal,

we introduced a conceptual model that has guided, and can continue to guide, research on transactional relations between children's individual characteristics (e.g., temperament, sex), the complex ways in which they interact with peers, the relationships that are formed as a function of repeated interactions and experiences with others, and the groups within which "all of the above" may take place. Also, we probed the meanings, measurement, and significance of these levels of social complexity; in so doing, we reviewed recent research on the correlates and consequences of friendship, peer acceptance, popularity, exclusion, victimization, rejection, and peer group involvement. Significantly, we have argued that impoverished peer relationships, specifically rejection, victimization, and exclusion, represent risk factors for all manner of negative consequences. We noted, however, that friendship quality and being friends with socially and emotionally competent others can serve as protective factors (as can the display of positive, prosocial behaviors).

One consequence of reviewing the literature on peer relations is that gaps in our understanding of the peer system have become increasingly clear. Thus, in this final section we look to the future by discussing several research directions that are likely to lead to new knowledge about children's and adolescents' peer experiences, which in turn, we hope will improve ways and means to help children whose behavior and relationships in their worlds of peers may be moving them onto negative developmental pathways.

## Culture

As noted previously, growing evidence indicates that peer experiences influence (and are influenced by) the cultural context (see Goodnow & Lawrence, Chapter 19, this *Handbook*, this volume). Whether it be the prevalence of a given behavior (e.g., anxious withdrawal or aggression) or the "meaning" of a behavior and its associated peer outcomes (e.g., peer acceptance, rejection, or victimization), recent research has pointed to notable differences in Western (e.g., United States, Canada) and non-Western societies (see Chen & Rubin, 2011, for relevant reviews).

Cross-cultural research on peer experiences, however, is still in its infancy. Additional studies are needed, especially in non-Western, "majority world" countries that have been heretofore ignored. Indeed, the consideration of children's and adolescents' peer interactions, relationships, and groups in understudied countries in Africa, Oceania, Latin America and elsewhere could reveal novel information about the ways in which culture may shape peer

experiences and their impact on development as well as new knowledge about cultural differences *among* "majority world" societies and how they affect the experiences that children have with their peers.

We would also suggest that researchers remove themselves somewhat from their relative security within the cultural constructs of collectivism and individualism. In almost all cultural and cross-cultural research on child and adolescent peer interactions and relationships, the conceptual basis is housed in these two aforementioned constructs. And yet, interactions and relationships within varying cultural communities are differentiated also along such continua as *power distance*, and *uncertainty avoidance* (e.g., Hofstede, 1980). For example, it has been suggested that societies may be categorized by how much power specific individuals have within the larger community. It may be that some cultures value social interactions and relationships that are more egalitarian, whereas others may value a hierarchical relationship structure. One may ask whether friendship or peer group structures, when explored through the lens of culture, may reflect greater-or-lesser propensities in the directions of dominance/submissiveness and egalitarianism (Rubin et al., 2008).

*Uncertainty avoidance* involves the extent to which cultures feel comfortable in unstructured situations (Hofstede, 1980). According to Hofstede, uncertainty-avoiding cultures try to minimize the possibility of such situations by adhering to strict laws and rules, and on the philosophical and religious level by a belief in *absolute truth*. Consequently, one may expect that rules and regulations pertaining to interactions, relationships, and groups are clearly demarked through socialization practices. In such cultures, the friendships or peer groups within which children may be engaged are selected by parents, not children. And the choice of friendships and groups may be marked by perceived similarities in familial/cultural beliefs and traditions. These notions may be particularly valid for immigrant families (and especially parents) that aspire to cultural (and ethnic, religious) connectedness for their children. In cultures that are more accepting of uncertainty, there may be greater tolerance for philosophical and religious diversity. In this regard, there may be greater degrees of freedom accorded to both the nature of the friendship and the peer group, who is considered an allowable friend or group member (by parents and family), and how autonomous/independent the friendships and groups (and the individuals) can be. Many of these notions have yet to be examined.

Significantly, in keeping with the above suggestions, research on cultural effects would benefit from stronger

assessments of concepts that supposedly distinguish between cultures. Between *country* comparisons can provide interesting findings, but in the absence of direct measures of such cultural dimensions as collectivism, individualism, power distance, and uncertainty avoidance a cultural interpretation of these between-country findings is limited to speculation based on essentialist assumptions about what particular places are like. Without being able to directly attribute contextual effects to specific aspects of culture, we may learn how places differ without a satisfying understanding of why these differences occur.

In summary, peer researchers would do well to focus on culture, ethnicity, and race, both within and across countries and communities. For example, an entire program of research could be developed around some of the following questions (that could be asked during individual interviews with children and adolescents of different ages and within different cultural communities): What *is* a friend and a friendship? What is it that defines a *good* friendship? How does one *become* a friend? How does one *end* a friendship? Thereafter, one could begin to observe the *whos*, *hows*, and *whats* of friendship, much of which we described herein for predominately Western samples of children and adolescents.

### Context

It has also become increasingly clear that other aspects of context help to explain variability in children's peer experiences, such as neighborhood (e.g., Leventhal, Dupéré, & Shuey, Chapter 13, this *Handbook*, this volume), and school and classroom contexts (e.g., Crosnoe & Benner, Chapter 7, this *Handbook*, this volume). For example, it is well established that the associations between aggression and peer rejection and acceptance depend on the prevalence of aggression in the classroom as well as the class norms about aggression (e.g., Stormshak et al., 1999). Ecological/social-contextual theories suggest that an individual's adjustment is determined by *multiple* features in the larger environment, and by subsequent adaptation to these features (Bronfenbrenner & Morris, 2006). Thus, it appears important for researchers to consider multiple contextual factors to best understand the ways in which context determines and regulates children's peer experiences.

### Studying Different Populations of Children and Their Peer Experiences

Research on peer relations is multidisciplinary. And yet, most studies of peer experiences focus either on typical,

community samples of children and adolescents or on similar social-cognitive, cognitive, academic, and psychological indices of adjustment, such as aggressive-related social information processing, grade point average, anxiety, loneliness, and depression. Additional research efforts that are truly multidisciplinary should help to reveal new knowledge about factors that predict the quality of peer experiences or how peer experiences may predict domains of functioning that have been relatively ignored.

### Health Symptoms

One area of research that has emerged in the past decade has been how peer experiences influence and are influenced by physical health symptoms and ailments, such as somatic complaints, obesity, chronic medical conditions, and neurologically based disorders (e.g., Swearer, Wang, Maag, Siebeker, & Frerichs, 2012; van Roekel, Scholte, & Didden, 2010). Indeed, it has become increasingly clear that stressful peer experiences, such as being victimized and harassed by peers, can lead to negative physical health *symptoms* (e.g., abdominal pain, headaches, bedwetting, feelings of fatigue; Nishina, Juvonen, & Witkow, 2005). Nishina et al. (2005) found that peer victimization among sixth-grade students predicted later psychosocial and physical health difficulties, which in turn, predicted academic difficulties—findings that clearly demonstrate the importance of considering physical health outcomes in studies of peer relations. To our knowledge, research on peers and physical health symptoms has been limited to *peer victimization*; it seems important to determine whether other peer experiences, at both the dyadic (e.g., friendlessness) and group levels of social complexity (e.g., exclusion), might also explain variability in children's physical health symptoms and associated outcomes. From an intervention perspective, it might also be worthwhile to consider protective factors in this area of research.

Another example may be taken from studies of obesity. Recent evidence suggests that overweight and obese children and adolescents are often rejected, victimized, and excluded by peers, likely due to societal stigma as well as the limited physical activity skills that are often associated with obesity (e.g., Zeller, Reiter-Purtill, & Ramey, 2008). Interestingly, however, support for a transactional model of influence has also been revealed: Children who are rejected and victimized by peers often avoid opportunities for physical activity and exercise (Storch et al., 2007); the lack of physical activity is one of the “Big Two” contributors to the obesity epidemic. However, programming in schools (inclusive versus segregated settings) and teachers can

influence the extent to which children and adolescents who are obese or suffering from a physical disability or ailment are included by, and have positive relations with their peers during the school day (e.g., Kwon, Elicker, & Kontos, 2011), suggesting that future research on physical health and peers should also consider school features to best aid in the design of intervention and prevention efforts.

### ***Peer Relations and Neuroscience***

As we noted in our discussion of individual characteristics that may influence children's peer experiences, researchers have recently begun to examine the neural correlates of such peer experiences as rejection and exclusion (e.g., Adams et al., 2011; Guyer et al., 2012; Peters et al., 2011). Others have examined the social interactions and peer relationships of children who have suffered mild to severe traumatic brain injury (TBI; e.g., Yeates et al., 2013). Indeed, Yeates et al. (2007) have proposed an integrative model of social outcomes of children with TBI in which social adjustment is not only moderated by injury related and environmental factors, but also may be mediated or bidirectionally related to social cognitive, and SIP factors. As noted above, these factors can predict various forms of social interaction, which in turn, may help to determine the quality of relationships that TBI children form in the peer group and with friends. Again, these individual, interaction, and relationship factors are likely to affect the TBI child's social and emotional adjustment. In recent studies, Yeates et al. have found that TBI children (a) demonstrate deficits in social cognitive processing (e.g., theory of mind, Dennis et al., 2012); (b) without a mutual friendship were rated by classroom peers as less prosocial and sociable and more rejected and victimized than those with a best friendship (Yeates et al., 2013); (c) whose injuries were the most severe performed most poorly on social cognitive tasks (Dennis et al., 2012) and least likely to have a best friend (Yeates et al., 2013); and (d) with poor peer relationships had focal volumetric reductions in white matter within regions of the brain involved in SIP (Yeates et al., 2013; Bigler et al., 2013). Although these studies shed light on some of the peer relations difficulties of TBI children many questions remain to be answered. For example, virtually nothing is known of the friendships of TBI children and whether high-quality friendships may buffer them from negative social, emotional, and academic outcomes. And certainly, intervention efforts that are focused on the social and emotional difficulties experienced by TBI children have yet to make headway in the empirical literature.

More generally, research on the intersection between peer experiences and neuroscience can and should begin to make reference to, or develop new theoretical underpinnings. These directions could include conceptually derived studies of the link between peer experiences and neural-based reward centers, the effect of peer contact on the entrainment of regulatory mechanisms and the processes underlying stress responsivity, and the association between success with peers and the short- and long-term activation of affect-related areas of neural architecture. It is difficult to overemphasize the importance of using a theory-based approach to this research domain. The absence of clearly articulated theories and hypotheses based on them will result in a disparate collection of facts rather than a clearer understanding of the peer system.

### **The Need for Clearer Articulation of Relevant Concepts and Increased Specificity of Variables and Processes**

A central point of this chapter is that researchers are fortunate to use constructs whose attraction lies in their link to theories that bring together processes at multiple levels of social complexity. It is this intersection between different forms of personal and social experience that makes research on peer relations relevant to so many developmental processes and outcomes. This use of broad, complex constructs, however, presents two risks. The first is the lack of a clear articulation of meanings and processes. Even in cases where there are widely replicated effects (e.g., demonstrations of the effects of friendship on behaviors such as aggression), the identification of the processes that account for these effects have been poorly specified.

A second risk stems from the multidimensional nature of the constructs we study. Again, consider two of our most widely studied constructs, popularity and friendship. Each comprises several more specific components. Friendship is characterized by closeness, security, opportunities for help, and other features. Popularity refers to how much someone is perceived to be well liked, to be well known, and to possess other indices of perceived status within the group. Progress in understanding what truly matters in the peer group and how the functioning of the peer system varies across contexts and cultures will benefit from a more specific assessment of the individual components of the broad constructs at the heart of peer research. This emphasis on specific features and processes will help us understand what really goes on in the groups of hockey players we met at the beginning of this chapter and why such interactions,

relationships, and group experiences matter in the lives of children and adolescents.

## OVERVIEW

High levels of maternal employment in the United States and throughout the world have led to substantive changes in the rearing of infants and young children (Waldfogel, 2002). Nonparental care during early childhood has become normative in the United States, Western Europe, and many countries in Asia, Africa, and Latin and South America. Beginning in the child's first year, about 50% of the children in the United States experience regular nonparental childcare and by the preschool years more than 75% of children have experienced some type of childcare (Pianta, Barnett, Burchinal, & Thornburg, 2009).

---

We thank Nina Forestieri for assistance in preparing the text, the volume editors for their many helpful suggestions, and our many colleagues for their contributions to our understanding of early care and education.

This pattern of child rearing diverges from earlier historical periods in which parents (most often, mothers), or siblings, provided most of the direct care for their young children.

The widespread use of childcare for young children raises several important developmental questions. These issues are related to multiple developmental theories, including those that focus on the importance of maternal care for social and emotional development as well as those that focus on educational activities to enhance cognitive and social skills for young children. The wide-scale use of nonparental early care and education (ECE) also challenges some deeply held beliefs and cultural models of child rearing (Brazelton, 1986). Consequently, some findings from research on the effects of ECE on children's development have been controversial (Lamb, 1998; Love et al., 2003).

Historically, the ECE research literature reflects deep concerns about developmental questions. The early literature had two different foci. One set of studies documented

the benefits of intervening with high-quality childcare for children from low-income families, whereas the other set of studies documented the potential harm to infant-mother attachment of nonmaternal care for middle-class families (Lamb, 1998). As described in more detail in this chapter, widespread concern about the lack of attention to important differences in family background in the later set of studies led to further research with improved measurement of family characteristics as well as the quality, quantity, and type of ECE children experienced. Several large- and many smaller-scale studies documented the huge increase in the proportion of young children receiving ECE between 1980 and 2000, which were primarily due to increases in maternal employment, and examined how childcare experiences predicted early development with increasing methodological rigor. More recently, there has been increased focus on identifying ECE practices and programs that are effective in improving children's school readiness skills.

Researchers have not yet agreed on whether childcare is "good" or "bad" for children. This is, in large part, because studies have identified both benefits and risks of ECE for children, depending on the specific question they are asking or population they are studying. For example, high-quality early care and education has moderate to large positive impacts on academic and social development in some studies of low-income children (e.g., Karoly, Kilburn, & Cannon, 2005). Yet, focusing on middle-class children and specifically their behavioral outcomes, other researchers have found detrimental effects of childcare early in life (e.g., Belsky, 2009). Finally, others scholars conclude that both the positive and negative consequences are likely to be negligible because, in observational studies of childcare, associations between ECE quality and quantity and children's outcomes are quite modest (e.g., Burchinal et al., 2009).

Early care and education serves two primary functions: supporting parental employment and promoting positive cognitive and social development, especially for children at risk for poor educational outcomes. Cultural norms that reflect the extent to which caring for young children is viewed as the responsibility of the families or of broader communities influence decisions about parental employment and ECE after the birth of a child (Lamb, 1998). In northern Europe, where ECE is viewed as a community responsibility, parents have access to generous government-subsidized family leave and low-cost, high-quality childcare. In the United States, where childrearing is viewed as primarily the family's responsibility,

parents choose from a range of options available in the private market, after weighing the benefits, costs, and other constraints (Waldfogel, 2002). Although the U.S. government has provided financial support to low-income families to offset the high cost of early care and education, these policy initiatives were designed primarily to incentivize employment by increasing parents' access to childcare and have done little to increase the quality of ECE. As a result, for most families ECE has remained a family responsibility.

Increasing concern that some children, particularly low-income children, arrive at school unprepared to succeed in elementary school, and that these differences in early skills have lasting consequences for later educational achievement, have fueled public support for investing in young children. At the same time, early childhood education has been identified as one of the most effective mechanisms for improving school readiness for all children regardless of ethnicity or social class (Heckman & Masterov, 2007). Experimental and quasi-experimental studies have found that participating in early education programs has positive effects on disadvantaged children's educational and labor market success. As a result, these ECE programs generate benefits not only to participants, but also to the economic and social health of communities (Barnett & Masse, 2007; Heckman & Masterov, 2007; Magnuson, Ruhm, & Waldfogel, 2007; Putman, Frederick, & Snellman, 2012). Such evidence has contributed to an expansion of compensatory preschool services for low-income children funded by federal and state governments (Barnett, Hustedt, Friedman, Stevenson Boyd, & Ainsworth, 2007).

Understanding how ECE affects children across multiple domains of outcomes, and along multiple dimensions of care characteristics, is especially important because it has become part of the typical child's early experiences and because of the need for public money to be spent efficiently. Fortunately, the interdisciplinary nature of ECE scholarship has resulted in a comprehensive and rigorous body of research that includes descriptive population-level studies and experimental evaluations of innovative programs, as well as rigorous evaluations of scaled-up interventions and small-scale laboratory research that advances both research and practice (Pianta et al., 2009). This large literature addresses important questions about policy initiatives, program design, and classroom practices.

This chapter reviews the current landscape of ECE programs in the United States as well as current directions in research and the accumulated findings from more than 50 years of research. We begin this chapter

with a discussion of developmental theories and their focus on how nonparental care for infants, toddlers, and preschoolers affects early development. Then we discuss the key dimensions of ECE—type, quality, and quantity—describing the experiences of children in childcare along those dimensions. Next we present empirical research describing associations between ECE and early development, along with the contextual challenges of addressing confounds between family characteristics and the selection of childcare arrangements. The next section examines whether ECE serves as a risk or protective factor with particular attention to some subgroups of children, especially low-income or ethnically diverse children. The final section describes public policies and programmatic strategies to improve quality and ensure access to ECE, including findings from recent experimental studies of professional development and curriculum studies.

## THEORIES OF NONPARENTAL CARE

To develop guiding conceptual models, scholars of early childhood care and education often rely on broad socioecological and transactional frameworks, which incorporate multidimensional and bidirectional influences of both children and their environment in shaping developmental processes (Bronfenbrenner & Morris, 2006; Overton, 2013; Sameroff, 2009). These general systems models have been instrumental in building definitions of childcare quality because of their attention to multiple systems that influence early development, ranging from the proximal family system to more distal influences of the community and society. Attention is paid to how factors in one system influence individuals in that system and other systems (see Overton & Molenaar, Chapter 1, this *Handbook*, Volume 1, for more details on developmental theories).

### General Systems Models

These theories all focus attention on the interactions between the young child and his or her primary caregivers, including the childcare providers, as providing the young child with emotional and intellectual support. The models posit that the primary caregivers play crucial roles in early development directly through interactions with the child and indirectly through determining the child's context. Furthermore, they emphasize bidirectional effects—caregivers influence children and the child's

characteristics and skills also influence the caregiver and how he or she interacts with the young child. These theories also draw attention to the continuity and communication between the child's caregivers at home, including parents and other primary guardians, and caregivers in the childcare context as being important for early development. The relations between the home and childcare contexts have both a direct and indirect impact on the young child's development in terms of their proximal interactions, and the bilateral influence of childrearing beliefs and practices of both parents and care providers. Finally, these models emphasize the need to examine early development within context, assuming that development will manifest differently when contexts are different.

These general system theories have been widely used in ECE research in two ways. First, questions about whether the effects of childcare experience differ (i.e., are moderated) by characteristics such as gender, ethnicity, and parenting practices and beliefs. Second, an important issue with ECE research has involved how the relationship and similarity of home environments to childcare environments affect early development.

Although useful as a conceptual framework, general systems theory frameworks, including Bronfenbrenner's Ecological Model and Overton's Relational Developmental Systems Theory, tend to be too general to yield specific hypotheses about how ECE directly affects children and families. Thus, researchers also use several other developmental theories that identify the specific aspects of children's ECE experiences thought to be consequential for specific developmental processes. Attachment theory focuses on the affective dimensions of interactions between children and their caregivers, specifically the role that the warmth and sensitivity of the caregiver plays in the social development of the young child (Bowlby, 1982; Howes & Spieker, 2008). Cognitive and social stimulation theories of development suggest that particular types of child-caregiver interactions promote cognitive skills and academic achievement (Piaget, 2007; Vygotsky, 2001). Finally, sociobiological theories argue for attention to the interaction between a child's biological systems and ECE settings to understand children's development, especially the development of self-control (Blair & Raver, 2012). These theories are complementary in many ways, but emphasize specific dimensions of children's childcare experiences, processes of influences, and dimensions of children's development. Thus, within a broad ecological framework, researchers draw from each theoretical orientation to pose different questions.

### Attachment Theory

Attachment theory argues that among the most fundamental influences on a child's development are the instrumental relationships that form between children and their caregivers, including ECE care providers, who consistently provide physical and emotional care for the child (Howes & Spieker, 2008). Because young children are so vulnerable, at their most basic level attachment relationships ensure children's survival, but they also promote physical and psychological development. Although children develop attachment relationships with more than one caregiver, these relationships develop in a hierarchical manner with the mother most often serving as the primary attachment figure (Ainsworth, Blehar, Waters, & Wall, 1978; Bowlby, 1982; Bretherton, 1985). Consistent, warm, and sensitive interactions with caregivers lay the groundwork for a child's view of the world as predictable and safe, and view of the self as deserving of others' positive attention. When caregivers are able to soothe a child's distress, tiredness, and hunger as well, the child is more likely to form secure relationships with the caregiver.

A salient feature of caregiving relationships, according to Attachment Theory, is the level of continuity, consistency, and sensitivity of care of in a child's life (Howes & Spieker, 2008). Children internalize their attachment relationships and bring these cognitive representations to bear on subsequent relationships with adults and peers. Within secure attachment relationships, children's bids for attention and need for comfort are met with sensitive responses from attentive caregivers (Bretherton & Mulholland, 2008). Children with secure attachment working models have positive perceptions of themselves in relational contexts and may elicit increased language and cognitive support and other positive learning experiences from adults (Ahnert, Gunnar, Lamb, & Barthel, 2004; Belsky & Fearon, 2002). Thus, secure attachment relationships provide a foundation for experiences that will lead to learning and development (La Paro, Pianta, & Stuhlman, 2004). In contrast, within insecure attachment relationships, less positive interactions result in more negative views of the world and self.

Building trusting relationships with a caregiver requires repeated, predictable, and sensitive interactions over time through which children can begin to predict the consistency of the caregiver's behavior. For this reason, higher turnover and instability in childcare placements is thought to be a significant problem in the field of early care and education, as it may interfere with children's ability to form attachment

relationships with caregivers (Peisner-Feinberg et al., 2000; Tran & Weinraub, 2006). Likewise, the caregiver's mental health and stress levels are viewed as factors that affect their ability to be sensitive to children's needs (Blair & Raver, 2012). Finally, large group settings and high ratios of children to staff might also be of concern if they reduce the ability of caregivers to attend to the individual needs of children under their care.

### Cognitive and Social Stimulation Theories

The constructionist learning theories focus on the types and quality of learning opportunities provided within ECE settings. Two constructivist theories, Piaget's and Vygotsky's, are prominent in the study of ECE. Both theories argue that children have qualitatively different cognitive skills and capacities than adults, and that they construct their own learning by interacting with and operating upon their natural environments (Piaget, 2007; Vygotsky, 2001). These theories have been influential in shaping our understanding of the quality of childcare, and specifically the importance of the child's opportunity to interact with varied and rich materials.

Piaget's constructivist theory focuses on active participatory learning, with the implicit assumption that children coconstruct knowledge through actively engaging with their environment, developing and testing hypotheses as they learn new concepts (Gopnik, Meltzoff, & Kuhl, 1999). According to this theory, cognitive development is a dynamic process in which children are building and revising their understanding of the world as a result of both experiences and biological maturation. The role of the caregiver is to provide enriched learning environments that provoke children's curiosity, thereby facilitating children's cognitive development. The child is viewed as a "little scientist" who is forming cognitive structures to explain the world and testing hypotheses to refine their understanding. Children assimilate new information into their cognitive frameworks until new experiences or skills lead them to recognize the frameworks are inadequate, and as a result modify them.

Based on this theory, high-quality childcare involves caregivers ensuring that children have easy access to a variety of open-ended, age-appropriate activities and materials, which in turn will promote their active engagement in learning (Harms, Clifford, & Cryer, 2005; Stipek & Byler, 2004). Conversely, settings in which caregiver-led activities and didactic instruction dominate are viewed as developmentally inappropriate because young children's passive

engagement in learning does not adequately promote their learning and development (Bredekamp, 1987).

Vygotsky's sociocultural theory further describes the types of interactions with teachers and peers that are most beneficial to children's learning, specifically scaffolded instruction. Scaffolded instruction refers to learning that occurs when a more skilled partner engages with a child to help the child complete a task that is slightly above the child's skill level and therefore enables the child to accomplish tasks the child could not otherwise complete (Bodrova & Leong, 2006; Vygotsky, 2001). The idea is that to learn, children must be both challenged by tasks, but also that their efforts must be guided and supported by others.

Within this framework, the definition of high-quality care is further refined by incorporating the important active role that caregivers take in promoting children's learning (Berk & Winsler, 1995). The caregiver provides scaffolded instruction through continuously monitoring and revising the learning experiences provided to the child or a group of children. The caregiver then actively tracks the individual child and the group's conceptual understanding of an activity, and provides learning experiences that promote concepts and competencies that are slightly beyond their skill level. A key component of scaffolded instruction is also the provision of complex language interactions that encourage children's use of analysis and reasoning and the extent to which caregivers are individualizing their instruction and interactions based on the specific skill level of a child.

These two theories have resulted in a strong emphasis on ECE on three key aspects of the environment: (1) the sensitivity and warmth of the caregiver; (2) the extent of time available for unstructured play and the active exploration of an enriched environment; and (3) the caregiver's role in actively matching interactive activities to children's interests and their current skill levels, and directly supporting their learning in these activities.

### Sociobiological Theory

A recent development in the field of developmental science is greater attention to understanding how biological processes interact with social processes to produce development. The recent focus in developmental sciences on epigenetics (see Wachs, Chapter 21, this *Handbook*, this volume) is beginning to have its impact on ECE research.

Recent evidence from epigenetics research has implications for ECE research. The study of epigenetics provides

evidence that the quality of caregiving, typically by the mother, can affect the gene transcription of stress hormones (Meaney, 2010), which in turn can have impacts on neural connectivity, which affects self-control (Blair & Raver, 2012). The frequency and sensitivity of parenting during infancy appears to interact with the genome, with certain genes showing greater responsiveness in terms of DNA methylation under stressful contextual circumstances (Meaney, 2010). Adversity in early life appears to alter the development of neural and endocrine responses to stress, but this association appears to vary depending on the quality of parenting. Infants who experience more responsive parenting appear to show greater genetic expression for certain genes that code for stress responses, and appear more buffered from the negative impact of adversity. Furthermore, the extent to which such epigenetic responses are facilitative or limiting appears to depend on the context in which the infant is being raised—such that being more vigilant and fearful might be protective in more dangerous contexts and less optimal in less dangerous contexts.

Researchers posit that experiences in ECE settings can also shape children's cognitive development by affecting the expression of genes related to stress reactivity. By influencing the expression of these genes, it is thought that ECE experiences (e.g., quality of interactions with primary caregivers, or stress from being exposed to multiple peers) could also have long-term influence on the child's stress reactivity, and therefore long-term effects on the child's neural connectivity and subsequently on children's self-control and problem behavior (Pluess & Belsky, 2010). Pluess and Belsky (2010) argue that individual differences in temperament determine the level of the child's stress reactivity that is triggered by exposure to nonparental care and/or large groups of peers. They submit that children with more extreme personalities—either more inhibited or more reactive—have higher levels of stress reactivity in childcare, and thereby may be more likely to be influenced by the quality and quantity of their childcare experiences.

### Summary

Different types of conceptual frameworks have informed ECE research. The general systems model serves as the underlying model for most studies because of its depth and breadth. Research that focuses on determining whether ECE experiences influence subgroups of children differently and on how relations between parents and caregivers might enhance early development tends to use these

models explicitly. Other, more specific, conceptual frameworks have been used in other ECE research: the potential negative impact of nonmaternal care examined through Attachment Theory; the impact of the quality, focus, and type of instruction examined through constructionists theories; and the differential impact of ECE based on genes (i.e., gene  $\times$  environment hypotheses) examined through sociobiological theories.

## DIMENSIONS OF CHILDCARE

Children's experiences in ECE settings frequently differ along several key dimensions that relate to the quantity and quality of nonparental care that children experience. Whether children experience any regular nonparental care before they enter formal school is the first consideration related to the quantity of nonparental care. For those children who routinely experience nonparental care, the dimensions of the childcare experiences also include the age at which they entered routine nonparental care and number of hours per week (and possibly weeks per year) that they experience that care. In addition, the mode of care is also important—with most researchers at minimum distinguishing between center- or group-based settings and more informal care settings. Finally, regardless of setting or mode of care, ECE research has also focused a lot of study on the quality of ECE settings, both measuring contextual quality and its association to children's developmental outcomes.

ECE dimensions are not independent, and children's experiences across these dimensions vary with age, family characteristics and governmental policies. The complexity of ECE experiences over the course of childhood as well as how these experiences differ by individual and family circumstances make the study of ECE or any one dimension of it quite challenging. In this section, we provide an overview of models of ECE choice and the most important ECE dimensions and the empirical results of related ECE research.

### Use of Nonparental Care

Many infants, toddlers, and preschoolers now experience nonparental care. About half of the infants and toddlers and over 75% of preschoolers in the United States receive regular early education and care by individuals other than their parents. Our analyses of the nationally representative longitudinal survey of U.S. children born in 2001, the Early

Childhood Longitudinal Survey-Birth Cohort (ECLS-B; Andreassen, Fletcher, & West, 2005; Andreassen & Fletcher, 2007; Najarian, Snow, Lennon, & Kinsey, 2010), indicated that 50% of children at 9 months and 24 months and 20% of preschoolers (approximately 52 months in the ECLS-B) were cared for exclusively by their parents. Analysis of the 2005 National Household Education Survey (NHES) indicates that 60% of all children younger than 1 year old are cared for exclusively by their parents, but that this proportion decreases to 47% for all 2-year-olds and continues to decrease as children age, with just over 20% of all 4-year-olds being cared for exclusively by their parents (Mulligan, Brimhall, & West, 2005). The proportions of infants, toddlers, and preschoolers in nonparental care in other countries vary widely (Organisation for Economic Co-operation and Development [OECD], 2007).

Families make decisions about ECE arrangements weighing their needs and childrearing goals as well as economic constraints and community resources. Economic theory assumes that parents make childcare choices based on both their preferences and budget constraints (e.g., Blau & Hagy, 1998), and that parental employment decisions, at least in part, are jointly determined with childcare choices (P. M. Anderson, 2010; Waldfogel, 2002). That childcare choices are linked to parental employment is not surprising given that whether both parents work in the formal labor market as well as their work schedules have implications for the amount and type of nonparental care that children experience. Financial considerations, however, are not the only influence on parents' decisions. The degree to which they view childcare, especially preschool care, as preparing the child academically for school and socially for interacting with peers are other factors motivating parents to use childcare (Early & Burchinal, 2001). Thus it is not surprising that families using ECE are much more likely to have employed mothers and families who view childcare as a means to prepare children for school academically and socially.

Families that do and do not use nonparental care differ on demographic factors, perhaps linked to the reasons they use ECE. On average, families using routine nonmaternal care tend to have higher family incomes and parents with higher levels of parental education who engage in more responsive and stimulating interactions with the child (NICHD ECCRN, 2006). They are also more likely to consist of a single mother living without a partner or extended family in the same household, to be African American than White, and to have fewer young children in the household (Early & Burchinal, 2001).

## Type of Childcare

Many children experience several different types of ECE settings prior to entry to primary education. Modes of childcare are typically classified into the following categories: care by relatives, home-based care by unrelated adults, and center-based care. Sometimes, the home-based care category is further differentiated based on whether the care is provided in the child's home, as in the case of babysitters or nannies, or in another home, as in the case of family-based daycare providers. Home-based settings are typically considered to be "informal" arrangements, even if they involve contractual obligations, and center-based settings are typically considered to be formal arrangements. Formal arrangements are often thought to be beneficial in preparing preschoolers to transition to primary school because, like primary school, they provide structured experiences in classrooms with same-age peers. Relative and other informal settings often provide more stability, engagement, and stimulation for infants and toddlers, whereas centers often provide higher-quality care for preschoolers (Dowsett, Huston, Imes, & Gennetian, 2008; Li-Grining & Coley, 2006). The experiences within and across these settings tend to vary markedly by child age. Many children in ECE start during the infant and toddler years in an informal setting with a relative or in a childcare home, and switch to a formal center program as a preschooler (NICHD ECCRN, 2004). In the NICHD Study of Early Child Care and Youth Development (SECCYD), of the children with infant care, 43% switched from informal to formal settings, 24% remained in formal settings, 13% remained in informal settings, and 20% used a combination of informal and formal settings between birth and 54 months.

## Relative Childcare

Having a close relative care for a child, typically while the mother is at school or work, is almost always the first preference of parents, especially parents of infants and toddlers (Early & Burchinal, 2001). Care by a grandparent is the most common type of relative care, but grandfathers, aunts, uncles, siblings, and other family members may also provide such care. Data suggest that that 48% of 0- to 4-year-old children with employed mothers are cared for by a relative (Federal Interagency Forum on Child and Family Statistics, 2011), but whether relatives are providing the primary or secondary childcare varies with the child's age. Our analyses of the ECLS-B suggested that relatives provided the primary childcare for 25% of

the children at 9 months, 19% at 24 months, and 13% at 52 months. Whereas relatives often provide primary childcare for infants and toddlers, they are more likely to provide supplemental care before or after the child's center care. Other data indicated that rates of relative care remain at about 20% to 23% throughout childhood (e.g., the 2005 NHES; Mulligan, Brimhall, & West, 2005).

Relatives provide early care and education in the child's home or in the relative's home (Early & Burchinal, 2001). Parents often prefer relative care because it most closely resembles the care they would provide for their children, including playing with the child as well as providing routine care such as feeding, diapering, and putting children down for a nap. Although there may be daily activities and enriching outings, few relatives providing ECE make use of any structured curricula or instructional materials. Such care arrangements often include multiple children from one family, and may also include children from different families (e.g., cousins cared for by a grandmother). In the NICHD SECCYD, the mean number of children in this setting ranged from 1.6 at 6 months to 2.4 at 36 months (NICHD ECCRN, 2006). More recent national data suggest a slightly lower group size with about 1.5 children per caregiver in relative care across early childhood (Mulligan et al., 2005).

Some features of relative care are quite attractive to parents, although it also may have some important drawbacks as well (Gordon, Kaestner, & Korenman, 2008). Many parents believe relative care is safer and of higher quality than ECE provided by an unrelated adult because the relative already cares about the child and will have a long-term relationship with him or her. In addition, parents often prefer relatives because they share language, values, beliefs, and childcare practices. Finally, relatives are rarely compensated for the care they provide and often are able to provide care during evening and weekend hours when it is difficult to find other childcare options. On the other hand, relative care is not subject to state regulations and may be less reliable than purchased care. The relative's schedule and, thus, availability may change suddenly, and in the absence of alternative care providers parents may be unable to find back-up childcare. For example, a relative's last-minute doctor's appointment or illness may leave the family without needed childcare (Gordon et al., 2008). As children age, many parents believe that they benefit from socialization with a wider set of peers and the more structured learning environments found in center-based early education programs. For these reasons, many parents transition from relative care into home-based

or center-based care when the child reaches the age of 3 or 4.

### *Home-Based Childcare*

Many children are cared for by unrelated adults in either their own home or someone else's home. Home-based care, or family daycare, typically describes purchased care in the home of the care provider. Because home providers are self-employed, they often take in more children than relatives, but fewer than center-based care. In the NICHD SECCYD, the modal size was one care provider and four to six children when the target child was an infant or toddler and five to seven children when the target child was a preschooler (NICHD ECCRN, 2006). The children's ages often vary, including infants, toddlers, and preschoolers during the entire day, and school-age children before and after school. The home provider is typically the only care provider in the setting, but she or he can hire an assistant or have her or his family members help when needed.

Home-based care is the modal type of care for infants and toddlers in the United States and most countries that do not subsidize other forms of care for children that age. Our analyses of the ECLS-B indicated that 15% of all children (30% of children in any type of childcare) at 9 and 24 months, and 8% of all children (10% of children in childcare) at preschool experience home-based childcare. Large survey studies suggest that most children are cared for in these settings for between 30 and 40 hours per week, although there is considerable variation (Mulligan et al., 2005; NICHD ECCRN, 2006).

Home-based care varies tremendously in the extent to which children's days are structured. Some home-based providers incorporate many of the practices found in center-based programs, such as the use of set schedules and routines with specified learning activities, access to a range of age-appropriate play materials, and the use of learning curricula. Others are far less structured and provide little in the way of stimulation, for example, relying on television or videos to keep children entertained.

### *Center Childcare*

Childcare centers provide care for infants, toddlers, and preschoolers. Typically, a center consists of several classrooms that are organized by age of the children, and often have at least one lead teacher and an assistant teacher. The number of children per classroom and the ratio of adult teachers to children are regulated by the state, and always require fewer children per adult for younger children. The classrooms tend to be more structured than

informal care and usually have daily routines and scheduled activities (Dowsett et al., 2008). A formal curriculum or teacher-led instructional activities is typically provided in preschool classrooms, but not in infant and toddler classrooms.

In the United States, the higher level of staffing and associated higher personnel costs makes the provision of infant care significantly more costly. Infant and toddler center classrooms, on average, include between 2 and 3 adult caregivers and 9 to 11 infants or toddlers in same-age classrooms (NICHD ECCRN, 2006), with an average of 3.9 children per caregiver in center-based care for infants (Mulligan et al., 2005). For this reason, most ECE centers have classrooms for preschoolers, whereas far fewer have classrooms for infants and toddlers.

Center-based care for infants and toddlers is more frequently used in countries that subsidize the childcare arrangements, such as Norway or the Netherlands, and is provided, but less frequently used, in countries where most parents pay for most or all costs such as the United States or the United Kingdom (OECD, 2007). For example, in the United States according to our analyses of the ECLS-B, the proportion of U.S. children in centers at 9 months was 9% of all children (18% of children in childcare) and at 24 months was 16% of all children (33% of children in childcare).

Center-based care for 3- to 5-year-old children is often labeled *preschool*, but it includes three broad types of programs serving children 2 years prior to kindergarten (Ages 3 to 5): private childcare centers and preschools, Head Start, and prekindergarten programs supported by state and local education funds. Center care for preschoolers is provided in classrooms, typically with children of similar ages with one or more teachers. In the NICHD SECCYD, on average there were 2 to 2.5 adults and 14 to 16 same-age peers per center classroom when the children were 36 and 54 months (NICHD ECCRN, 2006). Analysis of the NHES data found on average that the child-to-adult ratio in the preschool classroom was 6.6 (Mulligan et al., 2005).

In contrast to infant and toddler center care, for preschoolers there is typically some form of curriculum that is used to organize instruction in early academic skills, typically general concepts, reading, and math. Some programs are part-time, provided for a few hours per week, sometimes no more than 2 hours per day, whereas others are full-time, provided for 40 or more hours a week (e.g., from 8 a.m. to 5 p.m., Monday through Friday). Many programs share some common features in their daily routines. The class likely starts with "circle time" in which

the lead teacher gathers all the children for a discussion of the day, a book reading, and perhaps singing of a song. This is often followed with instructional activities, either involving the teacher talking with all children in the class or working with small groups. Full-day programs include lunch, naptime, and typically outdoor or other types of free-play in the afternoon. One study of public prekindergarten programs found that the 4-year-old children spend only 53% of the morning in academic related activities. The academically related activities tended to focus on developing literacy skills with only 6% of the time spent on math and 23% on science or social studies (Bryant et al., 2002). Their mornings were divided, on average, into 23% in whole group activities, 33% in free-choice activities, 6% in small groups, 14% on meals, and 21% on transitions, bathrooms, and other routine activities.

Center-based care in privately owned or nonprofit centers has been the modal form of childcare for preschoolers for over 20 years (Early & Burchinal, 2001), and center-based care for low-income children in federal- or state-funded programs has become widespread. Center care is widely used for preschoolers in the United States, Canada, Europe, and many Asian countries because, in part, it is viewed as a means to prepare children for the transition to formal education in primary schools. According to our analyses of the ECLS-B, 59% of all children and 73% of children in nonparental care attended a childcare center as a preschooler in 2005. About 75% of U.S. children attended a center-based program the year prior to kindergarten and just over half attended a center-based program the year before that (at Age 3) (Federal Interagency Forum on Child and Family Statistics, 2011).

Childcare centers can be further divided according to auspice into for-profit centers, nonprofit centers, and publicly funded programs. For-profit centers include those owned by an individual owner and centers that are part of either corporate franchises or chains. Nonprofit centers range from parent cooperatives to programs directed as part of organizations such as the YMCA and religious institutions. Finally, the federal government directly funds Head Start grantees to provide early education programs for low-income children, and state and local departments of education support early education for 3- and 4-year olds through public prekindergarten programs. These programs are discussed in detail in the section "U.S. Public Policy."

### *Family Selection of Type of Care*

Parents decide what type of care to use, and it is clear that the child's age, family resources, and parental values

all play a role in childcare choices. These decisions are constrained by their family's income and the cost of care (Chaudry, Pedroza, & Sandstrom, 2012). Given the high cost of care, it is not surprising that the use of center-based care increases with family income (Lamb, 1998; Rigby, Ryan, & Brooks-Gunn, 2007), and families are more likely to use center care than other types of care when their income increases or when parents have more education (Blau & Hagy, 1998). Similarly, parents are more likely to move their child from informal to center care during the preschool years than during the infant and toddler years, perhaps in part because costs of center care are much lower for preschoolers and in part because parents value a more home-like setting for very young children (Rigby et al, 2007). Decisions about the type of care to use are also related to the parents' work schedule. Most center-based programs operate only during the day; thus parents who need care during evenings and weekends often have no choice but to rely on more informal arrangements (Henly & Lambert, 2005).

Although economic considerations are central to understanding ECE arrangements, sociological and other perspectives argue for the consideration of a broader set of factors. Meyers and Jordan (2006) described childcare choice as a complicated and dynamic process of accommodation to the market, family, and child needs as well as social realities, including cultural preferences (see also Li-Grining & Coley, 2006). Some evidence suggests that parents are more likely to use center care when they value the perceived educational benefits of center programs for their children's early learning (J. P. Greenberg, 2011; Augustine, Cavanagh, & Crosnoe, 2009). Other evidence suggests that, particularly among low-income parents, parents face a complex task of trying to align their preferences and logistical constraints (Meyers & Jordan, 2006). Ethnicity has also consistently been linked to patterns of early childhood education, even after holding constant socioeconomic factors mentioned above. Compared to European Americans, preschool age African American children are more likely to be enrolled in center-based care settings and Latino/a American children and children of immigrants are less likely to be in such settings (Magnuson, Meyers, & Waldfogel, 2007). Two reasons have been given for these different patterns of enrollment. First, Latino/a American and immigrant groups may have less access to center-based ECE programs, as these programs may not be available in ethnic enclave neighborhoods (Gormley, 2008) and these groups may face language barriers. Second, some have argued that Latino/a American and immigrant

families may prefer informal settings because they view informal settings with caregivers of the same ethnicity or who speak the same language as providing care that is more consistent with their own cultural models of childrearing and better able to serve their children (Liang, Fuller, & Singer, 2000; Tang, Coley, & Votruba-Drzal, 2012).

### Childcare Quality

Another important dimension of early care and education is the quality of children's experience in a setting. The term *quality* is used frequently, but imprecisely, in the field of ECE. In the past 20 years, the study of ECE has been dominated by a few multidimensional global measures of classroom processes that taken together describe childcare quality. In addition, a few narrow measures of specific dimensions of classroom or program practices are regularly used in ECE studies and often referred to more generally as measures of ECE quality. Finally, some researchers measure structural dimensions of the programs, most often caregiver education and training and ratio of the number of caregivers to the number of children in the classroom, and use these constructs as indicators of ECE quality. Despite the many ways in which ECE experiences can be quantified, how best to define and assess ECE quality remains an important research and policy issue.

### ECE Quality

The position paper by the National Association for the Education of Young Children (2009) provides one of the most comprehensive and widely accepted views of what constitutes high-quality ECE. Based on theoretical models of development, it presents a framework for developmentally appropriate practices that offers five broad practice guidelines. The first guideline describes creating a caring community of learners, in which all individuals are respected and valued as individuals. Caregivers model and promote responsibility and self-regulation, set clear and reasonable limits, and listen to and acknowledge children's feelings, including feelings of frustration. The second guideline involves teaching to enhance development and learning. This involves understanding both the desired goals for instruction, and how best to scaffold each child's learning. Caregivers should understand and incorporate the child's cultural and linguistic background into teaching and all interactions with children. The third guideline involves planning curriculum to achieve important goals and involves understanding the selected curriculum and adapting it if needed to match children's skills

and background. The fourth guideline involves monitoring children's progress using assessments that are ongoing, strategic, and purposeful and used in planning and adapting instruction for the group and for individuals and in interactions with individual children. The final guideline involves establishing reciprocal relationships with families in which there is mutual respect and cooperation and the primacy of the families' choices and goals without abdicating responsibilities for supporting children's learning and development.

Each of these dimensions, all of which are based on developmental theory, is reflected in existing measures of ECE quality to varying extents. The most comprehensive measure of ECE programs is the environmental rating scales (ERS), including the Early Childhood Environment Rating Scale (ECERS; Harms, Clifford, & Cryer, 2005) to describe quality of preschool center care, Infant-Toddler Environmental Rating Scale (ITERS; Harms, Cryer, & Clifford, 2003), and Family Day Care Environment Rating Scale (FDCRS; Harms, Cryer, & Clifford, 2007). These measures are largely based on a constructive theory of cognitive development and emphasize the types and variety of activities provided and the extent to which the child is an active participant in the learning process. Each also assesses the following additional dimensions of care: the provider's sensitivity and responsiveness, health-related practices and the safety of the setting, and classroom management practices. According to these measures, high-quality classroom settings have at least five different interest centers, conversations during meal and snack time, a wide selection of books that are read in formal class activities and in informal interactions with the teacher, and activities that encourage children to think, talk about, and reason about their experiences (Harms et al., 2005). The breadth and applicability to differing modes of care likely explain the widespread use of these quality measures in research and policy contexts.

Other measures of quality, informed by attachment theory, focus more specifically on the quality of interactions between caregivers and children. Some capture the extent to which the caregiver provides a secure base for children and encourages autonomy (e.g., Observational Record and the Childcare Environment; see NICHD ECCRN, 1997). Others more generally consider caregiver warmth and sensitivity (Caregiver Interaction Scale, see Arnett, 1989). A recent development has been the Classroom Assessment Scoring System (CLASS; Pianta, La Paro, & Hamre, 2008), which like prior measures assesses the quality of the teacher-child interactions, but unlike earlier measures also

considers instructional support provided by caregivers and the management of the classroom. The CLASS instrument, which is applicable only to preschools, measures the extent to which the teacher is warm and sensitive, promotes language and concept development, and organizes the classroom to minimize misbehavior and maximize time spent in learning activities. According to this measure, the teachers in high-quality classrooms have frequent warm and responsive interactions with children, and they scaffold instruction. She/he is intentionally teaching academic skills through understanding the developmental learning sequence and ensuring that prerequisite skills are understood before higher-order skills are introduced. The teacher attends to each child, individualizing the feedback to match his or her skill level. The teachers talk frequently with each student in multiturn conversations in which the adult elaborates on the students' responses by asking open-ended questions (Pianta, La Paro, et al., 2008).

Other measures describe the quality of instruction within specific domains such as literacy (e.g., Early Language and Literacy Classroom Observation, ELLCO; Smith, Dickinson, Sangeorge, & Anastasopoulos, 2002) or math (Classroom Observation of Early Mathematics Environment and Teaching, COEMET; Clements & Sarama, 2008) or within both literacy and numeracy (e.g., ECERS-Extension, ECERS-E; Sylva, Siraj-Blatchford, & Taggart, 2003; Teacher Behavior Rating Scale, TBRs; Landry, Crawford, Gunnewig, & Swank, 2000). These measures often focus on the quality and time spent teaching specific literacy or numeracy content and skills.

Some of these measures are highly correlated, but others are relatively independent. Measures of caregiver warmth and sensitivity, such as the ECERS-total and CLASS Emotional Support, tend to be highly correlated, whereas measures of instructional quality are not strongly correlated with measures of warmth and sensitivity or with other content areas (Pianta et al, 2005; Burchinal, Kainz, & Cai, 2011). Therefore, it becomes important to identify which dimension of quality is being assessed when examining associations between ECE quality and child outcomes.

**Structural Quality.** As part of measuring the quality of ECE settings, researchers have examined factors that are thought to provide a foundation for high-quality care. Within this research literature, these factors have been labeled *structural quality* whereas the quality of a child's experiences in the ECE setting has been labeled *process quality*. These structural quality characteristics are both at the caregiver and program level. They include factors such

as the caregiver's education and training, adult-to-child ratio and group size, and administrative support. These are sometimes viewed as necessary, but insufficient, conditions for a setting to provide high-quality care; they are always viewed as factors that increase the likelihood of high-quality care (NICHD ECCRN, 1999, 2002a).

A relatively low child-to-adult ratio and group size are needed to permit adults to interact with individual children or small groups of children. The American Academy of Pediatrics (AAP, 2005) recommendations for adult-child ratios and group size vary by the type of setting and age of the child: 1:3 for infants (younger than 1 year) with a maximum group size of 6; 1:4 for young toddlers (1 to 2 years) with a maximum group size of 8; 1:5 for older toddlers (2 to 3 years) with a maximum group size of 10; 1:7 for 3- to 4-year-olds with a maximum group size of 14; and 1:8 for 4- to 6-year-old preschoolers with a maximum group size of 16 (AAP, 2005). Recommendations for mixed-age settings, such as typically occur in home-based settings, are 1:6 when there are no infants younger than 2 years, 1:5 with one infant younger than 2 years, and 1:4 with two infants younger than 2 years (AAP, 2005).

Adequate space, access to a variety of age-appropriate activities, and attention to health and safety concerns are other program-level characteristics that are regarded as important structural quality measures. These include hand-washing policies for caregiver and children after diapering and before touching food, safe play equipment, universal back-to-sleep practices, toxins out of reach, and safe administration of medicines (AAP, 2005).

Caregiver education is a common indicator of structural childcare quality, as it is viewed as a proxy for caregiver skill. It is widely assumed that higher levels of education, especially certification to teach in early childhood education or a related field, provide caregivers with the knowledge and practices that translate into higher-quality ECE. Noncredit professional development training for caregivers is also assumed to introduce and reinforce teaching skills, with growing recognition that focused, explicit, and intense mentoring and coaching provide the strongest opportunities for caregivers to acquire and maintain new skills (Advisory Committee on Head Start Research and Evaluation, 2012). The director's education, training, and administrative style are assumed to play a foundational role in determining the quality of care provided to children through hiring decisions, selection of curricula, and supervision. The American Academy of Pediatrics (2005) recommends that the director have a college degree in ECE and caregivers have

a child development associate's credential and ongoing in-service training.

Curricula are assumed to play a critical role in creating learning opportunities for young children. Curricula should provide the caregiver with a structured approach to providing children with learning opportunities. Curricula can vary from child-centered approaches that provide children with activities and scaffold learning opportunities (e.g., Montessori) to teacher-directed approaches in which the teacher has a manual with scripts that present the learning materials (e.g., Literacy Express). Many of these teacher-directed approaches are based on the assumption that there is a developmental trajectory—that children need to acquire a basic set of skills that lay the foundation for learning the next set of skills—and try to monitor the extent to which each set of skills is learned.

Some aspects of structural quality may be necessary to ensure the provision of high-quality care. The combination of low ratios and adequate teacher education has been the hallmark of high-quality care (NICHD ECCRN, 1999, 2002a). There is growing recognition that integration of focused, explicit, and intentional curricula used with implicit tools for monitoring children's learning and ongoing coaching in the use of that curriculum and child-monitoring system provides the strongest opportunity for quality improvement (Advisory Committee on Head Start Research and Evaluation, 2012).

**Level of ECE Quality.** Considerable evidence documents the level of childcare quality in the United States. Quality of childcare, regardless of measure, tends to be in the medium range for preschoolers and in the low-to-medium range for infants and toddlers, but there are differences depending on the type of childcare setting. The environmental rating scales (e.g., ECERS-R) define quality based on the quality and frequency of the interactions between caregivers and children and of the engagement in age-appropriate activities in the environment as a total score of 1–3, medium quality as a total score of 3–5, and high quality as a total score of 5–7. Analyses of ECERS and ITERS in the Cost, Quality, and Outcomes study in four states selected for variation in average income and state regulation of childcare policies indicated variability in the quality of childcare, but on average infant-toddler center-based care tended to be of low quality while preschool center care tended to be of medium quality (Phillipsen, Burchinal, Howes, & Cryer, 1997). Similar conclusions were drawn from the NICHD SECCYD when findings were simulated to represent the

United States (NICHD ECCRN, 2000a). More specifically, the quality of infant and toddler care was highest when provided by a relative, next highest in home-based care, and lowest in center care. In contrast, center care was of higher quality than home-based care for preschoolers (NICHD ECCRN, 2004). Our analyses of the nationally representative data from the children of the same age-cohort in the ECLS-B also suggested that quality of care was in the medium range according to the ERS, and that quality was lower in home-based care than in center-based care.

The quality of center-based care tends to vary across auspice. In the United States, low-income children are much more likely to experience higher-quality care when they attend publicly funded center-based programs (Helburn, 1996). Data from the National Center for Early Development and Learning's study of 11 state prekindergarten programs (Pianta et al., 2005) found large variability in quality of care across states, with the average level of care being in the medium to high range according to the ECERS and CLASS Emotional Support and in the low to medium range according to the CLASS Instructional Support. A more recent evaluation of the most promising prekindergarten programs suggested high quality, at least in the selected programs (Barnett, Epstein, Friedman, Stevenson Boyd, & Hustedt, 2008). The Head Start Impact Study (Puma, Bell, Cook, Heid, & Lopez, 2005) and the Head Start Family and Child Experiences Survey (FACES; 2006; Aikens et al., 2010) suggested that Head Start quality is also variable, albeit less so than in prekindergarten programs, and that average ECERS and CLASS scores are similar or slightly lower than those observed in the prekindergarten evaluations.

Quality of ECE ranges widely throughout the world. Quality of preschool center care in the United Kingdom tended to be in the medium to medium to high range according to the ECERS-R and in the low to medium range in terms of instructional quality in a large cohort study (EPPE, 2004). An earlier across-country comparison suggested that quality of care based on the ECERS-R was higher in Germany and Austria and lower in Spain and Portugal (Tietze, Cryer, Bairrão, Palacios, & Wetzels, 1996). A more recent study suggested that ECE quality remained relatively low in Portuguese centers where group sizes tend to be quite large (Barros & Aguiar, 2010; Pinto, Pessanha, & Aguiar, 2013). Small-scale studies in Asian countries, such as China and Cambodia, and East African countries, such as Uganda and Zanzibar, suggest quality tends to be low in general but higher in public preschools (Malmberg, Mwaura, & Sylva, 2011; Rao et al., 2012).

**Family Selection of ECE Quality.** Many of the same factors that predict use of center care also predict the use of higher-quality care (NICHD ECCRN, 2006). Not surprisingly, higher-quality care is more expensive on average, and parents selecting higher-quality care tend to have more money and more education, especially when selecting care for infants and toddlers (Rigby et al., 2007). The publicly funded programs such as Head Start and prekindergarten, on average, provide low-income families with higher-quality options in attempts to reduce the income gap in ECE for preschoolers (Pianta et al., 2009). Finally, home environments and parenting characteristics have also been linked to patterns of ECE. Generally higher-quality home environments as well as early literacy and educational activities in the home, such as book reading, are linked with greater likelihood of choosing center-based care (Burchinal & Nelson, 2000; Tang et al., 2012). There is also evidence that more authoritative parenting practices also predict higher-quality nonparental care for children (NICHD ECCRN, 2006).

### **ECE Quantity**

The final dimension of ECE experiences to be considered is the amount of nonparental childcare that children experience. Much of the impetus to study the quantity of nonparental care is rooted in a concern that too much ECE may be detrimental to children's development. As with quality, there are several dimensions of childcare quantity and, thus, in examining its relation with child outcomes. The basic definition involves the average or typical number of hours per week that the child is cared for by caregivers other than the parents at a particular point in time or averaged over time. These definitions are employed in many studies, including the nationally representative ECLS-B. A second dimension involves the age at which the child started nonparental care and the amount of time in terms of weeks or months that the child experienced nonparental care over a specified period of time. Many studies collect retrospective information, asking at what age children began experiencing ECE. These two definitions are often combined, as in most analyses of the NICHD ECCRN, which computes the average hours per week of care from the child's first month through the last preschool interview at 54 months (NICHD ECCRN, 2003a, 2006). A third dimension describes the number of different childcare arrangements and the amount of time spent in each setting (e.g., Loeb, Bridges, Bassok, Fuller, & Rumberger, 2007; Morrissey, 2008, 2009).

### **Hours per Week**

The number of hours of childcare children experience in an average week varies widely and depends on the extent of parents' employment and use of the arrangement to provide the child with educational and social learning opportunities. Not surprisingly, children tend to experience more hours of childcare when mothers are employed, and on average experience about 30 to 40 hours per week when mothers are employed full-time (Waldfogel, 2002). Our analyses of the ECLS-B indicated that the average hours of nonparental care per week for the 2001 birth-cohort ranged between 31 for infants, 33 for toddlers, and 29 for preschoolers, but the hours of care is considerably higher when the mother is employed full-time than when she is not.

Educational preschools, including some state prekindergarten and Head Start programs, often provide part-time programs, with growing focus on providing "wrap-around" care to children whose mothers are employed (Clifford et al., 2005). These programs typically offer about 20 hours of care per week to children, although they can vary from as few as 5 to 10 hours per week to 40 hours per week of care. The length of time in a given setting tends to vary, but relatively few children stay in the same childcare setting from entry into childcare to entry to primary school (NICHD ECCRN, 2004).

### **Number of Arrangements**

There is growing attention to the number of childcare arrangements that a child experiences at any given time or across time. Most children experience change, starting with home-based care or relative-care as an infant and moving into center-based care as a preschooler. Many children experience more frequent changes over time as parents switch caregivers or cycle in and out of employment due to job changes and the birth of siblings. Studies in the United States (Morrissey, 2009) and Australia (Neilsen-Hewett, Sweller, Taylor, Harrison, & Bowes, in press) suggest that common components of multiple setting arrangements include care by a relative (regardless of the child's age) and center care for preschoolers. For example, the Australian study indicated that the modal pattern involved part-time center care for preschoolers and grandparents who picked them up from the center and care for the child until parents finished working. The proportions of children experiencing more than one care setting among children in childcare ranged from 15% in the SECCYD (Morrissey, 2009) to 25% in the nationally representative surveys (Early & Burchinal, 2001; J. O. Johnson, 2005).

### *Continuity of Caregivers*

Whether the child experiences changes in the primary childcare provider has also been examined because attachment theory focuses on the quality and continuity of the relationship between the very young child and his or her caregivers. Careful study of changes in primary caregivers suggest that most preschoolers experience some changes as they switch from one setting to another or as they switch from one classroom to another within the same center, and many infants experience changes due to modifications in informal care arrangements (NICHD ECCRN, 1997). One study of caregiver continuity for infants and toddlers in center care indicated that teacher turnover made it difficult to ensure continuity for the infants and toddlers, even when that was the intent (Cryer et al., 2005).

### *Family Selection of Quantity of Care*

Whereas most of the studies of family selection factors have focused on whether childcare was used, and if so, the type and quality of the ECE, the family decisions about the amount of childcare seem to be driven largely by parental employment and the local childcare options. Children tend to spend longer hours in ECE settings when parents are employed full-time than part-time, have more income and education, and are in center settings as infants and toddlers and in informal settings as preschoolers (NICHD ECCRN, 2006). Children experience more different care settings when mothers work part-time or when the child is enrolled in a program that does not offer 8 hours of care a day (Morrissey, 2009).

### **Summary**

Parents select the childcare experiences of their very young children, but the quality, quantity, and type of care varies depending on public policies, family characteristics, and the child's age. Over half of U.S. parents decide to use ECE settings for their infants and toddlers, typically because the parents are employed. The proportions of infants in ECE are much lower in countries with more generous family leave policies. Much of the ECE for infants and toddlers is provided by relatives or nonrelatives in home-based settings, except in countries that subsidize center-based care for toddlers. Preschool-age children are more likely to be in ECE, and are typically in center-based care in the United States, Europe, and increasingly in South America, Asia, and Africa. Publicly funded programs, almost exclusively in center-based settings, were developed to increase

educational opportunities for low-income children in the United States and other countries. A few countries make publicly funded programs available to all 3- or 4-year-olds. These publicly funded programs (e.g., pre-K and Head Start) provide these children with higher-quality center care than they would otherwise experience. ECE quality, defined by the frequency, warmth, and stimulation of interactions between caregivers and children, varies widely across type of setting and the child's age. Overall, children are more likely to be in ECE, and to experience higher-quality care in center settings, when parents have higher incomes, more education, and provide more responsive and stimulating care at home.

## **EARLY CARE AND EDUCATION AND CHILD OUTCOMES**

A large body of scholarship examines how ECE experiences affect family well-being and children's development. In recent years this scholarship is notable for its emphasis on methodological rigor. Starting about 30 years ago, ECE researchers began to take child, family, and community factors into account when examining childcare effects on children (Lamb, 1998). The past 15 years have been marked by increasing sophistication in the methods used to account for the potential confounding effects of these factors when examining the impact of ECE. In addition, there has been growing attention to the need to examine ECE dimensions together, not separately (NICHD ECCRN, 2002b). ECE research during the past 10 to 15 years has attempted to examine each dimension while addressing concerns about selection bias and the potential overlap among different dimensions of childcare. These findings are discussed below, along with a discussion of the potential problems with inferring childcare effects due to selection issues and overlap among the ECE dimensions.

### **Selection Issues and Inferring Childcare Effects**

Studying the effects of differing dimensions of childcare is complicated by the fact that, as described above, ECE arrangements are made and changed in particular contexts, and thus it is difficult to estimate the effects of the childcare per se rather than the child, family (see Elder, Shanahan, & Jennings, Chapter 2 & Bradley, Chapter 12, this *Handbook*, this volume), and community factors (see Staff, Mont'Alvao, & Mortimer, Chapter 9, this *Handbook*, this volume) that influence ECE arrangements and early

development. Multiple aspects of family background have been associated with different aspects of care experiences. The NICHD SECCYD suggests that children with exclusive parental care at each age and children who entered ECE as preschoolers had mothers with less education, more depressive symptoms, less sensitive parenting styles, and families with less income than those who enter non-parental care at an earlier age (NICHD ECCRN, 1997, 2006). Multiple care arrangements were also more likely when mothers had more education and provided more sensitive parenting, but worked fewer hours (Morrissey, 2009). Children experienced longer hours of care per week when mothers had slightly more education and fewer depressive symptoms and families had higher incomes. ECE quality was higher when mothers had more education, and children were European American rather than African American or Latino/a American. In addition, ECE quality tended to be higher when the mother showed more sensitivity and respect for autonomy during interactions with the child. Similar findings with regard to associations between maternal education and family income with timing of ECE and the type and quality of care have been reported for Australian (Ungerer & Harrison, 2008), Canadian (Geoffroy et al., 2012), and Dutch families (van Gameren & Ooms, 2009). These complicated patterns of associations challenge researchers' ability to design studies that can tease out unique effects of care on children.

In addition, research has often focused on one particular dimension of ECE such as type, age of entrance, or quality despite the fact that these factors often cluster together in meaningful ways, which may influence the ability to identify their unique effects. In the SECCYD, children who experienced higher-quality ECE tended to experience somewhat fewer hours per week in childcare at 6, 15, 24, 36, and 54 months (NICHD ECCRN, 2003b, 2006). Higher quality was observed in informal settings, especially care by grandparents, during infancy, and in centers during the preschool years (Dowsett et al., 2008). Children in center care tend to experience longer hours of care during infancy, but shorter hours during preschool. Not surprisingly, children who enter ECE earlier tend to experience more hours per week of care and more weeks of care overall. Frequent changes in childcare settings are more common when the child experiences fewer hours of care per week, whereas multiple settings at a given age are more likely when one of the settings is center care (Morrissey, 2009). Analyses of the ECLS-B data reveal similar associations among use of childcare, and ECE type, quality, and quantity (Espinosa et al., in review).

Due to potential selection biases and clustering of ECE dimensions, research on many ECE topics has struggled to provide convincing estimates of causal effects rather than descriptive associations. The most convincing estimates of the effects of early childcare and education come from random-assignment experimental studies. The design of these studies assures that children in program "treatment" are compared to children who were not in the program but are otherwise equivalent on important background characteristics, and thus any differences in children's outcomes must be due to their experiences in care. However, random assignment studies are rare, and typically evaluate only the effects of program models compared to a no-treatment group. For example, the recent national Head Start impact study compared 3- and 4-year-olds who were and were not assigned to attend Head Start programs (Puma et al., 2005). There have been some early random assignments of quality improvement initiatives, but it is not surprising that there have not been experimental studies about the age of entrance into care or even the dosage of care for infants and toddlers.

Given the difficulty of implementing random assignment studies, the next best strategies are quasi-experimental, and although they typically use observational data, they employ analytic techniques that adjust for potential confounds across treatment groups. Variations on regression discontinuity designs have been used successfully in several evaluations of prekindergarten programs (Gormley, 2008; Weiland & Yoshikawa, 2013). In these studies, children who enrolled in the program and whose birthdays fall just before and just after the age eligibility cutoff are compared. As a result of their slight age differences, it is possible to compare those who attended prekindergarten during the academic year and the following year enter kindergarten, to children just a few days younger who did not start the prekindergarten program until the following year. Such variations on regression discontinuity (RD) designs are appealing, but as implemented they require some additional assumptions, and they can be implemented to evaluate program models only when programs have strict eligibility criteria. Thus, many research questions cannot be answered with these designs (see Weiland & Yoshikawa, 2011, for a discussion of RD design issues).

Another increasingly common quasi-experimental approach used in ECE research involves variations on propensity score modeling. These approaches use natural variation in ECE but use observed characteristics of the children and families to construct a comparison group that is similar to the "treatment" group, as defined by the

researcher. The analytic process involves a three-step estimation, in which the propensity to experience the treatment is modeled in the first step, comparison group individuals are matched to treatment individuals based on this propensity score, and then differences across the matched groups are compared. This method is particularly useful when there are large differences on many important measured characteristics across the groups being compared as long as there are sufficient numbers of families who overlap on these characteristics (Winship & Morgan, 1999).

Finally, there are other nonexperimental studies that consider the effects of typical early childcare and education on children's school readiness by comparing naturally occurring variation in ECE, with few adjustments for possible confounding differences. These observational studies have the well-known disadvantage of not being able to rule out the possibility that any presumed effects are due to unobserved characteristics of children or families that are associated with differential selection into alternative ECE experiences. Analyses often include only a few statistical controls for potential selection factors, raising the possibility that the resulting associations are spurious rather than causal (Winship & Morgan, 1999). Recently, "value-added" models have added a pretest score as a covariate to account, in part, for preexisting differences in child outcomes at entry to the ECE setting (Duncan et al., 2007). These models, even the value-added models, are relatively easy to implement, and can be applied to a wide range of ECE research questions. Consequently, although results from observational studies are often more generalizable to other programs and children, these results typically fall short of providing convincing evidence of causal effects (Duncan & Gibson-Davis, 2006).

### ECE and Child Outcomes

Early ECE research was concerned that routine nonmaternal care would impair security of the infant-mother attachment. Early evidence suggested that children with early and extensive childcare were more likely to have insecure attachments (see Belsky, 1999). The SECCYD was funded, in large part, to address this question. The study found that ECE experiences, including whether the child experienced nonmaternal care, were not related to the infant-mother attachment (NICHD ECCRN, 2001). Other research has examined whether exclusive maternal or parental care is related to early cognitive and social development. Comparisons of SECCYD children with and without exclusive maternal care through 15, 24, 36, and

54 months revealed children with exclusive maternal care tended to be from more disadvantaged families, and after accounting for this, there were no significant differences in preschool outcomes and only one significant difference favoring ECE children in infant and toddler outcomes (NICHD ECCRN, 2006). In contrast, analyses of the SECCYD and nationally representative studies indicated that middle-class European American children had lower levels of cognitive skills if their mothers were employed full time during the child's first year (Brooks-Gunn, Han, & Waldfogel, 2002; Han, Waldfogel, & Brooks-Gunn, 2001; Waldfogel, Han, & Brooks-Gunn, 2002). Similar findings were not observed among African American or Hispanic infants or infants from low-income families in the United States (Burchinal & Clarke-Stewart, 2007; Dunifon, Kalil, & Danziger, 2003; Fuller et al., 2002), Canada (Geoffroy et al., 2007), or Britain (Côté, Doyle, Petitclerc, & Timmins, 2013). Furthermore, some evidence suggests that maternal employment in the first year was related to more positive social-emotional functioning for African American low-income children (Coley & Lombardi, 2013).

### Childcare Type and Child Outcomes

Type of ECE setting has been related to children's cognitive and social development, with different patterns of associations for infants and toddlers than for preschoolers (Magnuson & Waldfogel, 2008; NICHD ECCRN, 2006). Most often researchers compare center-based settings (of any kind), informal care (sometimes differentiating between family-based daycare and relative care), and parental care. The vast majority of the research has focused on children of preschool age, with somewhat less attention given to infants and toddlers.

A few prominent studies have examined how center care experiences as infants and toddlers predict development. In the SECCYD, children 15 and 24 months old in center care had slightly higher cognitive skills, but slightly lower social skills, compared to children in informal care settings. Similar positive associations of center care during the first 3 years with later cognitive skills have been reported in the United Kingdom (Sylva, Melhuish, Sammons, Siraj-Blatchford, & Taggart, 2012) and Sweden (Andersson, 1989), and with problem behaviors in the United States among children who had attended centers as infants or toddlers in the ECLS-Kindergarten Cohort (Loeb et al., 2007). A few studies of specialized ECE interventions, for example, Abecedarian, Early Head Start,

and the Infant Health and Development Program, provide clear evidence that center-based care can be advantageous for infants and toddlers (Campbell & Ramey, 1994; Infant Health and Development Program, 1990).

Whether type of care is related to outcomes for preschoolers has been much more extensively studied in the United States and throughout the world. Center-based programs are thought to provide more instruction and opportunities to learn because typically such settings formally incorporate learning into their goals and caregivers provide explicit instruction and/or learning-related activities. A large literature has examined the impact of publicly funded programs, typically center care, and those results are discussed in the final section of public policies. Analyses of the nationally representative Early Childhood Longitudinal Survey–Kindergarten Cohort (ECLS-K) indicated that in the United States children with center care as a preschooler had higher cognitive and language skills (Magnuson, Meyers, Ruhm, & Waldfogel, 2004) and that greater exposure to center care (longer days or more months of center care) predicted higher reading and math scores (Loeb et al., 2007), although the magnitude of the average effect was modest. Entering center care between 2 and 3 years old was related to better outcomes in kindergarten, whereas starting center care at younger ages was negatively related to kindergarten outcomes such as language and social skills (Loeb et al., 2007). These data did not, however, have information about the quality of care that children experienced.

The analyses of the SECCYD (NICHD ECCRN, 2006) that examined type, quality, and quantity of care

simultaneously controlling for child and family characteristics indicated that center care was related to slightly higher language, academic, or memory skills and positive peer interactions at 36 and 54 months, but more behavior problems at 54 months. Figure 1 shows the estimated effect sizes for childcare type, quality, and quantity for 24-, 36-, and 54-month outcomes.

Preschool-center-based ECE has been linked also to enhanced academic and social outcomes in other affluent countries. Studies of the Effective Provision of Preschool Education (EPPE) in the United Kingdom and the Effective Provision of Preschool in Northern Ireland (EPPNI) found that preschool center care was related to stronger academic and social skills at school entry and during the primary school years (EPPE, 2004; Melhuish et al., 2006). Quality of the child's center care was related to language and literacy outcomes in the United Kingdom (EPPE, 2004), Portugal (Pinto et al., 2013), the Netherlands (van Tuijl & Leseman, 2007) as well as in a combined analysis of the Preprimary Project with centers from Europe (Finland, Ireland, Italy, Greece, Poland), the United States, and Asia (Hong Kong, Indonesia, Thailand; Montie, Xiang, & Schweinhart, 2006).

Preschool center-based ECE has been related to improved academic and social outcomes of children in less affluent countries, and is thus often suggested as a way to decrease the gap in schooling in these countries between high- and low-income children (Engle et al., 2011). In Bangladesh (Moore, Akhter, & Aboud, 2008), Cambodia (Rao, Sun, Pearson, et al., 2012), China (Rao, Sun, Zhou, & Zhang, 2012), Kenya, Uganda, and Zanzibar

**Figure 6.1** Effect sizes for ECE quality, quantity, and type from SECCYD.

Source: Adapted from "Child Care Effect Sizes for the NICHD Study of Early Child Care and Youth Development," by the NICHD Early Child Care Research Network, 2006, *American Psychologist*, 61(2), pp. 99–116.

(Mwaura, Sylva, & Malmberg, 2008), Chile (Urzua & Veramendi, 2010), Colombia (Bernal et al., 2009), and Uruguay (Berlinski, Galiani, & Manacorda, 2008), preschoolers attending ECE centers have higher academic outcomes at entry to or during primary school, with effect sizes ranging from modest to large. Reduced problem behaviors among children in preschool centers were also noted in Mauritius (Raine, Mellinger, Liu, Venables, & Mednick, 2003).

Nores and Barnett (2010) conducted a meta-analysis of these and other international studies, and concluded that ECE services, typically preschool center care combined with nutritional services, were related to higher cognitive skills (effect size = .35), behavioral adjustment (effect size = .27), health outcomes (effect size = .23), and schooling outcomes (effect size = .41), with slightly smaller effect sizes for more rigorous studies, longer-term outcomes, and studies conducted in low-income countries. Engle et al. (2011) used these and other data to argue that each increase of 10% in preschool attendance translates into a reduction of .26 grades in the schooling gap between the youths from the wealthiest 25% of the families and the youths from the remaining 75% of the families.

### **ECE Quality and Child Outcomes**

Higher-quality ECE has been linked to higher cognitive and social skills in both experimental and observational data. Evidence from both experimental trials and quasi-experimental studies of large-scale programs shows positive impacts of exposure to high-quality childcare in the preschool years (Pianta et al, 2009; Wong, Cook, Barnett, & Jung, 2008).

#### ***Experimental Studies and Child Outcomes***

The strongest evidence for quality effects on child outcomes is from experimental studies that did not actually measure quality of care. In a meta-analysis focusing on the evaluations of 20 early childhood programs that involved experimental or quasi-experimental designs, Karoly et al. (2005) found evidence of significant effects of center-based ECE on academic and social outcomes in approximately two-thirds of the programs. They also found that more intensive programs (e.g., 20+ hours per week) that focused on improving school readiness produced larger effects than other programs, with effect sizes that were half a standard deviation or larger on cognitive outcomes. It is assumed that these programs were high quality because they were based in research settings. Two of the studies conducted

long-term follow-up studies, reporting small, but meaningful differences in adult outcomes such as increases in income and educational attainment, and reduction in criminal activity (Belfield, Nores, Barnett, & Schweinhart, 2006; Campbell et al., 2012). Evidence from these studies and evaluations of programs like Head Start (see the section on U.S. public policy) suggest that early ECE may have its long-term effects through impacts on skills like executive functioning and social adjustment rather than through impacts on language and academic skills (Blair & Raver, 2012).

#### ***Process Quality and Child Outcomes***

Many large multisite and small local observational studies have examined the association between childcare quality and child outcomes, using a variety of measures of quality and child outcomes. Typically these studies find modest associations between preschool childcare quality and language, academic, and social outcomes using the ITERS for infants and toddlers (Burchinal, Roberts, et al., 2000) and ECERS for preschoolers (Howes et al., 2008; Montes, Hightower, Brugger, & Moustafa, 2005; Votruba-Drzal, Coley, & Chase-Lansdale, 2004). Similarly, childcare quality, as measured using the ORCE in the large multisite NICHD SECCYD, was associated modestly with concurrent language and academic skills for infants and toddlers (NICHD ECCRN, 2000a) and preschoolers (NICHD ECCRN & Duncan, 2003). As shown in Figure 6.1, the analyses of the SECCYD that included quality, quantity, and type of care while controlling for child and family characteristics indicated, compared to children in low-quality care, children in high-quality care had slightly higher cognitive, language, or academic skills at 24, 36, and 54 months, higher ratings of social skills and fewer problem behaviors at 24 and 54 months, and fewer negative interactions with friends and peers at 54 months. This positive effect of quality for at least some outcomes was still observed when children were in high school (Vandell et al., 2010). Likewise, modest associations between the CLASS and child outcomes have been found, with some evidence of differential prediction; CLASS Emotional Support is modestly related to gains in social skills, whereas CLASS Instructional Support is modestly related to gains in academic and language skills in the NCEDL pre-K study (e.g., Mashburn et al., 2008).

Guided by attachment theory, some research has specifically defined ECE quality in terms of the quality of the relationship between the caregiver and child, and on the caregiver as an attachment figure for the infant. The quality of the relationship between the child and their caregiver in

prekindergarten programs predicts later peer competence through the second grade, and at-risk children with secure attachment relationships with their caregivers were rated by their teachers as more socially competent with peers and having fewer problem behaviors than those with insecure attachment relationships (Howes & Ritchie, 1999; Howes, 2000). High-quality care might be especially beneficial for infants who are insecurely attached with their parents, by providing them with the opportunity to develop a secure attachment with the ECE caregiver (Howes, Rodning, Galluzzo, & Myers, 1988).

Specific aspects of ECE quality appear to enhance children's early development. Children have demonstrated larger gains in academic and social skills when they experience frequent, warm, and responsive interactions between caregivers and children (Mashburn et al., 2008; Raver et al., 2011). Gains in academic skills have also been enhanced when interactions with caregivers involve instructional support such as detailed feedback and sequenced and elaborated support for learning (Howes et al., 2008; Mashburn et al., 2008). In addition, larger gains in language and academic skills were observed when childcare providers encouraged children to talk, with interactions involving multiple turns in which the provider and child discuss and elaborate on a given topic (Justice, Mashburn, Pence, & Wiggins, 2008; Wasik, Bond, & Hindman, 2006). Both the warm and responsive interaction style and elaborated conversations also predict the persistence of gains into the school years (Dickinson & Porche, 2011; Vandell et al., 2010). Finally, some evidence suggests that preschool-age children who are given more opportunities to engage in age-appropriate activities with a range of varied materials such as books, blocks, water, and sand demonstrate larger language and social gains than those who have fewer opportunities, and that these gains persist into the school years (Peisner-Feinberg et al., 2001; Sylva et al., 2012).

ECE quality is associated with child outcomes throughout the world. Recent studies find that higher-quality care predicts better child outcomes in low-income and middle-income countries such as Bangladesh (Aboud & Hossain, 2011; Moore et al., 2008; Opel, Ameer, & Aboud, 2009), Kenya, Uganda, and Zanzibar (Malmberg et al., 2011), China (Rao, Sun, Zhou, et al., 2012), Jamaica (Baker-Henningham, Walker, Powell, & Gardner, 2009), and Costa Rica (Rolla, Arias, Villers, & Snow, 2006), and in high-income countries such as the United Kingdom (EPPE, 2004), the Netherlands (van Tuijl & Leseman, 2007), Germany (Tietze et al., 1996), and Australia (Harrison & Ungerer, 2005). Some research projects

involved studying structural quality measures such as ratios (Moore et al., 2008) or the introduction of evidence-based curricula to improve behavior (Baker-Henningham et al., 2009), language and literacy (Opel et al., 2009), whereas other studies compared programs that differed in terms of observed quality, typically using the ECERS (Aboud & Hossain, 2011; EPPE, 2004; Harrison & Ungerer, 2005; Tietze et al., 1996) but also observed classroom interactions (Rolla et al., 2006).

During the past decade, several meta-analyses of observational studies (Burchinal, Kainz, et al., 2011; Keys et al., 2013) have found consistent, but only modest, linear associations between quality and child outcomes (i.e., that as quality increases, child outcomes improve commensurately). As discussed below, much larger effect sizes have been observed when different types of programs or curricula have been compared, but the association between observed quality and child outcomes tends to be quite modest in recent studies. To examine this issue, Burchinal, Kainz, et al. (2011) conducted both a meta-analysis and coordinated secondary analyses with data from five large ECE studies. As expected, in the meta-analysis the magnitude of the effects was modest, with partial correlations ranging from .05 to .17. Stronger associations were found for language outcomes than for those related to social and emotional development across all ages, and stronger associations were also found for 2- to 3-year-olds compared to 4-year-olds. Related analyses were conducted with several large samples of low-income children in ECE programs and measures of specific dimensions of quality were more strongly associated with child outcomes compared with global quality measures. Similarly, Keys et al. (2013) conducted a meta-analysis of findings from parallel analyses across five large childcare studies, and found only very modest associations between childcare quality and child outcomes (i.e.,  $r_p = .04$ ). These comparisons—between the results from this meta-analysis of the association between childcare quality and child outcomes, and the meta-analysis of the impacts of experiments designed to study the effectiveness of high-quality programs—raise important questions and suggest that existing measures of quality may need more work, especially psychometric development (Burchinal, Kainz, et al., 2011; Gordon, Fujimoto, Kaestner, Korenman, & Abner, 2013).

Thresholds in the associations between childcare quality and child outcomes in early childhood have been offered as one possible explanation for the modest associations reported to date. It is hypothesized that ECE quality must reach some minimal level before it can affect children's

development. If true, then higher-quality ECE would translate into more learning only in programs above this threshold. Some, but not consistent, evidence supports this hypothesis. Burchinal and colleagues (Burchinal et al., 2009; Burchinal, Xue, Tien, Auger, & Mashburn, 2011) found evidence of a curvilinear relation between ECE quality and child outcomes in secondary data analyses of four large ECE studies. Other evidence emerged from piecewise or spline regressions, which suggested that gains in academic outcomes were more-strongly related to ECE measures of instructional quality in moderate- to high-quality classrooms than in the low-quality classrooms (Burchinal, Xue, et al., 2011; Burchinal, Vandergrift, Pianta, & Mashburn, 2010). Two follow-up studies failed to replicate this finding, but indicated higher-quality care was related to larger gains in executive functioning skills in higher, but not lower, quality classrooms (Burchinal, Vernon-Feagans, Vitiello, Greenberg, & Family Life Project Key Investigators, 2013; Weiland & Yoshikawa, 2013). Finally, recent analyses involving a nonparametric spline approach that estimated cut-points and slopes and piecewise regressions suggested that social-emotional development of infants, toddlers, and preschoolers was enhanced only in moderate- to high-quality childcare settings (Torquati, Raikes, Welch, Ryoo, & Tu, 2011).

Differential susceptibility to ECE experiences has also been offered as an explanation for the modest association between ECE quality and child outcomes. Belsky and Pluess theorized that some personality characteristics may increase the likelihood that children are affected by the quality of their interactions with parents and caregivers (Belsky, 2005; Pluess & Belsky, 2010). In particular, adult scaffolded interactions may have a larger impact on children who tend to be inhibited or highly reactive and negative than on the child with the more average and positive temperament. Evidence in terms of temperament x quality interactions supports this contention in analyses of the SECCYD (Pluess & Belsky, 2010) and the Infant Health and Development Project (Blair, 2002).

### *Structural Quality and Child Outcomes*

ECE quality is also measured by indicators of structural quality. Many studies have examined the extent to which the child-to-adult ratio and caregiver education and training predict quality of childcare and children's outcomes. Ratio has been the most consistent predictor, showing positive and significant associations with observed quality and child outcomes (NICHD ECCRN, 1999, 2002a; Phillipsen et al., 1997). Children's language and social competence were

higher when their ECE settings met the APA and NAEYC recommendations regarding child-to-adult ratios (NICHD ECCRN, 1999). Similarly, a meta-analysis indicated that children showed higher skills levels when caregivers had sufficiently intense training and when that training was aligned with a rigorous curriculum (Fukkink & Lont, 2007). By contrast, teacher education has been an inconsistent predictor. Neither educational degree nor whether the teacher was certified to teach predicted classroom quality or child outcomes in analyses of seven large childcare studies (Early et al., 2007).

Caregiver and program characteristics show a mixed pattern of association with ECE quality. Caregiver beliefs and knowledge tend to be among the strongest predictors of observed quality, with caregivers who believe in authoritative, not authoritarian, child-rearing styles showing more responsive and sensitive care (NICHD ECCRN, 2000a; Phillipsen et al., 1997; Pianta et al., 2005). The mental health of the caregivers has been related to the quality of their interactions with children, with higher levels of depressive symptoms predicting less frequent and harsher interactions in home-based setting (Hamre & Pianta, 2004). Caregiver mental health, however, was not related to observed quality in several studies, including the SECCYD & NCEDL pre-K study (Clarke-Stewart, Vandell, Burchinal, O'Brien, & McCartney, 2002; Pianta et al., 2005). Directors with more experience and those who use a more equalitarian leadership style also tend to oversee preschool classrooms with higher quality (Phillipsen et al., 1997). Caregiver wage and benefits show a mixed pattern of association with quality and child outcomes (Phillipsen et al., 1997; Pianta et al., 2005), with early work suggesting higher-quality ECE correlates with higher wages (Phillipsen et al., 1997) but more recent work suggesting lower-quality care and smaller effects on child outcomes when wages were higher in prekindergarten programs (Pianta et al., 2005).

### **Childcare Quantity and Child Outcomes**

Perhaps one of the most contentious issues during the past 10 years has been whether and to what extent higher quantities of ECE are related to lower levels of socioemotional well-being, specifically increased levels of insecure infant-mother attachments and problem behaviors and decreased levels of social skills. Theoretically, longer hours in ECE starting at a younger age, as well as frequent changes in childcare settings or caregivers were hypothesized to increase the likelihood of insecure infant-mother

attachments and of problem behaviors. The argument is both that time away from parents disrupts the ability of parental caregivers to develop warm affective relationships with their children, and that nonparental caregivers are less likely to provide emotionally nurturing care than parents.

Concern about nonmaternal care leading to insecure attachments fueled much of the early research on ECE. Very early studies suggested that children in ECE settings did not differ from other children with respect to attachment behaviors. However, a handful of studies found that ECE was linked to insecure attachment classification, but the studies tended to ignore family characteristics that are known to be confounded with both attachment and use of ECE (McCartney & Galanopoulos, 1988). This issue was addressed when the NICHD SECCYD reported that nonmaternal care was not associated with attachment security and there was only very limited evidence that the amount of ECE was related to attachment security (NICHD ECCRN, 2001). The only association between childcare experiences and infant attachment came from one of many interactions tested and suggested that children with more hours of care and less sensitive mothers were the most likely to show insecure attachments (NICHD ECCRN, 2001).

### *ECE Quantity and Problem Behaviors*

Quantity of childcare is also thought to relate to more general problem behaviors. Early research provided some evidence that full-time childcare beginning during infancy was related to more problem behaviors (Haskins, 1988; Vandell & Corasaniti, 1988). Analyses of the NICHD SECCYD suggested that at 24 and 54 months children were rated by caregivers as showing more problem behaviors if they experienced longer hours of childcare even with family characteristics and type and quality of childcare held constant (NICHD ECCRN 1998, 2003a). Childcare hours continued to predict the child outcomes through high school, showing significant modest associations with self-reports of risk taking and impulsivity during high school (Belsky et al., 2007; Vandell et al., 2010). Further work to disentangle age, type of care, and quantity effects using econometric approaches with a nationally representative sample indicated that both full-time care and center care predicted more behavior problems and lower levels of learning behaviors (e.g., task orientation and attention), especially if the child had experienced longer hours of childcare as an infant and toddler (Coley, Votruba-Drzal, Miller, & Koury, 2013). Similar patterns of associations between hours of childcare and problem behaviors were reported in other studies conducted in

the United Kingdom (Neighbourhood Nurseries Initiative Research Team, 2007), Canada (Côté, Borge, Geoffroy, Rutter, & Tremblay, 2008), and the United States (Loeb et al., 2007).

This association between childcare quantity and problem behaviors has been carefully examined in several ways. Findings from those studies suggest several caveats to the general conclusions that more hours of ECE leads to higher levels of problem behaviors. First, one study finds that longer hours of care are related to fewer, not more, problem behaviors for young low-income children (Votruba-Drzal et al., 2004). Second, evidence suggested that the finding is driven specifically by group care experiences, in terms of hours of center-based care during infancy or exposure to large numbers of same-age peers appeared to account for the negative effect (Loeb et al., 2007; McCartney et al., 2010). Third, an analysis of the NICHD SECCYD data found the average hours per day of nonparental care, not the number of days of care overall, accounted for associations between time in care and problem behaviors (McCartney et al., 2010). Fourth, McCartney et al. (2010) found the quantity-problem behavior associations were not statistically significant when they applied statistical methods that more rigorously address potential bias related to family and other potential selection factors. Similar results emerged in analyses of two birth cohorts in Norway (Solheim, Wichstrøm, Belsky, & Berg-Nielsen, 2013; Zachrisson, Dearing, Lekhal, & Toppelberg, 2013).

One pathway that some have argued accounts for associations between childcare quantity and children's problem behaviors is children's stress reactivity. The development of the stress response system is quite sensitive to early experiences. Based on an epigenetic framework (Gottlieb, 2007), low-quality caregiving by primary caregivers directly affects children's skills and indirectly does so by altering the gene expression in stress hormones. This, in turn, can change connectivity in the brain that can also impact the development of self-regulation (Blair & Raver, 2012). This epigenetic model has been applied to childcare, with some arguing that chronic stress of being in group care with multiple peers can alter children's stress responses. Children who spent more time in group care with multiple peers demonstrated higher cortisol levels than did children in exclusive parental care (Vermeer & van IJzendoorn, 2006). The children in childcare were more likely to show differences in the circadian patterns in which already elevated cortisol levels increase, rather than decrease, from the morning to the afternoon among children in

group care. Additionally, infants and toddlers showed the largest increases in cortisol levels when compared to their peers at home and older preschool peers in group care across several studies (Ahnert et al., 2004; Watamura, Kryzer, & Robertson, 2009). These atypical patterns in the cortisol levels of young children in ECE have been related to lower quality care (Watamura et al., 2009), large groups (>15 children even with 1:4 ratios; Legendre, 2003), insecure attachments with their caregiver (Badanes, Dmitrieva, & Watamura, 2012), and the temperamental disposition of the child and caregiver (Groenvelde, Vermeer, van IJzendoorn, & Linting, 2010; Pluess & Belsky, 2010). Groenvelde and colleagues reported that fearful children had better outcomes when paired with caregivers with decreased cortisol levels.

### ***ECE Quantity and Academic Skills***

A small body of research has examined whether more time in childcare is related to academic skills, and the evidence is mixed, suggesting that more nonparental care is not especially beneficial or harmful for academic skills. But a more careful look at particular types of care or ECE dimensions shows some interesting findings. Evidence suggests that more than 1 year of preschool, especially center-based preschool, is related to larger gains in academic skills, but that the added value of the second year is less than that of the first year (Arteaga, Humpage, Reynolds, & Temple, 2014; Magnuson et al., 2004), perhaps because many programs combine 3 and 4 years and thus children with 2 years often experience the same curriculum in each year rather than sequenced 2-year curricula. Other evidence indicates that children's language and academic skills are enhanced when they experience high-quality childcare in both the infancy/toddler years and the preschool years (Li, Farkas, Duncan, Burchinal, & Vandell, 2013).

### ***Number of Arrangements and Problem Behaviors***

The number of childcare arrangements is also associated with child outcomes, specifically problem behaviors. Based on attachment theory, some argue that very young children will have trouble trusting that caregivers respond sensitively and positively if they experience either instability in care settings over time or multiple care arrangements at the same time. Moreover, the young child who does not form positive, trusting relationships with their caregiver is thought to be at increased risk for manifesting problem behaviors. Somewhat higher levels of problem behaviors were reported among children with frequent changes in caregivers in the United States (Loeb, Fuller, Kagan, &

Carrol, 2004; NICHD ECCRN, 1998; Youngblade, 2003) and Australia (Neilsen-Hewett et al., in press). Multiple concurrent care arrangements are also associated with somewhat higher levels of problem behaviors in the United States (Morrissey, 2009) and the Netherlands (De Schipper, Tavecchio, van IJzendoorn, & Linting, 2003). There is some, but not consistently replicated, evidence that multiple care arrangements may be more predictive of problem behavior for infants with difficult temperaments (De Schipper, Tavecchio, van IJzendoorn, & Van Zeijl, 2004), girls, and younger children (Morrissey, 2009).

Studies linking child outcomes to caregiver continuity find that young children seem to show immediate, but not long-term, reactions to a change in caregivers. Cryer et al. (2005) examined this issue in childcare centers that served infants using quasi-experimental and experimental approaches. They found that teacher turnover due to factors such as pregnancy and mobility made it very difficult to maintain continuity. Furthermore, children showed increased behavioral issues during the transition periods, but these issues resolved within 4 weeks, and there was no evidence of long-term impact on cognitive, social, or behavioral outcomes.

### ***Peers and Child Outcomes***

Parents and policy makers want ECE to promote school readiness skills through teaching children to interact positively with both caregivers and peers in school-like settings (see Rubin, Bukowski, & Bowker, Chapter 5, this *Handbook*, this volume). However, there is some evidence that the influence of peers is variable dependent on structural and process features of the group care setting (McCartney et al., 2010). For example, the association between the number of hours in group care and an increase in problem behaviors is stronger for children who spent more hours in large groups of peers and in lower-quality care settings (McCartney et al., 2010). Additionally, the composition of peers in classroom settings seems to have an independent influence on children's acquisition of cognitive skills with higher-skilled peers having a positive influence on other children in the group (Henry & Rickman, 2007; Justice, Petscher, Schatschneider, & Mashburn, 2011), especially when classrooms were well managed (Mashburn, Justice, Downer, & Pianta, 2009). In both studies, children showed larger gains in receptive and expressive vocabulary when their peers had higher entry levels of language. These studies suggest that composition of the class, along with quality of the teaching, may be important in early childhood.

### **Childcare and Gender, Family Income, and Ethnic Diversity**

The general systems models that guide much of the childcare research posit that the impact of young children's context, including childcare, on early development will vary depending on individual child and family factors such as gender and the family's income and ethnicity. These three factors have been examined in many studies.

#### ***ECE and Gender***

The extent to which ECE affects boys and girls differently has been examined motivated by clear gender differences in early development. Evaluations of some early intervention programs, such as the Abecedarian Study or High Scope/Perry Preschool, found larger impacts on educational achievement for females (M. Anderson, 2008), but found larger impacts on other outcomes such as social adjustment for males (Duncan & Magnuson, 2013). Some evidence suggests that quantity of nonparental care or quality indices such as child-to-caregiver ratios are more strongly related to social outcomes such as problem behaviors for boys than for girls (Bornstein, Gist, Hahn, Haynes, & Voigt, 2001; Bornstein & Hahn, 2007; Youngblade, 2003). On the other hand, most large childcare studies have not found gender differences in associations between ECE type, quality, and quantity and children's cognitive development (Howes et al., 2008; NICHD ECCRN, 2000b; Peisner-Feinberg & Burchinal, 1997).

#### ***ECE as Protective Factor for Low-Income Children***

It is widely assumed that ECE is one of the most effective intervention approaches to improving the achievement of low-income children in the United States and throughout the world (Engle et al., 2011; Heckman, 2010). ECE during infancy has been related to better cognitive skills and lower levels of physical aggression among children with low-income parents or parents with low levels of education (Côté et al., 2008, 2013; Geoffroy et al., 2007; Votruba-Drzal et al., 2004). In particular, preschool and center care, especially with enrichment programs or programs using effective curricula, are especially beneficial for low-income children (Pianta et al., 2009). The evidence, however, ranges in terms of the degree to which selection bias issues are addressed and whether the estimated benefits are significantly larger for disadvantaged children compared to more affluent children.

Historically, disadvantaged children have had different ECE experiences than their more affluent peers.

Specifically, low-income children have been persistently less likely to attend center-based care than other children (Bainbridge, Meyers, Tanaka, & Waldfogel, 2005). This lower attendance is worrisome given that participating in preschool or prekindergarten programs seems to have larger beneficial effects for children from low-income families compared with other children. In the United States, children with more center care as preschoolers had higher cognitive and language skills than all children, but more preschool center care had a stronger impact for low-income children (Loeb et al., 2007; Magnuson et al., 2004; Votruba-Drzal, Coley, Koury, & Miller, 2013). Using econometric approaches to reduce selection biases, results suggest that children from low-income families showed larger gains associated with preschool center experiences, although such differences were not always significant. Similar findings are reported for Canada (Geoffroy et al., 2007), the United Kingdom (Côté et al., 2013), and Germany and the Netherlands (Burger, 2010).

Children from lower-resourced home environments may also be buffered against poorer cognitive, language, and social outcomes by the provision of high-quality ECE (Burchinal, Peisner-Feinberg, Bryant, & Clifford, 2000; Magnuson et al., 2004; NICHD ECCRN, 2005b). McCartney and colleagues examined whether observed ECE quality might benefit low-income children more than other children in predicting a variety of language and academic outcomes. In predicting school readiness and language skills and academic skills in elementary school, high-quality childcare was shown to buffer children from the negative effects of poverty in the SECCYD (McCartney, Dearing, Taylor, & Bub, 2007; Dearing, McCartney, & Taylor, 2009) and of exposure to more social risk in a smaller study of African American children (Burchinal, Roberts, et al., 2000; Burchinal, Roberts, Zeisel, Hennon, & Hooper, 2006). However, other large childcare studies have failed to document larger impacts of quality for low-income children (Howes et al., 2008; NICHD ECCRN & Duncan, 2003) so further work is needed to determine whether, and under what circumstances, ECE serves as a protective factor for low-income children.

#### ***ECE Experiences and Ethnicity and Home Language***

The increasing diversity of children in the United States in terms of ethnicity and home language (see Ganong, Coleman, & Russell, Chapter 4 and McBride Murray, Hill, Witherspoon, Berkel, & Bartz, Chapter 11, this *Handbook*, this volume), especially the increase in Latino/a American and Latino/a immigrant populations, has increased the

importance of understanding ethnic differences in patterns of ECE use as well as ECE effects. Ethnicity is related to whether the family uses ECE and if so, the number of hours per week spent in ECE. Compared to European American children at all ages, African American children were more likely and Latino/a American children were least likely to be enrolled in center care according to the Current Population Survey, 1968–2000 (Magnuson & Waldfogel, 2005). Lower rates of use by Latino/a American families have been explained by cultural factors and problems with access (Hernandez, Takanishi, & Marotz, 2009). In contrast to ethnic differences in ECE use, both African American and Latino/a American children in ECE spent more hours per week in center care during the year before kindergarten than European American children in ECE (Magnuson & Waldfogel, 2005).

Of particular interest to the field is the development of dual language learners (DLLs) and how they are affected by ECE experiences. DLL children, particularly children from Latino/a American, Spanish-speaking households or those living in linguistically isolated households (e.g., those households where no one over the age of 14 speaks English very well) tended to enroll in childcare centers and preschools at lower rates than native English-speaking children (Chernoff, Flannagan, McPhee, & Park, 2007; Iruka & Carver, 2006). Analysis of the ECLS-B (Espinosa et al., in review) also yielded large differences in ECE experiences between DLL and English-only families, but those differences were accounted for by large differences between DLL and English-only families in family demographics, country or region of origin, and maternal immigration generation. These findings suggest that these factors, rather than home language, might account for differences in ECE experiences related to DLL status.

Other studies have focused specifically on immigration status and country or region of origin. Data from the ECLS-K suggest that nearly 30% of children of immigrants experience no nonparental care in the year before entering kindergarten compared with only 18% of children of native parents (Magnuson, Lahaie, & Waldfogel, 2006). Analysis of the more recent ECLS-B data yields similar patterns with Latino/a American and Asian American children of foreign-born parents experiencing lower rates of center-based care prior to entering kindergarten than native-born children (Turney & Kao, 2009). Focusing on the specific country of origin, children whose mothers immigrated to the United States, especially from Mexico, were found to be the least likely to enroll in childcare centers (Crosnoe, 2007).

A recent literature review examined whether the measurement of ECE quality varies depending on the child's home language (Coley et al., 2013). The ECERS and CLASS have been examined in several studies, and evidence suggests that both instruments show similar psychometric properties and associations with child outcomes for children from English-only families and from DLL families for ECERS, ORCE, and CLASS. In general, these studies suggest that the classrooms may be taught in a language other than English with DLL children and should have books and activities relevant for the cultural backgrounds of the children, but the types of interactions that encourage children's academic, cognitive, and social development are similar regardless of the child's home language. Furthermore, children from diverse backgrounds may need additional supports for early learning, especially DLL children.

Developmentally appropriate practices involve providing young DLLs with education and care in their home language (NAEYC, 2009). This is recommended to provide DLL children with continuity between home and school and to ensure that they learn their first language with sufficient depth to provide a deep understanding for subsequent learning. A review of the research literature (Peisner-Feinberg et al., 2014) indicated that young Spanish-speaking DLLs tended to show substantial gains on English outcomes when instruction was in both Spanish and English in about half of the studies. These findings suggest that further research on the role of the home language in childcare may be warranted to ensure policies are promoting both short- and long-term outcomes for DLL children, especially DLL children from very low-income families.

Despite their potentially lower enrollment, children of immigrants and DLL children especially benefit from center-based care or high-quality care (Gormley, 2008; Magnuson et al., 2007). Some recent evidence suggests children of immigrants showed larger gains in academic skills when in center care than did children from native-born families in analyses of the ECLS-B (Votruba-Drzal, Levine-Coley, Collins, & Miller, in review). The gains for immigrants varied by home language, with children in English-speaking immigrant households gaining more in reading skills and children in DLL families gaining more in terms of expressive language. Similarly, evaluations of the Oklahoma Universal Pre-Kindergarten Program on Latino/a American children's early literacy and mathematical abilities reported that Latino/a American children who spoke English at home made positive, but statistically

insignificant cognitive gains, but Latino/a American children who spoke Spanish at home made large and significant gains in prereading and premath when assessed in English (Gormley, 2008; Gormley, Gayler, Phillips, & Dawson, 2005). Furthermore, there were differential effects of the program depending on when the family immigrated; Latino/a American children whose parents were born in Mexico made the largest gains in prereading, prewriting, and premath, whereas Latino/a American children with parents born in the United States made significant gains only in prewriting. The children from Spanish-speaking homes did not lose skills in Spanish while gaining skills in English, but the gains in Spanish were not as large nor were they statistically significant.

### Summary

Whether and how ECE influences early cognitive and social development has been the focus of much research. Because of the difficulty of isolating the effects of ECE from family characteristics that might affect ECE selection, studies have had to become increasingly rigorous methodologically. More rigorous studies suggest that children show modest gains in language and academic skills when they attend center care as preschoolers or attend higher-quality care compared with children not attending center care or attending lower quality care. These gains are maintained into adolescence and adulthood in at least some studies, with some evidence that long-term gains may be through impacts on “noncognitive” skills.

The modest ECE effects have been examined to determine whether thresholds in quality-outcome associations or differential effects related to child gender or temperament and family income might reveal stronger associations for subgroups of children. Center care and higher-quality ECE may be more strongly related to language and academic outcomes for DLL children or children from low-income families than from middle-income families. For middle-income children but not for low-income families, long hours of ECE, especially in settings like centers with many same-age peers, may be related to modest increases in problem behaviors. In addition, entry into ECE during the first few months of life might be related to modestly lower levels of cognitive skills for middle-income European American children, but not for low-income or African American children. Consistent with epigenetic hypotheses, evidence suggests that children with more difficult temperaments might show larger effects of ECE quality than do other children. Finally, there is some, albeit

inconsistent, evidence that ECE quality may need to be in the moderate to high range for children to show larger gains academically when they experience higher-quality care. Careful design and analysis is necessary in future research to examine these important questions about differential effects of ECE experiences.

## STRATEGIES TO ENSURE QUALITY AND ACCESS

ECE is increasingly viewed as the most cost-effective and successful means to improve educational opportunities for low-income children (e.g., Heckman, 2010), which has led to interest in practices and policies that ensure access to and quality of ECE. The evaluations of many programs to improve quality and child outcomes have found that not all programs result in positive outcomes. Why some programs work better than others is not always clear. First, issues of implementation loom large because complex interventions may be hard to implement in ECE settings in which the workforce often receives low pay and has relatively low levels of education and training. Another issue is that some interventions focus on improving aspects of quality that are only modestly related to child outcomes (Pianta et al., 2009). There have been, however, notable successes linked to two relevant initiatives. First, funding from federal research agencies increased for projects designed to improve the quality of instruction, especially in ECE. As a result, researchers have examined many curricula and a growing number of professional development strategies. Early childhood curricula with the strongest scientific evidence of positive effects on children’s outcomes are described in detail in the What Works Clearinghouse website ([www.whatworks.ed.gov](http://www.whatworks.ed.gov)) established by the Institute for Education Sciences (IES). Research on effects of various curricula and professional development efforts is described below. Second, state and federal policies have sought to improve ECE quality and accessibility through funding ECE programs, quality rating and improvement systems, licensing, and childcare subsidies. These initiatives are also discussed below.

### The Role of ECE Curricula and Professional Development to Improve ECE Quality

Concerns of ECE quality increased attention on curricula as a means to ensure that young children in ECE are provided with opportunities to acquire academic and

social skills. In this section we also examine how professional development can affect the quality of ECE.

### *ECE Curricula*

Since the late 1980s, early childhood curricula have been guided by the concept of developmentally appropriate practice as conceptualized by the largest association of early childhood professionals, the NAEYC. The concept emphasizes intentional instruction—both for young children in ECE and for their providers. Early education, like later education, is believed to be enhanced when skills are taught in a focused and sequential manner (Epstein, 2007). Sequence is thought to be important when it is believed that skills are acquired sequentially in a given content area, such as language and literacy, mathematics, or socioemotional skills—following a developmental progression in which basic skills provide the foundation for learning more complex skills. Focused scope is important because the acquisition of skills within a content area requires intensive and specific, rather than diffuse, instructional approaches. Ideally, children's progress is monitored and instruction is adapted to match the child's skills. NAEYC views developmentally appropriate practice in ECE as including effective curricula that are aligned, and ideally integrated, with progress monitoring and professional development (NAEYC, 2009). Ideally, the caregiver is trained in the curriculum and is receiving ongoing mentoring to ensure she or he is successfully implementing it. Curriculum selection is to be guided by evidence that it is successful in a rigorous evaluation, ideally involving randomized clinical trials with children similar to those in the classroom. The caregiver conducts formative assessments on each child, and then adapts instruction for that child or group of children depending on the results of those assessments. A meta-analysis and some of these individual programs and policies are described below to illustrate this line of research designed to improve ECE quality and the school-readiness skills of young children.

Two meta-analyses of experimental and quasi-experimental studies examined which specific aspects of programs and care settings improve outcomes for children. Camilli, Vargas, Ryan, and Barnett (2010) undertook such an analysis of 120 ECE programs spanning four decades (1960–2000). They reported small to moderate positive effects of ECE on children's cognitive, school, and social outcomes. Results indicated that use of curriculum, instructional focus, and pedagogical approach were modest predictors of children's outcomes. More recently, this database was updated and refined as part of a project

undertaken by Duncan and colleagues (see Duncan et al., 2011). Including studies conducted through 2007, initial findings indicate that the average effect size for ECE on cognitive and academic achievement scores was about .28, but there was considerable heterogeneity across programs in their effectiveness (Duncan & Magnuson, 2013).

One of the first large evaluations of curricula was conducted by the Preschool Curriculum Evaluation Research (PCER) initiative. The impact of 14 different curricula implemented in early childhood classrooms serving primarily low-income children was assessed (Preschool Curriculum Evaluation Research Consortium, 2008). In each of 12 different projects, early childhood classrooms or centers were randomly assigned to a target curriculum or to a control condition, typically the local business-as-usual curriculum. The 14 target curricula included some widely used resources (e.g., Creative Curriculum), several curriculum combinations, and curricula developed by project investigators (e.g., Curiosity Corner by the Success for All Foundation, Inc.). Each of 12 projects was evaluated, but statistical power for analyzing curricula effects in the PCER initiative was limited by relatively small numbers of randomly assigned units (typically centers) in each project. During the pre-K year, 8 of the 14 curricula had a positive impact on teacher instruction, and 2 had statistically significantly positive effects on child outcomes (effect sizes of .32 to .96). Both curricula were focused on teaching specific content areas. The Developmental Learning Materials (DLM) literacy curriculum had positive impacts on reading skills, phonological awareness, and language outcomes and the Pre-K Mathematics curriculum had a positive impact on math outcomes. In addition, curricula focused on teaching specific language and literacy skills had positive impacts on kindergarten outcomes—Curiosity Corner on reading and Early Literacy and Learning Model on language—but a more global curriculum, Project Approach, had a negative impact on behavior in kindergarten. In general, this study demonstrated that studies in which treatments are assigned at the center level must include sufficient numbers of centers to have power to detect modest to moderate effects, focusing attention on the content of pre-K curricula in promoting early learning.

Following the PCER, some of the innovations in curriculum development and evaluation focused on a specific domain of development and learning. The Chicago School Readiness Project (CSRP) is illustrative (Raver et al., 2011). Focused on the development of children's self-regulation, Raver and colleagues hypothesized that

increased attention and self-regulation would lead to gains in children's academic outcomes. Teachers trained in how to provide regulatory support and better classroom management who were provided with mental health expert consultations focused on classroom management and teacher stress reduction. In a randomized clinical trial (RCT), CSRP was compared with business-as-usual classrooms. Children in the CSRP classrooms showed larger gains in self-regulation skills (attention/impulse control and executive function) and in pre-academic skills (receptive vocabulary, letter naming, and early math) from fall to spring of the Head Start year than did children in the control classrooms. Effect sizes ranged from .37 to .63. Results provided partial support for the hypothesis that children's self-regulation skills mediated gains in academic readiness as measured by vocabulary, letter naming, and math skills.

The Building Blocks math program is also illustrative of recent early childhood curriculum work focused on a specific developmental domain. Developed by Clements and Sarama (2004), the curriculum includes large- and small-group instruction focused on teaching math skills in a focused and sequential manner and hands-on and computer activities that promote children's active involvement in solving problems and explaining their solutions. An experimental study reported that the Building Blocks curriculum significantly increased children's math knowledge when compared with a different math curriculum (effect size of .47) and a business-as-usual control group (effect size of 1.07) (Clements & Sarama, 2008).

In addition to curricula that focus on a specific domain, there has been the development of innovative early childhood programs that explicitly address multiple developmental domains (e.g., early literacy competence, social skills), sometimes by using several evidence-based curricula. This research often involves combinations of curricula to promote development in different domains. Three illustrations of rigorous research on innovative, multiple-domain curricula are the Evidence-based Program for Integrated Curricula (EPIC; Fantuzzo, Gadsden, & McDermott, 2003), Head Start's Research-Based, Developmentally Informed program (REDI; Bierman et al., 2008), and the Boston Pre-Kindergarten Program (Weiland & Yoshikawa, 2013). The first two were implemented as RCTs in Head Start classrooms, and the last as an RD in a pre-K classroom. EPIC and Boston Pre-K were designed as comprehensive stand-alone curricula, whereas REDI provided manualized resources to enrich and complement a classroom's existing curriculum.

The EPIC program was designed to improve children's math, language, and literacy skills through routine classroom experiences. EPIC included interactive reading, large- and small-group activities, transition activities, and environmental supports (e.g., props and visual cues that reinforce key vocabulary) plus weekly home-learning activities that reinforced classroom experiences. Teachers conducted brief curriculum-based assessments to help monitor children's progress and inform instruction. Professional development was provided to teachers through a learning community approach (Fantuzzo, Gadsden, & McDermott, 2011). (See section "Other Community-Based Initiatives" further on.) The EPIC classrooms were compared to a control group that received the DML Early Childhood Express Curriculum, a curriculum with positive effects on reading skills in the PCER study. Children in EPIC classrooms performed better than children in control classrooms on math and listening comprehension skills, but were not different on vocabulary and alphabet knowledge skills (Fantuzzo et al., 2011).

The REDI program targeted children's language, literacy, and socioemotional skills as key components of school readiness. The language and literacy content was based on Wasik and Bond's (2001) adaptation of the dialogic reading program that combined reading books aloud with scripted interactive questions and targeted vocabulary words with phonological awareness activities and games (Adams, Treiman, & Presley, 1998). The socioemotional content was based on the Preschool PATHS curriculum (Domitrovich, Greenberg, Kusche, & Cortes, 1999) with lessons focused on prosocial friendship skills, including interpersonal negotiation and conflict resolution. Teachers were provided with training and mentoring focused on implementing and integrating REDI enrichment resources into their base curriculum, and parents received complementary activities to use at home. Comparisons with control classrooms indicated the REDI group had larger gains (effect sizes of .15 to .39) on vocabulary, literacy (blending and elision), and social-emotional skills (emotional understanding, social problem solving, social behavior, and learning engagement).

The Boston Pre-Kindergarten Program developed their curriculum by integrating proven literacy, math, and social skills interventions. The academic component combined two effective curricula, Building Blocks for math instruction and Opening the World of Learning for language and literacy. Extensive training and coaching was provided. The RD evaluation (Weiland & Yoshikawa, 2013) indicated large impacts on vocabulary, math, and reading

(effect sizes of .45 to .62) and smaller impacts on executive functions (effect sizes of .21 to .28).

Finally, there is a small, but important, group of a few studies that have examined the effectiveness of different instructional approaches for dual language learners (DLL). One example, a study by Farver, Lonigan, and Eppe (2009), randomly assigned Spanish-speaking English-language learners to one of three conditions: (1) a standard Head Start curriculum—High/Scope (control condition), or (2) the Literacy Express Preschool Curriculum (LEPC) in English only, or (3) the LEPC delivered initially in Spanish but transitioning to English over the course of the year. The Literacy Express program focuses on oral language, phonological awareness, and print knowledge in teacher-directed small groups as a supplement to the High/Scope curriculum. Compared with children in the business-as-usual control group, the English-only LEPC and Spanish-transition LEPC conditions were equally effective in improving English literacy skills and only the Spanish-transition model was effective in improving Spanish literacy skills. Effect sizes for statistically significant outcomes across the three group comparisons ranged from .39 to .94.

### *Professional Development*

Professional development (PD) for in-service teachers is increasingly a central focus of efforts to increase the magnitude of ECE program impacts (Martinez-Beck & Zaslow, 2006). PD is commonly used to help teachers improve the overall quality of their classroom or implement a new curriculum. Large-scale PD programs have attempted to improve ECE quality by aligning training with quality measures such as the ECERS or CLASS. Other PD programs use workshops and/or coaches to support teachers' use of curricula. This PD can promote the implementation of a curriculum already in use, a new curriculum, or adaptations to ongoing practice or curricula (e.g., Powell, Diamond, Burchinal, & Koehler, 2010). Finally, some approaches to PD seek to help teachers generate their own lessons or practices within a common pedagogical or content framework (e.g., Buysse, Castro, & Peisner-Feinberg, 2010).

Research has not kept pace with the growth of interest in PD (Desimone, 2009). Several RCTs found positive effects of ECE PD on classroom quality (Bryant et al., 2009; Pianta, Mashburn, Downer, Hamre, & Justice, 2008) and children's outcomes (Powell et al., 2010), but a more common pattern is for investigators to examine or report effects on teachers' practices, not children's outcomes. With few

exceptions (Lonigan, Farver, Phillips, & Clancy-Menchetti, 2011), studies of PD that also involve teachers' use of a new curriculum typically do not systematically vary the PD and curriculum components, thereby making it impossible to determine causally the separate effects of the PD approach and the new curriculum on child outcomes. Furthermore, PD often entails a package of supports to teachers that may include, for example, coursework, individualized work with teachers in their classrooms, and the use of student progress monitoring tools (Landry, Anthony, Swank, & Monesque-Bailey, 2009). There is almost no research on the relative contribution of each component of a PD program.

In spite of the fledging line of research on early childhood teacher PD, an emerging conceptualization of effective PD emphasizes sustained opportunities for teacher learning, content focused on the outcomes teachers are expected to promote in their classrooms, the realities of a teacher's classroom, and active learning and collaborations with PD staff and/or other teachers (e.g., Wayne, Yoon, Zhu, Cronen, & Garet, 2008). These PD emphases have been shaped, in part, by largely theoretical arguments that adults learn new knowledge and skills through reflections on their own practice and interactions with content experts over extended periods of time (Bransford, Brown, & Cocking, 1999).

Below we describe research on outcomes of coursework, coaching (also referred to as mentoring), and professional learning communities in early childhood settings. Although each of these three broad approaches embraces the emerging conceptualization of PD briefly described above (e.g., active participation of teachers for a semester or longer), there are potentially important distinctions in each approach's theory of teacher change. In coaching, for example, an expert's feedback on a teacher's use of a new instructional practice is among the presumed drivers of change, whereas the hypothesized active ingredients of a professional learning community are collaborations with colleagues on lesson development and the collective discussion of reflections on the use of new lessons (Powell, Diamond, & Cockburn, 2012). Our description of PD approaches includes attention to recent technological innovations aimed at improving the efficiency and accessibility of PD.

Several rigorous studies have examined the effects of traditional coursework. Fourteen weeks of coursework within the framework of the CLASS was linked to improved emotional and instruction interactions with students and to higher levels of intentional teaching beliefs

and greater knowledge and skills in detecting effective interactions (effect sizes of .35 to .77) in an RCT (Hamre et al., 2012). Similarly, a 15-week course plus coaching was associated with significant improvements in providers' language and literacy practices (effect size was .77) in a quasi-experimental study (Neuman & Cunningham, 2009). A much shorter, 6-day course on early literacy development resulted in positive effects on observed teachers' instructional practices, with effect sizes of .48 to .60 (Dickinson & Caswell, 2007). The interpretation of these findings, however, has been challenged recently in studies that contrast the effects of coursework and coaching. Two studies contrasted coursework and coaching, regarding promoting literacy activities in one study (Neuman & Wright, 2010) and the CLASS framework in the other (Downer et al., in review). Both studies indicated that the coaching, not coursework, improved instruction and teaching practices.

Coaching entails a content expert (e.g., early literacy specialists) providing individualized support to a teacher or a teaching team in the context of their classrooms. This approach to PD is also known as "consultation" or "mentoring." The method typically involves tailored presentation of and feedback on a teacher's efforts to implement recommended practices (Powell & Diamond, 2011). Often coaching is provided as part of a multi-component PD program that includes introductory (e.g., Powell et al., 2010) or concurrent (e.g., Raver et al., 2008) workshops, an ongoing course (e.g., Neuman & Wright, 2010), and/or web resources (Pianta, Mashburn, et al., 2008; Powell et al., 2010) that offer related PD information on recommended practices. Coaches may also demonstrate the recommended practice in a teacher's classroom (Wasik et al., 2006).

Typically the coach observes a teacher in her/his classroom and then meets with the teacher to provide and discuss feedback on the observation. The feedback focuses on identification of appropriately implemented practices and recommendations for practice improvements, labeled "glows" and "grows," respectively by one PD developer (Landry et al., 2009, p. 452). Furthermore, some programs provide a teacher with opportunities to observe themselves to reflect on their practices through sharing snips from videotapes (Hamre, LoCasale-Crouch, & Pianta, 2008) or transcripts (Dickinson, Watson, & Farran, 2008).

Computer-based technology is being used to extend or enhance individualized support of teachers through a variety of methods, including web conferencing (Amendum, Vernon-Feagans, & Ginsberg, 2011), electronic mail

(Hemmeter, Snyder, Kinder, & Artman, 2011), webcams in classrooms (Pianta, Mashburn, et al., 2008), and software that links a coach's feedback to videotaped segments of a teacher's instruction (Powell et al., 2010). Technology may be employed to link teacher and coach concurrently or to provide feedback asynchronously.

The increased focus on improving ECE quality has led to the development of PD coaching that is aligned with quality measures such as the ECERS or CLASS. Two PD programs have received considerable attention. Partnerships for Inclusion (PFI; Wesley, 1994) is a mentoring model in which the consultant collaborates with the caregiver, using the ECERS-R or FDCRS as a framework to improve quality in center- and home-based ECE settings, respectively. MyTeachingPartner (MTP) is a mentoring model in which the consultants coach the caregiver, often via the web, using the CLASS as a framework to improve quality. Large-scale randomized clinical trials indicated that classroom quality improved (effect sizes of .2 to .6) according to the FDCRS with PFI and the CLASS with MTP, but there were only small changes in a few child outcomes (Bryant et al., 2009; Downer et al., in review; Pianta, Mashburn, et al., 2008).

The ExCELL program illustrates the use of coaching in combination with other PD supports (Wasik, 2010; Wasik & Hindman, 2011). ExCELL is a comprehensive PD model designed to help teachers to use instructional practices that promote children's literacy and language skills. Group trainings focus on five modules (e.g., interactive book reading, alphabet knowledge), and include presenting the specific practices and teaching strategies and asking teachers to practice them in small groups. Weekly coaching is provided during which the coach models the targeted teaching practice and observes the teacher's instruction related to targeted outcomes (e.g., emphasis on letters). Coach feedback on an observation checklist includes positive aspects of the teacher's actions plus recommendations for improvement. An RCT found that children in PD classrooms made significant gains in their vocabulary (effect size of .27) and phonemic knowledge (effect size of .35) (Wasik & Hindman, 2011).

Video libraries of effective instruction have been used in several studies of coaching (Hemmeter et al., 2011; Pianta, Mashburn, et al., 2008; Powell et al., 2010). Powell and his colleagues (2010) conducted an RCT of two literacy and language coaching conditions with Head Start teachers, in-person classroom coaching and technologically mediated coaching. Comparisons of the business-as-usual condition and the two PD groups indicated the two PD interventions improved the global classroom quality and

teachers' instruction of letters and sounds (effect sizes of .91 to .99), including enhanced children's acquisition of letters and sounds (effect sizes of .17 to .29). No differences emerged in comparisons of the in-person or technologically mediating coaching condition (Powell et al., 2010), suggesting that both are effective strategies. Another series of studies conducted by Pianta and colleagues indicates that access to video examples of evidence-based practices can enhance the impact of coaching. As part of the MTP PD, Pianta, Mashburn, et al. (2008) found that providing teachers with access to video exemplars only, without coaching support, leads to quite modest improvements in teachers' instruction, but providing both access to video and coaching resulted in gains in the quality of teacher-child interactions.

A professional learning community commonly consists of a small group of educators and other stakeholders who meet regularly to work collaboratively on improving instructional strategies (Vescio, Ross, & Adams, 2008). A core part of the group's focus is mutually supportive reflection on efforts to implement new or revised classroom practices. To date, most evaluations have relied on teachers' reports of their experiences in learning communities rather than independent observation of practices or assessment of child outcomes (Vescio et al., 2008). An exception, an RCT of a teacher study group approach to PD, found improved instruction by first-grade teachers in teaching reading comprehension and vocabulary instruction, but no differences in children's oral vocabulary (Gersten, Dimino, Jayanthi, Kim, & Santoro, 2010). Professional learning communities have been included in recent ECE programs such as EPIC that have had positive effects on children's math and listening comprehension skills (Fantuzzo et al., 2011), but it is not possible to determine the unique contributions of a PD component to the EPIC outcomes.

A variant on the professional learning community is the "communities of practice" model in which a knowledge base on best practices is developed from teachers' collective experiences and collaborations with researchers (Buysse, Sparkman, & Wesley, 2003). This approach was tested in a PD program for teachers of Latino/a dual language learners in which teachers created lessons around a commonly agreed-upon goal within a scientifically based content framework to provide feedback and reflection on the implementation of the lessons (Buysse et al., 2010). The RCT indicated that the quality of targeted instruction improved, and children showed gains in phonological skills in their primary language but not on other language or literacy skills in either language (Buysse et al., 2010).

## U.S. Public Policy and Early Childcare and Education

U.S. public policy related to childcare (see Dodge & Haskins, Chapter 17, this *Handbook*, this volume) has evolved substantially over several decades, and encompasses the interrelated goals of ensuring children's basic safety, supporting parental employment, and improving children's school readiness. ECE public policies include licensing of ECE settings, initiatives to improve childcare quality, and increasing access to childcare.

State and federal governments have invested heavily in ECE programs based on evidence that high-quality ECE is a cost-effective approach to reducing the income achievement gap (Heckman, 2010). As described above, these U.S. programs include Head Start and Early Head Start funded by the federal government and pre-K programs funded by state governments. Evaluations of these programs have produced mixed findings regarding their impacts on young children, typically those from low-income families.

### Head Start

The oldest, largest, and best known federally funded preschool program is Head Start. Conceived as part of the Johnson administration's War on Poverty, Head Start has served over 27 million children since its inception in 1965 (U.S. Department of Health and Human Services, Administration for Children and Families [ACF], Office of Head Start [OHS], 2011). Federal guidelines require that 90% of the families served in each Head Start program be poor (with incomes below the federal poverty threshold), although there is some discretion to serve children near poverty; the remaining 10% of children served by Head Start have developmental disabilities (USDHHS, ACF, CCB, 2008).<sup>1</sup> Head Start typically provides part- or full-day center-based ECE; more than 90% of Head Start programs are center-based, preschool programs, about half of which provide full-time center care (Hamm, 2006). In 1995, the Early Head Start program was established. It provides a mix of center-based and home-visiting services for children from birth to Age 3 and pregnant women (USDHHS, ACF, OHS, 2011).

Head Start programs are designed to enhance the development of economically disadvantaged children using

<sup>1</sup>Children from families receiving public assistance (TANF or SSI) or children who are in foster care are eligible for Head Start or Early Head Start regardless of family income level. Ten percent of program slots are reserved for children with disabilities, also regardless of income. Tribal Head Start programs may also have more open eligibility requirements (USDHHS ACF, CCB, 2008).

a holistic approach. It offers educational services and dental and mental health screening and access to care for the children, and parenting education and assistance in achieving education and employment goals for the parents (Puma et al., 2005). A high priority is placed on parents' involvement in their children's education and the local administration of Head Start programs (USDHHS, ACF, CCB, 2008). The majority of children enrolled in Head Start in 2009 were 3 (36%) and 4 years old (51%). Approximately 10% of participating children were enrolled in Early Head Start programming for children under 3 years of age. In terms of racial and ethnic composition, about 40% of Head Start attendees in 2007 were European American, 30% were African American, 4% were American Indian/Alaskan Native, and 2% were Asian American.<sup>2</sup> Approximately 36% of children were identified as Latin American, regardless of ethnicity (USDHHS, ACF, OHS, 2011).

Historically, Head Start has enjoyed strong bipartisan support, and Congress overwhelmingly reauthorized the program in November 2007. Funding increased between 1990 and 2002 and remained steady until 2012. In 2009, the federal Head Start appropriation of just over \$7.1 billion was distributed to 1,591 local private and public non-profit grantees serving 904,153 children. This amounts to an estimated average federal cost of \$7,600 per child (USDHHS, ACF, OHS, 2011). In 2007, about 48% of poor 3- and 4-year-olds were enrolled in Head Start<sup>3</sup>, down from 65% in 2000 (Currie & Neidell, 2007). This decline in the percentage of eligible children being served by the program appears to be due to the increase in rates of child poverty during that time and perhaps to increased enrollment in state pre-kindergarten programs among 4-year-olds (Besharov & Higney, 2007).

Since its inception in 1965, Head Start has been heavily studied, and the interpretation of evaluation findings has been contested. Separate RCTs examined the impacts of Early Head Start (EHS) on infants and toddlers and of Head Start on 3-to 4-year-olds. In both studies, the

control group experienced a mix of childcare experiences, including parental care and other forms of nonparental care. The evaluation of EHS indicated modest impacts (effect sizes < .20) on children's early language and social skills and on parenting (Love et al., 2005), but these effects had dissipated by the time children were in fifth grade.

The Head Start Impact Study (HSIS) was undertaken in the late 1990s to evaluate the effect of Head Start on preschoolers. This study randomly assigned children to Head Start or a comparison group in a randomly selected sample of Head Start grantees with wait lists (Puma et al., 2005). The study found small to moderate positive impacts (effect sizes < .4) after 1 year of the Head Start program for both 3- and 4-year-olds and across most child outcome areas assessed except for math—language, early prereading skills, health, and parenting, including reading with children and discipline practices (Puma et al., 2005). A potential explanation for the modest effects was that many of the control group children experienced ECE programs that were similar to Head Start, with some evidence of large effects for Head Start compared with children with home-based care and small effects compared with children with center care (Zhai, Brooks-Gunn, & Waldfogel, 2011). Conclusions about whether Head Start programs have as large of an effect on children's academic and social outcomes as prekindergarten programs differ across studies (Gormley, Phillips, Adelstein, & Shaw, 2010). Across many studies including the HSIS, having a comparison group that experiences other preschool education programs tends to produce smaller program impacts (Shager et al., 2013).

In the HSIS, children were followed through third grade, but the treatment effects largely disappeared by the end of first grade, with some exceptions. Again, alternative care arrangements was an issue with 50% of the 3-year-old control group and only 63% of the 3-year-old treatment group attending Head Start as 4-year-olds. Sustained effects were found for children who were dual language learners, entered Head Start with lower skill levels, or had mothers who reported mild depressive symptoms, and lived in nonurban settings. Other rigorous studies find that Head Start has long-term benefits for attendees such as higher levels of education and reductions in special education and grade retention even with impacts on academic and social skills fading during elementary school (Deming, 2009; Garces, Thomas, & Currie, 2002; R. C. Johnson, 2012; Ludwig & Miller, 2007).

Why program impacts on academic skills would not persist, but differences later in life on outcomes such as education and crime would be found is a puzzle that has not

<sup>2</sup>Other racial identification categories included Hawaiian/Pacific Islander (0.8%), Biracial/Multiracial (4.9%), and Unspecified/Other (18.8%) (USDHHS, ACF, OHS, 2011).

<sup>3</sup>Calculation by the authors, based on the number of 3- and 4-year-olds in poverty in 2007 (Douglas-Hall & Chau, 2008) and the number of children over 3 served by Head Start in the same year (USDHHS, ACF, 2008). Using the same formula, the authors estimate that only 3.3% of eligible children under 3 years of age living in poverty were enrolled in Early Head Start in 2007.

yet been solved. Some studies suggest that these programs may have affected other dimensions of development, such as executive function, self-regulation, or classroom behaviors (Heckman & Masterov, 2007). However, evidence for this as an explanation across studies is scant, as few of the studies have included good measures of these constructs, and program impacts have not been consistently found for some closely related constructs such as problem behavior (Deming, 2009). Thus, much more research is needed to understand for which groups and under what conditions ECE leads to positive outcomes later in life. Part of the puzzle undoubtedly hinges on better understanding how these programs affect a full range of children's skills before they enter schools, and also how later contexts, including school contexts, affect the persistence of these diverse effects over time (Duncan & Magnuson, 2013).

### *Prekindergarten*

Public pre-K programs are a second form of publicly provided preschool by states or local school districts. Most pre-K programs are targeted to low-income children (31 state programs have income eligibility requirements); however, a small but growing number of states either offer, or are currently considering, funding universal access for all 4-year-olds and, in some cases, 3-year-olds (Barnett et al., 2007). These state initiatives are intended to complement existing sources of funding like Head Start. Funding and enrollment in state pre-K programs and early education programs have increased dramatically over the past several years. As of 2011, 39 states and the District of Columbia had pre-K initiatives serving approximately 28% of 4-year-olds and 4% of 3-year-olds (Barnett, Carolan, Fitzgerald, & Squires, 2011). In tight budgetary times, states have decreased inflation-adjusted spending on pre-K.

An examination of state pre-K programs in 2010 to 2011 by the National Institute for Early Education Research (NIEER) reported substantial variation in funding, program design, and quality across states (Barnett et al., 2011). Although it is difficult to measure the costs of programs, NIEER reported that the average per pupil state pre-K expenditure in 2011 was \$4,151, with considerable state-to-state variation. It is important to note, however, that per pupil state expenditure figures may underestimate actual spending per student, as many state pre-K programs receive local funding, and it is difficult to calculate such support.

Of the 39 programs examined by NIEER, 11 were full-day programs, 12 were half-day programs, and 28 had

locally determined operating hours. Eight states enrolled over half of their state's 4-year-old population. Although some programs offer an extensive set of support services, such as transportation and health screenings and referrals, others offer very few. Most states use a mixed service delivery system that provides programming in schools as well as community-based settings, by contracting with privately run preschools and federally funded Head Start programs. Approximately one-third of children receiving pre-K services in 2011 were served outside the public schools (Barnett et al., 2011).

Using a combination of quasi-experimental methods, evaluations of state pre-K programs have generally yielded positive impacts. Children who attend state or local prekindergarten programs, on average, perform better at kindergarten entry on measures of math and literacy skills than children who spend their prekindergarten years exclusively in parental care or in other types of informal care (Magnuson et al., 2004; Phillips & Adams, 2001), with large effects in evaluations of two strong pre-K programs in Tulsa and Boston (Gormley et al., 2005; Weiland & Yoshikawa, 2013). A meta-analysis of some of the strongest prekindergarten programs revealed moderate to large impacts on academic skills and neutral to modestly positive effects on language and social skills, compared to children in all other types of care (parental and non-parental) and suggested that these effects persist through age 10 (Barnett et al., 2011). It is clear, however, these findings do not apply to all prekindergarten programs because of large differences across states in program quality and observed child outcomes (Howes et al., 2008).

### *Licensing*

Ensuring the basic safety of childcare is undertaken by state regulation of childcare providers. Every state regulates the childcare industry to some degree, as childcare establishments must obtain licensure to enter the market, but considerable differences exist across state in the extent of regulation and in how closely requirements are monitored (Hotz & Xiao, 2005).

State rules fall into two main categories: structural and safety. Structural regulations are those that mandate maximum child-to-staff ratios, minimum caregiver experience/education requirements, ongoing education requirements, and maximum classroom size. The child ratios and classroom size requirements vary, depending on the age of the children in the program. Safety regulations include stipulations regarding staff training in CPR/first aid, immunizations, criminal background checks, and compliance

with the provision of nutritional meals. In addition, some states have licensing rules and policies about the use of developmentally appropriate activities.

States also have varying levels of rigor related to monitoring programs to ensure that they are complying with childcare licensing requirements. Although the impact of state-level regulations on the level of quality in the regulated childcare market remains uncertain, both theory and evidence suggest that higher levels of state regulation are linked with higher-process quality care in regulated types of care, including family and center-based care (Blau, 2003). However, more stringent regulation, in particular regulations that increase staffing costs such as higher minimum levels of caregiver's education and lower staff-to-child ratios, have the adverse effect of reducing supply and increasing cost.

### ***Quality Rating and Improvement Systems***

Starting about 20 years ago, states created market-based incentive systems, termed quality rating and improvement systems (QRIS). QRIS are designed to assign early childhood education and care providers a rating level, along a quality continuum, and typically serve two functions. First, they provide a standard way of rating program quality, based on multiple criteria, and making the rating available to parents. Nearly all states include staff training and education and the classroom or learning environment (although the latter is only measured at higher levels of quality in some states). States differ on whether and to what extent they include parent-involvement activities, business practices, child-staff ratios, or national accreditation status. The assumption underlying this QRIS function is that parents often lack good information about program quality and if they had it they would be more likely to choose higher-rated settings. As a result, lower-quality providers would face an incentive to either improve the quality of their program or to leave the market (Zellman & Perlman, 2008).

Second, most QRIS provide a range of technical assistance, resources, and incentives for programs to improve program quality. Such efforts include consultation around quality improvement, increased investments for professional development scholarships, micro grants for other targeted quality improvement efforts, and in some instances higher levels of subsidy payments for more highly rated programs. The goal of these efforts is to foster and support providers' efforts to improve the quality of care they provide. Thus QRIS programs attempt to improve quality by affecting both the demand for high-quality care and the

supply of such care. Of course, the success of such efforts rests on the ability of rating systems to accurately identify and measure key aspects of quality and the willingness of providers to participate in a rating system (Zellman & Perlman, 2008).

Given the relative infancy of most state QRIS programs, it is not surprising that conclusions about their effectiveness are premature. To date most research has focused around issues of implementation and has been descriptive. Moreover, the difference in system designs across states makes it difficult to draw any general conclusions from an evaluation of any one state's system, and few states have examined child outcomes to date. A small study in Missouri found that low-income children in higher-rated programs learned more than their peers in lower-rated programs (Thornberg, Mayfield, Hawks, & Fuger, 2009). However, a large study of Colorado's rating system did not find that children's gains in school readiness differed systematically across star rating levels (Zellman, Perlman, Le, & Setodji, 2008). The Colorado report highlighted how difficult it is to study children in a system with such high levels of turnover (and thus low levels of exposure to a particular program). A reanalysis of extant data using the rating systems from several states found few associations between overall star ratings and either observed quality or child outcomes (Sabol, Soliday Hong, Pianta, & Burchinal, 2013).

### ***Community-Based Initiatives and Childcare Subsidies***

A few other states' quality improvement innovations have garnered attention and been scrutinized. Most prominent is North Carolina's Smart Start program, which began as a pilot place-based program in 1993 and expanded to statewide implementation by the late 1990s. The program provided funding for local, typically county-level partnerships to improve quality of early childhood education and care as well as other efforts to promote children's healthy development such as home-visiting and parenting programs. Discretion for how Smart Start funds should be spent was given to local boards, but partnerships were required to focus on improving quality and ensuring that more low-income children attended high-quality care. Early reports suggested that almost 30% of funds were spent on quality improvement efforts and that proportion of centers rated as high quality improved dramatically in these counties (Bryant et al., 2003; USDHHS, CCB, 2008). Moreover, recent rigorous work has found that when combined with funding for 4-year-olds to attend

preschool, the program improved children's test scores in third grade (Ladd, Muschkin, & Dodge, 2012).

Childcare can be quite costly for families, especially infant care and center-based care. In 2010, the average cost of full-time care for an infant for a year averaged about \$9,100 for center-based care and \$6,900 for family-based care (National Association of Child Care Resource & Referral Agencies, 2011). Maternal employment is depressed by the high costs of care and policies and programs that reduce such costs increase mothers' labor market efforts. In an attempt to support working parents, the federal government has undertaken several policy initiatives to offset the high costs of childcare.

Families with working parents receive some support through the federal child and dependent care tax credit as well as the dependent care assistance plan, and, in many states, through supplemental state childcare tax credits (Donahue & Campbell, 2002; Smolensky & Gootman, 2003). Currently, the expense limits are \$3,000 for one child and \$6,000 for two or more children. As a nonrefundable tax credit this subsidy primarily benefits middle- and high-income families.

Support for the employment of low-income families is provided by means-tested childcare subsidies (funded with both federal and state dollars). Childcare subsidies lower the cost of private, market-based nonparental care for low-income families in which parents work or participate in education or other training activities (Magnuson et al., 2007). Subsidies are most commonly distributed in the form of vouchers, but can be paid directly to childcare providers. Currently, childcare subsidy programs are funded by a combination of three federal block grants. The largest federal block grant, the Child Care and Development Fund (CCDF), is designed to provide childcare assistance for families with incomes below 85 percent of the state median. Four percent of CCDF funds must be used to improve childcare quality (M. Greenberg, 2007). State CCDF programs are required to ensure "parental choice" regarding type of care; so vouchers may be used for any eligible childcare provider, including informal care by friends, relatives, and babysitters. Slightly more than half of the children served by CCDF funding attend center-based childcare (USDHHS, ACF, CCB, 2008). In addition, state programs are required to set payment levels that allow families "equal access" to childcare comparable to more affluent families (M. Greenberg, 2007), with a recommended reimbursement rate that is 75 percent of current market rates (Schulman & Blank, 2008). States, however, have substantial flexibility to establish income eligibility

requirements, parental copayment fees, and provider reimbursement rates (M. Greenberg, 2007; Assistant Secretary for Planning and Evaluation [ASPE], 2008).

Proportionately few eligible families use subsidies, and the length of time that children are enrolled tends to be short. In 2005, estimates suggested that only 2.43 million (29%) of the 8.23 million eligible children ages 0 to 12 received subsidized care (ASPE, 2008). By 2011, 22 states had waiting lists for childcare assistance, although it is important to note that states with waiting lists typically have more generous eligibility guidelines than states without waiting lists (Schulman & Blank, 2011). Periods of subsidy receipt tend to be quite short, often less than 6 months (Ha & Meyer, 2010; Meyers et al., 2002). Reentry into subsidy programs was also common; with large proportions of children who exit the subsidy system returning within 12 months.

Use of childcare subsidies has been associated with the use of slightly higher-quality care, but not with improved child outcomes. Use of subsidies was related to increased use of center care, and thereby increased overall quality of care because, on average, the quality of ECE was higher in center care than in home-based care (A. D. Johnson, Martin, & Brooks-Gunn, 2013). However, subsidy receipt has not been linked to higher levels of school readiness skills, and some evidence exists that skill levels may be lower (Herbst & Tekin, 2010; A. D. Johnson et al., 2013).

## Summary

The ability of ECE to prepare children for school and to improve the school readiness of children who are economically disadvantaged has led to a wide variety of public policies focused on increasing access to ECE and to improving ECE quality. Publicly funded programs like prekindergarten and Head Start have provided higher-quality center care for children, often from low-income families, and evaluations suggest short-term effects on children and families. While long-term effects on academic skills are not observed, differences in other important long-term outcomes are found such as lower levels of special education placement, higher levels of educational attainment and earnings, and lower levels of crime. Why such important long-run effects are found is not clear, though some suggest that program impacts on executive functioning and social adjustment may be part of the explanation.

Overall, research has shifted from investigating whether and how childcare affects children to identifying

professional development and classroom practices that increase ECE effectiveness. Recent studies of specific teaching practices, curricula, child progress monitoring tools, and professional development are yielding information about how to create ECE systems and settings that support children's development and family needs. To address these questions, studies must include rigorous designs, adequate sample sizes, successful implementation of targeted practices and instruction, as well as child assessments that are likely to be affected by the changes in practices and instruction. Developing effective programs, however, is hard because the ECE workforce often works long hours for low salaries, this often results in workers with low levels of education and high rates of job turnover. Sometimes, these circumstances make implementing complex interventions quite challenging.

Overall, there is growing evidence that curricula and PD that are intensive, focused, and sequential can have positive impacts on ECE instruction and on children's learning. In addition, PD that involves either focused training aligned with a specific set of practices or curriculum and PD that involves professional learning communities have been proven effective in improving quality, and in some case, child outcomes. Public policies have evolved that focus on ensuring that providers meet basic health and safety benchmarks, improving quality of care (QRIS), and encouraging parental employment (childcare tax credits and subsidies). Not surprisingly, there is only limited overlap among all of these initiatives, and mixed evidence regarding the effectiveness of these policies.

## CONCLUSIONS

The developmental questions examined by ECE researchers have transformed over the past 50 years from questions about whether ECE is good or bad to a focus on identifying and promoting practices that promote developmental skills. Most children in many countries, often beginning in the first or second year, experience nonparental care. Although some types of ECE (e.g., high-quality intervention or prekindergarten programs) have large positive impacts on children's early language and academic skills, much of the ECE research documents modest associations in studies that use rigorous methods to account for potential confounds associated with parental selection of care. Accordingly, the focus of much of the ECE research has shifted from investigating whether ECE programs are linked with children's developmental outcomes to trying

to better understand how programs and care settings can be changed to improve outcomes for children.

Several overarching conclusions can be drawn from the extensive ECE literature examining immediate and long-term impacts of ECE type, quality, and quantity. Accumulated research demonstrates that high-quality ECE and center-based ECE improve the likelihood that children succeed in school, especially vulnerable children. Although ECE tends to have smaller effects than many family characteristics on early development, good-quality ECE has the potential to promote positive outcomes for all children, and serve as a protective factor for DLL children or children who experience social risk factors such as poverty. Long hours of childcare early in life may increase problem behaviors, at least for middle-class children, perhaps due to impacts of exposure to large peer groups on the young child's stress response.

Currently, research is focused on understanding heterogeneity in the effects of ECE, including what ECE experiences are beneficial (or harmful) for which children and under what specific circumstances. This important work is complicated by the need for large data collection efforts, with both large sample sizes and detailed measurements, in order to detect differences across groups of caregivers and children as well as across a variety of ECE dimensions. Attention to the role of specific teaching practices, curricula, child progress monitoring, and professional development is yielding information about how to create ECE systems and settings that support children's development and family needs. Program development and research efforts are also increasingly incorporating insights about the feasibility of program implementation, and taking the relatively low wages and education of the workforce into account. However, past efforts suggest that it can be difficult to improve quality and to maintain those improvements over time.

Historically, public policy has focused on ensuring the safety of children in ECE settings and increasing access for low-income children to early education programs and other forms of childcare if their parents are working. More recently, the recognition of early learning as an important foundation for all children has led to the expansion of investing in early education (prekindergarten programs), and efforts to improve the overall quality of care that children experience (QRIS). Many, though not all, of these policies and investments have led to descriptive and evaluative research projects that have been used to better understand how these efforts have affected communities, ECE settings, and children. These research efforts,

especially those focused on increasing ECE quality as a means to improve child outcomes, suggest that more attention needs to be paid to identifying specific practices that promote early development. An iterative process, in which research findings inform policy and programmatic responses, and then studying new efforts has the potential to build ECE systems and programs that better serve family and children's diverse needs and promote children's early learning.

## CHAPTER 7

# Children at School

ROBERT CROSNOE and APRILE D. BENNER

<b>INTRODUCTION</b>	268
<b>KEY THEORIES AND RESEARCH THEMES</b>	269
<b>Role of Schools in Developmental Theory</b>	269
<b>Significance of Schooling in the Short and Long Term</b>	271
<b>The Link Between Education and Inequality</b>	272
<b>Connecting School Effects and Disparities</b>	275
<b>Schools as Educational Institutions</b>	275
<b>Academic Outcomes</b>	276
<b>School Structure</b>	278
<b>School Composition</b>	280

## INTRODUCTION

Over three decades ago, a book by British researchers laid out the powerful role of schools in the life course. Its title, *Fifteen Thousand Hours* (Rutter, Maughan, Mortimer, & Ouston, 1979), refers to the sheer amount of time young people spend in school and in school-related activities over the course of childhood and adolescence, the point being that schools dominate the daily lives of youth in ways that give schools extraordinary power to shape child development. Although school time varies by stage of schooling and across countries, this point is remarkably generalizable. School is a dominant setting of the developmental ecology, and, as such, a major component of the organizational structure of society. What goes on in schools, therefore, influences the short- and long-term outcomes of

children and youth and, in the process, affects the stability, composition, and productivity of the population at large (J. Coleman, 1961; Crosnoe, 2011; L. D. Steinberg, Brown, & Dornbusch, 1996).

Given the wide-ranging significance of schools, the inner workings of schools and their effects on young people have long been subjects of social and behavioral research. This literature is interdisciplinary, cutting across psychology, sociology, economics, anthropology, educational science, and other fields, and developmental science has been well represented in school research. Together this foundation of theory and empirical evidence connects the macrostructures of the educational system to the microprocesses of learning and cognition and the complex layers in between (Arum, 2000; Eccles & Wigfield, 2002; Winne & Nesbit, 2010). The breadth of research on schools is evidenced in the representation of schooling-related topics in journals across disciplines, the centrality of schools to theories of child development, and the frequent focus on schools in translational research. Indeed, schools are such key parts of youth-focused policy in many countries that elucidating educational processes and impacts is one venue

The authors acknowledge the support of grants from the William T. Grant Foundation to each, as well as from the Eunice Kennedy Shriver National Institute of Child Health and Human Development (R24 HD42849, PI: Mark Hayward), and thank Chelsea Smith and Lauren McCarty Tonsi for the help with this review.

through which developmental researchers influence practice. Such research-policy connections surround numerous issues about children and youth, including school size, preschool investment, desegregation, reading instruction pedagogies, and STEM (science, technology, engineering, and mathematics) education. The importance of a careful account of school contexts is crucial to many actions taken to improve the lives of young people (Crosnoe, 2011).

Given the breadth of research on schools and related policy, any handbook chapter titled “Children at School” has enormous ground to cover. We cannot cover everything here and have to be more strategic. We start with the big picture: What are the general theoretical orientations toward schools in developmental science and what is the basic role of schools in the lives of young people and in the functioning of society? Working from this foundation, we then discuss two different but related sides of school: (1) schools as educational institutions, tapping into the formal, educational side of schooling involving processes of instruction and learning as a means of shaping students’ future socioeconomic prospects, and (2) schools as social contexts, tapping into the informal, socioemotional side of schooling involving interpersonal and psychological processes as a means of shaping students’ general well-being. In the process, we focus on the inputs of each side (e.g., what is occurring in schools and in interactions between children and schools) and also cover the outputs (e.g., what happens to children as a function of schooling). After sketching out these sides of schooling, we turn to concrete examples of how the two come together in the lives of young people, in terms of research insights and major policy interventions. The purpose is to demonstrate how the two sides of schooling are theoretically and practically meaningful in their own right but also difficult to disentangle in reality.

Moving through these four stages (big picture, schools as educational institutions, schools as social contexts, linking the two sides of schooling), we delve into fundamentals of the broad topic of schooling, such as student achievement, engagement, and attainment as well as school structure, composition, and climate. Many controversial issues will be addressed, such as school choice (e.g., vouchers, charter schools). Unfortunately, some important and timely topics will not get their due—such as disabilities and home schooling—simply because our space is constrained. For the same reason, we concentrate on U.S.-based research, although we bring in international research for key comparisons and contrasts. We also focus primarily on contemporary research, especially from the time since the sixth edition of the *Handbook* was published. The bottom line is

that we have tried to choose the topics that represent many different areas and interests.

## KEY THEORIES AND RESEARCH THEMES

A good way to set the stage is to sketch out how developmental scientists tend to think about schools and their role in the life course. We can then integrate the insights gleaned from such developmental perspectives with those from other disciplinary perspectives. Doing so makes the case for an affirmative answer to the fundamental question of this chapter: Do schools matter? We then delve into the question of *how* schools matter.

### Role of Schools in Developmental Theory

Theories of education abound, and several educational theories are explicitly developmental. For example, Eccles and colleagues have articulated, tested, and refined the expectancy-value model, which theorizes that achievement is grounded in the expectations that young people develop about their chances for success as well as how much they come to value that success (Eccles & Wigfield, 2002). Another example is the frog pond perspective, a variant of social comparison theory concerning the development of academic self-concept. It contends that young people evaluate themselves relative to their school and classroom peers regardless of how those peers compare to the larger educational system. As a result, children can come to see themselves as academically capable even if they are not so long as they do better than the children around them (Marsh & Hau, 2003).

Of greater concern here is the treatment of schools in more general developmental theory, not just in explicitly educational perspectives. Many models of development implicitly and explicitly incorporate schools. Typically, these models are contextually focused and emphasize environmental influences on developmental processes and, as such, offer a way to bring in schools even if they are not about schools or education per se.

For the most part, these theoretical models can be grouped within the “family” of theories—or a metatheory—generally referred to as relational developmental systems perspectives (Lerner, Lewin-Bizan, & Warren, 2010; Overton & Molenaar, Chapter 1, this *Handbook*, Volume 1). In contrast to predominant theories of development in decades past, relational developmental systems perspectives eschew false dichotomies between different facets

of development (or components of developmental ecology), deemphasize underlying assumptions of uniformity and permanence, and stress issues of diversity and dynamic change. The core unit of analysis is the mutual influence between individual and context, highlighting transactions across all levels of developmental organization inside and outside the individual. Importantly, the focus in relational developmental systems perspectives on plasticity, diversity, and historical embeddedness facilitates the translation between research and practice, as it suggests the potential for internal and external change that can be targeted by prevention, intervention and policy to promote positive development and reduce developmental disparities.

Schools fit well into the general approach of relational developmental systems perspectives. In this approach, the school is an institutional system in which the child is embedded, one that can be internally divided into subsystems (e.g., classrooms), is itself embedded within larger systems (e.g., community, policy), overlaps with more interpersonal systems in which children are also embedded (e.g., peer networks), and interacts with social systems to which children are exposed through their parents (e.g., work). Moreover, two children will likely experience even the same complex interactions among external systems in divergent ways if their internal systems (e.g., genetic capacities for learning, self-regulating capacities, attributional biases) differ and interact with each other in different ways (Lerner, Dowling, & Chaudhuri, 2004). Significantly, the school-related insights of this approach are useful for identifying and unpacking risk statuses in the educational system, thereby informing prevention and intervention efforts (Pianta & Walsh, 1996).

Having discussed the place of schools in relational developmental systems perspectives, we want to illustrate their relevance to specific examples of relational developmental systems perspectives: the bioecological model and the life course paradigm.

First, perhaps the most prominent example of a relational developmental systems perspective that allows for broader consideration of schools in general development is the bioecological model of development (Bronfenbrenner & Morris, 2006). Its main point is that development occurs within a web of overlapping contexts—the developmental ecology—that children are influenced by but also help to construct in a complex dynamic by which environmental and child (e.g., genetic, dispositional) characteristics interact. This model highlights various systems within the developmental ecology, all of which are frequently used to

motivate research on schools. The microsystem involves the direct influences of context on children, the mesosystem the interactive influences of multiple microsystems on children, and the macrosystem more distal contexts that influence children indirectly or interactively. Schools represent a microsystem—where children attend school and what happens to them there factors into their adjustment and functioning, including their learning but also more general behaviors (J. S. Hong & Garbarino, 2012). At the same time, schools are part of mesosystem interactions with other microsystems. For example, the importance of schools in children's development depends in part on what is happening within peer groups in school, in the homes of the children attending the school, and in the communities in which the schools are embedded (Christenson, 2003; Ryan, 2001). Schools are also concrete physical sites of the more diffuse institutional system of education that reaches across society and apportions opportunities, influences culture, and stratifies groups. In this sense, schools also represent a macrosystem (Arum, 2000; Morgan, 2005). Indeed, conceptualizing the developmental ecology of children in the United States (or most other countries) without ample attention to the multidimensional significance of schools is not possible.

Second, the life course perspective also emphasizes the developmental significance of context, but it goes further to consider macrolevel conceptions of context and to link individual developmental timing to societal historical timing (Elder, 1998). Like other relational developmental systems perspectives, however, its basic principles are especially relevant to thinking about the role of schools in children's lives. The central imagery of the perspective is of the life course as a tapestry of threads woven together over time and within context. Primary threads are developmental trajectories (unfolding patterns of physical and psychological growth and maturation), social convoys (continuity and change matrices of relationships and ties), and social pathways (sequences of institutional and organizational roles entered into and exited from over time). These dynamic threads are internally structured by transitions in role, stage, and setting that represent potential turning points. Moreover, context can range from the proximate settings of everyday life to abstract conceptions of social structure and history (Crosnoe & Johnson, 2011). One can think of the "educational life course," consisting of interactions among developing cognitive capacities within children (developmental trajectories), interpersonal ties with teachers and peers (social convoys), and school roles that children undertake (social pathways) as they transition

across grades and acquire credentials that mark changing statuses and settings of schooling. These interactions occur within particular contexts organized by schools and larger policymaking arenas (Benner, Graham, & Mistry, 2008; Langenkamp, 2010). The life course perspective has been particularly valuable in considering how developmental and ecological experiences are linked to inequality. It has been used to demonstrate how disparities (e.g., ethnic, socioeconomic) between segments of the child population build over time as they are acted on by schools (Entwisle, Alexander, & Olson, 2005).

This discussion of relational developmental systems perspectives in general and specific examples of such perspectives demonstrates some basic similarities in how schools tend to be treated in developmental models. It also reveals the special insights that can be gleaned by approaching schools in different ways depending on the questions of interest.

### **Significance of Schooling in the Short and Long Term**

The prominence of schooling in many developmental theories reflects the importance of schooling in the life course. Schools can have an enormous impact on how children turn out and their prospects for the future (Entwisle et al., 2005). Thus, theory reflects reality. The bulk of this chapter concerns the period in which children and youth attend school, focusing on how they are affected by what happens to them in the short term as a result of concurrent schooling experiences. Yet, although the length of the educational career is usually quite long for young people in developed countries, it is still many years and even decades shorter than the portion of their lives that unfold after the educational career is over. Thus, the long-term implications of schooling also need to be addressed.

In public discussions, the long-run impact of schooling is often conveyed in terms of “returns”—what do young people get over the course of their lives for the time, effort, and expense they put into their schooling? Return is an economic concept, but it translates well across disciplines. At the most basic level, returns to schooling refer to the increase in lifetime earnings associated with receiving a certain educational credential compared to receiving a lower-level credential (Goldin & Katz, 2008). For example, the earnings premium of receiving a bachelor’s degree (vs. a high school diploma) in the United States has increased rapidly over the past several decades, and it is now at an all-time high (Bureau of Labor Statistics, 2012). This change

has resulted from the restructuring of the global economy and its effects on the U.S. labor market. Historically, the labor market had a pyramid shape, with high-skilled, well-paying jobs at the top, low-skilled, unstable jobs at the bottom, and a solid stratum of secure jobs with benefits and opportunities for mobility in the middle. The decline of the manufacturing sector of the economy since the 1960s has hollowed out the middle, leaving an hourglass-shaped labor market in which advanced educational training and credentials are the primary means of pushing through the bottleneck (Fischer & Hout, 2006). Thus, matriculating at and graduating from a 4-year college has never brought greater returns than it does now, even in the context of the Great Recession (Grusky, Western, & Wimer, 2011). Such earnings premiums help connect the educational careers of individual youth to much broader social, economic, and historical forces. In light of these returns, the classroom and school experiences of children in the educational system right now can have effects on their lives long after they have left the system by contributing to the ultimate level of education and occupational status they attain.

Yet, considering the returns to schooling solely in financial or economic terms is too narrow. The general idea extends to many other domains of adjustment and functioning. Strikingly, educational attainment is powerfully related to mortality (Miech, Pampel, Kim, & Rogers, 2011). The more education one attains, the longer one lives. Although partially explained by the known and unknown factors that affect both educational attainment and life expectancy (including genetic predispositions and other heritable traits), this association seems to be at least partly causal. Moreover, it tends to grow stronger in both historical time (i.e., across cohorts) and developmental time (i.e., with age). It is rooted in aforementioned socioeconomic benefits of educational attainment but also in social, cultural, and cognitive resources that education cultivates (Lynch, 2003). For example, education tends to broaden social networks, which provide larger and more diverse pools of social support, and it enhances critical thinking skills that allow for better decision-making about health and health behaviors (Mirowsky & Ross, 2003). Moving beyond health, educational attainment is strongly related to family formation. Marriage and divorce rates vary widely by educational attainment, with college graduates overwhelmingly more likely to get and stay married than their counterparts with lower levels of education (Musick, Brand, & Davis, 2012; Schoen & Cheng, 2006). College graduates also have fewer children on average

but are much more likely to have children inside the confines of marriage (Cherlin, 2009). Again, these returns to educational attainment indicate that classroom and school experiences can have cascading effects if they contribute to how much education young people ultimately attain.

Importantly, the degree to which education shapes these varied dimensions of life course functioning then circles back around to affect children. According to the diverging destinies argument of McLanahan (2004), the increased coupling of educational attainment with economic status, marriage, and health among parents means that some children have more advantages growing up than others, including advantages meted out in their own educational careers. Such advantages are magnified by the greater tendency for more educated parents to engage in developmentally appropriate parenting practices, actively manage their children's opportunities, and advocate for their children in school (Hill & Tyson, 2009; Kalil, Ryan, & Corey, 2012; Lareau, 2003). Thus, the long-term implications of educational attainment are intergenerational.

The degree to which short-term experiences in school have long-term implications for the life course speaks to the need to carefully consider issues of timing in both theory and practice. Essentially, school effects on development appear to accumulate over time in interaction with children's genetically influenced traits and abilities and their developing skills and characteristics. Yet, this accumulation may not be strictly linear, with discontinuous bursts of progress (and disparities) at certain points. Consequently, interventions may create more change when they target early periods in the accumulation process, an argument borne out by econometric evaluations of early childhood education programs. This work suggests that early interventions have more payoff in the long run than those targeting later stages of development and schooling (Heckman, 2006). At the same time, later interventions may increase their effectiveness by targeting critical periods—even if action is taken “late,” it may succeed if it is strategically targeted. As will be covered later in this chapter, transitions between school levels represent one type of critical period. For example, given what researchers know about academic and social disruptions during the transition from middle school to high school, interventions aiming to reduce some academic or social issue targeting adolescents who are making this transition may be more effective than interventions targeting adolescents more generally, as certain social experiences may place adolescents at particular risk (Benner & Graham, 2009).

## The Link Between Education and Inequality

The importance of schooling is not limited to the individual life course. Schooling is also a key component of societal organization. How schooling unfolds in any society both reflects and shapes the economic, political, and social context of that society. One striking example of how the schooling of individual children is linked to the larger social structure is inequality. Schooling is shaped by the unequal statuses and opportunities tied to ethnicity, class, immigration, and gender, and it contributes to this stratification. To use Bronfenbrenner's terminology, schooling creates two-way exchanges between microsystems and macrosystems.

Beginning with the release of the Coleman Report in 1966 (J. S. Coleman et al., 1996), much of the discussion about the role of schools in *ethnic inequality* has concentrated on differences between schools serving predominantly European American populations and those serving predominantly minority populations. The segregation of ethnicities into separate schools long after the Brown decision in 1954 has been a major concern, and attention has slowly shifted from the traditional European American/African American divide to the segregation of a variety of ethnic and immigrant groups (P. R. Goldsmith, 2009; Reardon, Grewal, Kalogrides, & Greenberg, 2012). One reason that persistent segregation is problematic is that it tends to go along with stark disparities in resources. In a segregated system, European American and non-European American children simply do not receive the same quality of schooling because of differences between their schools in funding, teacher turnover, materials, and other factors (Rothstein, 2004; Schofield, 1995). Yet, one argument of the Coleman Report was that between-school resource differences did not explain away ethnic achievement gaps. Instead, between-school differences in climate needed to be taken into account. Developmentalists have contributed a great deal to this enterprise, exploring dimensions of climate such as intergenerational support, feelings of connectedness among students, and achievement values and how they encourage positive outcomes and reduce ethnic achievement gaps (Cook, Murphy, & Hunt, 2000; Graham & Juvonen, 2002; M. K. Johnson, Crosnoe, & Elder, 2001; L. D. Steinberg et al., 1996).

Despite the heavy focus on between-school differences in research and policy on the role of schools in ethnic inequality, within-school processes have also been examined and debated. Three provocative debates have concerned ethnic differences in peer influences, stereotype

threat, and identity development. First, the oppositional culture thesis contends that African American and Latino/a American peer contexts equate academic achievement with “acting White,” thereby disincentivizing achievement. Empirical support for this thesis, however, is weak. Moreover, some qualitative studies have argued that, when such academic denigration does occur, it is not ethnic in nature (Harris, 2006; Tyson, Darity, & Castellino, 2005). Second, stereotype threat refers to the ways in which youth can be negatively affected by their perceptions about how others see members of their own ethnic group, regardless of whether they accept or reject these views. Simply knowing that negative stereotypes about the academic abilities of one’s ethnicity are out there in the world can disrupt concentration and confidence in academic tasks by creating a fear of fulfilling those stereotypes. Although criticized for seemingly blaming the victim, the theory actually demonstrates how insidious prejudice can be (Blascovich, Spencer, Quinn, & Steele, 2001; McKown & Strambler, 2009). Third, ethnic identity concerns the meaning attached to ethnicity within individuals’ overall senses of self. Evidence suggests that strong ethnic identities—characterized by salience, centrality, regard, and positive ideology—promote positive outcomes among youth from traditionally disadvantaged groups (Seaton, Sellers, & Scottham, 2006; Umaña-Taylor, Gonzales-Backen, & Guimond, 2009). Importantly, such identity development and related attitudes about ethnicity are influenced by schools in the form of ethnic diversity, positive ethnic relations, and prodiversity curricula (Graham & Juvonen, 2002; Pfeifer, Brown, & Juvonen, 2007). These examples illustrate how the link between ethnicity and schooling goes beyond the tendency for members of different groups to attend different schools.

Although between- and within-school differences have been central to research and theory on *socioeconomic inequality* in the United States (Rothstein, 2004), this literature has also highlighted out-of-school settings as factors in socioeconomic disparities in in-school behavior. The focus has been on context more than psychological or emotional processes. Research on community contexts has established how the prevalence of socioeconomically advantaged or disadvantaged residents in a neighborhood can shape networks of information, support, and assistance available to children as they navigate the educational system, how crime and disorganization in neighborhoods can interfere with schooling, and how a community’s characteristics can shape the effectiveness of its schools (Briggs, 2003; Leventhal & Brooks-Gunn, 2000). Tellingly,

one large theoretically grounded research-based policy program—Moving to Opportunity, in which low-income families were given vouchers to relocate from high poverty to low poverty neighborhoods—had disappointing results in terms of child outcomes in part because changing school contexts was not emphasized as much as changing neighborhood contexts (Kling, Liebman, & Katz, 2007). Community and school processes can be difficult to disentangle, especially when trying to explain and address socioeconomic disparities in educational outcomes (Clampet-Lundquist, Edin, Kling, & Duncan, 2011; DeLuca & Dayton, 2009).

The families living within neighborhoods, rather than the neighborhoods themselves, have more often been the major subject of research on socioeconomic inequality, out-of-school contexts, and in-school performance (Bradley & Corwyn, 2002). Drawing on Elder’s pioneering study of the Great Depression (1974) as well as investment models from economics (Conger & Donnellan, 2007), the family process model exemplifies how developmental researchers have viewed the family context as a mechanism of socioeconomic disparities in child outcomes. This model posits that the effects of socioeconomic disadvantage on schooling are filtered through intrafamily dynamics. Poverty and economic stress influence parents’ functioning and relationships, which affect their parenting behavior and how they manage their children’s learning and education (e.g., disciplinary styles, sensitivity), which, in turn, affect children’s academic functioning (Crosnoe & Cooper, 2010; Davis-Kean, 2005; Mistry, Biesanz, Taylor, Burchinal, & Cox, 2004; Raver, Gershoff, & Aber, 2007). Echoes of the family process model can be found in other theoretical approaches outside of developmental psychology, such as the concerted cultivation thesis of Lareau (2003). Unlike the family process model, this thesis focuses on the advantages of high socioeconomic status. It contends that the rituals, norms, and philosophies that develop as a function of families’ long-term positions in the class hierarchy of the United States stratify children’s educational prospects. Socioeconomically advantaged parents internalize and practice concerted cultivation, which involves their active orchestration of children’s skills, talents, and opportunities for achievement through formal activities, active advocacy at school, and socialization into reason-based discussions. Through such cultivation, they and their children demand investments from schools that give them a competitive edge academically. The basic insights Lareau (2003) gleaned from her intensive ethnographic work have been replicated in quantitative studies (Cheadle, 2008).

These parenting-focused approaches have been criticized for ignoring institutional and structural forces, but they shine a light on how parents are rewarded or victimized by the socioeconomic stratification system in ways that they then pass on to their children.

Another angle on the role of families and schools in socioeconomic disparities in educational progress concerns the summer learning gap. This gap refers to group differences in learning and skill development that occur during the summer months compared to during the school year. The importance of these differences is that any summer gap is not strongly a function of school contexts and, is therefore, more difficult to target through traditional educational policies (Alexander, Entwisle, & Olson, 2007). Ample research, primarily occurring outside of psychology, has explored the summer learning gap. The consensus is that, once children have entered formal schooling, much of the growth in socioeconomic disparities in academic achievement occurs during summer. The same is not true of ethnic disparities, which tend to widen during the school year and the summer months reflecting stronger differential treatment in schools related to ethnicity than socioeconomic status. This socioeconomic phenomenon reflects many of the family processes discussed above, speaks to the equalizing role of schools, and suggests policy interventions targeting schools (e.g., extending school years), families (e.g., building family-school partnerships), and communities (e.g., programs for continued stimulation outside of schools; Burkam, Ready, Lee, & LoGerfo, 2004; Condon, 2009; Downey, von Hippel, & Hughes, 2008).

One form of stratification that connects ethnicity and socioeconomic status involves disparities in schooling related to immigration. Interest in immigration-related disparities has grown as the size and heterogeneity of the immigrant population have increased in the aftermath of the reform of federal U.S. immigration laws in the 1960s (Kao, 2004). In many ways, immigrants would appear to be disadvantaged in U.S. schools. On average, they are more likely than their peers to come from poor families with less-educated parents. Language barriers among immigrant children can interfere with learning, and language barriers among immigrant parents can interfere with their ability to interact with schools in support of their children. Most immigrants are members of minority ethnic groups and, as such, are likely subject to overt and more-subtle discrimination in schools as well (Benner & Graham, 2011). Moreover, strong anti-immigration rhetoric has become more common in political debates and public discussions (García Coll & Marks, 2009).

Such factors suggest that the children of immigrants should perform poorly in U.S. schools, but that is not the case in general. In secondary school, evidence points to an immigrant paradox, in which children with immigrant parents score or rate higher than their peers with native-born parents in school completion, grade point average, test scores, and other academic factors, especially when their generally more disadvantaged socioeconomic circumstances are taken into account (Glick & White, 2003; Hao & Woo, 2012; Pong & Hao, 2007). The evidence of an immigrant paradox is less consistent at the beginning of formal schooling. In many ethnic groups, the children of immigrants enter school with less-developed math and reading skills and have lower levels of achievement in the first few years of school. Yet, as they move through elementary school, they tend to catch up and even surpass peers with native-born parents (Crosnoe, 2006; Fuller et al., 2009; Glick & Hohmann-Marriott, 2007; Han, 2008; Reardon & Galindo, 2009). Of course, these patterns vary according to ethnicity and national origin, with Asian-origin children following the paradox pattern more closely than children of Latin American origins. Moreover, the discrepancy between secondary and elementary school patterns could reflect immigration-related biases in high school samples, as older immigrants are more likely to drop out or not even enter American schools in the first place (Han, 2008; Kao, 2004; Oropesa & Landale, 2009). Still, the weight of the evidence suggests that the children of immigrants, including many from poor ethnic minority families, are doing better than expected in U.S. schools. Similar trends also seem to be occurring in other developed countries with large immigrant populations from the developing world (Washbrook, Waldfogel, Bradbury, Corak, & Ghangro, 2012).

Compared to research on ethnic, socioeconomic, and immigration-related inequality in schooling, research exploring gender inequality in schooling has been more likely to focus on social psychological phenomena. For many years, most attention was on girls' disadvantages in school, especially in math and science, which forecasted lower prospects for educational and occupational attainment in adulthood (Hyde & Kling, 2001). One of many social psychological mechanisms explored to explain these disadvantages concerned girls' perceptions that math and science classrooms were inhospitable to them (Riegle-Crumb, Farkas, & Muller, 2006). Specifically, the idea was that girls thought that they were given subtle messages that they were unwanted and, consequently, avoided such classes. Much has been made about gender

differences in attribution styles, with girls attributing success to external causes and failure to internal causes and boys much less likely to change their perceptions of their academic abilities even when confronted by seemingly objective criteria (e.g., tests, grades) to the contrary. The same stereotype threats discussed earlier for ethnicity also have been applied to gender, with girls negatively affected by their awareness of stereotypes of girls being less capable in math and science than boys even if they reject the veracity of those stereotypes (Correll, 2001; Eccles, 2004; Huguet & Regner, 2007; Riegle-Crumb & Humphries, 2012). The conclusion that can be drawn from this rich literature is that the interaction between children and their proximate environments within broader cultural contexts with gendered messages about ability, skill, and interest can keep girls from realizing their academic potential.

Interestingly, concern is now shifting from girls to boys. This shift reflects the highly publicized pattern in which girls have surpassed boys academically. Girls earn higher grades and are more likely to graduate from high school, and they have overtaken boys in all levels of higher education (Buchmann, DiPrete, & McDaniel, 2008). Even within the highly gendered areas of math and science coursework during secondary school, girls have, at the very least, pulled even with boys (Shettle et al., 2007). As a result of girls' gaining advantage, the question of how boys are disadvantaged in schools is increasingly driving research and attracting policy interest. Much of this discussion has concerned the possibility that schools (especially elementary) are organized and run in ways that are better-suited socioemotionally to girls than boys. Examples include the emphases on self-control and passive learning, which are more in line with the childhood socialization of girls to be compliant and obedient. The tendency for grades to reflect nonachievement dimensions such as behavior and effort also may benefit girls. As is often pointed out, most teachers in the K–12 system are women, a factor important to the extent that their teaching might subtly and unconsciously favor girls (DiPrete & Jennings, 2012; Jacob, 2002; Legewie & DiPrete, 2012). Critiques of the shift in attention to boys have noted the continued gender segregation of areas of study in higher education, particularly in STEM disciplines, continued disparities in standardized test performance favoring boys, and the fact that the gender reversal in educational attainment has not greatly impacted the male advantage in earnings and advancement in the labor market (Buchmann et al., 2008). The reality is that gender stratification of the educational system is strong but also quite complex, working in

different ways for different areas of schooling and varying across stages of schooling.

Ethnicity, socioeconomic status, immigration, and gender disparities are visible representations of stratification in schooling recognized as problematic and targeted by policy. Moving into the new century, other forms of inequality in schooling are increasingly recognized, such as disparities related to sexual identity, obesity, and other bases of peer victimization and discrimination (Crosnoe, 2011; Russell & Sigler-Andrews, 2003). Although we do not delve deeply into these “new” dimensions of stratification, the growth of research related to them suggests that they will garner much attention in future volumes of this *Handbook*.

### Connecting School Effects and Disparities

Theoretically grounded research on the connections between schooling and young people and disparities in schooling processes and outcomes across diverse groups of youth can be organized in two broad ways. The first concerns formal educational processes, the concrete academic functions of schooling, and their implications for students and society. The second concerns informal educational processes, the social dynamics of schools and their socioemotional implications. In the sections that follow, we review research on schooling—including but not limited to developmentally oriented research—that falls under each of these two broad umbrellas before then discussing specific ways in which the two go together.

### Schools as Educational Institutions

The educational system is a societal institution with official and unofficial tasks. We discuss the latter in the next section and the former here. The explicit publicly sanctioned mission of schools is to deliver curricula to students in order to produce a skilled workforce capable of boosting economic productivity and an informed populace able to be civically engaged. Early architects of public schooling also espoused a common school philosophy, which holds that the education of children from diverse backgrounds in the same school could reduce tensions among groups and promote social and political stability (Labaree, 1997). The formal processes of schooling refer to the concrete inputs and outputs most closely linked to this official mission of educating young people. Broadly speaking, they include aspects of school and classroom organization that structure the academic careers of young people as they develop cognitive, intellectual, and work skills and accumulate the credentials

needed to enter the labor market and participate in civil society (Arum, 2000).

### Academic Outcomes

A focus of this chapter is on how schools work as settings of young people's lives. The ultimate barometer of how well they work is how they affect children's development in the present and future. Thus, before deconstructing schools as settings, some discussion of the outcomes influenced by such setting characteristics is in order. Given that this section of the chapter highlights the formal processes of schools as educational institutions, an overview of some key academic outcomes is a good place to start. The running theme is that these outcomes reflect the interplay of child and environment over time.

First, *learning* refers to the accumulation of cognitive and academic skills, or the gradual mastery of academic materials. Learning requires appropriate cognitive and intellectual capacities for handling the materials and tasks at hand as well as the commensurate effort, not to mention the skills and investment of the teacher or any other person guiding the learning activity (Connor, Morrison, & Katch, 2004; Pianta, Belsky, Houts, Morrison, & the NICHD Early Child Care Research Network, 2007; Siegler, Thompson, & Schneider, 2011). Learning is most often measured by scores on standardized tests. Although the stand-alone value of standardized tests can and should be debated, these tests provide a straightforward way of comparing students across diverse contexts as well as over time. As a result, they are a central focus of educational research and policy, as exemplified by the testing focus of the federal No Child Left Behind (NCLB) legislation (Darling-Hammond, 2006).

The National Assessment of Educational Progress (NAEP)—often referred to as the nation's report card—is a periodic nationally representative administration of tests to gauge learning in basic fields (e.g., math, science, reading) in specific grades. It allows tracking of test score performance among American children and youth over time as well as state-by-state comparisons. The over-time trends, for example, have shown improvement in basic academic skills for children over the last several decades, but less so for adolescents. State comparisons have been used to show that the assessments developed by individual states to meet NCLB assessment requirements vary widely in quality and rigor, as states with similar accountability ratings from NCLB often differ greatly in NAEP performance (National Center for Education Statistics, 2005, 2009). More globally, the Programme for

Individual Student Assessment (PISA) is a standardized test for adolescents in basic subjects, administered by the Organisation of Economic Co-operation and Development (OECD) across multiple countries. PISA results have shown that the United States has a mediocre ranking and, as a result, have spurred much talk about school reform in the United States (Peterson, Woessmann, Hanushek, & Lastra-Anadón, 2011). Finally, one of the most prominent standardized assessments of learning at the secondary level is the Scholastic Aptitude Test, a “gatekeeper” in college admissions in the United States (Ceci, Williams, & Barnett, 2009). Overall, achievement tests gauge where children and youth stand relative to others in the K–12 system in terms of their learning—school readiness on entry into the system, preparedness for higher education or work at the end of the system, and general progress at all points in between.

Second, *graded achievement* is closely related to learning but is broader in scope. It reflects mastery of tasks and materials but also other student and teacher considerations. As a result, it may not align with test scores, although the two are correlated. The value of test scores is that they support comparisons across diverse schools, whereas the value of grades is that they tap into success within a particular school environment. Grade point averages among U.S. students have risen in a more dramatic fashion than test scores, suggesting a change in the norms of grading not reflected in actual instruction and learning (Kelly, 2008; Riegle-Crumb & Humphries, 2012; U.S. Department of Education, 2005). High grades are tied to not only meeting teachers' expectations for academic behaviors and attitudes but also how much effort they exert in meeting these expectations. High grades also are influenced by nonacademic behaviors, with compliant, attentive, engaged, and warm students evaluated by teachers more positively than others (Johnson, McGue, & Iacono, 2005; Pace, 2003; Trautwein, Lüdtke, Marsh, Köller, & Baumert, 2006).

Because grades have a subjective element, they can be responsive to aspects of student-teacher relationships, such as ethnic- or gender matching. A seminal study by Alexander, Entwisle, and Thompson (1987) revealed how middle-class teachers were more likely to give poor minority students low marks than in other teacher-student dyads. Some experimental studies, however, have provided evidence of a positive bias, in which European American teachers are more likely to downplay poor work among minority students by offering greater praise and fewer critiques (Harber et al., 2012). Immigrant students' work habits are also more likely to be rated positively by teachers

than those of their native peers, differences in teacher perceptions that could affect grades (Crosnoe, 2006). Despite these potential behavioral and demographic biases, grades are a widely recognized, interpretable dimension of academic progress, and, importantly, they and closely related factors (e.g., class rank) predict college enrollment and persistence as well as labor market entry into adulthood (Alon & Tienda, 2007; Rosenbaum & Kariya, 1991; Zwick & Sklar, 2005).

Third, *coursework* is a marker of academic progress in secondary school. It is akin to tracking in the elementary and secondary school grades—in which students are placed in classes of specialized curricula and instruction based on perceived ability—in that it denotes position within an academic hierarchy and exposure to challenging material. Much has been written about tracking and ability grouping and their relations with student background on one hand and achievement on the other (Eccles & Roeser, 2011; Gamoran, 2011; Liem, Marsh, Martin, McInerney, & Yeung, 2012). Secondary school coursework is somewhat different. Technically, it is more voluntary, as students enroll (vs. being assigned), some courses are optional (i.e., can be taken as electives), and a much broader menu of courses is available. Moreover, courses are vertically hierarchical (i.e., building on each other from grade to grade in a sequence) in ways that make secondary coursework pathways more cumulative. In other words, any academic or nonacademic factor that influences course enrollment in any one year can have cascading effects. Unlike grades or test scores, the number of seats in classes is a finite commodity, so that coursework is a source of competition. Consequently, coursework is not only based on the skills and interests of youth but also the skills and interests of their schoolmates as a whole, which then set course offerings in a school as well as who is attempting to select into any given course. The combination of uncertainty about available options, limited supply, and the cumulative nature of coursework contributes to increasing ethnic and socioeconomic disparities over the course of high school (Crosnoe & Huston, 2007; McFarland, 2006; Morgan, 2005).

One example of the cumulative stratifying nature of secondary school coursework is math. Evidence from national studies has revealed a fairly standardized sequence of math course-taking in U.S. middle and high schools, with a hierarchy of courses from less to more advanced. Roughly, this sequence is: general math, pre-algebra, algebra, geometry, algebra II, advanced math (e.g., statistics), precalculus, and calculus. In most states, high school students are required to take 3 years of math, which can be accomplished by

taking low- to medium-range courses (e.g., algebra I, geometry). The students who go beyond minimum requirements to take more demanding courses (e.g., calculus) are accruing more tangibly elite academic credentials while also developing more advanced skills. These credentials and skills then increase the likelihood of college matriculation and persistence, which is why they engender a great deal of competition within the student body (Adelman, 2006; Riegle-Crumb & King, 2010; Schneider, Kirst, & Hess, 2003). Coursework in math, science, and other areas, therefore, reflects and supports achievement and is a marker of both engagement and inequality.

Fourth, *attainment*—how much education one ultimately accrues—is the most basic summary measure of the educational career. Although a crude measure, the number of years in school is a commonly used metric of attainment with a surprisingly robust power to predict long-term outcomes in a variety of domains from occupational attainment to health and mortality (Hauser & Koenig, 2011; Mirowsky & Ross, 2003). A finer-grained approach to educational attainment considers the actual degrees attained; for example, a high school diploma, bachelor's degree, or advanced degree (e.g., master's, doctorate). Degrees are concrete markers that signify to others, such as potential employers and even prospective mates and spouses, perceived differences in skill, competence, and value. Thus, degree attainment can differentiate two individuals who have the same years of schooling and even the same skill level. The earnings premium of a college degree compared to a high school diploma discussed earlier is an example of the importance of degree attainment (Attewell & Domina, 2011; Goldin & Katz, 2008; Warren, Grodsky, & Lee, 2008).

One key dimension of educational attainment is high school dropout. Historically, dropout has been one of the most oft-studied markers of student performance, given its connection to student background as well as the long-term disadvantages that dropouts face (Rumberger, 1987). Furthermore, it is often used as a marker of school performance, especially in light of NCLB requirements that hold schools accountable for their graduation rates and recognize the “push” role of schools in some students exiting the system without a diploma (Jimerson, Reschly, & Hess, 2008). Evidence suggests that dropout is best thought of as a trajectory or sequence, with many personal, family, school, and other factors coming together over time to influence the actual dropout event. Effective prevention tends to recognize how this process works (Bloom, 2010; Finn & Zimmer, 2012).

Fifth, in contrast to the concrete indicators of academic progress discussed so far—indicators that come with fairly straightforward definitions and standard measurement strategies—*engagement* is a more psychosocial process, one that underlies these other indicators. Engagement is a broad term that encompasses many dimensions of how much students are connected to the processes and contexts of education (Newmann, Wehlage, & Lamborn, 1992). Young people can be behaviorally engaged in school, meaning that they are active participants in school and classroom activities, from signing up for school clubs to taking part in discussions with teachers and fellows students in class. They can be emotionally engaged, meaning that they have positive feelings about schooling. Such feelings can be about their schools (e.g., feeling a sense of belonging at school and acceptance by school peers) or about education more broadly (e.g., valuing education in and of itself). Cognitive engagement refers to the extent to which youth are willing to invest the time and energy needed for academic challenges (Fredricks, Blumenfeld, & Paris, 2004).

Academic achievement and educational attainment are assumed to be predicated on student engagement, in its varied forms, and problematic schooling outcomes (e.g., dropping out) are assumed to arise from disengagement. Thus, engagement is often a major part of discussions about how to intervene in the educational careers of students, especially those considered to be at risk (Finn & Zimmer, 2012). Yet, as the work of Eccles and colleagues (e.g., Eccles & Wigfield, 2002) has shown, the links between engagement and achievement are complex. Achievement can spur engagement, just as engagement lays the groundwork for achievement. Moreover, both arise from the interaction between students' own capacities, skills, and psychological orientations (e.g., motivation) with the norms, processes, and characteristics of their school contexts. Students are engaged when the tasks that they are charged with undertaking in their schools and classrooms are a good fit with their own abilities, values, goals, and expectations. The key is for students to be challenged enough to maintain their interest but not so much that they see these challenges as hopeless (Eccles & Wigfield, 2002). In this way, their approach to engagement aligns with the concept of flow, or the phenomenon in which individuals become completely absorbed in a task that offers just the right amount of challenge (Csikszentmihalyi & Schneider, 2000).

With these student outcomes most commonly linked to the formal processes of schooling having now been

described, we turn to the types of school settings that tend to promote the most positive outcomes. In doing so, special attention is paid to theoretically meaningful aspects of school context that also have a history as targets of policy intervention.

### School Structure

Structure refers to the physical and organizational setup of schools, including school and classroom size and sector (e.g., private, public). The structural characteristics of schools often have been viewed as the aspects of school context most amenable to external manipulation. The ways that schools are organized can be straightforwardly changed, albeit not always easily so. As a result, these school features represent a starting point for intervention, especially large-scale educational reforms. This applied importance of school structure has generated more theoretically oriented research attempting to understand why it matters to youth (J. S. Coleman, 1990).

Almost five decades ago, the Coleman Report (J. S. Coleman et al., 1966) generated an enormous amount of debate about school structures with its claim that the structure and funding of schools mattered less to achievement rates and ethnic disparities in those rates than the general culture of schools. This conclusion was repeatedly deconstructed by subsequent studies correcting some of the methodological limitations of the report, even some studies that used the same data but produced different results (Konstantopoulos & Borman, 2011). In short, the basic ways that schools are organized (and funded) matters to young people's outcomes, both directly and indirectly through climate and culture.

School and class size are two structural components of schools that have received a great deal of attention. These factors tap into important theoretical discussions about belongingness and also provide policymakers a concrete lever for intervention in the form of manipulating student enrollment and student-teacher ratios (Fouts, Baker, Brown, & Riley, 2006). In both theory and policy, *school size* has had a curious history, with support and action alternating between two camps. For many years, the economic organizational argument held sway. It contended that larger schools are desirable because they increase organizational efficiency and enable economies of scale. In short, large schools can pool resources, cut costs, and offer a more diverse curriculum than small schools. This argument supported school reforms like the consolidation of smaller schools into larger ones. Over time, an

ecological argument gained traction. It contended that small schools allow for a more personalized educational environment and greater sense of security by promoting connections among students and staff. They also enable a common curriculum that reduces educational disparities. This argument supported efforts to reduce school size and carve up large schools into schools-within-schools or academies. A middle ground has now been staked out in which medium-sized schools (e.g., 600–900 students) are viewed as balancing the economic efficiency of large schools with the social cohesion of small schools (V. E. Lee & Smith, 1997; Ready, Lee, & Welner, 2004).

Throughout this school size debate, the actual evidence for or against any one side has been mixed. Although some studies have shown that changes in school size are associated with changes in academic outcomes, these observed effects have been inconsistent, and large-scale policy efforts targeting school size (e.g., the Gates Foundation; see Fouts et al., 2006) have declined. Explanations for the lack of consistent success in the school size arena touch on numerous issues, including the tendency for even reduced-sized schools to remain large and findings that school size is not strongly implicated in actual classroom instruction (Iatarola, Schwartz, Stiefel, & Chellman, 2008; Supovitz, 2002). Perhaps the narrow focus on achievement (especially test scores) in discussions of school size also matters. Evidence of school size effects on a broader array of student outcomes, especially socioemotional adjustment, tends to be more positive and consistent. For example, youth have stronger attachments to school, participate in more school activities, and experience less isolation and peer victimization as school size decreases (Crosnoe, Johnson, & Elder, 2004b; Gottfredson & DiPrieto, 2011). Thus, school size may be a more important factor when discussing schools as developmental contexts, which we do shortly, than as educational institutions, which is our focus here.

*Class size* is related to but different from school size. After all, even large schools can have small classes if they have the necessary teacher capacity to staff more classes, and even small schools can have large classes if they do not. Over the years, class size has gained more attention, reflecting that classrooms are the most proximate sites of instruction. This attention has also been fueled by Project STAR (Student-Teacher Achievement Ratio). This randomized control trial in Tennessee revealed that reductions in elementary school class sizes led to moderate increases in achievement that, in the long run, brought significant returns to the initial investment (Mosteller,

1995; Nye, Hedges, & Konstantopoulos, 2000). Moreover, achievement gains increased with the number of years that children experienced smaller classes, indicating a cumulative learning boost from low student-teacher ratios over time (Finn, Gerber, & Boyd-Zaharias, 2005). Many socioemotional mechanisms often discussed in the school size debate are likely at work in observed effects of class size reduction, but the link between student-teacher ratio and classroom instruction also matters. Standardized assessments of elementary school classrooms by the NICHD Early Child Care Research Network (2004) have indicated that instruction in core subjects is of higher quality in small classrooms and that such classrooms are also characterized by more emotionally supportive interpersonal climates. Time sampling studies also have indicated that children are more active and engaged in small classrooms as opposed to larger ones (Blatchford, Bassett, & Brown, 2005). Although not entirely consistent and certainly not conclusive, the evidence suggests that small classrooms might be more positive learning environments for children. Less is known about how these patterns apply to adolescents in secondary school.

School and class size issues are often implicated in research on *school sector*, which refers to whether a school is private or public, with the former generally being smaller and having lower student-teacher ratios than the latter (Coleman & Hoffer, 1987). These features of private schools—along with their greater and more flexible funding, higher-quality teaching, less curricular differentiation, and other factors—are often used to explain why their levels of academic achievement are higher than public schools. This achievement difference, which extends well beyond the United States, is often cited as evidence of the need for voucher programs and methods of school choice that we discuss in a later section of this chapter (Dronkers & Robert, 2008; Lubienski, Weitzel, & Lubienski, 2009).

Of particular importance in such school sector comparisons is the subset of private schools operated by the Catholic Church. For some time, research has shown that students do better academically in Catholic schools than in public schools or non-Catholic private schools, especially ethnic minorities and poor students (Bryk, Lee, & Holland, 1993). Yet, this evidence has often been viewed skeptically, given the strong possibility that observed Catholic school effects reflect the characteristics of students who select into Catholic schools more than the superiority of Catholic school curriculum and instruction. This “selection” or “endogeneity” problem is relevant to the larger public versus private school comparison, with evidence suggesting that

the single biggest factor in the private school advantage is the composition of the student bodies of private schools more than what actually goes on academically inside them (Hallinan & Kubitschek, 2012; V. E. Lee & Ready, 2009; Morgan, 2001). Efforts to address such selection biases have suggested that at least some portion of the Catholic school effect is real, especially for the students who are least likely to be selecting into Catholic schools in the first place; in other words, a student-by-school interaction (Morgan, 2001). Whatever formal advantages Catholic schools have is likely rooted in their more constrained curriculum. In Catholic schools, all students typically take the same kinds of classes, are exposed to more challenging curricula, and receive higher-quality instruction than in the public schools (Carbonaro & Covay, 2010).

Related to the issue of school sector is the *school choice* debate. Choice refers to many issues subsumed under the general umbrella of “free market” approaches to schooling in the United States. The argument is that giving families more choice in where to send their children for school creates competition that ultimately improves the quality of public schools overall while also promoting the achievement of individual students, especially those from more disadvantaged backgrounds (DeLuca & Dayton, 2009).

Magnet schools, in which districts lift attendance restrictions and create specialized schools for applied entry, were the first wave of school choice. One school in a district might be focused on math and science and another focused on the arts, and students would have some latitude about which to attend. For the most part, magnet policies have not had consistent or large effects on student achievement, although they have helped to create more diverse student bodies by encouraging European American students to enroll in the predominantly minority schools where magnets are often purposely situated (Archbald, 2004; Smrekar, 2009). Attention has shifted toward voucher programs, in which low-income families or families served by low-performing schools are given vouchers to attend private schools. Vouchers have been hotly debated, seen by some as a means of spurring innovation in schools by creating outside competition and by others as a threat to public schools by siphoning off funding that could be used to improve them. Evaluations have generally revealed mixed results for academic outcomes (Cowen, Fleming, Witte, & Wolf, 2012; Hess & McGuinn, 2002). Charter elements represent a third aspect of school choice. Charter schools are publicly funded but freed from many regulatory constraints so that they can test potentially innovative approaches to schooling.

Again, although some charter schools (e.g., Knowledge is Power Program, or KIPP schools) have been high-profile successes, the overall impact of charter schools on formal educational outcomes has been highly variable (Angrist, Dynarski, Kane, Pathak, & Walters, 2010; Lubienski, 2003; Renzulli & Roscigno, 2005).

Overall, the sense of disconnect between the strong arguments advocating for various elements of school choice and the results of choice programs could reflect several factors. The achievement benefits of choice might be concentrated within specific segments of the population, defined by family background or student ability, rather than distributed more broadly (Bitler, Domina, & Penner, 2012). Student and teacher satisfaction and turnover also need to be taken into account (Cowen et al., 2012; Renzulli & Roscigno, 2005). Choice programs are often flashpoints of conflict and are deeply influenced by broader stratification processes in society. Ethnic and socioeconomic compositions of schools, for example, are often unspoken but powerful forces in how parents choose schools (Renzulli & Evans, 2005). In this way, school choice leads to the next general dimension of formal school organization: who attends a school, not just how that school is structured.

### School Composition

With whom a child attends school matters a great deal. Perhaps the most important factor is simply whether fellow students are academically oriented and high achieving, but the issue of school composition is much broader than those academic considerations alone (Hoxby & Weingarth, 2005). Going back to the common school philosophy, composition also taps into which kinds of groups are mixed together in schools. This sociodemographic dimension of school composition goes beyond matters of social justice to be relevant to the academic outcomes of individual students. In other words, its significance is not just about issues of equity and equality on the societal level but also about how individual youth learn. This aspect of school composition also speaks to important theoretical issues about peer influence and social context and underlies many contentious educational policy issues (Crosnoe, 2009; Hallinan & Kubitschek, 2012).

The *ethnic composition* of public schools has long been a source of conflict and focus of research. Worth stressing is that the common school philosophy driving the creation of public schooling in the United States did not extend to ethnic diversity. Indeed, early on, African Americans were barred from schools, and later on they were barred from

attending schools with European Americans (Labaree, 1997). Yet, ethnicity has been the dominant storyline of discussions of school composition for the past century. In terms of educational policy, two landmark Supreme Court cases serve as major historical markers. First, the 1954 *Brown v. Board of Education* decision ruled that ethnically segregated schools violated the Equal Protection clause of the U.S. Constitution, leading to decades of contentious policy actions to desegregate public schools. Such actions had a major impact on the diversity of public schools' student bodies, but, over time, schools have become more segregated again (Orfield & Lee, 2007). This "resegregation" results from a variety of forces, notably the movement of European Americans into suburban areas (Cottrol, Diamond, & Ware, 2003; Reardon et al., 2012). Second, the 2007 *Parents Involved* decision curtailed the consideration of ethnicity in the assignment of students to public schools, narrowly interpreting the appropriate circumstances for ethnicity to be taken into account and effectively ending large-scale programs of desegregation (Bazelon, 2008).

The reasons that these court cases and related policy actions are so important are evident in major themes of research on school composition. Ethnically segregated schools are problematic for instruction and learning, not only for ethnic minority youth but also European American youth (Schofield, 1995). On the most basic level is the fallacy of the separate-but-equal argument that ethnically segregated schooling is acceptable if the schools exclusively serving different groups are otherwise equal. In reality, segregated schools are not otherwise equal. In terms of curriculum, teaching, resources, and other formal processes, schools serving predominantly ethnic minority populations are well below schools serving predominantly European American populations. In this way, the ethnic composition of a school, beyond its socioeconomic composition, is a marker of opportunity, putting ethnic minority students at a learning disadvantage that has little to do with merit (Lleras, 2008).

Yet, the disadvantages of segregated schools are not just confined to organizational and curricular resources and are not solely experienced by minority youth. To the extent that ethnic diversity itself, regardless of resources, supports cognitive development and learning, then European American students also may be disadvantaged by attending segregated schools. The link between diversity and learning is rooted in developmental theory. For example, Piaget's (1983) concept of disequilibrium contends that intellectual capacities are enriched by encountering and then working

through contradictions and discrepancies in everyday life. In this sense, being exposed to diverse worldviews and life perspectives and sorting through knowledge about a range of life experiences provides opportunities to exercise cognitive capacities (P. Y. Gurin, Dey, Gurin, & Hurtado, 2003). This argument is directly relevant to school ethnic composition, in that diverse schools will provide more opportunities for such cognitive exercise. Indeed, studies indicate that students in diverse colleges have more experience critically analyzing their own assumptions about the world and their own lives than students in less diverse colleges and, as a result, are more engaged in the learning process and do better academically (P. Gurin, Dey, Hurtado, & Gurin, 2002). These benefits extend across ethnic groups but may be stronger among European Americans, who have far less exposure to diversity outside of school than ethnic minority youth. Studies of children attending diverse elementary schools echo these basic patterns (Benner & Crosnoe, 2011).

In this light, the resegregation of American schools presents new challenges about how to ensure equal learning opportunities for children and youth from different groups. These challenges are made even more complex by findings that the learning benefits of school ethnic diversity may come with socioemotional risks that undermine those learning benefits, such as less connectedness and belonging to school. In other words, the link between school ethnic composition and youth outcomes may differ when schools are approached as educational institutions or as developmental contexts. Consequently, we return to the topic of school ethnic composition in the section of this chapter that focuses on the intersection of formal and informal processes of schooling.

The *Parents Involved* ruling has helped to fuel the gradual shift in educational policy and school composition research from ethnic composition to *socioeconomic composition* (Clotfelter, Ladd, & Vigdor, 2005; Reardon, Yun, & Kurlaender, 2006). The same arguments about opportunity and the value of diversity in discussions of ethnic composition apply to socioeconomic composition. Moreover, much of the impact of ethnic composition on students is actually a result of socioeconomic composition, given the strong correlation between ethnic stratification and socioeconomic stratification in the United States. Thus, increasing socioeconomic diversity in schools could help to equalize opportunities to learn through many of the same processes discussed earlier for ethnic diversity, while still abiding by the *Parents Involved* decision and avoiding much of the contentiousness surrounding matters

of ethnicity in schools. Doing so would directly target the socioeconomic achievement gap, which is important in its own right, while indirectly targeting the ethnic achievement gap. This argument, which was highlighted in Parents Involved, has supported socioeconomic desegregation plans in multiple locales in the United States (Grant, 2009; Kahlenberg, 2001; Rothstein, 2004).

The socioeconomic composition of schools appears to be related to formal academic outcomes. In the United States as well as in other developed countries, students tend to test higher when exposed to more socioeconomically diverse peers at school. This pattern is most likely to be found in the case of children from low-income families attending schools with greater concentrations of middle-class students (Lee, Smith, & Croninger, 1997; Perry & McConney, 2010; Rumberger & Palardy, 2005; Willms, 2010). Part of this relation is due to the higher quality curricula and instruction, lower levels of teacher and student mobility, and broader extracurricular programs that children from socioeconomically disadvantaged families are exposed to in socioeconomically advantaged schools. It also reflects the supportive, entitled, and powerful parent and community networks that form around such schools, which have benefits that trickle down to all students regardless of their own socioeconomic circumstances (Coleman & Hoffer, 1987; Kahlenberg, 2001; Mayer, 2002). Much of the observed link between academics and school socioeconomic composition is interpreted through the lens of peer influence, highlighting how children from socioeconomically disadvantaged backgrounds can access academically valuable information, assistance, and role models by attending school with middle-class peers, whether or not they are friends with these peers (Crosnoe, 2009).

Selection biases, which we discussed in relation to school sector, are also relevant to understanding the apparent effects of school socioeconomic composition on the young people's academic outcomes. After all, given how socioeconomically segregated American schools are (Reardon et al., 2006), a child from a low-income family who attends a predominantly middle-class school is likely to be different than other children from low-income families in many ways. She or he may be intellectually or athletically gifted or have especially involved and agentic parents. Such qualities would then also lead to more positive academic outcomes regardless of school location. Because most of the evidence for school socioeconomic composition effects comes from survey data in national or community samples, selection biases have not been effectively ruled out, although the implementation of school desegregation

plans offers quasiexperimental opportunities that suggest that at least some of these effects are causal (Crosnoe, 2009; Plank, 2000). Another issue is that, like ethnic composition, some apparent risks arise when looking at school socioeconomic composition with an eye toward socioemotional functioning rather than academic achievement. This potentially offsetting nature of formal and informal processes in school composition will be discussed later in this chapter.

Ethnicity and socioeconomic status have dominated research and policy related to school composition for decades, but they are not the only dimensions of school composition that have gained the attention of researchers and policymakers. One increasingly prominent dimension concerns gender, either the creation of *single-sex* schools or creating single-sex classrooms within coeducational schools. Of course, private schools have long offered single-sex environments, but Title IX and later federal regulations gave states more freedom to experiment with such environments in the public school arena (Billger, 2009; Salomone, 2006). The arguments for single-sex schooling are rooted in concerns about the ways in which girls may be frozen out of academic opportunities based on lingering sexism among peers, parents, and teachers. They also reflect newer ideas about gender differences in learning driven by contemporary concerns about boys' underachievement in school relative to girls (Halpern et al., 2011). Some evidence suggests that single-sex (versus coeducational) schooling has positive effects, for example, in terms of girls' attitudes about math and science. Yet, other studies do not. Overall, the soundness of the evidence base (e.g., the degree to which observed effects are indeed causal) has been hotly debated in the United States and internationally (Billger, 2009; OECD, 2009; Shapka & Keating, 2003; U.S. Department of Education, 2005). Furthermore, critics have argued that single-sex schooling actually may be harmful, in that it could reify gendered ideas about learning and achievement and leave youth ill-prepared to function in a decidedly coeducational world (Halpern et al., 2011). The conflict over single-sex schooling is likely to intensify in the years to come.

### Curriculum and Instruction

Beyond the ways that schools are structured and who attends schools is the most fundamental formal activity of schools: instruction. Thus, one crucial way to characterize schools and to differentiate among schools is how classroom instruction is organized, in terms of packages of

instructional activities across classrooms (the curriculum) as well as student-teacher interactions within classrooms.

Issues of tracking and curricular differentiation already have been introduced in this chapter. Here, we focus on a specific dimension of these issues: the degree to which classes and courses are cognitively and intellectually challenging for young people. As already noted, many developmental perspectives on learning and achievement emphasize how *challenging coursework*—within realistic parameters—is an integral component of learning (Csikszentmihalyi & Schneider, 2000; Eccles & Wigfield, 2002). Indeed, youth tend to learn more and exert more effort in classes that cognitively challenge them, and schools in which the curriculum includes more academically advanced courses tend to have higher achievement levels and lower dropout rates (Carbonaro, 2005; V. E. Lee & Burkam, 2003). Such patterns have been used to argue for a reduction in tracking and curricular differentiation in the United States and other countries. In an effort to tailor instruction and materials to the abilities of individual children, such practices often result in children perceived to be lower in ability receiving watered-down curricula that do not challenge them and ultimately lead to lower levels of learning (Lucas & Berends, 2002; Montt, 2011). This stratification of opportunities to learn by real or perceived aptitude points to the potential value of detracking (i.e., mixing students of differing abilities in the same classrooms) and creating a common curriculum (i.e., all students taking the same classes or kinds of classes). Such educational approaches—often seen in Catholic schools—are thought to even out differences across classes that are based on often artificial assessments of what students are capable of doing. In secondary school, these educational approaches are aimed at reducing socioeconomic and demographic disparities in who takes advanced coursework that is optional (Hallinan & Kubitschek, 2012; Loveless, 1999).

Theoretical recognition of and empirical evidence for the benefits of reducing curricular differentiation have resulted in policy action. *Curricular intensification* refers to the push to have more secondary school students enroll in higher-level coursework and persist further in their coursework, major foci of the federal Gear Up program aiming to increase the academic preparedness of students from low-income families for college (U.S. Department of Education, 2012). In effect, intensification aims to create a higher standard for course-taking that applies more consistently across students; for example, increasing required math coursework in all years of high school or making biology a required science class for all incoming

students in a high school rather than allowing students to choose between biology and other less challenging courses (Kelly & Carbonaro, 2012). In line with insights from the expectancy-value and flow models, challenging coursework seems to increase learning. Rather than being discouraged, students tend to rise to the challenge and even are energized by it. In other words, students who may be perceived as unsuited for taking algebra often do well when forced through policy to do so, posting greater gains in mathematical knowledge over time (Attewell & Domina, 2008; V. E. Lee & Ready, 2009).

Such seemingly encouraging patterns also come with caveats. For example, a historical analysis of national data revealed that the trend toward curricular intensification in secondary schools was associated with narrowing socioeconomic and ethnic achievement gaps. Yet, this same analysis indicated that this pattern did not apply to the most advanced courses (e.g., calculus), lending credence to theoretical arguments that intensification might simply change the way that inequality is manifested rather than eliminate it (Domina & Saldana, 2012; Lucas & Berends, 2002). As another example, evidence from the NICHD Study of Early Child Care and Youth Development—which included observational protocols of elementary classroom practices—suggested that cognitively challenging math classes promoted achievement for lower-skilled children but only in the context of emotionally supportive student-teacher relationships. When such challenges came in less emotionally supportive classrooms, these children achieved less than they would have in less challenging classes (Crosnoe et al., 2010). Importantly, analyses of the implementation of intensification policies (e.g., in Chicago public schools) have yielded more disappointing evidence than analyses of survey data, suggesting that selection biases may be inflating the value of this practice (V. E. Lee & Ready, 2009). The issues around curricular intensification illustrate how the translation between theory and practice is sometimes quite uneven.

The emphasis on academic coursework in the intensification push is, in practical terms, at cross-purposes with *vocational training*. In many European countries (e.g., Germany), vocational education and academic education are complementary paths. Such systems have distinct branch points, in which, after a certain number of years, young people select or are selected into either vocational or academic schools. Having such branch points makes clearer what the options are for students, but it also concentrates socioeconomic and other inequalities in very specific periods. The same is not true in the United States, where no

explicit branching between vocational and academic education occurs. As a result, the relative value of vocational versus academic education is harder to discern, vocational opportunities are less readily available, and inequalities are more diffusely distributed across the educational career (Buchmann & Park, 2009). In the United States, vocational education in secondary school increases the risk of dropping out, reduces the likelihood of attending college, and depresses achievement. At the same time, it does not consistently improve labor market outcomes, especially for youth from traditionally disadvantaged groups (Ainsworth & Roscigno, 2005). Thus, in the push for curricular intensification and the broader “college for all” atmosphere in the United States (e.g., Rosenbaum, 2001; the Obama administration’s American Graduation Initiative, 2009), what happens to youth not well suited to or interested in higher education or who want to directly enter the labor force is not given enough attention.

Of course, one consideration for this line of research is not so much the curriculum itself but who is delivering it to students; in other words, *teacher effectiveness*. In the policy world, the role of teachers in student learning has been hotly contested, especially in the context of issues like teacher unions and teacher tenure. In the research world, what is not contested is that having a “good” teacher is one of the most important factors in children’s educational success (Darling-Hammond, 2006; Konstantopoulos, 2011).

Partly, teacher quality concerns what and how teachers teach specific materials. For example, different teaching methods have been associated with greater growth in reading and math skills. In reading, debates about phonics learning (teaching the relation between spoken words and written letters) versus whole language learning (teaching to infer words and their meaning from context) have raged for years (Armbruster, Lehr, & Osborn, 2001; Sonnenschein, Stapleton, & Benson 2010; Xue & Meisels, 2004). Yet, this dichotomy is likely false. Children tend to learn reading more quickly through a mixture of the two approaches or, more generally, when they gradually transition from a more basic-skills instructional approach into more of a higher-order approach, especially in socioemotionally supportive contexts (J. L. Brown, Jones, LaRusso, & Aber, 2010; Connor et al., 2004). Such patterns suggest that what matters is tailoring instruction to the needs and skills of individual children. This conceptual framework is often referred to as the child  $\times$  instruction approach (Connor et al., 2009). It is not limited to reading. In math, developmentally oriented approaches recognize the cumulative nature of learning beginning with fundamental basic skills

(e.g., understanding numerical magnitude) that then are built on over time and emphasize how math instruction is facilitated by more socioemotionally supportive teaching styles (Booth & Siegler, 2008; Burchinal et al., 2011; Duncan et al., 2007; Siegler et al., 2011). Still, although the child  $\times$  instruction approach is theoretically validated, it can be hard to implement in practice, as it demands more time and attention from teachers. For example, one survey revealed that nearly half of elementary school teachers made no adjustments for individual students in their approach to teaching spelling (Graham et al., 2008).

Other aspects of what makes a good teacher are difficult to isolate. Value-added assessments—in which the achievement gains of students are measured during their time with specific teachers—have revealed that some teachers have strong influences on student learning and others do not, but they have not consistently indicated what policy-amenable factors identify the former or latter. For example, years of teaching experience, advanced credentials, and certification are concrete characteristics of teachers that could be supported through policy. Although some studies suggest that these factors are related to student learning, others do not and instead emphasize attitudes and personal characteristics (e.g., efficacy, expectations) that are more difficult to manipulate (Goldhaber & Anthony, 2007; Hanushek, 1997; Palardy & Rumberger, 2008; Wenglinsky, 2000). In other words, teachers matter a great deal, but which teachers matter is still uncertain.

## SCHOOLS AS DEVELOPMENTAL CONTEXTS

Although schools’ central mission revolves around teaching and learning, schools are also developmental contexts that promote (or not) well-being across developmental domains. Schools encompass a web of personal relationships between and among students, school personnel, and parents. Such relationships and how students consider and connect to others in their schools more broadly influence academic success and have implications for students’ social and emotional development as they move through the educational pipeline. Thus, just as the structure and composition of schools and the curricula and instruction implemented within them can support students’ educational success or derail educational trajectories, so too can relationships within and connections to schools. Such relationships also matter in ways that extend far beyond this narrow educational lens (see Wigfield et al., Chapter 16, this *Handbook*, Volume 3).

The fundamental components of this informal side of schooling are relationships. Given the structure of K–12 schooling in the United States, students are constantly establishing new ties to teachers on an annual basis across elementary school and often a semesterly basis across secondary school. Although relationships with peers may be more consistent than those with teachers, school moves and transitions can disrupt peer networks as children and adolescents are thrust into new and often larger and more impersonal school environments (see Rubin, Bukowski, & Bowker, Chapter 5, this *Handbook*, this volume). Similarly, as students move through the educational system, family-school connections are forged, maintained, and lost, and the role of the student in these family-school connections evolves. Despite the ever-changing nature of the set of relationships that form in and around school, these relationships consistently play a key role in child and adolescent development. In the section that follows, we consider three primary sets of relationships—relationships with teachers, relationships with peers, and family-school connections—and how each drives students' academic performance. We also discuss other components of the developmental contexts of schools that are shaped by or involve these relationships. Later in this section, we will revisit these relationships and relationship-based processes and explore how they are linked to youth's social and emotional well-being.

### Relationships in School

Great attention has been placed on the role that supportive *relationships with teachers* play in the lives of young people. Much of this research is focused on the elementary school years, which is not surprising given that, during this period children generally spend the vast majority of their school day with a single classroom teacher. In contrast, secondary schools in the United States are structured so that students generally rotate through courses and classrooms throughout the day. Consequently, students are exposed to more teachers overall, and their time with any one teacher is constrained to a single class period. Regardless of school level, however, teachers remain important socializing agents children and adolescents' lives, and student-teacher relationship quality is an important mechanism of educational success. Longitudinal work suggests that certain patterns of student-teacher relationships emerge across elementary school. Considering the two primary domains of teacher-students relationships—warmth/caring and conflict—reveals that some students have consistently

positive experiences with their teachers, others consistently rate their relationships with teachers quite negatively, and still others see improvements or declines in these relationships across time (E. O'Connor & McCartney, 2007; Spilt, Hughes, Wu, & Kwok, 2012). Our conclusion is that this work suggests that students' relationships with teachers are complex and changing, complicating scientific inquiry exploring how they might matter.

Regardless of individual experiences of teacher-student relationships, ample research suggests that elementary students receive higher teacher ratings of their language, literacy, and mathematics skills, earn higher grades, and exhibit greater school engagement when they have more positive relationships with their teachers. Here, positive refers to greater warmth and support and low levels of conflict (Hughes, Luo, Kwok, & Loyd, 2008; Maldonado-Carreño & Votruba-Drzal, 2011; Valiente, Lemery-Chalfant, Swanson, & Reiser, 2008). In contrast, when children have more conflicts with their teachers, they tend to be less engaged in school and have poorer work habits (Hamre & Pianta, 2001; E. O'Connor & McCartney, 2007; Stipek & Miles, 2008). Work at the secondary level suggests similar benefits, including better grades in school, enhanced school compliance, greater motivation, and a decreased likelihood of school dropout (Croninger & Lee, 2001; Crosnoe et al., 2004a; Patrick, Ryan, & Kaplan, 2007; Wang & Eccles, 2012a). Although these within school level studies consistently highlight the advantages of strong teacher-students relationships, studies looking across the school levels and across academic domains suggest such links are more tenuous. These studies identify academic benefits of positive relationships in some domains but not others (e.g., sound awareness but not letter-word identification or applied problems; Curby, Rimm-Kaufman, & Ponitz, 2009), at certain grades (e.g., later but not earlier in elementary school; Crosnoe et al., 2010; Hamre & Pianta, 2001), or for only certain groups of students (e.g., boys, students with moderate or highly positive relationships; E. O'Connor & McCartney, 2007; Spilt et al., 2012).

Relatedly, certain aspects of the student-teacher dynamic appear to be more beneficial for specific groups of students. For example, studies show that struggling students and students with less educated mothers tend to benefit more from strong instructional support than students exhibiting less academic and social risk (Croninger & Lee, 2001; Curby et al., 2009). In contrast, initially higher-performing students and girls seem to benefit more from teachers' emotional support than initially lower-performing students and boys (Curby et al., 2009; Hamre &

Pianta, 2001). Along similar lines, student-teacher relationship quality can boost the effectiveness of instructional support. For example, Crosnoe et al. (2010) found that inference-based instructional practices lessened the achievement gap between high- and low-skilled mathematics students during elementary school but that these effects were not as strong when children and teachers had conflictual relationships.

In addition to the significant role that educators play in young people's educational lives, *peers* are also critical agents of academic socialization, particularly as students move from childhood to adolescence (see Rubin, Bukowski, & Bowker, Chapter 5, this *Handbook*, this volume). Given the prominence of peers in the efforts of adolescents to meet key developmental tasks (e.g., individuating from parents), the focus of scholarship on peer relationships during adolescence is not surprising (Ryan, 2001). This work generally finds that both the academic and social support dimensions of peer interactions contribute to educational success across secondary school.

In the academic domain, friends' academic achievement seems to be a potent predictor of adolescents' school performance. When adolescents associate with higher achieving peers, they advance further in their high school coursework, particularly when already performing well academically (Crosnoe, Riegle-Crumb, Field, Frank, & Muller, 2008). Other research suggests that such links may be conditional based on gender. Riegle-Crumb et al. (2006) observed a link between having high-performing same-sex friends and advanced course taking for girls but not boys. Having more same-sex than opposite-sex friends also promoted more advanced course taking for girls, but having more same- versus opposite-sex friends was detrimental to boys' advanced course taking. Such work follows the trend discussed earlier in this chapter toward boys' disadvantages in the educational arena.

The academic backgrounds of adolescents' friends also have repercussions for decisions to dropout. For example, Ream and Rumberger (2008) found that, when youth had more friends who had dropped out of school, they had a much higher probability of leaving school without an academic credential. Although it is a less-robust predictor, the extent to which these friends valued (or devalued) education also was linked to later school dropout. In addition to the academic characteristics of friends, the academic support these friends offer has repercussions for academic well-being. For example, when early adolescents have classmates who provide more academic support (e.g., encourage and help the student learn), they exhibit

better self-regulation and engage in more on-task academic activities with their peers (Patrick et al., 2007). Scholarship on friends' achievement and academic support, however, is complicated by the fact that friendship ties tend to reflect achievement homophily—that is, high-achieving students are more likely to nominate other high achievers as their friends, and friendship groups tend to become more academically homogenous over time (Flashman, 2012).

In addition to the academic support that peers can provide, the emotional tone of friendships and the quality of socioemotional support promotes positive school outcomes. At the most basic level, simply having friends supports academic achievement. Consistent with research documenting the socioemotional advantages to reciprocated friendships (i.e., in peer nominations, when the sender and receiver both nominate each other as close friends), middle school students with at least one reciprocated friendship earn higher grades than those students whose friendships are not reciprocated (Wentzel, Barry, & Caldwell, 2004). The emotional quality of friendships also matters. For example, Benner (2011a) found that the negative repercussions of feeling lonely at school for Latino/a adolescents' academic progress and achievement test performance were less severe when adolescents reported greater support from friends. Similarly, although extracurricular participation, school identification, and subjective valuing of learning all generally decline across secondary school, greater acceptance and emotional support from friends was associated with less severe declines in these academic outcomes (Wang & Eccles, 2012b). A more complex picture, however, emerges for school compliance, or adherence to school and classroom rules and norms, suggesting that not all peer relationships are created equal. Specifically, when adolescents primarily associate with a deviant peer group, heightened peer support leads to faster declines in school compliance across secondary school. In contrast, when adolescents associate with more prosocial peers, greater peer support is linked with more attenuated declines in school compliance (Wang & Eccles, 2012b).

Much of the work on peer influences on academic outcomes, therefore, is positive, reflecting the value of social support for meeting the challenges of school. Yet, as the work of Wang and Eccles (2012b) just described suggests, peer influences can also be negative. Because peers are such powerful agents of socialization, they can disrupt academic progress when they devalue academic success or when the social demands of peers distract from academic pursuits (Crosnoe, 2011). Indeed, the potential for peers to have negative influences on schooling has long been a

major source of debate in research and theory on ethnic and socioeconomic achievement gaps. As discussed earlier in this chapter, this line of research has moved toward a consensus that some peer dynamics can be major risks for academic factors but that these risks are not confined to any one ethnic or socioeconomic group (Harris, 2006; L. D. Steinberg et al., 1996; Tyson et al., 2005).

### Relationships Outside School

The relationships that young people have with teachers and peers are largely (although certainly not completely) anchored in schools. Of course, they also have many relationships that are more or less removed from the actual school context even if they still have implications for what goes on in that context. Parents are perhaps the best example (see Bornstein, Chapter 3, this *Handbook*, this volume). Parents influence their children directly—they are the most consistent socializing agents of young people across the early life course—while also having indirect influence through schools (L. Steinberg & Morris, 2001). Earlier we discussed how the demographic characteristics of families influence young people's performance in schools, and here we expand our focus to discuss the implications of parents' involvement and connection to schools for children's adjustment.

Parents' educational involvement and school-family connections can take many forms, but they most commonly consist of three general activities (X. Fan & Chen, 2001; Hill & Tyson, 2009; Jeynes, 2007). The first encompasses home-based educational involvement. Such activities occur outside the walls of the school but are explicitly implemented to reinforce school learning and promote educational engagement and academic success. Home-based involvement can include monitoring and supervision, such as limiting screen time (i.e., television, video games) and checking homework as well as academic enrichment, when parents seek out extracurricular activities and experiences that promote children's development (e.g., concerted cultivation; Lareau, 2003). The second is school-based involvement activities encompassing parents' active and visible presence in schools through volunteering in the classroom, attending parent-teacher conferences, and participating in school governance or other school-family partnerships (e.g., parent-teacher organizations). The third is academic socialization, in which parents engage in active communication about academics and the value of education and either explicitly or implicitly convey their educational aspirations and expectations

to children. Work comparing different facets of parent involvement suggests that parents engage in home-based involvement activities more frequently than school-based activities across elementary and secondary school (Green, Walker, Hoover-Dempsey, & Sandler, 2007), and longitudinal studies find that both home- and school-based parental involvement decrease from elementary through high school (Cheung & Pomerantz, 2011; Crosnoe, 2011; Green et al., 2007).

The factors that promote parents' educational involvement have been the focus of much study, including the constraints on parents' behavior and personal characteristics that affect both values and behavior. In terms of constraints, parents' work schedules can limit active involvement in school-based activities. Given the scheduling constraints associated with full-time employment, parents who work or attend school full-time unsurprisingly report the least amount of educational involvement. Yet, mothers who work or attend school part-time tend to be more involved in their children's school than those not working or attending school (Weiss et al., 2003). Other constraints related to demands on parents' time and energy due to family needs are associated with less school- and home-based involvement (Green et al., 2007). When parents face more economic stressors, they are generally less involved in school-based activities, have lower educational expectations for their children, and engage in fewer educationally oriented discussions at home. These findings are robust regardless of the marker of disadvantage being considered, such as low parent education or low family income (Hill et al., 2004; J. S. Lee & Bowen, 2006). Parents in more disadvantaged households, however, are more likely than their more advantaged counterparts to engage in activities related to managing their children's time, such as limiting television exposure or encouraging reading (J. S. Lee & Bowen, 2006).

Worth stressing is that the characteristics of students may elicit parental involvement. For example, when children performed better academically early in their educational careers, parents' educational involvement subsequently increased later in elementary school (Englund, Luckner, Whaley, & Egeland, 2004). Similarly, at the beginning of high school, academic involvement was highest for parents of students in college-preparatory academic tracks and lowest for students in remedial academic tracks. The general declines observed in parental involvement across high school, however, seemed limited to parents whose children were in college preparatory tracks (Crosnoe, 2001). These differences are echoed in work that

suggests that, when children and adolescents begin to struggle in school, parents may ramp up their involvement activities as a means of helping to get their children back on track academically (Pomerantz, Moorman, & Litwack, 2007).

Research on the consequences of parental involvement generally suggest academic benefits, although there is some evidence that not all parental involvement activities are equally effective. Lee and Bowen (2006) found that parents' school-based involvement was linked to children's academic performance in reading and mathematics during elementary school. Higher parent involvement is also associated with greater school investment, more time spent on homework, more self-regulated learning strategies, greater academic competence, and higher achievement at the end of middle school, and the more parents maintained their involvement over middle school, the more positive their children's academic outcomes were (Cheung & Pomerantz, 2011). Meta-analyses of urban elementary and secondary students identified consistently positive effects of parental school involvement for both European American and minority children in urban schools, although effect sizes were stronger at the elementary level (Jeynes, 2007). More explicit comparisons of the various parent involvement components suggest differential effects. A meta-analysis by Hill and Tyson (2009) found that parents' school-based involvement activities are stronger predictors of middle school students' achievement than home-based involvement activities, and numerous studies and meta-analyses document the particular potency of parents' aspirations and expectations for their children and adolescents' educational success (Benner & Mistry, 2007; Hill & Craft, 2003; S. Hong & Ho, 2005).

Other studies report that parents' involvement in their children's schooling does not increase educational success. Instead, this work suggest that parents' reported involvement in schools has either no effect on young people's academic achievement (El Nokali, Bachman, & Votruba-Drzal, 2010; Hill et al., 2004) or actually is associated with poorer achievement test performance (Domina, 2005). Studies using teacher reports of parents' educational involvement at home and at school have yielded similar null findings or findings only cross-sectionally for children's verbal and math skills, academic aptitude, and achievement test scores once school readiness, personal characteristics, and peer performance were taken into account (El Nokali et al., 2010; Englund et al., 2004; Kurdek & Sinclair, 2000). Reasons for these differential effects likely reflect many issues, including differences in study design. One important issue, however, is that

the observed effects of parental involvement may simply reflect the characteristics of parents who are (or are not) involved more than it does the benefits of involvement itself. In other words, unmeasured selection biases may be at work. Although the range of selection factors that might increase parental involvement while also affecting child outcomes is broad, ranging from parents' personalities up to policies, one concrete selection factor that has received a great deal of attention is parent socioeconomic status (Domina, 2005; Pomerantz et al., 2007).

Indeed, the socioeconomic circumstances of parents appear to play a critical moderating role in the academic outcomes of parental involvement, such that children who are in the most need of educational support—who generally come from more disadvantaged families with less economic, human, and social capital—tend to benefit most from parents' educational involvement. More specifically, Domina (2005) found that parent involvement activities, including PTA attendance, volunteering, and checking children's homework, were stronger predictors of the achievement of children from low- (versus high-) socioeconomic status (SES) families. Similarly, parent involvement in their children's schooling was particularly critical for the literacy development of children whose mothers had lower levels of education (Dearing, Kreider, Simpkins, & Weiss, 2006). Hill et al. (2004) observed that educational involvement was positively associated with children's educational aspirations when parents had less education, whereas involvement was unrelated to aspirations for children with more highly educated parents. Yet contrary evidence suggests that children who are in the least need of educational support—those children from more advantaged homes with greater resources—benefit most from parental involvement, particularly when it is tied to the concerted cultivation efforts of expanding children's and adolescents' academic repertoires. For example, J. S. Lee and Bowen (2006) observed that parents' educational expectations promoted achievement test scores more for children from higher-income families than for children from more economically disadvantaged homes (i.e., those children receiving free- or reduced-price lunch; FRPL). These socioeconomic patterns also appear to vary in complex ways by ethnicity (Hill & Craft, 2003; Hill et al., 2004).

### School Statutes

When discussing relationships in school, we focused a great deal on peer relationships. In doing so, we considered the ways in which young people interacted with and drew

support from their friends. These individual friendships also aggregate into much broader layers of social life, creating the basic social structure of schools—the networks of ties and relationships that organize social activities and create a status hierarchy. Where young people fit in this broader social landscape of schools is also important, not just their own individual relationships (Crosnoe, 2011).

One major component of the social structure of schools involves the large peer crowds that cut across the student body. These crowds tend to emerge in the larger and more diverse environments of secondary school as schools grow in size, curricula become more differentiated, and activities become more plentiful. In short, crowds are age- and gender-diversified identity groups of students who share the same basic image or reputation (e.g., jocks, druggies; B. B. Brown, Von Bank, & Steinberg, 2008). Crowds are often tied to aspects of school organization, such as classes, clubs, and activities, but are not necessarily so. They refer to young people who share the same basic “space” in school even if not all youth within a crowd are directly tied to each other, serving as pools of potential friends and romantic partners (Barber, Eccles, & Stone, 2001; Frank et al., 2008). Crowd identification and affiliation is particularly strong in early adolescence, a central time for identity development, and certain crowds afford more status than others (B. B. Brown, Eicher, & Petrie, 1986). As a result, membership in a certain crowd can convey status on individual students, even as individual students within the same crowd have different statuses both in and out of the crowd (Crosnoe, 2011).

Social status is not solely a function of peer crowds. Youth can be characterized in terms of popularity among peers, which can refer to how many other students want to hang out with or be friends with that youth or, more diffusely, how much influence they have even if they are not well-liked (Garandeau, Ahn, & Rodkin, 2011; Crosnoe, 2011). Although crowd membership is a force in popularity, other factors also matter, such as body size, physical appearance, family background, and, among adolescents, participating in a little (but not too much) risky behavior (Allen, Porter, McFarland, Marsh, & McElhaney, 2005; Crosnoe, 2011). Similarly, sexual activity can support popularity for boys and reduce it for girls (Kreager & Staff, 2009). Indeed, gender differences drive peer preferences and perceptions of social status. Girls are more likely to be nominated as popular than boys and are less likely to be rejected by peers, but girls lose out more than boys for being aggressive (Garandeau et al., 2011; Ladd, Herald-Brown, & Reiser, 2008).

Regardless of how crowd membership, popularity, status, and social preference emerge, their academic and other benefits are readily apparent, and not just during adolescence. Elementary students who are well liked by their peers espouse more positive academic and social self-concepts, and they tend to score higher on global self-worth measures. Peer social preference and popularity, however, do not seem to be strongly linked to teacher ratings of students’ academic performance and students’ grades (Gest, Domitrovich, & Welsh, 2005; Schwartz, Gorman, Nakamoto, & McKay, 2006), which is not surprising given that popularity is more tied to social rather than academic intelligence (Meijs, Cillessen, Scholte, Segers, & Spijkerman, 2010). Popularity and social preference also have been found to exert differential effects on school engagement—whereas increases in popularity are linked to greater school absenteeism, improvements in social preference (i.e., want to be friends with someone) are linked to better attendance (Schwartz et al., 2006). At the other end of the spectrum, experiences of peer rejection can be quite detrimental for young people’s educational success. Students who are less accepted by their peers subsequently earn poorer grades and express poorer academic self-concept (Flook, Repetti, & Ullman, 2005). Similarly, experiences of rejection seem to fluctuate conjointly with students’ academic engagement. When students experience heightened or chronic rejection, they are less involved in classroom activities and are less able to work independently. In contrast, when rejection levels decline, classroom involvement and independent work efforts improve (Ladd et al., 2008).

In adolescence, social status and academic progress are also related. On one hand, being popular, being a member of popular peer crowds, and having high social status in school can support academic endeavors by increasing the pool of social support, facilitating students’ liking of school, and creating a halo effect in which behaviors and attitudes are viewed more positively by others. On the other hand, such students may have entrée to parties and other social activities, feel pressured to engage in “cool” behaviors, and devote more time and energy to physical appearance and other social considerations in ways that distract from schooling. Overall, social status is an academic benefit, but one that is suppressed somewhat by distractions that chip away at assets (Crosnoe, 2011).

### School Culture

At their core, schools are communities of students and educators who come together within the school walls to

engage in the learning process. How these groups coalesce to foster an overall school climate has received much attention, and the consensus is that school climate influences young people's development across domains (J. Cohen, McCabe, Michelli, & Pickeral, 2009). Yet, wide variation exists in exactly how to best capture and describe the climate of American schools. Guided by J. Cohen et al. (2009), our own view is that positive school climate as a multidimensional construct encompassing school belonging and connectedness, perceptions of fairness and safety, and strong interpersonal ties. Not surprisingly, research has shown these factors tend to be interconnected. For example, when students feel connected to their schools, they are also more likely to view school rules as clear and fair and their schools as safe places to be and learn (Akiba, 2010; M. T. Hallinan, 2008).

The demographic and structural characteristics of schools seem to play key roles in certain aspects of school climate. Although smaller schools are often assumed to foster more positive climates due to their more limited physical space and fewer students and educators under one roof, a multitude of studies indicate that this is not the case. In fact, research spanning elementary to high school suggests that school size has little to no effect on students' feelings of connections to their schools or their perceptions of either the fairness of school rules or the supportive nature of their schools more generally (Anderman, 2002; Fan, Williams, & Corkin, 2011; Gregory, Cornell, & Fan, 2011; Koth, Bradshaw, & Leaf, 2008). How school demographic composition plays into perceptions of school climate has received less attention, and findings are more equivocal. For example, Gregory et al. (2011) highlight correlations between attending schools with more disadvantaged peers and students' perceptions that their schools are supportive environments, but they do not find similar links for students' perceptions of fairness within school. Koth et al. (2008) similarly observe no links between school-wide levels of FRPL receipt (a marker of poverty in school) and students' perceptions of school order and discipline or the academic press of schools. In contrast, research suggests that having more same-ethnicity peers and attending schools with greater academic press promote greater connections and belonging to school (M. K. Johnson et al., 2001; Smerdon, 2002).

Student characteristics also factor into their perceptions of the school climate. For example, African American students tend to express lower levels of school belonging than their European American counterparts, and younger students tend to feel greater levels of school belonging than

their older peers (Anderman, 2002; M. K. Johnson et al., 2001). Research in the school climate area also suggests that girls tend to feel stronger connections to their schools than boys (Anderman, 2002; Smerdon, 2002), although there is some evidence that this gender difference may weaken or reverse as students move from middle to high school (M. K. Johnson et al., 2001). High-achieving and more academically engaged students also express greater school membership and connections than less engaged and lower-achieving students (M. K. Johnson et al., 2001; Smerdon, 2002).

School climate has clear repercussions for young people's educational success and socioemotional well-being. When students feel a sense of belonging and connection to their schools, when they view their schools as safe places to be, and when they perceive relationships within the school to be positive, they earn higher grades in school, perform better on standardized tests, are more engaged in the school process, and are more motivated to do well academically (Anderman, 2002; Brand, Felner, Shim, Seitsinger, & Dumas, 2003; Gottfried, 2011; Hopson & Lee, 2011; Nasir, Jones, & McLaughlin, 2011; Wang & Eccles, 2012b). The potential upside of school climate also extends to school persistence and completion (Reyes, Gillock, Kobus, & Sanchez, 2000). Similar beneficial effects have been observed for students' mental health and well-being. When students view their school climates more favorably, they exhibit fewer depressive symptoms and other mental health issues, express less social rejection, and report less behavioral maladjustment and engagement in risky behaviors, including delinquency, and substance use (Anderman, 2002; Blum, McNeely, & Nonnemaker, 2002; Brand et al., 2003). This attention to the social and emotional repercussions of school climate leads us to our next area of focus: the nonacademic implications of students' experiences in schools.

### Social and Emotional Outcomes of Schooling

The research reviewed so far makes clear that students' social and emotional experience of school influences their educational success on a number of fronts, including grades, school engagement and participation, motivation, and achievement. The developmental implications of schools are not limited to the academic domain. Students' interactions with and connections to their schools and the people in these schools and their general social positions in school also influence their mental and physical health (Bond et al., 2007). These apparent effects of the informal

processes of schooling are critical given a plethora of research that shows consistent associations between psychological well-being and subsequent academic success (Benner, 2011a; Juvonen, Nishina, & Graham, 2000) and between health behaviors and educational attainment (Frisco, 2008). In discussing socioemotional outcomes here, our intent is to explain how some of the formal processes of schooling described in the previous section of this chapter have effects that extend beyond the academic realm while also showing how the informal processes of schooling described in this section are best thought of as having academic and nonacademic implications. In other words, the reality is that both formal and informal processes matter to both academic and nonacademic outcomes.

Beginning at the macro level, the equivocal findings related to the academic benefits of small schools have been well detailed in the section of this chapter on schools as educational institutions, and similar equivocal or null findings have been observed for school size influences on young people's social and emotional development. In their comprehensive review of the school size literature, Leithwood and Jantzi (2009) identified no effects of school size on adolescents' self-esteem, and the very limited research on health and social behaviors allows no firm conclusions regarding school size effects. The implications of school composition for young people's socioemotional well-being, however, are clearer but also add complexity to the previously discussed academic effects. The vast majority of this work focuses on the ethnic composition of schools and the complementary issues of diversity and same-ethnic representation. Although diversity, as noted earlier, promotes positive academic outcomes in youth, diversity comes at a social and emotional cost. Diversity entails having many groups represented and relatively equal representation among groups (Simpson, 1949), and thus any one group's representation within a school declines as diversity increases. More limited same-ethnic representation at the school level holds a host of challenges for students, including greater loneliness, increased experiences of discrimination and racism, and poorer perceptions of schools (Benner & Graham, 2011; Benner et al., 2008; Seaton & Yip, 2009). Yet, other research suggests that diversity can protect against feelings of vulnerability and improve inter-group relations (Juvonen, Nishina, & Graham, 2006; Moody, 2001). We revisit issues of diversity and representation later in this chapter.

Moving the focus to micro-level personal relationships, both peer acceptance and social status confer socioemotional advantages for young people. Students who are more

popular are perceived as exhibiting more prosocial behaviors and more positive social interactions and being less withdrawn (McElhaney, Antonishak, & Allen, 2008; Xie, Li, Boucher, Hutchins, & Cairns, 2006). Greater popularity is also associated with higher self-esteem, fewer depressive symptoms, and a better ability to form and maintain close friendships (Allen et al., 2005; B. B. Brown et al., 2008). Students who feel more socially accepted have similar positive outcomes outside the formal academic domain (McElhaney et al., 2008). Some work, however, has attempted to disentangle sociometric popularity (a gauge of social acceptance and peer preference) from perceived popularity (a measure of reputation rather than social preference). This work suggests that, although both sociometric and perceived popularity are tied to prosociality and peer cooperation, those students who are perceived as popular exhibit significantly higher levels of overt and relational aggression than their sociometrically popular peers (Cillessen & Rose, 2005). Other work echoes the downsides to popularity in ways that reflect what we discussed earlier about the academic distractions faced by high-status students. For example, Allen et al. (2005) found that more popular students were more likely to use alcohol and drugs and engage in minor delinquent behaviors. These findings, however, were conditioned on larger peer effects, such that the links between popularity and risky behaviors were stronger when adolescents' peers placed greater value on such behaviors.

This literature on peer relationships in school is, of course, tied to a much broader literature on general peer influences on child and adolescent behavior. This broader literature covers the norms and values of peers and how they influence youth (especially adolescent) engagement in risky behavior (Allen, Chango, Szewedo, Schad, & Marston, 2012; Espelage, Holt, & Henkel, 2003; Mangino, 2009). Another closely related literature focuses on the many problematic outcomes of young people who are isolated from, rejected by, or victimized by their peers (Buhs & Ladd, 2001; Flook et al., 2005; Mangino, 2009; Wentzel et al., 2004). These related literatures are the primary focus of the chapter on peer relationships by Rubin et al. (Chapter 5, this *Handbook*, this volume), and so we do not dwell on them here. The important point is that schools are sites of these peer dynamics—where peer relations form and play out—but also contexts with power to condition these dynamics. As just one example, the well-documented tendency for peer homophily in substance use (Bauman & Ennett, 1996) is actually weaker in schools in which norms against substance use are strong (Cleveland & Wiebe, 2003).

Although the vast majority of research on the socioemotional implications of schooling focuses on the peer context, a more limited body of research highlights the role of relationships with teachers and school involvement of parents in young people's mental health. When elementary students have more positive relationships with their teachers—that is, when they feel their teachers are warm, when they feel connected to their teachers, and whether the teacher-student dynamic is characterized by low levels of conflict—students exhibit fewer externalizing and internalizing behaviors (Maldonado-Carreño & Votruba-Drzal, 2011). Moreover, consistently strong relationships with teachers across elementary school are tied to lower levels of externalizing behaviors as compared to consistently poor or variable relationships, and increases in teacher-student conflict are linked to increases in students' aggression (E. E. O'Connor, Dearing, & Collins, 2011; Stipek & Miles, 2008). Similarly, when students feel their secondary school teachers treat them in a discriminatory way, they feel more depressed, report lower self-esteem, and perceive their school climates more negatively (Benner & Graham, 2011; Fisher, Wallace, & Fenton, 2000).

Having parents who are actively involved in their children's education both at home and at school seems to promote children's socioemotional outcomes, including better psychological adjustment and fewer problem behaviors (Cheung & Pomerantz, 2011; Domina, 2005; El Nokali et al., 2010; Hill et al., 2004; see O'Connor et al., 2011, for an exception). Similarly, when parents increase their own educational involvement across time, their children show improvements in emotional functioning and social skills and declines in problem behaviors (Cheung & Pomerantz, 2011; El Nokali et al., 2010). Thus, the formal processes of schooling matter for socioemotional outcomes, not just academic ones, and the same can be said for the informal processes of schooling.

## HOLISTIC DEPICTIONS OF SCHOOLING

Up to this point, we have largely separated the two sides of schooling from each other. This separation allowed many intricacies of schooling to be discussed in finer-grained detail while constructing some organizational coherence for the chapter.

Doing so revealed clear disciplinary differences in theory, methodology, and goals. Scholarship from macro-oriented fields (e.g., sociology, economics) was overrepresented in the review of research on formal processes, was

conceptually geared toward inequality, drew on methods emphasizing causal inference and generalizability, and spoke to broad debates of federal and state educational policy. Scholarship from micro-oriented fields (e.g., psychology), in turn, was overrepresented in the review of research on informal processes, was conceptually geared toward child well-being, drew on methods emphasizing dynamic change and child  $\times$  environment interactions, and spoke to focused issues of intervention.

Even though separating the two sides of schooling is useful organizationally, it does not reflect the reality of children's lives. The truth is that the formal and informal processes of schooling cannot be separated so easily. Developmental scientists have been at the vanguard of connecting these seemingly disparate processes into more holistic representations of child development within school context, and the insights gleaned from such holistic research have laid a foundation of theoretically grounded empirical evidence for efforts to reform schools and better serve children. Here, we highlight some specific issues of research and practice in which the payoff of such holistic treatments is clear.

## Desegregation

As discussed at several points in this chapter, the socioeconomic and demographic composition of schools has garnered substantial attention from both researchers and policymakers. In the policy arena, much of the attention has been on the achievement boosts of integration (Crosnoe, 2011). Developmentalists have played a key role in crafting theoretical arguments for why ethnic and socioeconomic integration should promote student achievement, arguments that touch on peer influence and the role of diversity in cognitive development. To a large extent, theory has been borne out empirically, as students from disadvantaged groups often have higher achievement in more diverse contexts (Gurin et al., 2003; Kahlenberg, 2001). At the same time, developmentalists have been leaders in crafting theoretical arguments about the potential socioemotional risks of diverse schooling environments, arguments that have been borne out empirically (Benner & Graham, 2011; Schofield, 1995). Bringing together the two sides of schooling, therefore, provides a more nuanced portrait of school composition and student outcomes, one crucial to the ultimate effectiveness of educational policies targeting composition.

Starting with ethnic diversity in schools, developmentally oriented research suggests some reasons to be

concerned with the simple conclusion that diversity is good and segregation is bad. Yes, segregation is problematic overall and certainly antithetical to civil rights, but creating diverse schooling environments without regard for the socioemotional implications for children is likely short-sighted. Ample evidence suggests that such socioemotional implications may be negative. Ethnic minority students often have less positive identifications with school when attending more diverse schools, especially when student-teacher mismatches on ethnicity are more common. Some research indicates that teachers experience such schools in similar ways (Crosnoe et al., 2004b; Goldsmith, 2004; M. K. Johnson et al., 2001; Renzulli, Parrott, & Beattie, 2011). Although diverse environments tend to foster more cross-ethnic contact and relationships, this pattern comes with diminishing returns, and such contact may actually be impaired in highly diverse schools. Moreover, as diversity grows, perceptions of discrimination increase (Benner & Graham, 2011; Moody, 2001). Similar findings have been reported for school socioeconomic diversity, with low-income students appearing to have more adverse socioemotional functioning and a greater likelihood of being cut out of competitive learning opportunities in middle-class schools. Importantly, these problems tend to be especially pronounced for ethnic minority youth (Crosnoe, 2009; Plank, 2000).

One possibility for reconciling such empirical patterns is that the socioemotional risks of school diversity may chip away at the academic benefits. If so, the potential academic boost of desegregation plans or related policies will not be fully realized unless they also attend to the socioemotional risks that might come along with more diverse schooling environments. Thus, the conclusion to be drawn from this intersection of formal and informal processes is not that segregated schools are somehow desirable. Instead, it is that making desegregation work academically requires more than simply creating school environments that are statistically desegregated; they need to be socially integrated too (Crosnoe, 2009; Schofield, 1995). This conclusion echoes research conducted in the wake of detracking. Moving beyond strict ability grouping to create heterogeneous learning classrooms was expected to boost achievement among children from more disadvantaged backgrounds. When these gains were weaker than expected, efforts were undertaken to figure out why. The resulting scientific evidence concluded that mixed classrooms often created status hierarchies that differentially elicited and rewarded the participation of students from diverse backgrounds. This research then led to classroom

interventions, such as complex instruction, aimed at reducing such status problems and making learning opportunities more equitable (Cohen & Lotan, 1995).

At the school level, some balance in formal and informal processes is needed, promoting the learning benefits of diverse environments but not hindering the sense of connection often found in less diverse environments. In an analysis of the Early Childhood Longitudinal Study, Benner and Crosnoe (2011) demonstrated that children have higher levels of achievement in diverse elementary schools only if their own groups are amply represented. This connection between diversity and critical mass or tipping points is one way to consider balance, a policy goal that demonstrates the value of developmental approaches (Linn & Welner, 2007). Implementing developmentally appropriate multicultural curricula alongside school diversity plans is another consideration, one that can be extended to other issues of culture and diversity such as social class (Pfiefer et al., 2007).

### School Transitions

As American youth move through the K–12 pipeline, they generally make structured transitions from elementary to middle school and middle school to high school. These transitions, although normative, create rifts in both formal and informal processes of schooling. With each transition, the curricula become more compartmentalized and academic standards become more “high stakes” (Baker et al., 2001). Failing a course takes on added meaning when credit accrual determines whether a student graduates on time, and grades in core courses and electives hold more weight when they determine class rank, a key factor in determining entrance into 4-year educational institutions. At the same time, school transitions also upend interpersonal relationships among students and staff (Benner, 2011b). With each transition, students encounter shifts in their social networks as they move into larger educational sites with older peers and often unfamiliar same-age classmates. Students must also forge new relationships with a different cadre of educators, who are often less available and more limited in the social support they can provide to students.

Within school levels (e.g., middle schools, high schools), approaches to teaching and learning are not always well matched with students’ developmental needs, and this mismatch has repercussions for the formal and informal processes that unfold as students transition across school levels. Such attention to mismatches is most readily apparent in the transition from elementary to middle school.

At a time of biological, cognitive, and social changes (Lerner & Galambos, 1998), when identity development is initiated and the desire for autonomy grows, young adolescents transition to middle schools that are structured in ways that do not meet their developmental needs for greater autonomy balanced with continued strong connections to educators. This poor stage-environment fit, in which middle schools are mismatched instructionally and socioemotionally, complicates students' transition experiences (Eccles, 2004). The resulting difficulties span developmental domains and are apparent at other transitions in the K–12 system. Across school transitions, students experience declines in their academic performance, school engagement, and social and emotional functioning, although heightened feelings of depression, anxiety, and loneliness more often emerge in the transition to high school than in other transitions (B. K. Barber & Olsen, 2004; Benner & Graham, 2009; Rudolph, Lambert, Clark, & Kurlakowsky, 2001; Seidman, Lambert, Allen, & Aber, 2003).

Although school transitions generally pose challenges for students, they also provide opportunities for reinvention that bridge the formal and informal processes in schools. For example, Kinney's (1993) ethnographic work highlighted a group of students who became active agents in a transformation from "nerds to normals," a shift in social status that was accompanied by heightened self-esteem. For these students, the high school transition enabled them to establish new peer relationships, escape middle school reputations, and climb the ladder of social status. Along parallel lines, Langenkamp (2010) revealed that the academic benefits of school transitions are contingent on the intersection of prior student performance and feeder pattern structures (i.e., how schools feed into the next school level). Specifically, for students who performed more poorly in middle school, transitioning to high school with fewer middle school peers promoted stronger academic performance. In contrast, those students who were higher achievers in middle school had more academic benefits when they transitioned with many middle school peers. Just as school transitions can serve as a mechanism for more positive social pathways, they can also provide a means for academic reinvention, particularly when adolescents are free of the negative expectations of their former middle school classmates.

### Public Health in Schools

Increasingly, the classrooms, activities, and programs of schools are being used to create changes in student

behavior as a means of promoting public health. These efforts expand the reach of schools beyond their official educational mission, moving more into the realm of how schools may be used to achieve the broader goal of a more stable and successful society. They represent the intersection of formal and informal processes in several ways: (a) the use of formal processes to regulate informal processes, (b) the recognition that informal processes may undermine formal processes if left unattended, and (c) the complexity of taking formal approaches to nonacademic issues.

One example of formal school programs targeting students' nonacademic behavior is sex education. Teaching students about sex has long been a highly contentious issue and a source of debate about the appropriate reach of schools into students' lives. Historically, formal curricula designed to raise students' knowledge about sexual and reproductive health have been successful. Over the last decade, many states have moved toward an abstinence-only sex education curriculum that emphasizes virginity as the only way to avoid sexual risks and downplays or eliminates discussions of other sexual practices. Evaluations of such curricula using experimental designs have shown that they are not generally effective in delaying initial sexual encounters or engagement in unprotected sex (Trenholm et al., 2007). The implementation of these curricula and related practices also seem to be shaped by the broader socioeconomic stratification system. Schools serving more socioeconomically disadvantaged populations are more likely to have abstinence-only education, and any other programs that are implemented tend to be more risk-focused and regulatory than those targeting youth from more socioeconomically advantaged families. In part, this difference arises because of what parent communities demand of their children's schools and how their demands are answered (Fields, 2008).

How peer contexts can undermine or support the effectiveness of formal school programs targeting health also warrants discussion. For example, peer network analyses have revealed that the degree to which virginity pledges, abstinence clubs, and other school-based activities factor into teenagers' sexual behavior depends on what peers are doing. Such activities are only effective if a small subset of students in a school engages in them. In these situations, the activities create a small close-knit community with strong powers of regulation. As activities become more widespread, they are more indicative of general peer processes of "following the crowd" and lose their power (Bearman & Brückner, 2001). The need to better account

for the peer settings organized by schools that implement public health prevention programs extends to other areas of risky behavior. One explanation for the ineffectiveness of efforts to incorporate peers into school-based health programs targeting youth (e.g., peer mentors or counselors) is that, in focusing on micro-contexts of peer relationships, they ignore the larger peer contexts in which these micro-contexts are embedded. In other words, schools house youth cultures with often-complex systems of norms and values. In some schools, those systems may be at odds with the goals of the programs in question, regardless of the individual peers participating in the programs. Consequently, public health researchers have called for more attention to the ways that peer-focused intervention efforts aimed at reducing risky behavior can be adapted to local school contexts (Crosnoe & McNeely, 2008; Holleran, Dustman, Reeves, & Marsiglia, 2002).

The use of schools as sites of public health intervention—and the larger issue of how schools can be leveraged to address broad social problems—is applicable to issues beyond risky behavior. As obesity rates have risen in the United States, schools have been viewed as frontlines of the battle to reduce this “epidemic.” Through incorporating nutrition into health education, regulating food sales, tinkering with food offerings in school lunches, or increasing physical activity opportunities, reducing obesity and increasing physical health have become official goals of school districts with concomitant formal programs and curricula (Story, Kaphingst, & French, 2006; Van Hook & Altman, 2012). Given the strong links among body size, social status, and mental health across the life course but especially in adolescence and childhood (Brownell, Puhl, Schwartz, & Rudd, 2005; Janssen, Craig, Boyce, & Pickett, 2004), the success of such formal efforts is also likely to be influenced by the overall peer contexts of schools regarding weight-related issues.

Discussing how schools have been viewed as appropriate sites of public health promotion indicates how the impact of schooling on youth extends beyond formal academic indicators emphasized by policy. At the same time, discussing how school-based public health efforts might be undermined by inadequate consideration of the informal processes of schooling indicates ways that developmental research can support public health efforts.

### High-Stakes Testing

A hallmark of contemporary educational policy is the push to hold schools and students accountable for their

performance. Given the attractiveness of simple measures of performance and the comparability of standardized tests across schools and over time, testing is now the benchmark of accountability. As a result of the penalties associated with failure to meet accountability, standardized tests have become high-stakes competitions. The argument is that raising the stakes puts more pressure on schools and students, which, in turn, motivates effort (McNeil & Valenzuela, 2001). NCLB is a prime example of accountability policy based on high-stakes testing, with schools penalized for failing to meet progress goals on standardized tests over time (Gamoran, 2007). On the student level, high stakes tests linked to accountability policies take many forms, including exit examinations that students must pass to graduate from high school even if they have fulfilled all of the curricular requirements for graduation (Warren & Jenkins, 2005).

Much has been written about the variable standards that go into high-stakes tests and the limitations of using narrow criteria for measuring learning (McNeil & Valenzuela, 2001). Given our focus on the intersection of formal and informal processes, we highlight a different angle; specifically, psychosocial experiences of high-stakes testing. High stakes testing is usually viewed through the narrow prism of formal academic processes. Yet, they also tap into other aspects of development and, even when considered in strictly academic terms, elicit different kinds of responses from the environment.

For example, the stakes associated with a specific test can engender anxiety and stress in young people. They know that much is riding on their performance, leading to worries that may disrupt performance (Ramirez & Beilock, 2011). Theoretically, the potential for test anxiety to interfere with the demonstration of academic skills is related to the basic logic of stereotype threat, which was discussed earlier in this chapter. In stereotype threat, the psychological perceptions of the context of some test performance—specifically, the link to ethnic stereotyping—can impair student performance (Blascovich et al., 2001). Here, the context would be the personal stakes associated with the performance, which act as artificial interference by impairing concentration and careful consideration—students have trouble doing their best work when anxious and worried about what the outcome might reveal about them. Importantly, the high-stakes nature of testing is not consistently related to school dropout, suggesting that any such pressure that may affect performance may not necessarily lead students to take steps to avoid testing altogether (Warren &

Jenkins, 2005). Still, some work indicates that there are socioemotional repercussions for failure of high-stakes tests, particularly when the academic performance of same-ethnic peers is higher (Benner, 2013).

As another example, perceptions of high-stakes testing developed by teachers and school personnel can shape instructional settings and opportunity structures for youth. Both qualitative and quantitative evidence has highlighted how schools respond to high-stakes testing in ways that hurt the educational prospects of some students. Those deemed at risk for not doing well on tests may be funneled into special education classes, which are often exempted from testing (Heilig & Darling-Hammond, 2008). Debate continues to rage about the degree to which teachers also resort to triage, focusing attention on the students near the cusp of passing standards on high-stakes tests at the expense of students who are seemingly likely or unlikely to pass (Booher-Jennings, 2005; H. F. Ladd & Lauen, 2010).

Despite the argument that standardized tests offer objective assessments of student performance, youth and adult perceptions can influence how much such tests actually capture a standardized experience and how they shape current and subsequent educational contexts (McNeil & Valenzuela, 2001). In these ways, a core component of educational policy is not quite the example of a formal process it is made out to be—informal processes can interfere with the degree to which actual formal processes are being tapped. Given how much of the work of unpacking informal processes in schooling has come from developmental traditions, developmentalists have a role to play in elucidating this interplay of the formal and the informal as a means of leading to more theoretically grounded policy.

## CONCLUSIONS

In this chapter, we have discussed many traditional topics of developmental research, from learning to motivation to engagement to peer influence. Yet, in discussing the role of schooling in the lives of children and adolescents, we have also gone beyond the conventional boundaries of developmental science to engage with research from a variety of disciplines on aspects of schooling that are frequently targeted by educational policy. In many cases, developmental scientists have been active participants in theorizing about and empirically studying these aspects of schooling, but, in other cases, they have not. Our rationale for this more expansive discussion of children in schools was twofold. First, we wanted to make the point that

understanding child development within the contexts of schools is facilitated by a broader consideration of schools as organizations embedded in a larger educational system shaped by cultural, historical, and political forces. Second, we wanted to emphasize that macro-level understanding of schools and school systems—and policies informed by this understanding—is facilitated by getting a more complete picture of what is going on in the everyday lives of children within schools. In exploring developmental and institutional approaches to schooling, and their links to large-scale policy and targeted intervention, this chapter covers a multidisciplinary landscape.

This multidisciplinary review suggests that the field is moving toward consensus on long-standing subjects of debate related to schooling, consensus aided by developmental insight. As examples, evidence suggests that that diverse schooling environments come with both academic benefits but also other risks worth considering, that studying child  $\times$  context interactions leads to better understanding of how to support child learning, that theoretical and policy attention to school size may be better directed elsewhere, and that narrowly focused assessments of student and school performance are likely short-sighted. These are not the only topics that are slowly getting closer to being settled.

When the next volume of the *Handbook* comes out, therefore, such topics may receive far less attention from the authors of the chapter on children and schools than we have devoted to them here. Instead, more space will likely be devoted to (a) issues that are still being contentiously debated, such as the role of genetics in educational outcomes and culture as a mechanism of schooling disparities, (b) important issues that we did not have the space to include here but that may be too central to schooling in the coming years to bypass in the next volume, such as home-schooling and the place of technology in instruction, and (c) and emerging issues that are likely to increasingly be the focus of developmental scientists in the future, such as the schooling experiences of sexual minority youth and the inclusion of children on the autism spectrum in public schools.

In pursuing these “new” lines of research while working on the “old” lines that need attention, educational researchers can do well by staying true to some of the themes emerging from our developmentally leaning review of research on children in schools. One theme is that the schooling of children and youth should be viewed within the larger life course, considering early experiences that shape educational trajectories into and through school as

well as what happens after young people have left school and moved into adulthood. Another is that schooling occurs at the intersection of multiple systems—those external micro- to macro-systems in which children and schools are embedded down to those internal systems developing within children—and should be examined as such. This theme comes with the qualifier that, in this intersection of systems, children are the central point, so that child-focused perspectives are paramount. A final theme is that one of the clear values of developmental research on children and schooling is its power to document risks and elucidate resilience in the face of risk, a value that lends itself to creating theoretically grounded best practices in policy and intervention.

## OVERVIEW

This seventh edition of the *Handbook of Child Psychology and Developmental Science* reflects the growing recognition that family and school are only two of the developmental settings that are part of young peoples' lives. Chapters in this volume recognize the importance of neighborhoods,

---

virtual worlds and online communities, work experiences, and additional contexts that influence the development of children and adolescents. *Organized activities* (including afterschool programs, extracurricular activities, sports, community service, drama, summer camps, and other school and community-based programs) have an important place in this wider ecology of developmental contexts. They account for a significant and growing segment of children and adolescents' time. Like schools, they are institutionalized settings that are often deliberately designed to facilitate young people's development. However, they have a distinct pedagogical and philosophical approach that is

more focused on engaged, hands-on, child-driven experiential learning, and that typically involves youth working collaboratively with peers. This approach is aimed at providing young people opportunities for learning socioemotional and other life skills (Eccles & Gootman, 2002), opportunities that occur more frequently in organized activities than in schools (Larson, Hansen, & Moneta, 2006). Although research on organized activities is comparatively young, it is beginning to suggest that activities can be powerful settings in which school-aged children and adolescents develop self-direction, initiative, teamwork, emotional skills, and a fuller sense of their place in the world.

In the first section, we provide a bioecological and sociocultural framework for understanding organized activities as developmental contexts. In the second section, we describe methodological strategies and common assessments that have been used to study organized activities. Next, in the third section, we focus on key parameters and processes, including dosage, type of activities, and program quality, that have been systematically studied. In the fourth section we turn to the individual, family, peer, and school/community factors that predict participation in organized activities, including who joins activities (and why) and who drops out of activities (and why). The fifth section reviews evidence on the influences of organized activities on child development outcomes and the child, family, and community factors that moderate these relations. The following section focuses on experiences and outcomes associated with unsupervised settings, which can be juxtaposed to those found in organized activities. In the seventh and final section, we summarize the current research evidence and propose future directions for research.

## CHILDREN'S ORGANIZED ACTIVITIES IN CONTEXT

To understand young people's participation in organized activities, it is essential to examine how their experiences in these settings are embedded in a broad social and cultural ecology. In this section, we begin by defining organized activities and we then situate these experiences within bioecological theory and sociocultural perspectives. At the end of the section we place organized activities within historical and global contexts. The great majority of research on organized activities comes from the United States, hence that is our primary focus; nonetheless, we include findings from other nations when possible.

## Defining Organized Activities

In this chapter, *organized activities* encompass a broad array of out-of-school settings that share essential elements. These activities include afterschool programs, extracurricular activities, summer camps, and informal learning programs offered by museums and libraries. Relatively distinct bodies of research have developed around these different settings. In this chapter, we focus primarily on the two largest bodies of research, those dealing with afterschool programs and extracurricular activities.

*Afterschool programs*, sometimes called *formal afterschool programs*, refer to activities that (a) meet on a regular basis throughout the school year; (b) are supervised by adults; (c) offer more than one type of activity (e.g., homework help, recreation, arts and crafts); and (d) are structured around group-based activities (Roth, Malone, & Brooks-Gunn, 2010; Vandell, Pierce, & Dadisman, 2005). Almost 60% of the public elementary schools in the United States provide onsite afterschool programs, and 37% of the schools offer more than one program. Together, these school-based programs serve an estimated 4 million children (Parsad & Lewis, 2009).

Afterschool programs serve multiple functions. They typically provide homework help, recreational activities, and sometimes cultural activities (Parsad & Lewis, 2009). In the United States, about one-third of the programs in public elementary schools are supported by fees. Other afterschool programs are specifically targeted to low-income children or youth, and are typically free or charge only a nominal fee. An example is the 21st Century Community Learning Centers, a federally funded afterschool program found in all 50 states and attended by more than 1.6 million children (Afterschool Alliance, 2013). Some states also provide direct support to afterschool programs that serve low-income children and youth. California's After School Education and Safety (ASES) program, for example, is located in more than 4,000 schools and receives more than \$550 million in state funding (California Department of Education, 2013). Other afterschool programs serving low-income youth, such as the Boys and Girls Clubs, are sponsored by community-based organizations. Still other community-based programs, such as 4-H and the YMCA, serve middle-class as well as low-income youth. Many of the programs, both fee based and publicly funded, are used by working parents as childcare arrangements.

A second broad category of organized activities is *extracurricular activities*, which include both school-based

and community-based activities. Extracurricular activities, unlike afterschool programs, tend to focus on a single activity such as a sport, club, performing art, or vocational preparation (Mahoney, Vandell, Simpkins, & Zarrett, 2009; Vandell, Pierce, et al., 2005). However, they resemble afterschool programs in other ways. Like afterschool programs, they meet on a regular basis. They are supervised by adults, involve groups of young people, and offer activities that are structured. Like afterschool programs, they often serve as childcare arrangements for working parents (Laughlin, 2013). Their primary focus, however, is on facilitating positive development (Eccles & Gootman, 2002). Indeed, most parents believe extracurricular activities are valuable arenas for socializing children to important values and skills that extend beyond the skills of ball handling or creating a character in a play (Kremer-Sadlik & Kim, 2007).

These two broad categories of activities (and other organized activities like summer camps and programs offered by museums and libraries) share important elements. They are supervised by adult leaders, and activities typically involve peer interaction. They have regular participation schedules, offer opportunities for hands-on experiential learning, and allow young people to pursue their interests. Organized activities fall outside the regular school curriculum and, unlike school, participation is voluntary. Youth often develop meaningful relationships with peers and leaders that can provide a context for development of identity, initiative, and social skills (Hirsch, Deutsch, & DuBois, 2011; Larson et al., 2006). These elements help define organized activities and provide affordances for distinct developmental processes.

Not included in our definition of organized activities are individual music or art lessons, sports instruction, and academic tutoring. We also exclude extended day programs in which the traditional school day is lengthened until 5 or 6 p.m., because these extended day programs are not voluntary.

### A Bioecological Approach

Bronfenbrenner's theoretical contributions—*ecological systems theory* (Bronfenbrenner, 1979) later expanded and amended as *bioecological theory* (Bronfenbrenner & Morris, 2006), provide a rich and generative framework for studying organized activities, particularly in drawing attention to important active ingredients and features of these activity settings, and in formulating ways to conceptualize relations between these activities and other developmental settings.

Bronfenbrenner (1979) identified four types of systems, from small to large, that are useful in conceptualizing the different levels of factors that influence young people's experiences in organized activities. The *microsystem* is defined as "the pattern of activities, roles, and interpersonal relations experienced by the developing person in a given face-to-face setting with particular physical and material features" (p. 22).

Vandell and colleagues (Vandell & Posner, 1999; Vandell, Pierce, et al., 2005) utilized Bronfenbrenner's framework to highlight key processes and features to be considered in studies of organized activities. These include examinations of the patterns of activities that occur in a particular setting (e.g., sports, arts, community service) and the roles and identities (swimmer, scientist, dancer, cookie salesperson, committee chair, stage manager) that young people assume in each setting or microsystem. Understanding organized activities, Vandell and colleagues argued, also requires consideration of interpersonal relations, including the interactions between adult staff and youth and between peers who are program participants. Finally, activities have particular physical and material features and resources (e.g. a gymnasium or science lab; video, gardening, or cooking equipment) that support or constrain the ways that youth experience these activities. Researchers can study each of these components of organized activity microsystems to understand *why* youth participate in some activities and not others (or to self-care or other microsystems that might otherwise occupy her time) and *why* some activities are linked to positive developmental outcomes and others are not.

Bronfenbrenner (1979) also highlighted the importance of *mesosystems* or "the linkages and processes taking place between two or more settings containing the developing person (e.g., the relations between home and school). In other words, a mesosystem is a system of microsystems" (p. 25).

An important, but understudied, mesosystem consists of the connection between the home and children's organized activities. Ecological systems theory suggests that the cohesion of goals, quality of communication, and coordination between both the home and an organized activity are likely to influence children's program participation and its influence on them. One might ask, for example, are the day-to-day transitions between an afterschool program, soccer practice, and self-care well coordinated so that a child is not exposed to risky situations? Do the norms of the program conflict with the family values of the youth they are trying to serve? For older children, is participation curtailed because of familial responsibilities, such as the

need to care for younger siblings or to work part-time to contribute income to the family (Simpkins, Ripke, Huston, & Eccles, 2005)? These issues are all reflective of the mesosystem.

Other examples of mesosystems are seen in the overlap or connections between organized activities and schools (Bennett, 2013). In some cases, there is no communication between the school and the organized activity microsystems, and linkages are weak. In other cases, the school and organized activity microsystems are coordinated and aligned. There are regular lines of communication, and resources and curriculum may be shared. Bennett (2013) has found that this alignment between programming of schools and afterschool programs was associated with gains in students' language arts and math test scores.

Other linkages take the form of *exosystems*, or linkages or relations between microsystems, in which one of the microsystems does not include the developing child (Bronfenbrenner, 1979). An example of an exosystem can be found in the connections between afterschool programming and parents' work schedules, as this relationship often dictates whether a child is able to regularly attend a program.

Finally, Bronfenbrenner (1979) highlighted the importance of the *macrosystem*, or the overarching beliefs and value of the society as reflected in culture, religion, and the socioeconomic organization. A crucial point is that the macrosystem is *not* separate from young people's immediate environments. Rather, it influences what happens in the micro-, meso-, and exosystems. As we discuss in the next subsection, social class and culture influence what youth bring into the program and what opportunities are open to youth. Funders and community organizations may target programs or programming approaches for specific populations of young people. For example, the federally funded 21st Century Community Learning Centers program was developed to serve students in high poverty schools. In contrast, 4-H was originally developed to serve rural youth. The point is that understanding the meaning and impact of the organized activities requires placing the activities within the broader macrosystem in which they occur.

In the 2006 *Handbook of Child Psychology*, Bronfenbrenner and Morris presented a substantially revised theory, renamed *bioecological theory*, in which development is hypothesized to be the joint product of four defining properties: *Person*  $\times$  *Process*  $\times$  *Context*  $\times$  *Time*. The revised theory emphasized that characteristics of the developing *Person*, such as age, gender, temperament, and competencies, interact with characteristics of the environment to

influence developmental opportunities and outcomes. In this chapter, we consider two broad ways in which *Person* characteristics are essential to understanding organized activities. One way is as *selection factors*. In the fourth section we look at individual factors associated with participation versus nonparticipation in activities. *Person* characteristics also are important as *moderators* of the effects of organized activities on developmental outcomes. In the fifth section, we see that effects of activities on outcomes are not always universal, but vary as a function of individual characteristics such as age, gender, prior adjustment, and skills.

A second defining property of bioecological theory is *Process*, which refers to the developing person's experiences within microsystems, including their social interactions with others and their engagement in particular activities with particular materials. Bioecological theory argues we should pay close attention to the *proximal processes* that occur within organized activities, including the quality of social interactions of youth with peers and leaders, the experiences that young people have with materials and resources in the setting, and the opportunities to choose among activities with much greater autonomy than that afforded by schools. Bronfenbrenner and Morris (2006, p. 996) posit that proximal processes are "the primary engines of development."

The third defining property of bioecological theory is *Time*, which is formulated to include minute-by-minute exposure to proximal processes as well as the periodicity of these processes over longer intervals such as days or weeks. The intensity (minutes or hours per week) and duration (months and years) of organized activities correspond to micro-time and meso-time, respectively, and have been linked to the effects of organized activities on child developmental outcomes. In general, and consistent with the predictions of bioecological theory, greater intensity and longer durations (Blomfield & Barber, 2009; Fredricks & Eccles, 2010) are found to predict larger program effects than does less exposure. Bronfenbrenner and Morris also propose consideration of *Time* at the macro level. Historic changes in society across generations and the evolution in the institutional philosophies of child services, described later in this section, are examples of macro-time processes that influence organized activities. The fourth property, *Context*, includes the micro-, meso-, exo-, and macrosystems of his original theory.

At the same time that Bronfenbrenner was developing his framework, other theorists were proposing related ecological theories, each expanding on different psychological, social, and cultural components that are relevant

to organized activities. Lerner's relational developmental systems theory (Lerner, von Eye, Lerner, Lewin-Bizan, & Bowers, 2010) provides a more differentiated accounting of "living systems" that make up the human ecology, and it gives particular attention to how the strengths of youth and the assets they experience in organized activities influence their development. Spencer's (2006) phenomenological variant of ecological systems theory focuses on the experiences of youth of color and their attempts to make sense of their experiences with social inequality and injustice. In the next subsection, we give special attention to sociocultural theories, derived from sociology and anthropology, which contribute to understanding how macrosystems, specifically social class and culture, influence organized activities.

### Sociocultural Perspectives

Sociocultural perspectives are vital to understanding the experiences of different groups of children in organized activities and the developmental fit of programs to these groups.

#### *Social Class*

Social class encompasses both the income and material assets of a child's family and its social capital (i.e., social resources and knowledge). Financial assets influence which programs a child is able to attend. Upper-middle-class families spend much more each year on afterschool activities (Carver, Iruka, & Chapman, 2006); youth from low-income families have fewer and less varied choices (Laughlin, 2013). Safety concerns, transportation, parents' irregular working hours, and families' needs for help at home, which may be related to families' resources, also influence participation.

Youth at different social class levels bring different social capital and developmental needs into a program (Lareau, 2011). Some programs in low-income neighborhoods are designed to provide experiences and social capital that improve life chances for young people. They provide experiences that help prepare them for the work force or college, connect youth to high-resource adults, and socialize them in middle-class values (Halpern, 2002). Other programs are directly targeted at ameliorating academic deficiencies and narrowing the academic achievement gap. However, some critics express concern that these programs coopt low-income youth into a middle-class agenda, which some parents or youth may not endorse (Kwon, 2013).

### *Culture and Ethnicity*

Both youth and programs have a culture (behavioral norms, values, modes of thinking and acting), and the fit between the culture of a child and the culture of the program shapes his or her experience, continued participation, and developmental outcomes. Yet, although there is much at stake in this fit, researchers have generally neglected this issue. Researchers, as well as many programs, adhere to a "one size fits all" perspective on programming (Fredricks & Simpkins, 2012).

Whether it is visible or not, young people bring their culture into a program. The ingredients include family beliefs and values, parents' ongoing expectations for their children, and the shared history of a cultural group (e.g., shared hardships, discrimination, and a sense of ethnic privilege, pride, or injustice). The cultural backgrounds of youth from outside the dominant culture in a society are sometimes viewed from a deficit perspective. Yet a culture provides its members with funds of knowledge, tools, norms, and ways of thinking (Rogoff, 2003), and these can contribute to young people's engagement in and learning from program activities (Morland, 2007; Villarruel, Montero-Sieburth, Dunbar, & Outley, 2005). For example, Salusky et al. (2014) found evidence that the high cultural value placed on mutual trust and cooperation (*confianza*) in Latino/a culture was a valuable asset among the Latino/a youth in programs they studied. The Latino/a youth were more likely to engage in collaborative work on projects, and this appeared to both increase their motivation and catalyze peer processes that helped youth grow in responsibility, confidence, and maturity.

A critical question is, "How can programs provide a developmentally positive fit that respects the cultural background of youths?" A lack of fit can create misunderstandings between youth and staff, breed peer conflicts, and discourage the participation of youth. For example, Simpkins, Delgado, Price, Quach, and Starbuck (2013) found that Latino/a youth and parents frequently cited discrimination as a reason for the low participation of youth. To address this question, it must be recognized that youth programs (and the larger organizations in which they often reside) are cultural systems: They engage youth in activities and role-relationships within a framework of beliefs, values, meanings, and expectations. This framework is typically rooted within the culture of the wider society, or a subcultural group.

Some programs are deliberately designed to provide this fit for a specific cultural group; and research with

adolescents suggests that these programs can strengthen cultural consciousness and ethnic identity (Riggs, Bohnert, Guzman, & Davidson, 2010). For adolescents from nonmajority cultural groups, cultural consciousness and identity are consistently found to be valuable to the well-being of youth (Chao & Otsuki-Clutter, 2011). Having membership from the same ethnic background provides conditions for youth to engage in identity work in a safe and supportive environment, with peers who are dealing with similar issues. This can be especially valuable for youth from ethnic groups that have experienced collective trauma, injustices, or marginalization by society (Ginwright, 2010; HoSang, 2006). These ethnically focused programs may provide opportunities for youth to become proactive in asserting their ethnic identities and to develop civic skills for addressing grievances (Ginwright, 2010; Kwon, 2008).

Some program models are developed with youth from one ethnic group and then used with another, which creates a high risk of misfit. Cole (2006), however, provided an instructive example of best practices for adapting programs across cultural groups. He describes how his team implemented their program, the Fifth Dimension, to increase cultural fit for fifth graders in a Latino/a neighborhood. They recruited Latino/a staff, and infused Spanish language and Mexican American heritage into activities, games, and program relationships. They also drew on Latino/a norms of multigenerational assistance as a cultural asset, cultivating parent participation and encouraging older youth to take responsibility for younger youth.

It is more challenging to conceptualize how programs can provide cultural fit and build on young people's assets when the youth in a program are from diverse cultural backgrounds. The many possible combinations and proportions of youth from different groups in these programs vary enormously, and theory suggests that these different combinations may contribute to widely varying program dynamics. Okamoto, Gast, and Feldman (2012) express concern that programs serving multiple ethnic groups are likely to be much less effective in meeting the culture-specific needs of youth from any group, because it is harder for them to provide same-ethnicity staff and a critical mass of peers for all youth.

But research suggests that when multiethnic programs make cross-cultural understanding a central focus, they can have substantial positive effects on youth. They can facilitate peer processes among teens that also facilitate changes in their value perspectives from an egocentric to more inclusive worldview (Larson, Jensen, Kang, Griffith,

& Rompala, 2012). The most dramatic examples are peace education programs that create structured interactions between youth from conflicting groups (e.g. in Israel/Palestine, Latin America, Sierra Leone, South Africa). Findings suggest that they can provide context for understanding and reconciliation between youth (Norman, 2009; but see Hammock, 2011).

### *Immigrant Youth*

Youth from immigrant families can present distinct issues and opportunities for programs. In these families, parents and children are typically involved in an ongoing process of cultural adaptation, one in which children often assimilate more quickly to the new culture; and this can lead to family conflict (Berry, 1997; Chao & Otsuki-Clutter, 2011). At the same time, recently arrived immigrant youth are often quite isolated in their schools and neighborhoods (Gaytan, Carhill, & Suarez-Orozco, 2007).

Programs can play important "bridging roles" in facilitating young people's adaptation to their new, evolving situation (Cooper, 2011; Gaytan et al., 2007). They can connect youth to peers in similar situations and to program staff and service professionals who serve as cultural guides (Gaytan et al., 2007). They can provide opportunities for young people's cultural backgrounds to be recognized as assets (Morland, 2007), as well as to help youth develop bicultural competencies, including helping youth better understand their parents (Larson et al., 2012). But the role of programs and practitioners in providing "culturally competent" support for youth is complex, and not well researched. Immigration is experienced in widely varied ways between (and within) groups, as a function of economic, cultural, sociological, political, and other factors (Berry, 1997). It is important for researchers and programs to be sensitive to these variations.

### *Activities in a Historical Context*

Although afterschool programs and extracurricular activities in the United States developed for different purposes, their rise occurred concurrently during the progressive movement to overhaul public education (Halpern, 2002). Prior to the creation of robust child labor laws and publicly funded high schools, many young people worked full-time alongside adults in the workplace (Mahoney, Parente, & Zigler, 2009). As child labor laws moved youth out of the workforce and into schools, their school days ended earlier than their parents' workday, leaving a gap in parental

supervision. This led to a growing concern regarding how youth spent their time outside of school (Halpern, 2002; Mahoney, Parente, et al., 2009).

These concerns spurred the growth of community-based organizations such as the Boys and Girls Clubs, 4-H, and Boy Scouts. In the case of the Boys and Girls Clubs, an early focus was placed on keeping inner-city youth safe and off the street during afterschool hours (Mahoney, Parente, et al., 2009). In contrast, 4-H was founded to make public school education more connected to traditional rural life. Part of the organization's initial goal was to expand new agricultural technologies through working with the youth of farming families, as researchers from public universities found that adults were not as receptive as their children to adopting new technologies (4-H History, 2013). In 1928, The National FFA Organization was founded for a similar population with the goal of ensuring the conservation of agricultural education in public schools (FFA History, 2013). The formation of Boy Scouts of America (BSA) was driven by different goals. Because the progressive movement to expand primary schooling was seen as a feminine initiative, some upper- and middle-class men became concerned that boys were getting too much exposure to feminine culture (Macleod, 2004). The BSA was founded as a way to "re-masculinize" adolescent boys (Hantover, 1978).

The growth of public education in the latter half of the 19th century also led to the expansion of what was called "extracurriculum," as education reformers emphasized a "holistic" education that extended beyond academic instruction. The beginning of the 20th century saw the expansion of high school band, orchestra, and speech and debate from novelty classes sparsely included in school curricula to robust and well-organized youth activities (Rhodes, 2006). Physical education also became part of holistic education, and the loosely affiliated youth-led athletic clubs of the late 19th century became fully organized, adult-lead, organizations (O'Hanlon, 1980). Contemporary organized activities continue to reflect some of these early origins with middle class children participating in extracurricular activities at higher rates and publicly funded afterschool programs serving higher proportions of low-income children (Kleiner, Nolin, & Chapman, 2004; Parsad & Lewis, 2009).

### Activities in a Global Context

In 2010, the first International Conference on Out-of-School Time was held in Geissen, Germany, and focused

on the topic of out-of-school education in a global context. Scholars from England, Germany, Holland, Japan, Korea, Sweden, Switzerland, and the United States discussed historical and political changes in their respective nations that have resulted in out-of-school time playing a substantive role in their education systems. Both the *International Journal of Extended Education* and an edited volume, *Extended Education—An International Perspective* (Ecarius, Klieme, Stecher, & Woods, 2013) were outgrowths of this conference. Findings from Canada, Australia, New Zealand, and Finland, among other nations, were reviewed.

Stecher and Maschke (2013) have described the rise in organized activities across several developed nations. They conclude that, "numerous efforts have been observed over approximately the last 10 to 20 years to expand and develop the institutional learning and care opportunities to supplement (traditional) schooling. Further development of these opportunities is the focus of educational reform efforts in many countries in the future as well" (p. 12). Some examples from Stecher and Maschke (2013) follow.

In South Korea, the expansion of afterschool activities was included as one of the 50 most important tasks listed in Vision 2030, the national strategy for the future of South Korea. Within the Korean context, an extensive system of private learning and tutoring has developed to prepare students for high school exams at the transition to university studies. These private systems, similar to the Japanese Juku schools, begin in elementary school and approximately 73% of children participate in the private out-of-school educational activities. In addition, in recent years an alternative system of publicly funded afterschool programming has been developed to provide a more affordable opportunity aimed at closing the achievement gap between economically disadvantaged students and their more affluent counterparts.

Sweden has adopted a different model, one that focuses more on recreation and less strictly on academic activities. The goal of these centers is to complement the school day in terms of both time and content, and to offer children between the ages of 6 and 12 meaningful leisure to support their positive development. Swedish municipals also provide recreational centers for teenagers. The centers serving older youth are less structured than the programs for children and are designed to provide adolescents with a place to meet and talk, buy refreshments, play board games, floor ball, and so forth, as opposed to having explicit developmental goals (Haglund & Klerfelt, 2013).

The academic and political debate in Germany has focused on the educational benefits of all-day schools, mainly because of Germany's poor performance on the Programme for International Student Assessment (PISA) studies. It is anticipated that the extracurricular activities—such as academic enrichment, art, music, and sports—offered at all-day schools will boost academic achievement, particularly for students needing special support such as children and adolescents from immigrant families. As a result, the number of German all-day schools has more than doubled from 4,951 in 2002 to 11,825 in 2009.

Vest, Mahoney, and Simpkins (in press) used data from the Trends in International Mathematics and Science Study (TIMSS) that includes measures of out-of-school time and achievement of eighth-grade students from nearly 50 countries worldwide. Variables included technology-based (e.g., using the Internet), labor (e.g., chores), and leisure activities (e.g., sports, playing with friends). They found that, beyond the large contribution of a country's human development index (health, education, and living standards), out-of-school time was a statistically significant, meaningful predictor of achievement, suggesting that a broader view of education that includes organized activities outside of school is needed, both within and between nations.

## METHODOLOGIES FOR STUDYING ORGANIZED ACTIVITIES

The great diversity of organized activities presents researchers with challenges of how to measure youth experiences in these diverse microsystems. Four strategies have been used with success: (1) qualitative interviews and ethnographies, (2) experience sampling and time diaries, (3) questionnaires and surveys, and (4) observations.

### Qualitative Interviews and Ethnography

Qualitative methods are often the method of choice for examining new uncharted topics, and these methods have been used effectively by researchers who study organized activities. These studies provide an exploratory view of ongoing human interactions and processes as they are embedded within their *natural ecological contexts*. For research on organized activities, this contextual view spans interactions between children, staff, the program culture, physical and institutional environments, and the surrounding ecological systems. These open-ended methods have enabled researchers to identify pertinent language, concepts, frameworks, and questions for future

research. The role of these methods extends beyond this initial exploratory stage. Data in the form of words and narratives—and operations like interpreting, contextualizing, and theoretical analysis—make important contributions to understanding person-process-context dynamics within organized activities. Two general qualitative approaches (i.e., qualitative interviews and ethnographies), have proven to be particularly informative.

Qualitative interviews provide information about people's conscious experience of the person-process-context dynamics in programs. They have been used to study the internal thought processes of program staff, youth, parents, and program management. Longitudinal interviews, for example, have illuminated what staffs' planning process and goals are for an activity, and then, how program members experience the activity and what they learn from the experience (e.g., Larson & Angus, 2011a).

A model of the potential contributions of interview research is seen in a large cumulative record of interview studies on youth sports. These studies have led to the identification of 40 distinct sources of stress across the multileveled ecology of experience in sports (Scanlan, Babkes, & Scanlan, 2005). These include *intrapersonal sources* of stress (such as threats to self-esteem, worries about mistakes, guilt related to hurting opponents, and coping with injuries), *situational sources* of stress (such as pain after losing by a close margin), *interpersonal sources* (such as hostile interactions with teammates and negative experiences with coaches and parents), and others. These studies have helped "plumb the depth" of these different types of experiences (Scanlan et al., 2005, p. 280). In one interview, for example, a runner said of his coach: "If you had a bad race, he doesn't even talk to you. That's how you know you didn't do well" (Fraser-Thomas & Cote, 2009, p. 15).

Sports researchers have used this charting of sources of stress along with enjoyment and other dimensions of sports experience as the basis for conducting *quantitative studies* that evaluate their impact on athletes' well-being and continued participation in a sport (Scanlan et al., 2005). This work has also contributed to the design of interventions to train novice coaches to create positive learning environments (Smoll & Smith, 2010).

Researchers in the wider field of youth development have begun to use interview methods to realize this potential, addressing topics such as the reasons that immigrant youth stay in or drop out of organized activities (Simpkins et al., 2013), the challenges and expertise of program staff (Larson & Walker, 2010), the processes in programs

through which adolescents are active agents of their own development (Kirshner, Pozzoboni, & Jones, 2011; Larson, 2011), and the interactions between parents and youth around the program (Larson, Pearce, Sullivan, & Jarrett, 2007).

Ethnography, which involves intensive observation and interviews, can offer a more integrated view of processes across systems in the ecology of organized activities. Fine (1987) documents how interaction between boys and coaches in five Little League teams socialized the boys into a code of toughness, emotional control, loyalty, masculinity, and homophobia. Heath (1998), a linguist, used intensive observation to discover how youth in project-based programs learned a distinct “language of work,” including “if-then” constructions, modals (e.g., can, should, could), and mental state verbs (think, believe, wish, feel). A study of Boys and Girls Clubs by Hirsch, Deutsch, et al. (2011) demonstrates how ethnography can provide holistic understanding of the processes influencing program quality within youth organizations. They conducted 233 participant observations over a year at three clubs in similar low-income urban neighborhoods. They also interviewed youth (Ages 10 to 17) and staff at the program. The study provides a picture of the ecological processes differentiating a high-quality club, West River, from a low-quality club, North River.

At West River there was synergy between management, staff, and youth. The director communicated a strong, consistent focus on young people’s positive development. Staff members were encouraged to develop new activities, especially those that allowed youth to exercise initiative. As a result, West River had many more activity choices than North River, and West River’s activities provided “a steady diet of opportunities for exercising leadership and responsibility” (Hirsch, Deutsch, et al., 2011, p. 244). The activities also provided more opportunities for youth to form close mentoring relationships with staff. For example, a young man formed a bond with Victoria, a staff member, through a dance group she organized. The trust that he developed with her allowed Victoria to challenge his disrespectful behavior and provide coaching that helped him learn to work effectively with younger children.

In contrast, disorganization and conflict characterized the ecosystem of North River. The director was authoritarian. He reprimanded employees in front of youth and undermined an activity started by one youth. Given this hostile climate, conflicts “spread like wildfire” through the organization (Hirsch, Deutsch, et al., 2011, p.147). Front-line staff rarely collaborated and often clashed with

each other. The researchers observed *10 times* the number of staff conflicts here compared with West River. In this authoritarian and punitive climate, staff felt they had to keep children on a short leash. A youth complained that the staff member leading the cheerleading team was “having us do a bunch of cheers that we don’t like. And she won’t let us do any of ours” (p.165). When asked about mentoring, a staff member described advising youth to “learn to respect adults” (p.192). The study provides insight on how program quality is shaped by interactions within and between every level of an organization.

Ethnographic studies have also highlighted the roles of organized activities in family life and child development. In a study of 32 families, Kremer-Sadlik and Kim (2007) conducted interviews and observations of middle-class U.S. families during formal participation in organized sports (e.g. Little League), informal participation (e.g. backyard pick-up games), and passive participation in sports (e.g. watching televised athletic events). Their detailed analysis of parent-child interactions and conversations revealed sports activities as an arena in which parents sought to socialize their children to values and skills that went beyond the benefits of participation in athletic activities. The ethnographic data helped illuminate the function that sports have in family daily life as a socializing tool for culturally cherished skills and values.

### Time Diaries and Experience Sampling Reports

Kenny describes systematic direct measurement of daily experience as “one of the most exciting developments in social and behavioral methodology” (Bolger & Laurenceau, 2013, p. viii). Research on organized activities has used two of these methods, experience sampling and time diaries, to determine how young people’s *time use* and *subjective states* during organized activities differs from their experience in other settings. These methods have the advantage of obtaining ecologically valid data, in the moment, that reduce effects of retrospective bias and memory selectivity. When these methods are used to obtain repeated quantitative measures, they yield additional benefits, including permitting the study of *within-person patterns and processes over time*, using statistically controlled multivariate analyses.

Time diaries can be used to measure the “dosage” of particular types of experience, for example, amount of exposure or experience in a given activity, setting, or interacting with adults or peers. In early research, Posner and Vandell (1994) employed telephone time diaries to

study differences in how low-income 8- and 9-year-olds spent their time in afterschool programs as compared to other settings such as self-care and babysitters. They found that, at programs, children spent much more time actively involved with adults and with peers in contrast to children in self-care or informal adult supervision arrangements.

In other work, Vandell, Shernoff, et al. (2005) employed experience-sampling methods to obtain reports from middle school youth at random times during the afterschool period. While at programs, youth spent less time in passive activities like watching TV and eating snacks than was the case when these same youth were at home after school. Experience sampling also has identified differences in the subjective states experienced by older youth in organized programs, as compared to other daily settings (Larson & Rusk, 2011). The strong consistent finding across multiple studies is that mean levels of different dimensions of engagement—including intrinsic motivation, effort, concentration, investment, and challenge—are higher when young people are in organized activities than in other parts of their lives. In contrast, during schoolwork, youth report their concentration and challenge are high but their motivation is low, whereas during leisure activities with friends motivation is high, but concentration and challenge are low (Larson, 2011; Vandell, Shernoff, et al., 2005). The implication is that organized activities are a unique context in adolescents' lives in which their hearts and minds are "meaningfully engaged" in learning activities (Shernoff, 2013).

These methods provide tools for understanding how different aspects of the bioecology of young people's experience in organized activities change over time. For example, Traves, Harre, and Overall (2012) used intensive sampling to study youth in a dance program over 5 months as they prepared for a competition. Over nine data collections points, youth reported significant increases in excitement, enthusiasm, and "togetherness" as a team. This progressive increase in engagement suggests collective processes that may be activated as young people work together toward a final product. A future step for these methods is examining mediating processes (e.g., leader and parent support, peer dynamics) that influence these variables and, ultimately, the developmental outcomes for youth.

### Survey Measures, Archival Data, and Questionnaires

Survey measures provide the backbone for many of the studies of organized activities. In this section, we describe several publicly available, nationally representative

surveys, as well as other questionnaires, developed to assess the quality of youth experience in organized activities.

One useful survey is the Before- and After-School Programs and Activities Interview, which is part of the National Household Education Survey (NHES) conducted by the U.S. Department of Education (see <http://nces.ed.gov/nhes/questionnaires.asp>). This nationally representative survey was administered in 1999, 2001, and 2005 to parents of students in grades kindergarten through eighth grade (roughly Ages 5 to 13) who responded to questions about regularly used arrangements during the afterschool hours, including programs and activities for individual children. Parents report amount of time (hours, weeks, months) their child spends each week in the activity, its location (e.g., school, church), the number of participants in the group, number of staff, costs, language spoken, transportation to and from the activity, and the specific kinds of programming that occurred. Parents also respond to questions about informal afterschool care arrangements by relatives and by nonrelatives, as well as how often the child typically cares for him or herself.

These NHES data have been used to draw a nationally representative picture of the prevalence and intensity (hours and duration) of organized activities in the United States. Because the data set also includes information about family and child characteristics, such as ethnicity, country of origin, grade level, receipt of special educational or social services, and the academic and behavioral functioning of the focal child, it is a rich resource for secondary data analyses on a wide range of questions about the bioecology of organized activities. However, it is limited in two respects. First, the survey is cross-sectional, so only concurrent associations can be studied. Second, all data were obtained from a single data source—parent reports.

A second nationally representative study, the Early Childhood Longitudinal Study (ECLS-K), is also publicly available (at <http://nces.ed.gov/ecls>). Begun in 1999, the study is longitudinal and utilizes multiple research methods and includes multiple respondents. The first round of data collection began when children were in kindergarten (1998–1999) and continued when children were in first, third, fifth, and eighth grades. Parents answer questions about their children's out-of-school activities in third, fifth, and eighth grades, including participation in specific types of activities (sports, clubs, dance, music, performing arts, and art). Reading and math achievement are assessed by trained survey staff. Social and behavioral outcomes, such as approaches to learning, are reported by parents and by classroom teachers.

Several investigators (Covay & Carbonaro, 2010; Dumais, 2006) have used this data set to study social class and ethnicity differences in extracurricular activity participation and concurrent associations between activities, as well as cognitive and noncognitive outcomes in Grade 3. A notable strength of this data set is that investigators can employ numerous controls for family and school characteristics, in addition to controls for children's earlier functioning. Other aspects of this data set (e.g. studies of effects associated with cumulative participation in organized activities over time) have not been analyzed.

The National Longitudinal Study of Adolescent Health (Harris et al., 2009) is a third nationally representative survey that includes questions about organized activities. It is an interesting complement to the ECLS-K because it follows a nationally representative sample of adolescents in Grades 7 to 12 (roughly 13 to 18 years). Begun in 1994–1995, adolescents answered questions about their extracurricular activities. The sample was then followed up in 1996, 2001–2002, and 2007–2008, and expanded to include interviews with parents, teachers, peers, and romantic partners as well as the adolescents themselves. Some of the data from this survey are publicly available, and other parts of the data set are available under restricted use to preserve confidentiality. Simpkins, O'Donnell, Delgado, and Becnel (2011) used the Add Health to study Latino/a young people's selection into organized activities. Feldman and Matjasko (2007) used the Add Health data to identify profiles of students who participate in extracurricular activities, and Daniels and Leaper (2006) investigated connections between activity participation, self-esteem, and peer acceptance.

Three additional nationally representative data sets support secondary data analyses of the antecedents and consequences of organized activities within a bioecological framework. The Survey of Income and Program Participation ([http://www.census.gov/sipp/top\\_mod/2004/topmod04rev.html](http://www.census.gov/sipp/top_mod/2004/topmod04rev.html)) is conducted by the U.S. Census Bureau and focuses on organized activities within the broader context of child care and the needs of working families. The Panel Study of Income Dynamics (<http://psidonline.isr.umich.edu/Guide/documents.aspx>) is a long-running study conducted at the University of Michigan. The third data set, and most frequently used to study extracurricular activities, is the National Education Longitudinal Study (NELS), which began in the spring 1987–1988 and resurveyed the same students in 1990, 1992, 1994, and 2000. Data were collected from parents, schools, and teachers, and from extant high school

and postsecondary transcripts. Lipscomb (2007) used the NELS to study extracurricular involvement and later academic achievement. Dumais (2008) used the NELS to relate extracurricular involvement to math achievement and college expectations. Although developmental scientists have used these data sets to study child and family factors associated with participation in activities (i.e., selection) as well as investigating links between participation and student outcomes, these data sets are still under-utilized resources.

A limitation of all of the currently available national surveys is that they do not ask youth about the *quality* of their experiences in organized activities. Several questionnaires have been developed, however, that do collect this information. One questionnaire, the After-School Experiences Survey (Rosenthal & Vandell, 1996) and its abbreviated version, the After-School Experiences, Short-Form (Vandell, 2012) have been used in several large-scale studies, including the public data set of the NICHD Study of Early Child Care and Youth Development. A variant of this questionnaire, the *Summer Program Experiences Survey* has been used in summer programs (Vandell, Hall, O'Cadiz, & Karsh, 2012).

These surveys ask children to rate the quality of their experiences with respect to interactions with adult staff, interactions with peers at the program, and their interest in the activities, all rated on 4-point scales. Sample items include: "I trust the staff here," "I like the activities here," and "I get to know other kids here really well." Youth reports of the quality of their experiences are significantly related to observations conducted by trained observers (Rosenthal & Vandell, 1996). More frequent negative staff-child interactions, as reported by independent observers, are associated with youth reports of more negative staff-child relationships. Observers' reports of a greater variety of program activities are related to youth reports of greater interest in program activities. Youth reports of the overall quality of their experiences at programs and reports on individual subscales are related to classroom teacher reports of social competencies, (reduced) problem behaviors, and academic functioning (Kataoka & Vandell, 2013a; Vandell et al., 2012). These findings indicate convergent and construct validity of the scales.

The Afterschool Experiences Short-Form has been adopted by the State of California as part of its ongoing quality improvement process at state-funded afterschool programs (see <http://www.afterschooloutcomes.org>). Programs receive reports summarizing the student ratings at their program with respect to three subscales: youth reports

of the quality of experiences with staff, the quality of experiences with peers, and interest in program activities. For comparison purposes, programs also receive summary information on these same scales for the state as a whole. The goal of the project is to provide afterschool programs with information about youth experiences at their program that can be used to inform efforts about aspects of programs that are working well and modify aspects of programs that are not working as well.

### Observational Assessments

As noted earlier, ethnographies have provided rich qualitative descriptions of young people's experiences in organized activities. In addition, the study of organized activities has been enhanced by an expanding array of systematic observational tools that *quantify* the *quality* of organized activities, particularly, the quality of afterschool programs. Yohalem, Wilson-Ahlstrom, Fischer, and Shinn (2009) have provided an analysis and critique of 10 observational assessments that offer setting-level observations of program quality that can be used in a range of school and community settings, and which have established psychometric properties.

The assessments differ in their particulars. Some use 4-point ratings; others use 5- and 7-point ratings. Some use time-sampled checklists in addition to ratings. The length of the observational periods vary, as does the amount and type of observer training. Some of these observations, like the Youth Program Quality Assessment (C. Smith & Hohmann, 2005), the School-Age Care Environment Rating Scale (Harms, Jacobs, & White, 1996), Dimensions of Science (Noam & Papazian, 2011), the Promising Practices Rating System (Vandell et al., 2006), and the Program Quality Observation Scale (Pierce, Hamm, & Vandell, 1999; Pierce, Bolt, & Vandell, 2010) are conducted by trained independent observers for purposes of research and evaluation. Others, like the Assessing Afterschool Program Practices Tool, developed by the Intercultural Center for Research in Education and National Institute on Out-of-School Time, were developed by practitioners to study and improve their own programs, sometimes for the purposes of accreditation by professional organizations.

Despite these differences, the observations reflect shared views about key aspects of program quality, which correspond to views of quality identified in the qualitative interviews, ethnographic reports, and the youth questionnaires of program experience. All include items or scales that assess supportive social interactions and relationships

with adult staff. All assess the types of activities being offered in term of opportunities for skill building, and all evaluate whether youth appear engaged or interested in the program's activities. Most assess how well the program is organized or structured. Most also measure the quality of interactions with peers at the program. Some, like the Program Observation Tool developed by the National Afterschool Association, are especially concerned with accreditation and program improvement. These instruments rate aspects of the physical settings, including space, furnishings, health, and safety provisions. Several measures also assess the quality of the settings as a work environment for the adult staff, including interactions between staff. There are some differences in emphasis in assessments designed for K–5 programs versus programs serving older youth, with a greater focus on supports for autonomy and leadership in the observational assessments of adolescent programs.

### CONCEPTUALIZING KEY PARAMETERS AND PROCESSES

The research methods described in the preceding section tell something about *how* organized activities have been (and can be) studied. In this section, we turn to considerations of the salient parameters that need to be understood and measured. We focus principally on quantitative research, because nearly all of the large national and multisite studies have taken this approach; and we focus on parameters in which the individual child or adolescent is the unit of analysis because that has been the focus of nearly all developmental research on organized activities.

This research has examined five broad sets of dimensions, each tapping different aspects of children's experiences in organized activities. These parameters are: (1) participation, (2) specific types of activities, (3) breadth of activities, (4) dosage or amount of exposure, and (5) the quality of experiences or developmental processes in the organized activities. These conceptualizations serve as building blocks for addressing questions about which youth participate in organized activities and what they gain from their participation, topics that are addressed in subsequent sections.

#### Participation

At its broadest level, organized activities are conceptualized in terms of *participation*, a categorical designation of

whether or not a young person participates in organized activities. In some studies, participation is a dichotomous (yes/no) variable. In other studies, participation in organized activities is juxtaposed with participation in other types of experiences, like relative care, sitter care, or self-care.

Researchers have posed two broad sets of questions about *participation*. The first considers *participation* as the dependent variable and asks, “What child, family, and community factors predict youth participation in organized activities?” This approach is concerned with selection into activities. The other set of questions considers *participation* as the independent variable and asks, “What are the effects of participation on child developmental outcomes?” This question has been asked in randomized control trials and in quasiexperimental studies, both aimed at assessing the impact of program participation on youth outcomes, relative to a control or comparison group. Researchers have also studied effects of participation using prospective longitudinal designs that include statistical controls for selection effects.

A shortcoming of these categorical designations is that participation is treated as a black box or, to use Bronfenbrenner’s terminology, a *social address* that pays minimal attention to what a child’s experience is like, what kinds of social interactions occur, or how activities and relationships in the setting could affect the child. In the case of organized activities, use of a categorical designation allows minimal insights into *why* participants differ from nonparticipants or sources of differences within participants or within nonparticipants.

Efforts to move beyond organized activities as a categorical designation have led researchers to consider four additional aspects of organized activities: *specific types* of activities, *breadth* of activities, *dosage* or amount of exposure to activities, and the *quality* of experiences or developmental processes within organized activities. Each of these dimensions is described in turn in this section.

### Specific Types of Activities

One distinction among activity types is the differentiation between afterschool programs and extracurricular activities, a distinction we introduced earlier and will return to in subsequent sections. Indeed, separate robust literatures have developed around these two types of organized activities as reflected by recent meta-analyses and research syntheses of afterschool programs (Durlak, Weissberg, & Pachan, 2010; Roth et al., 2010) and

extracurricular activities (Farb & Matjasko, 2012; Feldman & Matjasko, 2005).

Further distinctions have been made within these two classes. Within afterschool programs, researchers have studied specific types of programs, for example, those that emphasize homework help and academic remediation (Vandell, O’Cadiz, & Hall, 2010), hands-on science (Vandell, Warschauer, O’Cadiz, & Hall, 2008), digital literacy (Cole, 2006), and positive youth development (Lerner et al., 2005). An important research question is whether these different foci and attendant activities are differentially associated with academic and psychosocial outcomes.

Within extracurricular activities, researchers have studied sports, performing arts, service clubs, and faith-based youth groups. Theorists have suggested that these different activities may provide different “nutrients”—distinct constellations of developmental experiences (Eccles & Gootman, 2002). Surveys of adolescents indicate what some of these differences might be. For example, youth report more opportunities for developing initiative in sports, whereas they report having more opportunities related to personal identity and positive relationships with others in faith-based youth groups (Larson et al., 2006). Hansen, Skorupski, and Arrington (2010) have discussed differential affordances provided within different types of activities. Hockey and swimming, for example, share some affordances, such as physical training, social relationships with coaches and teammates, and emotional challenges resulting from wins and losses, but they differ in physical contact and aggressive play.

In addition to studies that contrast types of activities, others have focused on variations within specific extracurricular activities, resulting in in-depth examinations of experiences in youth sports (Scanlan et al., 2005), arts programs (Heath, 2001), civic activism programs (Ginwright, Noguera, & Cammarota, 2006), and youth music (O’Neill, 2005). An underlying theme in the collective literature on specific activities is that, although there are differences in the developmental affordances of specific activities, there are also fundamental similarities across them.

### Breadth of Activities

Many young people participate in multiple activities—simultaneously and over time. *Breadth of activities* has been used to describe participation in multiple activities. Busseri and Rose-Krasnor (2009) defined breadth as the *total number of activities* that a young person engages, whereas Eccles and Barber (1999) conceptualized breadth

as the total number of *different* types of activities, a potentially meaningful distinction that has not been explored in any detail in the literature.

In both formulations, greater breadth is posited to be beneficial because it exposes young people to a broader range of learning opportunities, a larger network of potentially supportive adults, and a larger network of different types of peers than does a single activity engaged in for an equivalent amount of time (Bohnert, Fredricks, & Randall, 2010; Eccles & Barber, 1999). Consideration of these processes has led researchers to hypothesize that breadth is particularly important in early adolescence, relative to later adolescence, because early adolescence is a period when youth are exploring different interests and strengthening ties with peers (Bohnert et al. 2010; Busseri & Rose-Krasnor, 2009).

Conceptualizations of breadth also are relevant for research in comprehensive afterschool programs that serve elementary school and middle school students. Some programs offer young people a wide variety of enrichment, academic, and recreational activities, whereas others have more restricted options. Children report more positive experiences in afterschool programs that offer a wider variety of activities (Rosenthal & Vandell, 1996). There also are indications that greater breadth of activities predicts higher program attendance (Smith et al., 2012) and more positive child developmental outcomes (Pierce et al., 1999; Pierce et al., 2010).

### Dosage

A third source of variation in organized activities is *dosage*, or the amount of time that young people participate in the activities (Bohnert et al., 2010; Busseri & Rose-Krasnor, 2009). This focus on dosage is consistent with the admonition that “to be effective, the interaction must occur on a fairly regular basis over extended periods of time” (Bronfenbrenner & Morris, 1998, p. 797). Dosage in organized activities has been measured in terms of *intensity*, defined as minutes per day, days per week, and total attendance days. Dosage also has been measured in terms of *duration* or the total length of time in the activity, assessed as months or years of participation. Finally, dosage has been conceptualized in terms of *consistency* and *continuity* over time, measured as the proportion of periods or epochs in which youth engage in activities (Auger, Pierce, & Vandell, 2013).

A repeated observation, across studies that have examined dosage, is the wide variability in this aspect of youth

involvement in organized activities. Daily attendance in afterschool programs varies widely across and within programs, from a single day to more than 180 days in a school year (Reisner, White, Russell, & Birmingham, 2004; Vandell et al., 2008), with “high” dosage defined in varying amounts ranging from 30 days to 140 days in different studies. Similarly, longitudinal studies have documented wide variations in the continuity and consistency of youth participation over time.

These variations raise questions. One set of questions asks *why* exposure to activities is so variable. What are the program, child, family, and community characteristics that predict these variations in attendance? Other questions pertain to how these variations in continuity and dosage are related to child developmental outcomes. Can children who attend programs sporadically still benefit?

### Proximal Processes and Quality

Bioecological theory—and decades of research on other developmental contexts like families and school—suggests that the *quality* of experiences that young people have in organized activities settings is crucial. Ethnographic studies, such as the Hirsch, Deutsch, et al. (2011) study of Boys and Girls Clubs (described under research methods), show that there can be enormous differences in what children experience in programs, ranging from a disorganized and conflict-laden environments in which staff see their role as teaching youth to “respect all adults,” to settings in which program directors support line staff, staff support youth, and youth have a wide variety of opportunities for activities and meaningful interactions with adults and peers.

Efforts to quantify these “proximal processes” have focused on whether a program provides activities that youth find to be challenging and engaging, whether interactions with adult staff and peers are supportive or are conflict-ridden, and whether the program provides opportunities for choice and voice in the activities. Other processes that are believed to be hallmarks of high quality organized activities are opportunities for youth to be active learners who can engage in projects in which they can develop and build skills in areas that interest them.

Defining, measuring, and testing the features of program quality has been a bootstrapping process. In their National Research Council report, *Community Programs to Promote Youth Development*, Eccles and Gootman (2002) drew on developmental theory, research on effective families, school, and youth programs, and accumulated youth practitioner wisdom to conceptualize program quality. They

identified eight features in young people's experience of a program that were likely to support positive developmental outcomes in youth.

1. *Physical and psychological safety.* Young people are safe and feel safe (e.g. from hostile peer interactions).
2. *Appropriate structure.* Staff provides clear and consistent structure and a level that is appropriate to the developmental experience and cultural model of authority of the young people in the program. Activities are not chaotic or disorganized nor are they rigid or autocratic.
3. *Supportive relationships.* Staff is responsive to youth needs, care about them, and communicate effectively with them. Detachment, rejection, and over-control are negative exemplars of this feature.
4. *Opportunities to belong.* Youth feel valued, included and experience themselves as members of the program, regardless of their gender, ethnicity, sexual orientation or disabilities.
5. *Positive social norms.* Youth experience strong norms, expectations, and a "culture" within the program that supports prosocial behaviors and sanctions deviant and antisocial behaviors.
6. *Opportunities for efficacy and mattering.* The program offers young people opportunities for active participation, meaningful challenges and empowerment.
7. *Opportunities for skill building.* Program activities provide opportunities for youth to learn physical, intellectual, psychological, and social skills.
8. *Integration of family, school, and community efforts.* There is meaningful communication and concordance between the program and other arenas of a young person's life.

Many of these features are incorporated into the existing measures of program quality, including youth-report measures of the quality of their experiences in program (Rosenthal & Vandell, 1996; Vandell et al., 2012) and observational measures such as the Promising Practices Rating System (Vandell, Reisner, & Pierce, 2007) and the Youth Program Quality Assessment (C. Smith & Hohmann, 2005).

In addition to these eight features, researchers recognize that there may be other dimensions of the program, organization, or staff that are pertinent to these proximal processes. These include features such as staff education, staff professional development, group size, staff to child ratio, and materials. These features are especially important because they can be controlled by management or regulated. All of these diverse factors have been

hypothesized to be important to program quality, and studies have been conducted to evaluate whether these factors predict proximal processes in the programs as well as youth outcomes at school.

## SELECTION IN (AND OUT) OF YOUTH ACTIVITIES

Multiple factors—children's own characteristics and interests, their family circumstances, their peer groups and friendships, school and neighborhood characteristics, and aspects of the organized activities themselves—are associated with whether young people begin a particular organized activity, persist in that activity, or terminate the activity. Identifying these factors is part of the general research topic of *selection effects* in organized activities

Understanding when and how child, family, peer, and school characteristics are related to participation is important for several reasons. First, it can inform practitioners and policy makers about why some activities are more successful than others in attracting and sustaining involvement. With this information, programs can better align their offerings to the interests and needs of the children and families they seek to serve. This understanding includes identifying factors that "pull" youth to join and persist in an activity as well as illuminating the factors that "push" children and families out of activities. Some attrition occurs when youth experience program staff or youth as unsupportive, disinterested, or hostile, or the activities are boring or poorly organized (Butcher, Linder, & Johns, 2002). In other cases, attrition reflects a developmental progression as children try out multiple activities and then begin to focus more deeply on a smaller number of activities as their interests become more defined (Rose-Krasnor, Busseri, Willoughby, & Chalmers, 2006).

Researchers also study selection in order to identify appropriate statistical controls to be used in quantitative analyses of links between organized activities and child developmental outcomes. Because many of the factors that influence selection are related to child outcomes, they (and not organized activities) may account for obtained links. Statistically controlling for selection can strengthen analyses and lessen the likelihood that obtained "program effects" are artifacts of selection bias.

Finally research studies of selection are important because they may reveal systematic inequities in access to activities. By virtue of where youth live or their family income or their sexual orientation or physical disability,

youth may be systematically excluded from activities that they would otherwise enjoy and want to participate in. In this section, we examine child, family, peer, school/community, and program factors that are associated with young people's joining activities, persisting in the activities, and dropping out of the activities.

### **Child Characteristics That Predict Participation**

Two broad classes of child characteristics have been considered as predictors of participation in organized activities. The first is demographic characteristics such as gender, age, and ethnicity. The second is various indicators of child competences and adjustment.

#### ***Gender, Age, and Ethnicity***

The Selected Indicators of Child Well Being survey conducted by the U.S. Census Bureau (2009) reports participation rates in extracurricular activities in the United States. The survey describes participation in sports, clubs, and lessons of 48.6 million young people, ages 6 to 17 years. It includes participation in all extracurricular activities and is not restricted to activities that are used as child care.

Drawing on detailed tables from the U.S. Census Bureau, participation rates can be disaggregated by child gender, age, and ethnicity. These tables suggest that gender is associated with participation during both middle childhood and adolescence. Boys are more likely than girls to participate in sports, whereas girls are more likely than boys to participate in lessons and clubs. These findings are consistent with the multivariate analyses of earlier waves of nationally representative surveys (Kleiner et al., 2004).

Child age is a second individual characteristic linked to extracurricular activities. In the Selected Indicators of Child Well Being, participation in sports is higher in adolescence than in middle childhood, whereas lessons are more common in middle childhood than adolescence. Participation in clubs is similar in the two age groups; about 30% of the children and adolescents regularly participate in club activities. These findings are also consistent with the multivariate analyses of earlier national surveys (Kleiner et al., 2004). In other longitudinal analyses of U.S. and Canadian youth in large, but not nationally representative samples, it appears that activities become more specialized in older children and adolescents as youth move from participating in a broad range of activities to a small number of activities over time (Denault & Poulin, 2009; Eccles & Barber, 1999; Rose-Krasnor et al., 2006).

Finally, there is evidence that ethnicity is linked to participation. In the Selected Indicators of Child Well Being, European American children (Ages 6 to 11 years) participate in sports at higher rates than Asian American, African American, and Latino/a American children. Asian American children participate in lessons at higher rates than other groups. Asian American and European American children participate in clubs at higher rates than African American and Latino/a American children. European American adolescents have the highest participation rates in all categories of extracurricular activities (sports, clubs, and lessons) and Latino/a American youth have the lowest participation rates. Multivariate analyses of the extracurricular activities in middle childhood and adolescence, which utilized large nationally representative data sets, also have found lower rates of participation in Latino/a American adolescents (Covay & Carbonaro, 2010; Dumais, 2006; Simpkins, O'Donnell, et al., 2011).

#### ***Child Competencies and Adjustment***

Other studies have considered child competencies as predictors of participation. Methodologically stronger studies in this area are longitudinal and predict child activities at Time 2, controlling for family factors and child activities at Time 1. In analyses of this sort, Posner and Vandell (1999) found that academic performance and emotional well-being in Grade 3 (roughly 8.5 years) was linked to participation in extracurricular activities in Grade 5 (roughly 10.5 years), suggesting that more competent children are more likely to participate in activities when they are older. Competencies and adjustment also predict participation in adolescence. In one longitudinal study involving almost 4,000 Canadian high school students, Good and Willoughby (2011) found higher levels of academic achievement in one grade predicted more frequent club involvement the next year, associations that were replicated across grades. In a second longitudinal study of Canadian adolescents, Busseri, Rose-Krasnor, Willoughby, and Chalmers (2006) found developmental success (a composite variable that includes academic orientation, well-being, and interpersonal relations) predicted greater breadth of activities and greater intensity of activities almost two years later. Finally, self-esteem is a significant positive predictor of adolescents' participation in extracurricular activities (Larson, 2000). On the negative side, research conducted in Sweden found that delinquency at Time 1 predicted switching to hanging out in the streets at Time 2, measured 1 year later (Persson, Kerr, & Stattin, 2007).

Another finding is that children's level of engagement in an activity predicts subsequent participation in that activity

and other activities. Using data from the Childhood and Beyond Study, a large, longitudinal study conducted in Michigan, Simpkins, Vest, and Becnel (2010) found that children who participated in organized activities across multiple years and children who were “highly active” participants were more likely to engage in activities as adolescents.

As children move into middle school and high school, access to some structured activities also becomes dependent on children’s skill levels. Tryouts and auditions determine placement on sports teams and musical performance groups. Historically, athletics, fine arts, and cheerleading were the most closed activities in the United States; newspaper and yearbook, the most open (McNeal, 1998). The likelihood that students will participate in an activity in high school is greater if they have experience with the activity in middle school. Young people sometimes drop out of activities because of concerns that they are not “good enough” to continue the activity (Vandell, Pierce, et al., 2005).

Researchers should also keep in mind that youth are sometimes kicked out of programs. In some school-sponsored extracurricular activities, students are required to maintain a certain GPA to continue participation; and bad behavior—in the program or in other parts of their lives—can lead to them being excluded from participation. This kind of selection may contribute, for example, to the associations of participation with higher grades and with less delinquency.

There are important gaps in our understanding of other child characteristics in relation to participation in organized activities. Only a handful of studies have considered children with special needs. In one study of 427 children with physical limitations (Law, Petrenchik, King, & Hurley, 2007), children of low-SES (socioeconomic status) families were less likely to participate in organized activities than more economically privileged families. In a second study of young people who have cerebral palsy, children were more likely than adolescents and young adults to participate in activities, raising the question whether older youth feel unwelcome or otherwise excluded from these programs (Orlin et al., 2009). More research is needed on the opportunities and barriers for youth with special needs.

### **Family Characteristics That Predict Participation**

In addition to the child’s own characteristics, family factors are linked to participation in organized activities. These characteristics include demographic factors

such as parental education and family income as well as parent-child relationships and parental beliefs.

### ***Parental Education, Income, and Employment***

There are dramatic differences in participation associated with maternal education. Roughly 3 times as many children, Ages 5 to 12 years, whose mothers have a 4-year college degree are involved in sports, clubs, and lessons compared to children whose mothers did not graduate from high school (U.S. Census Bureau, 2009). Similar differences are evident for adolescents, Ages 12 to 17 years. These differences echo findings of earlier national surveys in the United States (Kleiner et al., 2004; K. E. Smith, 2002) and remain significant in multivariate analyses.

Social class and family income are similarly linked to differences in participation rates. Based on their multivariate analyses of the ECLS-K data set, Covay and Carbonaro (2010) determined that all three factors—parental education, social class, and family income—were significant predictors of extracurricular activity participation during middle childhood, findings replicated in other longitudinal studies of adolescents (e.g., Feldman & Matjasko, 2007).

These SES differences may well be mediated by less availability of programs in low-income neighborhoods, by parents’ safety concerns, and by high-income families having the discretionary income to pay program fees. Studies of elementary (Casey, Ripke, & Huston, 2005) and middle school (Hultsman, 1992) students reveal that joining an activity also is related to the availability of transportation, cultural attitudes, and needs for older children to provide child care for younger siblings. These same factors are cited as reasons for dropping out of an activity.

Lareau’s (2011) ethnographic study further illustrates social class differences in out-of-school time. Lareau conducted an intensive observational and interview study of 12 families of 10- to 11-year-olds. Children in the low-income families spent more time after school and on weekends in unstructured activities with relatives and friends, whereas the middle-class children participated in a complex array of organized activities—sports, choir, church groups, music lessons—that called for balancing time demands and performing before groups. In Lareau’s analysis, parents in the low-income families emphasized “natural growth” in which children were given freedom to go outside and play with relatives or friends. In contrast, parents in the middle-class families emphasized “concerted cultivation” and parents devoted much effort to providing their children “a steady diet of adult organized activities” (Lareau, 2011, p. 3), with the belief that these

would advance their children's development and future life chances.

Chin and Phillips (2004) have reported similar social class differences in children's summer activities, although they disagreed with Lareau's contention that working-class parents believe children's development unfolds spontaneously. Instead, they found that working-class parents faced financial and time obstacles that prevented them from involving their children in many activities.

Other reports have focused on maternal employment as an influence on participation in organized programs. Here, consistent findings are reported in several national surveys (Capizzano, Tout, & Adams, 2000; Kleiner et al., 2004; K. E. Smith, 2002). Children are more likely to attend afterschool programs when their mothers are employed, when mothers work more hours, when mothers work traditional "9-to-5" schedules, and when children reside in single-parent households rather than two-parent households.

### ***Family Processes and Beliefs***

Processes within the family context also are associated with children's participation in organized activities. Parental modeling appears to be important. Youth spend more time in organized activities when their parents are involved in community activities, and they spend less time in activities when their mothers spend more time watching television (Coulton & Irwin, 2009; Fletcher, Elder, & Mekos, 2000).

Parental beliefs also are linked to participation. Maternal beliefs about the value of sports, music, and math positively predict youth selection into these activities 1 year later (Simpkins, Fredricks, & Eccles, 2012). Parental warmth (Fletcher et al., 2000; Larson, Dworkin, & Gillman, 2001), encouragement of activities (Mahoney & Stattin, 2000), and specific instrumental support such as being able to drive children to activities (Anderson, Funk, Elliott, & Smith, 2003) are positive predictors of youth being more involved in organized activities.

Persson et al. (2007) have identified other ways in which parents influence program participation. In a large longitudinal study of Swedish youth (Ages 13 to 17 years), they determined that adolescents who switched to hanging out on the streets had less positive feelings about their families and more negative interactions with parents. Similarly, Bohnert, Martin, and Garber (2007) found negative family processes and maternal depression were related to lower rates of participation in activities. Research conducted by McGee, Williams, Howden-Chapman, Martin, and Kawachi (2006) in New Zealand identified other family

processes to be linked to program participation. In this case, positive attachment to family, friends, and school predicted participation in clubs, sports, and cultural youth groups.

Other researchers, such as Simpkins and colleagues, have utilized a mixed methods approach to identify family factors associated with organized activities. In one report, 31 Mexican American seventh-grade adolescents and their parents were studied over 1 year. Nine families were labeled as "continuous" participant families. In these families, parents valued their own experiences in organized activities as youth and encouraged their children's participation (Simpkins, Vest, & Price, 2011). In a second report (Simpkins, Fredricks, et al., 2012), focus group interviews were conducted with adolescents, their parents, and activity leaders. These interviews indicated that family financial resources and parents' work were barriers to adolescents' participation, especially for low-SES families. The physically demanding jobs and long work hours of parents also limited participation. Cultural values and practices (i.e., religiosity and language) also factored into participation.

### ***Peers and Friendship Networks***

Although less researched than individual and family factors, peers and friendship networks also have been identified as predictors of participation in organized activities. In a qualitative study involving in-depth interviews with 41 adolescents, Patrick et al. (1999) investigated the role of peer relationships in sustaining youth involvement in arts and sports activities. Quantitative analyses corroborate the qualitative data. In an analysis of the National Longitudinal Study of Adolescent Health, Simpkins, Vest, Delgado, and Price (2012) found adolescents were more likely to participate in activities if their friends were also participants and more likely to drop out of activities when their friends stopped the activities. Similar relations are reported in Sweden (Persson et al., 2007). Compared with youth who remained in organized activities, those who dropped out of the activities are less likely to have friends in their activities.

Some research suggests that the role of peers and friendships is moderated by age and cultural context. Simpkins, Vest, Delgado, and Price (2012) observed that associations between friendships and participation are stronger for European Americans than other ethnic groups, and for older adolescents than younger adolescents. In analyses that focused on within group variations in the Latin American sample of the Add Health Study, Simpkins, Vest, et al. (2011) found that youth who participated in

organized activities had higher proportions of non-Latino/a friends than did other Latino/a American youth in the sample.

### School and Community Factors

The availability of organized activities across schools and communities is highly variable, which means that young people have uneven access and opportunity to participate in different types of programs. This point is demonstrated by the Survey of After-School Programs in Elementary Schools, conducted by the U.S. National Center for Education Statistics (Parsad & Lewis, 2009). This survey reports the availability of different types of school-based after-school programs disaggregated by region of the country, type of location (urban, rural, small town), and school poverty level. Availability of four types of programs is measured: (1) fee-based stand-alone day care programs, (2) stand-alone tutoring programs such as the Supplemental Educational Services funded for schools not making satisfactory academic progress, (3) 21st Century Community Learning Centers, and (4) all other school-based programs.

This survey demonstrates that fee-based programs are primarily located in schools that serve higher income students, whereas the stand-alone tutoring programs that receive federal funds as part of Supplemental Educational Services are housed primarily in high-poverty schools. The 21st Century Community Learning Centers also are almost exclusively located in high-poverty schools. The types of activities offered by these programs differ. The fee-supported afterschool programs are more likely to offer a broader range of recreation and enrichment activities whereas the programs serving high poverty schools tend to focus on academic activities.

Other features of the school context are linked to the availability of organized activities. Larger schools and higher income schools offer more organized activities, although students are more likely to participate in activities in smaller schools compared to larger schools (Feldman & Matjasko, 2007), in rural and suburban schools versus urban schools, and in private schools compared with public schools (Marsh, 1992).

Finally, neighborhood safety ratings are related to participation. Youth are more likely to participate in programs when they and their parents perceive their neighborhoods to be safe, although participation among African American and Latino/a American youth is less inhibited by unsafe conditions than is participation by European American youth (Coulton & Irwin, 2009). Part of the reason may

be that many African American and Latino/a American parents in unsafe urban neighborhoods are highly invested in locating programs that provide safe spaces for their children after school (Jarrett, 1999).

### Program Characteristics as Predictors of Participation

Finally, program participation is influenced by how programs are structured and by the quality of youth experiences at the programs. Administrative structure and organization help to set the stage for well-functioning programs, which in turn predicts concurrent program attendance, and then higher retention rates the following year. Programs that employ directors with more advanced educational credentials, that utilize parent liaisons, and offer a strong academic component along with enrichment activities have higher concurrent program attendance rates (Blazevski & Smith, 2007) and higher retention rates the following year (Pearson, Russell, & Reisner, 2007).

Other studies have focused on young people's experiences in the programs. Youth report feelings of safety and strong relationships with staff as the most important reasons for attending a program (Halpern, Barker, & Mollard, 2000). A sense of belonging and opportunities to develop skills for the future also are commonly mentioned reasons for participation (Dawes & Larson, 2011). Finally, youth report that they are more like to participate when activities are freely chosen and enjoyable (Passmore & French, 2001).

## LINKING ORGANIZED ACTIVITIES TO CHILD DEVELOPMENTAL OUTCOMES

An important motivation for creating and funding organized activities is the belief that these activities promote psychosocial and academic competencies while limiting exposure to risky environments that promote problem behaviors. In this section, we review the quantitative literature that tests these propositions. The findings pertaining to afterschool programs are presented first, followed by studies of extracurricular activities. For each of these broad classes of organized activities, we consider effects associated with participation as well as more differentiated parameters, including the types and breadth of activities, dosage, and quality of experiences. We then turn to consideration of the child, family, and community factors that moderate linkages between organized activities and youth outcomes.

### Afterschool Programs

Studies of relations between afterschool programs and child developmental outcomes have considered a wide range of academic (grades, standardized test scores), social-emotional (friendships, identity, anxiety), behavioral (substance use, delinquency), noncognitive (task persistence, motivation), and physical (weight, physical activity) outcomes. A goal of research, conducted over the past 25 years, has been to identify conditions under which organized activities are associated with positive outcomes.

#### *Linking Program Participation to Child Outcomes*

A useful starting point in examining effects associated with participation in afterschool programs is a meta-analysis conducted by Durlak et al. (2010). This analysis, based on 68 studies conducted between 1980 and 2007, includes studies of programs serving elementary, junior high, and high school students. Thirty-five percent of the eligible studies were randomized control trials. Others utilized quasiexperimental research designs that included treatment and comparison groups. In two-thirds of the studies, effects were tested after less than a year of program dosage.

Durlak et al. (2010) found significant differences between program participants and nonparticipants in (a) self-perceptions, (b) bonding to school, (c) positive social behaviors, (d) achievement test scores, (e) school grades, and (f) reductions in problem behaviors. Effect sizes ranged from .12 to .34.

A second meta-analysis (Lauer et al., 2006) focused on effects of afterschool, before-school, and summer programs on the academic achievement of low-income students. To be included in this meta-analysis, the studies needed both treatment and control groups and direct assessments of reading and/or math achievement. Lauer et al. reported significant program effects in both domains, with an effect size of .13 for reading and .17 for math achievement.

Other large program evaluations, conducted since 2007, were not part of either the Durlak et al. (2010) or Lauer et al. (2006) meta-analyses. One of these evaluations studied the impact of After School Matters, a youth apprenticeship program that emphasized work culture and accomplishing tasks (Hirsch, Hedges, Stawicki, & Mekinda, 2011). In this randomized control trial, high school students were assigned either to an apprenticeship in technology, arts, or sports, or a waitlist control group. Nearly all of the students in the control group participated in other organized activities or paid work, thus, the comparison was to alternative treatments of unknown effectiveness. Findings indicated benefits of the apprenticeship program.

In an intent-to-treat analysis, apprentice students showed higher self-regulation and were less likely to sell drugs or participate in gang activity (effect sizes ranged from .15 to .19). Using a treated-on-treated design, apprentice students showed higher self-regulation, performed better on a mock job interview, and identified more with school, although school attendance was lower for apprentice students (effect sizes of .11 to .28).

In sum, research is consistent in showing that mere participation in afterschool programs is associated with positive outcomes, albeit with small effect sizes.

#### *Linking Program Features to Child Outcomes*

An important question is whether effects of organized activities are higher for high quality programs. To answer this question, researchers have sought to evaluate whether features of programs they thought to be related to quality (such as those discussed earlier) have greater associations with developmental outcomes.

In a follow-up meta-analysis conducted by Durlak et al. (2010), the investigators contrasted afterschool programs that met or did not meet SAFE criteria. The SAFE programs provided programming that was (a) *sequenced*—meaning that activities were connected and coordinated for skill development, (b) *active*—activities utilized “active” forms of learning, (c) *focused*—at least one component of the program was devoted to developing personal or social skills, and (d) *Explicit*—the program explicitly targeted specific personal or social skills. When SAFE programs were separated from other afterschool programs in meta-analyses, significant differences between program and comparison youth were found only for youth who attended SAFE programs. Participation in SAFE (Sequenced, Active, Focused, Explicit) programs was associated with substantially larger effect sizes for child self-perceptions, positive social behaviors, school bonding, achievement test scores, school grades, and (reduced) problem behaviors relative to comparison youth who did not attend a SAFE program.

Durlak et al.'s meta-analysis identifies one set of features of afterschool programs that are related to child outcomes (and by extension, to program quality). Qualitative research has illuminated other features that can lead to the development of socioemotional skills (e.g., responsibility, teamwork, initiative, and skills for managing emotions, Larson & Angus, 2011b; Rusk et al., 2013; Salusky et al., 2014). In many programs, participants work on projects or take on roles that actively engage them in a sequence of work over time. These provide cycles of learning through

which youth learn to persevere through unexpected obstacles, observe and learn to manage frustration, and develop skills for collaborating with peers. Program leaders provide focused and explicit input not only on the work of young people, but also on how young people approach projects.

Other quantitative research has examined additional factors associated with program quality. Blazeovski and Smith (2007) measured features such as safety, supportive environment, opportunities for interaction, and engaged learning at program sites serving almost 3,500 youth. Youth reports of a “sense of belonging” were related to higher program attendance, which then predicted higher reading achievement. “Opportunities to reflect” was also a significant predictor of reading achievement. “Opportunities to set goals and make plans” was negatively associated with long-term suspensions at school.

Pierce et al. (1999) focused on other aspects of program quality, including emotional climate, positive interactions with staff, positive interactions with peers, availability of age-appropriate activities, and programming flexibility, in relation to child developmental outcomes. They also controlled for possible confounding factors, like parenting practices in children’s families, parental income and education, and children’s functioning at the beginning of the school year. Findings showed that children who attended afterschool programs that offered more positive emotional climates (vs. less positive climates) exhibited fewer problem behaviors at the end of the school year along with improved academic performance at school, according to their first-grade teachers. Additionally, children who attended programs that offered autonomy and choice displayed gains in social skills according to their first-grade teachers. In a follow-up study of these same children over a 3-year period (Pierce et al., 2010), positive staff-child relationships in afterschool programs were associated with gains in reading grades, math grades, and social skills. Access to a diverse array of activities at the program was also linked to gains in math grades and classroom work habits at the end of the 3 years.

Other researchers have focused on negative features of programs to understand why programs have mixed success in reducing problem behaviors. In an analysis of some 3,000 5-minute intervals collected during 400 observations of afterschool programs in five public middle schools, Gottfredson and colleagues have found that when program leaders ignored deviant behavior it allowed deviant behavior to be reinforced by peers (Rorie, Gottfredson, Cross, Wilson, & Connell, 2011). They further determined that higher levels of structure in the activities were an effective

counter to peer reinforcement of deviance. More structured activities were associated with decreased levels of violence and counter-normative behavior.

Other research has confirmed the importance of program structure. In studies of Swedish recreation programs, which had few structured activities and were poorly monitored, participation (vs. nonparticipation) predicted increased antisocial behavior, including antisocial behavior assessed several years later (Mahoney & Stattin, 2000; Mahoney, Stattin, & Lord, 2004). In contrast, afterschool programs characterized by appropriate levels of adult support (programs that are not chaotic, but also not rigidly controlled) and structured skill-building opportunities are linked to gains in work habits and reductions in misconduct over the course of a school year (Vandell & Reisner, 2006). These studies also suggest that positive relationships with program leaders can deter antisocial behavior.

Research shows that other variables related to program leadership and staffing are linked to youth outcomes. In a study involving more than 4,100 young people and 78 programs, the Massachusetts Afterschool Research Study (United Way of Massachusetts Bay, 2005), for example, found higher staff education, lower staff-to-child ratios, and more structured and organized programming predicted higher staff engagement, which in turn predicted higher youth engagement and more positive youth outcomes (homework completion, initiative, positive relationships with others). These findings suggest that “regulable” factors like staff training and staff-to-child ratios can set the stage for supportive interactions and activities.

Again, qualitative research has illuminated how these factors make a difference on the ground in the daily interactions of youth with program leaders. The Hirsch, Hedges, et al. (2011) study shows how positive (vs. negative) interactions with staff influence young persons’ feelings of safety, their engagement in program activities, and their trust in staff advice and instructions. Deutsch and Jones (2008) provide a nuanced account of how the dynamics of trust and respect can differ for African American and European American children. And Larson and Walker (2010) identify the wide array of unexpected challenging situations that staff navigate, situations for which staff engagement, education, and lower staff-to-child ratios can make a difference between youth being turned off by a program versus having valuable learning experiences.

The ultimate test, however, is whether changing staff practices influences program outcomes. Sheldon, Arbretton, Hopkins, and Grossman (2010) studied the effects of continuous program improvement efforts (targeted staff

training throughout the year, regular observations and coaching of staff, and the use of data to measure progress) to improve the quality of afterschool literacy activities in a multisite afterschool program in California. They found that these interventions increased program quality, as measured through observations. Furthermore, the size of students' reading gains was positively correlated with the quality of literacy programming provided by each instructor.

In sum, research is beginning to provide a foundation of evidence that relate the features of programs to positive child developmental outcomes. These include characteristics of the activities—such as the SAFE features—and the training of staff and their abilities to provide appropriate structure and supportive relationships. Whether this potential is realized, however, may depend on how often and for how long young people attend programs, the next dimension that we consider in relation to child developmental outcomes.

### ***Linking Program Dosage to Child Outcomes***

Dosage includes both the intensity and duration of program participation. Intensity can be defined by hours/day, days/week, and total number of attendance days. Research syntheses of findings related to program intensity are now available. A limitation of these studies is that program quality was not typically considered.

In Lauer et al.'s (2006) meta-analysis of programs targeting academic achievement of at-risk students (discussed previously), follow-up analyses determined that significant program effects in reading and math achievement were evident only when programs exceeded a minimum dosage (44 hours in reading and 45 hours in math). In other work, Roth et al. (2010) conducted a research synthesis examining participation in "formal afterschool programs." Their focus was on 35 studies of programs that served elementary school children and that met on a regular basis throughout the school year, were supervised by adults, offered more than one type of activity (e.g., homework help, recreation, arts and crafts), and were structured around group-based activities. Studies that did not control for child performance at baseline and did not control for family preexisting differences were excluded from the analysis. Most of the studies examined concurrent associations between program dosage and child outcomes.

Roth et al. considered four outcomes: (1) academic performance (21 studies); (2) school attendance (11 studies); (3) problem behaviors (13 studies); and (4) peer relations (13 studies). They found that intensity of program

participation, defined as days or hours per week, was significantly related to gains in academic performance in 24% of the studies in which it was assessed. It was related to gains in school attendance in 64% of the studies, reductions in problem behaviors in 38%, and to positive peer relationships in 31% of the studies in which each was assessed.

Roth et al. (2010) also considered effects associated with the duration of program participation, defined as more than one year of participation versus one year or less of participation. In the 12 studies they identified that met their selection criteria, 42% reported significant associations between program duration and academic performance, indicating larger effects when children attended programs for more than one year.

An evaluation of The After-School Corporation (TASC) programs in New York City yielded similar findings (Reisner et al., 2004). Data collection occurred over 4 school years and included 52,000 afterschool participants and 91,000 students enrolled in the host schools who did not participate in TASC. Observations confirmed that the programs offered a broad array of enrichment opportunities, had positive relationships with their host schools, offered staff training, and had strong and experienced leader/managers. The investigators found gains in mathematics achievement for youth who attended the programs more regularly. Effect sizes were .13 for 1 year of active participation and .79 for 2 years of active participation.

In sum, findings suggest outcomes of afterschool programs are a function of both the intensity and duration of a young person's participation, with some evidence of larger effects when program quality is also high.

### ***Extracurricular Activities***

Research that has examined extracurricular activities shows somewhat similar relations between participation and child developmental outcomes as observed in studies of afterschool programs. In contrast to the work involving afterschool programs, much of the available research on extracurricular activities is based on nationally representative longitudinal surveys, not program evaluations. Consequently, there are fewer experimental and quasi-experimental studies, and more correlational analyses.

Findings from the studies of extracurricular activities, like the studies of afterschool programs, can be organized around participation and dosage. In addition, studies of extracurricular activities have examined the effects associated with specific types of activities such as sports and arts. The quality of youth experiences in their extracurricular activities has been only rarely assessed and is limited to

youth-report measures. One strong point of the literature examining extracurricular activities is that it includes large longitudinal studies in which young people have been studied into adulthood. This work enables us to examine whether extracurricular activities provide youth with human and social capital that benefits them in college completion and adult employment. In these studies, human capital is reflected in the concurrent and longitudinal measurements of academic, cognitive and noncognitive outcomes, whereas social capital is reflected in the development of social relationships with adults and peers who provide long-term instrumental and emotional support.

### ***Linking Participation in Extracurricular Activities to Child Outcomes***

As is the case with research on the effects of afterschool programs, much of the early research on the effects of extracurricular activities asked if mere participation (a yes/no variable) predicts child developmental outcomes. Three research syntheses, all focusing on extracurricular activities in adolescence, have asked this question. Holland and Andre (1987) provide a critique of 31 studies that were published prior to 1981. A research synthesis by Feldman and Matjasko (2005) examined 36 new publications on this topic that were published between 1981 and 2004. A third research synthesis prepared by Farb and Matjasko (2012) reviewed an additional 52 papers published between 2005 and 2009.

In all three reviews, the conclusion is that extracurricular activities are consistently related to more positive youth outcomes, and this relationship extends into the post-high school years. These outcomes include higher grades, school bonding, self-esteem, psychosocial adjustment, positive peer networks, college plans, college completion, and adult employment. These reviews also conclude that participation in extracurricular activities is linked to fewer negative outcomes such as tobacco, alcohol and drug use, antisocial behavior, and truancy.

Over time, the studies included in these syntheses have become more rigorous analytically and now routinely incorporate controls for selection, including youth behavior at baseline. Fixed effects analyses and replication across different data sets lend further credence to the findings. Nonetheless, some important caveats should be applied to these findings. Much of this literature is based on secondary data analyses of the same data sets, so these analyses are not independent replications. Another limitation is that much of the data was collected in the 1980s and 1990s, and cohort differences may have occurred.

### ***Linking Specific Types of Extracurricular Activities to Child Outcomes***

Other studies, sometimes utilizing the same national data sets, have examined relations between specific types of extracurricular activities (e.g., sports, performing arts, leadership) and child developmental outcomes. In their analyses of the Michigan Study of Adolescent Life Transitions, a longitudinal study involving more than 1,200 youth, Eccles and Barber (1999) found participation in leadership activities and academic clubs in Grade 10 was associated with a greater likelihood of attending college full time after high school graduation, whereas community service in Grade 10 was linked to reduced use of alcohol and marijuana in Grade 12, controlling for substance use at baseline. Community service, leadership activities, and performing arts during Grade 10 predicted higher rates of graduation from college, controlling for maternal education and student math and verbal ability. Community service also predicted higher self-esteem and lower use of alcohol and marijuana 6 years later.

In a second longitudinal project, the Maryland Adolescent Development in Context Study, Fredricks and Eccles (2008) examined the associations between extracurricular activities during early adolescence and adjustment in a diverse sample of African American and European American youth. Controlling for child and family characteristics measured in Grade 7 prior to activity involvement, participation in school clubs in Grade 8 predicted gains in resiliency and prosocial peers in Grade 11. Participation in sports in Grade 8 predicted an increase in resiliency, but a decrease in valuing of school.

Others have focused on participation in organized sports using the National Education Longitudinal Survey (NELS) and the Education Longitudinal Study (ELS). This work shows participation in school sports in Grade 10 to predict higher math scores and higher expectations for going to college in Grade 12 (Dumais, 2008). In other longitudinal analyses of the NELS, sports, as well as academic extracurricular activities, predict educational attainment and earnings 10 years later (Lleras, 2008). Relations between sports activities and other outcomes such as alcohol use are more variable, and appear to depend on the school environment and peer networks at the school.

A separate body of research is developing around the study of extracurricular activities in middle childhood. The Early Childhood Longitudinal Study-Kindergarten (ECLS-K) survey includes measures of specific extracurricular activities and child developmental outcomes during

the elementary school years. Using this data set, Dumais (2006) examined participation in activities during kindergarten, first, and third grades and found both sports and dance activities were linked to gains in reading scores, controlling for SES, gender, ethnicity, and kindergarten reading scores. Using this same data set, Covay and Carbonaro (2010) found participation in sports and dance to predict gains in children's noncognitive skills such as approaches to learning.

A general finding, then, is that many different kinds of activities are related to positive outcomes. What is less clear, to date, is whether specific types of activities are systematically and consistently related to different sets of outcomes.

#### ***Linking Breadth of Extracurricular Activities to Child Outcomes***

The idea that a more diverse set of activities is beneficial for children's development has also been studied. *Breadth* is defined as the number of different types of activities that a youth participates in. Breadth is believed to be important because it exposes young people to a broader array of adults, peers, and opportunities than is afforded by a single activity, even one engaged in for a similar amount of time.

Busseri and Rose-Krasnor (2009) tested this hypothesis in fifth- and seventh-grade students who reported the frequency of involvement in six types of activities (e.g. school sports, volunteering), controlling for intensity or net amount of time in all the activities. Breadth, but not intensity, was uniquely and positively predictive of academic engagement and of fewer risk behaviors, controlling for family and prior functioning. In other work, Busseri et al. (2006) found that breadth (assessed 20 months earlier) and increases in breadth over the 20 months predicted increases in a composite measure of successful development, as well as decreases in risk behavior.

Bohnert and Garber (2007) examined similar issues in older youth and found that the total number of organized activities (i.e., breadth of activities) served as a protective factor for psychopathology at the end of high school, controlling for earlier problem behaviors. Breadth of activities in high school also predicted fewer externalizing symptoms, less tobacco use and less substance abuse in Grade 12, findings which are similar to those reported by others (Denault & Poulin, 2009; Fredricks & Eccles, 2006).

Breadth of extracurricular activities also has been studied using cluster analyses, a person-centered analytic technique. In a study of low-income Canadian children, Morris and Kalil (2006) identified five groups of children

based on their clusters of activities: (1) *high clubs*, (2) *high sports*, (3) *high sports and clubs*, (4) *high sports, clubs, and lessons*, and (5) *low sports, clubs, and lessons*. Similar clusters were identified by Linver, Roth, and Brooks-Gunn (2009) in their examination of activity patterns of youth in the Panel Study of Income Dynamics and also in other studies of children and adolescents that used other data sets (Bartko & Eccles, 2003; Vandell et al., 2006; Zarrett et al., 2009).

In these analyses, consistent findings are found. Youth who are involved in multiple organized activities demonstrate more favorable academic and psychological adjustment and fewer risk behaviors than children who are involved in a single activity, who fare better than children who are not involved in any activities.

#### ***Linking Dosage of Extracurricular Activities to Youth Outcomes***

Questions about dosage of extracurricular activities—measured as minutes, days, or years—have centered on two issues. The first issue is whether there is a level of exposure at which youth who participate in extracurricular activities become overscheduled. That is, can the amount of time spent in organized activities become excessive and detract from schoolwork or foster psychological distress? This concern has been referred to as *the over-scheduling hypothesis* (Mahoney, Harris, & Eccles, 2006). An alternative hypothesis, *more is better* posits that benefits of extracurricular activities accrue in a linear form in which more time in activities is related to more positive outcomes.

Because youth are not assigned to participate for different amounts of time, the methodology used to evaluate the overscheduling versus more-is-better hypotheses ordinarily involves a comparison of outcomes among youth participating at different levels of intensity. Mahoney et al. (2006) reviewed existing research and conducted their own investigation that involved an analysis of the time diary information in the Panel Study of Income Dynamics. Results of their analyses indicated that (a) youth, Ages 12 to 18, primarily participate in organized activities for intrinsic reasons (e.g., excitement and enjoyment, to build competencies, and to affiliate with peers and activity leaders), (b) pressures from adults or educational and career goals are seldom given as primary reasons for participation, and (c) findings show consistent, strong evidence of positive linear associations between participating in organized activities and multiple indicators of positive development. Spending greater time in activities was related to increased benefits.

A longitudinal follow-up of these same youth at Ages 18 to 24 (Mahoney & Vest, 2012) showed similar linear relation. Controlling for demographic factors and baseline adjustment, intensity was a significant predictor of positive outcomes (e.g., psychological flourishing, civic engagement, educational attainment) and unrelated to indicators of problematic adjustment (e.g., psychological distress, substance use, antisocial behavior) at young adulthood.

Other longitudinal studies that utilized national and regional data show similar relations between intensity of activities and positive psychological and school-related adjustment. For example, Fredricks (2012) evaluated the over-scheduling hypothesis using data from a large, national representative sample of youth from the Educational Longitudinal Study. In 10th grade, students self-reported the overall hours/week they spent in activities. The average amount of time spent in extracurricular activities was about 5 hours per week, with only a very small proportion of youth (3.3%) reporting more than 20 hours per week in activities. Tenth-grade students' self-report of the overall number of hours/week they participated in school-sponsored activities predicted positive academic outcomes such as math achievement and educational status at Grade 12 and 2 years post-high school for students participating up to 14 hours/week (89% of the sample). Thereafter, academic outcomes declined somewhat as intensity increased. However, even youth at the highest level of intensity showed significantly better academic adjustment than the large of number of youth who were uninvolved in any school activities.

Using data from the National Education Longitudinal Study (NELS), Gardner, Roth, and Brooks-Gunn (2008) assessed high-school students' intensity of participation in school- and community-based activities in relation to outcomes at young adulthood. In general, intensity of participation, particularly when measured over a 2-year period, was positively associated with educational attainment, civic engagement, and occupational outcomes up to 8 years after high school. For a few outcomes, the positive association reached a plateau or decline at very high intensity (i.e., close to 20 hours/week), but this was the exception.

Regional longitudinal studies show similar findings. For instance, Bohnert and Garber (2007) found more time in extracurricular activities was related to fewer externalizing behaviors and less tobacco and substance use in Grade 12, controlling for psychopathology before high school. Likewise, Dotterer, McHale, and Crouter's (2007) longitudinal study of African American adolescents

showed that more time spent in extracurricular activities was positively related to self-esteem and school bonding. Moreover, a longitudinal investigation by Denault and Poulin (2009) found that participation intensity, in a sample of mostly European American, middle-class, Canadian early adolescents in Grades 7 to 11, was positively related to subsequent ratings of school commitment and values towards society. Similar positive linear relations have been found in middle childhood. Amount of time in enrichment activities in Grades 3 to 5 predicts positive changes in children's emotional adjustment in Grade 5 (Posner & Vandell, 1999).

When the body of research is considered in aggregate, the answer to the question of whether North American youth are overscheduled in organized activity participation appears to be "No" for the vast majority of youth who have been studied. Although some outcomes suggest diminishing returns as intensity increases, participation is generally associated with benefits for children and adolescents.

### *Linking Consistency of Participation to Child Outcomes*

Consistency of participation has been used to distinguish between sporadic versus more sustained participation in extracurricular activities. Summing or averaging hours over time does not tell us if youth are involved in activities sporadically but intensively or involved regularly but with less intensity. To make this distinction, consistency has been measured by assessing participation at regular intervals (called *epochs*) and by determining the proportion of epochs in which participation occurs.

Findings from the NICHD Study of Early Child Care and Youth Development (SECCYD), a prospective longitudinal study of more than 1,300 youth, suggest that consistent participation in organized activities confers academic advantages for children during middle childhood (NICHD Early Child Care Research Network, 2004). Children who consistently participated in organized activities during kindergarten and first grade had higher scores on a standardized math test at the end of first grade, compared to children who never or only sporadically participated in structured activities, controlling for numerous individual, family, and school factors, including math scores prior to kindergarten. Almost all of these activities had a nonacademic focus—sports, music lessons, and clubs like Daisy scouts, and the absolute amount of time spent in the activities was modest, about 90 minutes a week.

Auger et al. (2013) extended the study of consistency of participation in the SECCYD data set by examining structured afterschool activities from kindergarten

through Grade 5. Controlling for child functioning prior to kindergarten and other child, family, home, and school characteristics, these investigators found that more consistent activity participation in organized activities predicted higher report card grades, work habits, and mathematics achievement in Grades 3 and 5.

Consistency in participation in middle school and high school has also been linked to positive educational outcomes. Mahoney, Cairns, and Farmer (2003), for example, assessed consistency in participation across Grades 7 and 8 (early adolescence) and Grades 9 and 10 (middle adolescence), which were then related to educational status at Age 20. In regressions that controlled for child gender, SES, interpersonal competence in both middle school and high school, and educational aspirations at age 18, consistency of participation in both middle school and high school (none, 1 year, or 2 years at each school level) predicted enrollment in college at Age 20. Path analyses indicated that consistency was associated positively with interpersonal competence in middle adolescence, educational aspirations at Age 18, and educational status at Age 20.

These findings are similar to those found in the National Education Longitudinal Study (Zaff, Moore, Papillo, & Williams, 2003). More consistent participation in extracurricular activities from 8th through 12th grade predicted academic achievement and prosocial behaviors in young adulthood, including attending college, voting in national and regional elections, and volunteering for community and religious organizations. These relations remained after accounting for control and individual, parent, peer, and school process variables.

Examining older youth, Darling, Caldwell, and Smith (2005) also found that consistent participation in high school extracurricular activities (sports, performing arts, leadership groups, interest clubs), across two school years was predictive of higher grades, greater educational aspirations, and better attitudes toward school compared to students who did not participate in the activities, controlling for adjustment in the first year and youth and family factors (grade, sex, ethnicity, parent education).

### ***Linking Quality of Extracurricular Activities to Child Outcomes***

The research we reviewed earlier in this section showed that measures of the quality of afterschool programs, as measured by proximal processes, are linked to youth outcomes. Given those findings, it is unfortunate that few studies have evaluated quality of proximal processes in extracurricular activities. One reason is that the large national data sets,

the data sources for many of the studies, have not included these types of measures.

The available quantitative literature, coupled with qualitative studies, suggest that youth reports of the quality of their experiences in extracurricular activities are linked to child developmental outcomes. In one study (Kataoka & Vandell, 2013a), middle school youth reported the quality of their experiences at their primary afterschool activity over a 2-year period. Youth reports of more positive experiences (a composite that included emotional support from adult staff, positive relationships with peers, and opportunities for autonomous activities) were associated with gains in work habits, task persistence, and prosocial behavior with peers as reported by classroom teachers, controlling for family factors and student pretest scores. Similarly, Rutten et al. (2008) found that youth reports of the quality of relational support from the coach, exposure to sociomoral reasoning about sports dilemmas, and positive attitudes about fair play predicted both on the field and off field antisocial and prosocial behaviors. These findings mirror those for afterschool programs, showing that supportive staff and structured activities that allow youth agency are features of program quality.

Other studies have begun to focus on the role of the child's developing competencies as mediators of relations between extracurricular activities and child developmental outcomes. An example is the research by Covay and Carbonaro (2010) that asked whether relations between extracurricular activities and academic achievement in middle childhood are mediated by children's noncognitive skills. In analyses that controlled for family background and child performance at baseline, these investigators found participation in sports, clubs and music predicted gains in math scores, relations that were partially mediated by the children's noncognitive skills (a composite measure of approaches to learning that included attentiveness, organization, flexibility, task persistence, learning independence, and eagerness to learn). Participation in clubs and music activities predicted significant gains in reading scores, and these relations were also partially mediated by gains in the children's noncognitive skills.

In other research, Simpkins, Eccles, and Becnel (2008) have explored relationships with peers as a potential mediating mechanism. They tested the hypothesis that associations between breadth of activities and developmental outcomes are mediated by peer group relations. In their longitudinal analyses, breadth of activities (sports, religious, volunteering, community, school) was assessed when youth were in Grade 7 (Time 1). Friends' positive

characteristics were then measured in Grade 8 (Time 2), and youth outcomes (depressive affect, problem behavior, alcohol use, and self-worth) were measured at Time 3 (Grade 9 in one sample and Grade 10 in the second sample). As they hypothesized, youth who participated in a larger number of activities at Time 1 demonstrated more positive developmental outcomes at Time 3 (that is, less depressive affect and problem behavior and more positive self-worth), and these relations were mediated by friends' positive characteristics at Time 2.

Gardner, Roth, and Brooks-Gunn (2009) identified negative peer processes as another factor to consider in understanding effects of extracurricular activities. In their study of a large sample of urban adolescents, they compared youth who participated in sports to those who only participated in nonathletic activities and to those who did not participate in any organized activities. The odds of nonviolent delinquency were higher among boys who participated in sports when compared to boys who participated only in nonathletic activities but less than that of boys who did not participate in any organized activities. Two peer processes—friendships with deviant peers and unstructured socializing—mediated the relation between sports participation and boys' nonviolent delinquency, especially for boys with earlier externalizing problems. Similar findings have been reported by Gottfredson, Gerstenblith, Soule, Womer, and Lu (2004) who found afterschool program participation diminished substance use and that this relation was mediated by intentions not to use drugs and more positive peer associations for program participants.

Although not well tested, positive peer processes may also contribute to desirable developmental outcomes. Organized programs have long viewed constructive peer interactions as a vehicle for cultivation of positive development (Halpern, 2002). Based on quantitative findings, Barber, Stone, Hunt, and Eccles (2005) suggest that activities can "provide peer group niches in which adolescents may do the work of co-constructing values and identities" (p. 204). Qualitative research has described how youth in programs learn through talking out loud to each other, analyzing situations collaboratively, sharing information and feedback, and observing and comparing each other's experiences (Heath, 1998; Larson et al., 2012; Perry, 2013).

### **Combining Type, Quantity, and Quality of Organized Activities**

Almost all of the available research examining associations between organized activities and youth outcomes has

focused on quantity *or* type *or* quality of organized activities. Examination of these three dimensions in the same study or in the same analyses is limited. Such examinations are needed if we are to identify whether dimensions are uniquely associated with youth outcomes.

Analyses by Li and Vandell (2013) suggest the utility of such an approach. These investigators determined that quality, type, and amount of organized activities were each significant predictors of child developmental outcomes, controlling for the other dimensions. Intensity of participation (measured as days per week) predicted later gains in the Woodcock Johnson Applied Problems (mathematics) achievement and assertiveness, whereas youth reports of the quality of the activities were associated with decreases in internalizing problem behaviors and externalizing problem behaviors, and these relations were embedded within different types of activities.

### **Moderators of Organized Activities**

Thus far in this section, we have focused on various aspects of young people's experiences in organized activities (their type, breadth, intensity, duration, consistency, and quality) as "main effects" in relation to academic and social outcomes. Now we review the research evidence that considers whether relations between organized activities and child developmental outcomes vary as a function of the child's own characteristics and dispositions, their family circumstances, the broader school and community context, and the broader cultural context. In contrast to the large corpus of research examining "main effects" of different aspects of organized activities, systematic investigation of moderated relations is less well developed.

Examinations of moderated relations have considered two hypotheses. The first is that effects of organized activities are larger for youth who are at risk because of individual, family, or community circumstances. This hypothesis is consistent with a view that organized activities can play compensatory or protective role in children's development. A rival hypothesis is that effects of organized activities are larger for youth who are advantaged as a result of individual, family, or community circumstances, and thus are positioned to derive greater benefit from organized activities.

We start by considering children's own individual characteristics as moderators of the effects of organized activities on child developmental outcomes. We then turn to family characteristics and conclude by examining school and neighborhood as moderators.

### *Gender and Ethnicity*

Two individual demographic variables (gender and ethnicity) have been examined as moderators of relations between organized activities and child development outcomes. Although the research literature is modest, there are suggestions that organized activities are more impactful for boys than girls (Pierce et al., 1999; Pierce et al., 2010; Posner & Vandell, 1999). In these studies, associations with positive settings (and with negative settings) are greater for boys than for girls. A similar pattern has been reported by Urban, Lewin-Bizan, and Lerner (2009) in their longitudinal analyses of organized activities during adolescence. More research on possible gender differences in effects of organized activities is needed.

Researchers have also studied ethnicity as a moderator of organized activities. Again, research is limited. In a longitudinal study of low-income urban African American and European American children, Posner and Vandell (1999) found larger positive associations between amount of time spent in extracurricular activities and academic performance and social competencies in an African American sample than a European American sample. In other work that draws from the Panel Study of Income Dynamics, Mahoney et al. (2006) found intensity of organized activities was more highly associated with reading achievement gains in African American youth than in European American youth. In contrast, analyses of the National Education Longitudinal Study of 1988 (NELS 88) found relations between extracurricular activity involvement and achievement were higher among European Americans, especially in the area of math (Gerber, 1996). The discrepancies between the studies could be attributed to a wide range of reasons including SES, the nature of programs experienced by these different groups, or how well the program was matched to the cultural assets of each group. Mixed method and within group analyses are needed to understand how experiences, proximal processes, and fit play out for youth from different cultural backgrounds.

### *Child Prior Adjustment*

Other studies have asked if program effects are larger for youth who are at-risk because of earlier behavior problems. In one study, Mahoney (2000) identified four groups of youth, based on cluster analyses of physical maturity, aggression, popularity, academic achievement, and SES. Students in the high-risk group were more likely than students in other configurations to show antisocial patterns in young adulthood. However, participation in school-based

extracurricular activities during Grades 6 to 10 was associated with reduced rates of school dropout and criminal arrest among the high-risk students. Program participation appeared to be a protective factor for these at-risk youth.

Kataoka and Vandell (2013b) studied individual psychological dispositions as moderators of effects of organized activities in a sample of low-income youth who were studied over a 2-year period. Participation in organized activities over 2 years, compared to low supervision after school, was particularly beneficial for youth who exhibited high oppositional defiance at baseline. At follow-up, organized activities served as a protective factor against drug use and school absences for youth who had been reported by parents as being oppositional and defiant.

Other research, conducted as part of the 4-H Study of Positive Youth Development (Urban et al., 2009), reveals an additional complexity in which both youth characteristics and community characteristics interact in relation to child developmental outcomes. For young people growing up in low asset neighborhoods, the ability to self-regulate placed youth in a stronger position to benefit from extracurricular activities, compared to their peers with less capacity to self-regulate. This suggests that although program participation can be protective for at-risk youth, youth who have certain level competencies may benefit most. An important question is how the design of programs might make them better suited to the needs, culture, and assets of different populations.

### *Family Circumstances*

Family circumstances are potential moderators of the linkages between organized activities and child developmental outcomes. In secondary analyses of the Early Childhood Longitudinal Study–Kindergarten Cohort (ECLS-K), Covey and Carbonaro (2010) determined that extracurricular participation between kindergarten and Grade 3 predicted larger gains in noncognitive skills for low-income children than for higher-income children, controlling for numerous child and family factors and for child performance at baseline.

Similar findings, pointing to larger gains for low-income children, have been reported in the Study of Early Child Care and Youth Development (Auger et al., 2013). In this study, consistent participation in organized activities was more highly associated with math achievement test scores for low-income children than for middle-income and high-income children, controlling for numerous child and family background characteristics. There were no differences in the scores of low-income and high-income

children who consistently participated in organized activities, but large differences in the math scores of low-income and high-income children who rarely participated in activities.

Differential effects associated with family income also have been found in a longitudinal study conducted in Australia (Blomfield & Barber, 2011). Relations between extracurricular activities and self-concept and feelings of self-worth were larger for low-income students than for high-income students. These and other findings generally support the compensatory hypothesis: that the benefits of organized activities are greater for economically disadvantaged and at-risk youth. Given the evidence (as shown in the fourth section of this chapter) showing that low-income youth have *less access* to organized activities, these findings suggest that increased attention should be given to the role of high-quality organized activities in reducing the persistent achievement gap separating low-income and middle-income youth.

### *School and Community*

Organized activities are embedded within the broader school and community context, and these contexts also appear to moderate relations between organized activities and youth and child developmental outcomes. Work by Urban et al. (2009) found that neighborhood assets, measured as percent of college educated residents and presence of local libraries, moderate effects of participation in organized activities on child developmental outcomes. Additionally, these researchers found that girls living in low-asset neighborhoods derived greater benefits from their participation in organized activities than did girls living in high-asset neighborhoods, reflected in more positive youth development outcomes and less risk taking. Boys living in high-asset neighborhoods derived greater benefit from organized activities than did boys living in low-asset neighborhoods. Boys who lived in low-asset neighborhoods and participated in organized activities engaged in more risk taking behaviors than other boys in their community, a finding that is consistent with observations reported from McCord (1992) and Dishion, McCord, and Poulin (1999) of peers encouraging and reinforcing deviant behavior. A critical challenge for organized activities is the development of programming that supports positive youth development without inadvertently promoting deviant and antisocial behaviors.

A study by Guest and Schneider (2003) suggests that the effects of participation are also moderated by the school context. In this research, high school students who

participated in sports attained a higher GPA and held greater educational expectations compared to students who did not participate in any extracurricular activities, controlling for gender, ethnicity, grade level, parent education, course sequence in math, and delinquency. However, the effects of sports involvement differed by the school context. Being seen by others in the school as athletic, which was linked to sports involvement, had a positive association with GPA in schools where a smaller proportion of students went to college after high school graduation, but a negative association with GPA in schools where most students went to college.

Finally, effects of sports and other organized activities are embedded within the broader cultural context. Analyzing data from the Trends in International Mathematics and Science Study (TIMSS) 2003, Won and Han (2010) found that playing sports was a positive predictor of achievement in the United States, but a negative predictor in South Korea. In contrast, doing homework was a negative predictor in the United States but a positive predictor in South Korea. The meaning of the activities appeared to be embedded within the cultural context.

## UNSUPERVISED OUT-OF-SCHOOL TIME

The previous sections of the chapter focused on organized activities. The primary rationale for the development of organized activities stem from concerns about what happens to young people when they are unsupervised during out-of-school time. In this section, we describe research findings obtained in two types of unsupervised time: (1) self-care and (2) unsupervised time with peers. Paralleling the organization of research pertaining to organized activities, we first examine the factors that predict participation in unsupervised time. We then review the evidence of relations between unsupervised time and child developmental outcomes. Finally, the moderating influences of child, family, and neighborhood characteristics on unsupervised time are considered.

Several distinct approaches have been taken in defining unsupervised time. Whereas some work has designated a child as “unsupervised” if he/she spends as little as 30 minutes per week without adult supervision (Lovko & Ullman, 1989), other research has asked parents to report if self-care is used “regularly” or consistently each week (e.g. Aizer, 2004; Messer, Wuensch, & Diamond, 1989; Posner & Vandell, 1994). Some qualitative work has highlighted blurred boundaries between “supervised” and “unsupervised” care, emphasizing the complexity

and fluidity of these care arrangements (Belle, 1999). In reviewing literature on unsupervised time in this chapter, we will denote the various operational definitions used to classify a child as “unsupervised,” and we consider how these conceptualizations result in different interpretations of the effects of unsupervised time.

### Self-Care

An estimated 4.2 million children (Ages 5 to 14) care for themselves on a regular basis in the United States (Laughlin, 2013). As might be expected, the use of self-care increases with age. An estimated 5% of elementary aged children regularly care for themselves for part of the afterschool hours compared to 27% of middle-school and high-school aged children (Laughlin, 2013). The amount of time spent in self-care averages 7 hours each week. Again, increases with age are found, with middle-school and high-school youth spending more than 10 hours per week in self-care. These figures point to the need to understand the effects of unsupervised time.

In order to identify the factors that lead families to use self-care as a regular arrangement during the after-school hours, we examine Casper and Smith's (2004) analysis of Survey of Income and Program Participation (SIPP), a nationally representative dataset. Using OLS regression models, they found that three primary factors predicted higher rates of self-care use: (1) availability of parents and other adults to care for children, (2) the child's level of responsibility and maturity, and the (3) neighborhood context. They found ability to pay for childcare was not related to the choice of self-care, a finding that has been replicated in subsequent papers (Shumow, Smith, & Smith, 2009). Furthermore, self-care is related to child and family characteristics in predictable ways. Single parents and parents with older children are more likely to use self-care. Similarly, neighborhood safety and higher maternal work-hours are associated with more time in self-care for older children, but not younger children.

Other research has examined the effects of self-care on important developmental outcomes. The weight of the evidence indicates that time spent in self-care is associated with negative child outcomes. In one study of eighth graders from Southern California, youth who spent more time in self-care after school showed poorer grades, more risk taking behavior and evidence of substance use (Dwyer et al., 1990). Furthermore, children who began spending time in self-care during elementary school showed the greatest risk of substance abuse problems.

Similarly, Marshall et al. (1997) found that children from lower-income families who spent substantial time in self-care exhibited greater externalizing problems than students who attended after-school programs or remained in the care of their parents.

In analyses that incorporated multiple controls for selection effects and utilized a family fixed effects analytic strategy, Aizer (2004) used the National Longitudinal Survey of Youth–Child-Mother file to examine the effects of self-care on youth Ages 10 to 14. The prospective longitudinal design of the data is such that Aizer's sample was predominantly low-income and disproportionately children of adolescent mothers. The analysis focused on four problem behaviors: skipping school, getting drunk or high, stealing, and violence. Unsupervised time was classified dichotomously based on maternal reports of whether there was no adult regularly present when the child returned home from school. Lack of supervision predicted poorer school attendance, greater alcohol or marijuana use, and more problem behaviors, problems that were exacerbated in single-parent households and when mothers had not graduated from high school. Family fixed analysis showed that, within the same family, children who received more supervision were less likely to exhibit problem behavior.

### Unsupervised Time With Peers

Unsupervised time with peers, sometimes called “hanging out with peers,” is a second form of unsupervised out-of-school time (Osgood, Anderson, & Shaffer, 2005). Routine Activity Theory from the field of criminology has particularly influenced research questions related to unsupervised time with peers (Cohen & Felson, 1979). According to Routine Activity Theory, there must be a “perfect storm” in order for an individual to commit a crime. This perfect storm involves the convergence of three factors: a motivated offender, a suitable target, and the absence of guardians capable of preventing the act. Thus, crime is committed when opportunities arise in congruence with every day, routine activities.

Osgood, Wilson, Bachman, O'Malley, and Johnston (1996) extended Routine Activity Theory to juvenile crime and misbehavior. Drawing on Briar and Piliavin's (1965) formulation of situational motivation, which suggested that crime is not inherent in the person but rather in the situation, Osgood et al. argued that youth deviance would arise when youth were (a) without adult supervision, (b) “hanging out” with a lack of structure, and (c) in the presence of peers.

Although Osgood's theory has had a sizeable impact on current conceptualizations of unsupervised time, the importance of peer influence on unsupervised activities is not a new concern. Steinberg's (1986) early study of "latchkey" adolescents found important distinctions between the contexts in which unsupervised youth spent their time after school. Steinberg contrasted youth who were home after school, those who were unsupervised at a friend's house, and those who were "hanging out" in other settings. Results indicated that youth who were not at home and on their own were most susceptible to peer pressure. Steinberg theorized that youth who were at home could still be indirectly monitored by their parents through telephone calls or neighbors. However, as youth spent time with peers in other unsupervised settings, susceptibility to experiencing peer pressure increased.

Similar findings were reported by McHale, Crouter, and Tucker (2001) who determined that unsupervised "hanging out" with peers was associated with lower grades and higher amounts of negative behavior whereas time spent alone in self-care was not related to behavioral problems or poor grades. Similarly, Goyette-Ewing (2000) found that children who spent time "hanging out" with peers in unsupervised settings had lower school achievement, were more susceptible to peer pressure, had higher levels of self-reported problem behavior, and were involved in more experimentation with alcohol when compared to both supervised children and self-care children.

Research has begun to investigate family and neighborhood characteristics as moderators of unsupervised time with peers. Maimon and Browning (2010) found that relations between unsupervised time with peers and youth violence were moderated by neighborhood collective efficacy. Higher levels of neighborhood efficacy were associated with a reduction in the likelihood of an adolescent's violent offending even when youth spent time with unsupervised peers. Similar results were reported by Coley, Morris, & Hernandez (2004), who determined that negative effects of unsupervised times with peers were mitigated by parental monitoring and neighborhood collective efficacy.

Research conducted in unsupervised settings has highlighted a very different developmental context than the one offered by organized activities. While participation in organized activities is found to be associated with positive developmental outcomes, time spent in unstructured and unsupervised settings is associated with negative outcomes. The controlled studies we reviewed in the prior section demonstrate that the benefits of organized

activities are related to the *quality of experiences* youth have in organized contexts—they are not just a "holding pen" in which to keep young people out of trouble. Nonetheless, part of the value of organized activities may be that they lessen the amount of time that youth spend in unsupervised settings.

## CONCLUSIONS AND FUTURE DIRECTIONS

What happens in organized activities is decidedly different from what youth experience in classrooms during a typical school day and what they experience during informal leisure and unsupervised time with peers. Organized activities provide a space in which young people can follow their interests in areas as diverse as swimming, basketball, science clubs, computer graphics, dance, political activism, community service, band, and chess, and to build skills in these areas over time. In contrast to school classrooms, they provide more opportunities for self-regulated learning and experiences of self-efficacy as a learner. In contrast to informal leisure and unsupervised time, organized activities are structured, have goals and expectations that incorporate arcs of effort that extend over days, weeks, and months that lead to culminating events. Organized activities also offer substantial opportunities for collaboration and constructive conversations with peers and adult leaders around shared interests, interactions that are constrained at school and much less common in leisure settings. Because of these differences, organized activities provide fertile opportunities for children's own interests to help guide and support positive developmental outcomes in social, academic, and behavioral domains.

### Linking Activities to Youth Outcomes

A growing body of controlled longitudinal research, employing robust measures, has documented these types of effects of organized activities on children's development. First, participation in *afterschool programs*—activities that meet on a regular basis throughout the school year and provide a variety of hands-on, structured experiences with peers and adults—predicts a wide range of child developmental outcomes, including students' self-perceptions (self-esteem, identity, self-efficacy), bonding to school, positive social behaviors, noncognitive skills (persistence, teamwork, emotional regulation) as well reductions in problem behaviors such as truancy, substance use, and delinquent acts. Participation in afterschool programs also

has been linked to academic outcomes, including math and reading achievement and school grades. Participation in *extracurricular activities*—activities that meet regularly but focus on a single activity, similarly predicts academic grades, school bonding, noncognitive skills like persistence and work habits, self-esteem, psychosocial adjustment, and reductions in antisocial behaviors and truancy. The similarity in findings from these two bodies of research (extracurricular activities and afterschool programs) supports the use of the more inclusive term, *organized activities*, to represent both types of activities.

Although effects associated with participation are statistically significant and replicated in meta-analyses, it should be noted that effects of participation tend to be modest in size. Larger effects are found in research that has taken into account within-group variations in organized activities. Four broad sets of factors—*quality* of youth experiences, *dosage* or amount of time in activities, *breadth* of activities, and activity *type*—have been studied. For the most part, researchers have considered each of these factors separately.

A consistent and robust finding is that the *quality* of youth experiences in organized activities is related to gains in academic and social-emotional functioning and reductions in problem behaviors in both middle childhood and adolescence. Effect sizes are higher for participation in high quality programs. Two types of features of programs appear to stand out.

First, the organization and structure of the programs' activities are important to the quality of youth experiences. A meta-analysis indicates that programs that fit the SAFE criteria (Sequential, Active, Focused on social-emotional development, and Explicit) are associated with positive academic (test scores and grades), social-emotional (prosocial behaviors, self-esteem, self-regulation skills), noncognitive (task persistence, work habits), and behavioral (reductions in aggression and misconduct) outcomes. This combination of features is important because they support opportunities for children and youth conditions to become deeply engaged and to obtain focused information and feedback that helps them learn.

Second, researchers find that interpersonal dimensions of programs are important to quality. Studies show that supportive and positive relationships with adult staff and peers are linked to academic and social gains at school and reductions in misconduct. Further, studies find that more highly educated staff, regular staff professional development, and lower staff to child ratios predict higher staff engagement, which predicts higher youth engagement,

which predicts both academic and social outcomes at school. These findings on the vital importance of interpersonal dimensions of programs to children's learning and development is consistent with decades of research on other contexts, such as families and schools (Eccles & Gootman, 2002), and they also pose a challenge to funders and policy makers. When organized activities fail to provide these features of quality, programs have been found to have either no effects or even negative effects on these youth outcomes.

Effects of organized activities also have been related to *dosage*. Effects of participation are larger when youth participate in activities more frequently and for a longer duration. Effects of participation are substantially larger when youth persist in activities for a longer duration. There is little evidence to support the over-scheduling hypothesis. Most youth are not heavily scheduled in organized activities, and negative effects of activity are not evident until very high hours of participation are reported. The more common pattern is that youth lack opportunities to participate in activities.

Finally youth appear to benefit from engaging in a wide variety of activities. *Breadth* of activities, in the context of extracurricular activities and of afterschool programs, is predictive of greater academic engagement and fewer risky behaviors. These benefits are thought to accrue from youth gaining diverse experiences (i.e., developmental nutrients) and developing relationships with different leaders and groups of peers.

Research examining how these benefits differ across *specific types* of activities is thus far inconclusive. The developmental outcomes associated with participation in specific activities—sports versus arts versus community service—are variable across studies, leading some investigators to argue that type of activity is not as important as the quality of youth experiences in the activity. The value of specific types of activities also may depend more on the match between the activity and youth interest and less on the specific experiences afforded by the activity. This is a topic in which more research is needed.

### Moderators of Organized Activities

Other studies have asked if effects of organized activities are larger for some youth than others. One set of studies has asked if these effects differ for children who are at-risk because of individual, family, or community circumstances. Here, the available research points to organized activities as serving a compensatory function. For example,

youth who are at-risk (because of prior behavior problems, poverty, or unsafe neighborhoods) appear to derive greater benefits from high-quality activities or more program dosage than youth from more advantaged circumstances. In studies that control for youth prior adjustment and a host of family characteristics, researchers ascertained that drug use, school absences, school dropout, and delinquent activities are less in high school among at-risk students who consistently participated in organized activities in middle school. Consistent participation during elementary school is associated with gains in mathematics achievement in low-income children, gains not observed in low-income children who participated less consistently in organized activities.

### Factors That Predict Program Participation

Despite the evidence of benefits of organized activities for children's development, access to organized activities is variable. Large national surveys, augmented by in-depth qualitative and quantitative investigations, find that participation in extracurricular activities varies as a function of family, community, and child characteristics. Children whose parents are more educated and who earn higher incomes are much more likely to participate in organized activities than children whose parents are less educated and/or have lower incomes. In the United States, for example, youth whose mothers have a college degree are 3 times as likely to be involved in extracurricular activities as youth whose mothers did not graduate from high school. Youth participation in low-income families is constrained by fees, but also by the family needs for older youth to provide child care for younger siblings and by family concerns about safety.

Studies of afterschool programs also show differential access to these programs. Federally funded programs like the 21st Century Community Learning Centers and the Supplemental Educational Services tutoring programs are concentrated in schools serving low-income children, whereas fee-based programs are concentrated in schools that have lower proportions of low-income youth. These programs also have different offerings. The federally funded programs tend to focus on academic achievement and have school-like orientations, whereas fee-based programs tend to focus on enrichment and recreation.

If part of the power of organized activities is that they offer opportunities not typically found at school, then young people who attend school-like afterschool programs may be further disadvantaged. An ongoing debate between

some youth-serving organizations and federal and state funders of afterschool programs is whether organized activities that serve educationally at-risk students should be academic and "school-like" in their programming or whether organized activities should have a more youth-centered approach. This is an important topic for future research.

### Directions for Future Research

There are a number of other pressing issues that call for future research. The needs are so great we can only provide a partial list.

#### *Developmental Changes in Organized Activities*

Although the focus of this chapter has been on *development*, the available literature reveals remarkably little about what youth of different ages bring to organized activities or how their experiences in programs change across developmental periods. Work is needed to identify commonalities in programs serving children and adolescents and also what needs to be different to stretch children and teens at different developmental levels. Research suggests that some basic processes, such as a need for trusting and supportive relationships with program staff, are quite similar across age periods. In other respects, programs serving children and adolescents may need to be distinct. Children may benefit from greater structure and somewhat more constrained choices whereas opportunities for greater autonomy may be more important for adolescents. Older adolescents have the potential to utilize more advanced cognitive skills, an "executive suite" that includes capacities for inhibiting impulses, perspective taking, analyzing causal processes, hypothetical reasoning, and understanding the interaction of multiple abstract systems, which has implications for their organized activities. The study of organized activities at this point suffers from "silos" in which some investigators focus on middle childhood and others on adolescence.

#### *Disentangling Key Features and Processes*

Bioecological theory stresses the importance of process in context. A limitation of most of the research conducted to date is that it has focused on one or another aspect of organized activities—quality, breadth, dosage, or activity type. Research is needed that considers multiple dimensions simultaneously in order to determine both unique and synergistic effects associated with particular aspects of organized activities and how these might vary by child,

family, and community characteristics. To understand these processes, it is necessary to have micro-genetic studies and qualitative research that examines the proximal processes as experienced and enacted by youth and leaders in different program settings and different populations of youth as well as quantitative research that includes quality, dosage, and type in the same analyses.

### ***Additional Moderators of Organized Activities***

Researchers need to move beyond the default assumption of a one-size-fits-all model of programming. Differences by social class, ethnicity, and immigration need to be evaluated, with a focus on identifying youth assets, appropriate structures, intervening processes, and program fit for different groups. We in the field need to understand when, for whom, and how culture matters. Similarly, we also need to better understand how programs can facilitate relationships across groups.

### ***Program Thresholds***

Recent research in early childhood (see Burchinal, Magnuson, Powell, & Soliday Hong, Chapter 6, this *Handbook*, this volume) has moved beyond consideration of linear relations between early childcare quality and hours and child developmental outcomes to the identification of thresholds for various childcare parameters. These studies have found, for example, that effects of early childcare quality are not evident until quality meets a minimum standard. Our understanding of organized activities could similarly benefit from studies of threshold effects. Consideration of nonlinear effects of participation, quality, dosage, and breadth of organized activities is needed.

### ***Youth With Special Needs***

There has been little attention paid to organized activities as a developmental context for youth with special needs. Research is needed to identify obstacles to participation and to determine what accommodations and programming are needed. At this point, it is not possible to assess how well special needs youth are served by organized activities because this basic information is not available.

### ***Expanding the Definition of Organized Activities***

Other activities, such as summer camps and classes sponsored by museums and libraries, share many of the features of afterschool programs and extracurricular activities. Understanding of the role of organized activities in youth development will be advanced by integrating these additional settings in definitions of organized activities.

### ***Studies of Program Staff***

Research has consistently shown that the quality of organized activities depends a great deal on the skills and engagement of staff. Across age periods, program leaders organize and monitor activities, provide scaffolding for youth work, serve as mentors, and provide cultural bridging, among many other roles. Much more research is needed to understand the expertise of effective program leaders—how they play these roles in the complex situations of daily practice. For example, how do staff balance youth needs for connection with youth needs for autonomy?

Research is also needed to identify effective strategies for training and development of line staff and directors of organized activities. Programs need staff and site directors who have expertise in youth development and who, in aggregate, have substantive competencies in areas such as music, science, math, or drama. However, a national survey of more than 4,000 afterschool workers found that most staff lack formal education in the content areas they lead and receive only minimal training (National Afterschool Association, 2006). There is a compelling need for researchers to work with policy makers and intermediary organizations to develop and evaluate training programs that better prepare line staff and program directors to lead organized activities.

### ***Moving Beyond Child Outcomes***

The focus of this chapter has been on organized activities in relation to children's development. Additional research is needed to examine effects of organized activities on a broader array of constituencies, including families, schools, and communities. Families are likely influenced in multiple ways by their children's participation in organized activities. Promising areas to study include effects of organized activities on family roles and responsibilities. Research also is needed to examine effects of afterschool programs and extracurricular activities on schools. These effects could be studied as changes in school-level performance on standardized tests, daily attendance, delinquent activities, and/or neighborhood crime statistics. Effects of organized activities on process variables within the school can also be studied. What does it mean, for example, when program staff works with teachers at a school to introduce afterschool learning principles to their classrooms?

### ***Final Thoughts***

This chapter represents the first time that the *Handbook of Child Psychology and Developmental Science* has devoted

a full chapter to the topic of organized activities. Our goal has been to highlight the value of organized activities for developmental scientists who are interested in studying processes of positive development. Knowledge gained from the careful study of organized activities can be used, we believe, to improve the life opportunities of young people. This knowledge may also be used to inform efforts to improve schools as developmental settings that support children's development. Our hope is that this chapter will encourage others to join us in this work.
